Email: fred.pozzuto@netl.doe.gov		

Abstract: Enclosed for your review and comment is DOE's and the California Energy Commission's joint *Preliminary Staff Assessment/Draft Environmental Impact Statement (PSA/DEIS)*(DOE/EIS-0431D). This document was prepared in accordance with the *National Environmental Policy Act of 1969* (NEPA) and applicable implementing regulations. The CEC must also comply with Title 20, California Code of Regulations section 1701 et seq., and the California Environmental Quality Act (CEQA) (Pub. Resources Code, § 21000 et seq.). The Energy Commission must decide whether to certify the Hydrogen Energy California's Integrated Gasification Combined Cycle Project (HECA); this certification is in lieu of any permits required by state, regional, or local agencies, and federal agencies to the extent permitted by federal law (Pub. Resources Code, § 25500). The PSA/DEIS analyzes the potential environmental impacts of DOE providing financial assistance under the Industrial Carbon Capture and Sequestration (CCS) program to the HECA project.

This PSA/DEIS addresses DOE's proposed action, which is to provide approximately $408 million in financial assistance to HECA, LLC to support the construction and demonstration of the HECA project. The HECA project would demonstrate integrated gasification combined cycle (IGCC) and carbon capture technology on a commercial scale turning a fuel blend consisting of 75% western sub-bituminous coal and 25% petroleum coke (petcoke) into a synthesis gas (syngas) in a new power plant consisting of a single gasifier with gas cleanup systems, a gas combustion turbine, a heat recovery steam generator, a steam turbine, and associated facilities capable of generating 405 MW gross power. Because of its multiple production capabilities, the plant is referred to as a poly-generation (or polygen) plant designed so that it could sell urea, ammonia, and perhaps other nitrogenous compounds.

DOE invites interested parties to comment on this draft EIS during the 45-day comment period that will begin when the U.S. Environmental Protection Agency (EPA) publishes a notice of availability in the *Federal Register*.

Availability: DOE encourages public participation in the NEPA review process. A Notice of Availability will be placed in the Bakersfield Californian. This draft PSA/DEIS is also being made available for public review on DOE's National Energy Technology Laboratory web site, *http://www.netl.doe.gov/publications/others/nepa/ea.html, and DOE's NEPA web site at http://nepa.energy.gov/DOE_NEPA_documents.html* and posted on the California Energy Commission Docket at, *http://www.energy.ca.gov/sitingcases/hydrogen_energy/*

HYDROGEN ENERGY CALIFORNIA
(08-AFC-08A)
PRELIMINARY STAFF ASSESSMENT AND
DRAFT ENVIRONMENTAL IMPACT STATEMENT

Environmental Assessment

Engineering Assessment

EXECUTIVE SUMMARY

John Heiser

INTRODUCTION

This Preliminary Staff Assessment and Draft Environmental Impact Statement (PSA/DEIS) contains the California Energy Commission (Energy Commission) staff's and the US Department of Energy's (DOE) independent evaluation of Hydrogen Energy California, LLC's (applicant) Amended Application for Certification (08-AFC-8A) for the proposed Hydrogen Energy California project (HECA).

Energy Commission staff has completed an independent assessment under the California Environmental Quality Act (CEQA) and has revealed significant, and for the most part, unresolved issues. The issues are summarized as follows and discussed further in the Executive Summary and in detail in each related section of the PSA/DEIS.

DOE has completed its assessment pursuant to the National Environmental Policy Act. In accordance with Council on Environmental Quality implementing regulations (40 CFR 1500 thru 1508) and DOE's implementing procedures (10 CFR 1021), DOE has identified and evaluated the potential environmental impacts of the Proposed Action (providing financial assistance for the construction and operation of the applicant's project) and the alternatives. The PSA/DEIS describes the affected environment and the environmental consequences of the alternatives among various resource areas. DOE is also using the PSA/DEIS to fulfill certain responsibilities for documenting wetlands and floodplain impacts (10 CFR 1022), conformity with air quality standards (40 CFR Part 93), and consulting with expert agencies and tribes as required by the National Historic Preservation Act (Section 106), the Endangered Species Act (Section 7), and the Native American Graves Protection and Repatriation Act.

Air Quality

The San Joaquin Valley Air Pollution Control District has completed the Preliminary Determination of Compliance (PDOC) for HECA, and the District's analysis concluded that the HECA facility as proposed would comply with all applicable laws, ordinances, regulations and standards and would not create a health risk to the residents of the Valley. The PDOC contains upwards of 1,000 conditions applicable to the project. The District has approved two mitigation agreements with HECA to receive funds in the amount of $8,747,160 for the purpose of mitigating air quality impacts of the facility.

Greenhouse Gas Emissions

The applicant has described the facility's expected electrical capacity and hours of operation using more than one potential operating profile. Different operating profiles may need to be evaluated to determine which set of conditions represent actual operations and worst case impacts. Some operating profiles may result in the facility not complying with certain regulatory requirements. The California Air Resources Board (ARB) currently has not finalized regulations for geologic sequestration under the cap and trade program. If a methodology is not in place once the project is operational, it would have to purchase allowances or offsets for all CO_2 that HECA would sequester in addition to the direct CO_2 emissions. Once the methodology is in place, the project would still be required to purchase allowances for the CO_2 it is unable to sequester.

Biological Resources

The proposed HECA project would result in a significant, unavoidable impact to Blunt Nosed Leopard Lizard, a California Fully Protected species. During May 2013, the applicant submitted a Section 2081 Incidental Take Permit application for project impacts to state-listed wildlife species for which the applicant would be seeking incidental take coverage which staff has preliminarily reviewed. The U.S. Fish and Wildlife Service (Service) is reviewing the Biological Assessment that DOE sent to the Service on March 1, 2013. This is the process by which DOE complies with the consultation requirements of Section 7 of the Endangered Species Act.

Cultural Resources

Staff is still awaiting additional information from the applicant and has not reached any final conclusions regarding impacts to cultural resources. Approximately 75 percent of the HECA project components are located in areas considered sensitive for the presence of buried archaeological sites. There are potentially 21 known archaeological resources that would require mitigation along the proposed process water pipeline. At least five archaeological resources at the Enhanced Oil Recovery (EOR) site have been identified so far that would need to be mitigated. Additional sensitive resources may be identified as additional information is submitted prior to the publication of the FSA/FEIS.

Environmental Justice

Socioeconomics Figure 1 identifies an environmental justice population in the buffer area surrounding HECA and associated Elk Hills Oil Field EOR operation. Currently, several members of the technical staff have identified significant impacts from the construction and operation of the proposed HECA project, including the associated EOR operation. Staff does not have the necessary information to determine if these impacts can be mitigated below a significant level. If not, some or all of these impacts could have adverse or disproportionate impacts on an environmental justice population. Staff has requested the information they need to complete their impact analysis for inclusion in the FSA/FEIS.

HECA may result in an increased use of the Wasco coal transloading facility which could result in impacts related to air quality, public health, and traffic and transportation, among others. The potential need for expansion and improvements of the coal transloading facility near Wasco was not analyzed in the PSA/DEIS. Staff will be analyzing these potential impacts in the FSA/FEIS. **Socioeconomic Table 2** shows that on April 1, 2010 there was an 86 percent minority population in Wasco. Staff will assess whether there is an environmental justice population in the immediate vicinity of the transloading facility that could be adversely or disproportionately impacted. Staff will provide updated information in the FSA/FEIS

Land Use

HECA would result in a loss of 495 acres (for project site and rail spur) of Prime Farmland and Farmland of Statewide Importance. The project would require cancellation of Williamson-Act contracts for the facility site and lands associated with the rail spur. A Williamson Act contract cancellation request was scheduled for a public hearing with the Kern County Planning Commission on June 13, 2013. A continuation of this request has been re-scheduled for June 27, 2013 for Kern County Planning Commission consideration. Final determination of the cancellation request is to be made by the Kern County Board of Supervisors sometime thereafter. The proposed rail spur will require both private and public rail crossings to ensure that it will not divide the community, potentially resulting in a significant impact. Staff is waiting for additional information from the applicant.

Traffic and Transportation

HECA would result in a substantial increase in number of vehicles on local roads during construction and operation. Specifically, during construction the project would add 615 construction worker trips, 25 truck deliveries, and 80 trips for soil deliveries peak daily roundtrips.

Two alternatives are under consideration for transporting coal to the HECA facility: 1) constructing a rail spur or; 2) using trucks to deliver coal after it has been transported by rail from New Mexico. For the rail spur option (listed as Alternative 1 in the amended AFC), an approximately 5-mile-long new industrial railroad spur would be constructed to connect the HECA facility to the existing San Joaquin Valley Railroad (SJVRR) Buttonwillow railroad line. This railroad spur would also be used to transport some HECA products to market. For the no rail spur option (listed as Alternative 2 in the amended AFC), an approximately 27-mile-long truck transport route would be used via existing roads to transport the coal from an existing coal trans-loading facility located northeast of the HECA project site. The applicant is currently requesting that both options be certified.

During operation with the rail spur, the project would add 51 operations and maintenance, 71 process materials and byproducts, and 55 feedstock materials delivery peak daily roundtrips. Without the rail spur, the project operation would add 51 operations and maintenance, 133 process materials and byproducts, and up to 400 feedstock materials delivery daily roundtrips.

Visual Impacts

Staff's preliminary determination of HECA would likely result in unmitigable significant impacts to visual resources.

Water Supply

The applicant has estimated that the HECA project will use 7,500 acre feet of groundwater per year. Applicant believes that the water is high in total dissolved solids (TDS) and therefore acceptable for process use in accordance with SWRCB Resolution

75-58. However local farmers argue the groundwater has greater beneficial uses for irrigation of pistachio crops. Buena Vista Water Storage District (BVWSD) developed a Brackish Groundwater Remediation Plan, which indicates the HECA project could play a large role in its implementation. Staff has been unable to confirm that the plan for HECA to use this groundwater has any beneficial effect on water quality in the aquifer. In fact staff believes, given current data, that there could be a significant impact on water quality that could affect other users. In addition, staff has concluded that the planned well field extraction rate (7,500 AF/yr) may exceed the annual storage increase characterized by historical water level trends. This would be a significant impact for which no mitigation has been identified. The applicant and BVWSD have indicated there is additional information staff has not considered in the analysis. Staff has repeatedly requested this information and to date has not received it.

Staff is in the process of investigating the feasibility of dry cooling the facility, which would reduce project water demand by approximately 90 percent of the proposed amount and could reduce water costs by approximately $76,000,000 over the 25-year life of the project. Such an analysis could mitigate potential impacts from overdraft and to water quality.

Waste Management

A major byproduct of the HECA project will be gasification solids (coal/petcoke/limestone ash and slag). The applicant is researching possible ash and slag markets, including for use in asphalt, sandblasting, or other industrial uses. If no market can be found, however, then it will have to be landfilled, which could cause Kern County to exceed CalRecycle's acceptable waste/recycle ratio. Kern County has requested a modification from CalRecycle that would exempt these wastes from the requirement, but so far CalRecycle has not responded. It would be helpful to get CalRecycle to weigh in on whether it would grant the modification prior to the Final Staff Assessment. The applicant is assessing the economics and logistics of train transportation of ash and slag to out-of-state landfills. It is unclear how this would affect Kern County's CalRecycle compliance. Additionally, as a result of previous site activities, recent soil sampling and analytical testing indicated elevated concentrations of petroleum hydrocarbons and other contaminants. Prior to publication of the FSA/FEIS staff recommends that the project owner develop a Soils Management Plan (SMP) to describe procedures to be followed during soil disturbance so workers can be protected from soil contamination that may be encountered. Staff proposes Condition of Certification **WASTE-1** to ensure the applicant has procedures in place to properly handle and dispose of contaminated soil.

PREPARATION AND USE OF A JOINT-ENVIRONMENTAL DOCUMENT

The Energy Commission has exclusive permitting jurisdiction for the siting of thermal power plants of 50 megawatts (MW) or more and their related facilities in California. The Energy Commission also has responsibility for ensuring compliance with the California Environmental Quality Act (CEQA) through the administration of its certified regulatory program and as the lead agency under CEQA. Through the Energy Commission's certified regulatory program, this document is functionally equivalent to an

Environmental Impact Report (EIR), and examines engineering, environmental, public health and safety aspects of the proposed HECA project, based on the information provided by the applicant and additional independent information available from other sources at the time the PSA/DEIS was prepared.

The U.S. Department of Energy (DOE) proposes to provide financial assistance to Hydrogen Energy California, LLC to design, construct and demonstrate the HECA. DOE selected HECA for funding through a competitive process under the Clean Coal Power Initiative program (CCPI), round three. Because DOE proposes to award funding to the HECA project, DOE's proposed action is subject to the National Environmental Policy Act (NEPA) process which, in this case, requires preparation of a Draft Environmental Impact Statement (DEIS) followed by a Final Environmental Impact Statement (FEIS).

The Energy Commission staff and the DOE have cooperated to complete an assessment of the project's engineering design and identify the potential impacts on the environment, the public's health and safety, as well as determine whether the project conforms to all applicable laws, ordinances, regulations and standards (LORS). Additionally, upon identifying any potentially significant environmental impacts, Energy Commission staff recommends mitigation measures in the form of conditions of certification for construction, operation and eventual closure of the project, in order to comply with CEQA.

This PSA/DEIS is not a decision document for DOE or the Energy Commission, nor does it contain findings of the Energy Commission related to environmental impacts or the project's compliance with local/state/federal legal requirements. This document serves as a precursor to the Final Staff Assessment/Final Environmental Impact Statement (FSA/FEIS).

Energy Commission and DOE staff will hold a joint PSA/DEIS public workshop to receive public and agency comment on the PSA/DEIS after its publication. The workshop is used to receive comments from individuals and organizations, to identify and resolve areas of disagreement and to discuss additional informational requirements. In addition, DOE and Commission staff will accept comments on the PSA/DEIS for at least 45 days after publication of the U.S. Environmental Protection Agency's notice of availability of the PSA/DEIS.

After close of the comment period on this PSA/DEIS, DOE and Energy Commission staff will prepare and publish the FSA/FEIS, the FSA portion of which will serve as Energy Commission staff's formal testimony in evidentiary hearings to be held by the Energy Commission Committee assigned to hear this case. The Committee will hold evidentiary hearings and will consider the recommendations presented by the staff, applicant, intervenors, government agencies, and the public, prior to issuing a proposed decision. Following a 30-day comment period and a public hearing(s), the full Energy Commission will make a final decision. The FSA/FEIS will also be used by the DOE to inform its decision on whether to award funding to Hydrogen Energy California, LLC. DOE's decision will be announced in a Record of Decision.

PROJECT HISTORY

The original Application for Certification (08-AFC-8) was filed with the Energy Commission on July 31, 2008; and a Revised AFC was submitted in 2009 to reflect a change of the project site to an alternative location. In 2011, Hydrogen Energy California, LLC was acquired from the previous owners by SCS Energy California, LLC. On May 2, 2012, SCS Energy, LLC, submitted an Amended Application for Certification (08-AFC-8A) reflecting several changes to the original project design.

The new Amended AFC has been assigned a separate distinguishing docket number, 08-AFC-8A. The Amended AFC for the project supersedes and replaces all previous filings from the earlier proceeding (08-AFC-8).

PROJECT LOCATION

The proposed project would be located on a 453 acre site (currently used for agricultural production of alfalfa, cotton, and onions). The applicant has an option (contract) to purchase an additional 653 acres adjacent to the project site, which would allow for controlled access and land use. The project site would be located in an unincorporated portion of Kern County, approximately 7 miles west of the western border of the city of Bakersfield. The proposed site is 1.5 miles northwest of the unincorporated community of Tupman, and approximately 4 miles southeast of the unincorporated community of Buttonwillow. Refer to **Project Description Figure 1** for a map showing the location of the project. An irrigation canal (California State Water Aqueduct) lies to the south, and the Elk Hills Oil Field is located approximately 3 miles southwest of the project site. The project would have a 13-mile long natural gas pipeline, 1-mile long potable water pipeline, 2-mile long transmission line interconnecting to a new Pacific Gas and Electric (PG&E) switching station east of the project site, approximately 3-mile long CO_2 pipeline, a 15-mile long process water pipeline and a 5-mile long rail spur.

The western border of the Tule Elk State Natural Reserve (California State Park) is located approximately 1,700 feet to the east of the project site. The nearest residential dwellings are located approximately 370 feet to the northwest, 1,400 feet to the east, 3,300 feet to the southeast of the proposed project site, and 4,000 feet to the north.

PROJECT DESCRIPTION

HECA would use an integrated gasification, combined-cycle power system to produce and sell electricity, carbon dioxide, and fertilizer. Coal and petroleum coke (a refinery byproduct), would be gasified with oxygen (obtained from the air separation unit - ASU) to produce synthesis gas (syngas). The ratio of coal and petroleum coke used would be approximately 75 percent and 25 percent, respectively. The syngas would be cleaned via scrubbers and absorbers to filter out chlorides, sulfur, mercury, particulates, and impurities. Lastly, the syngas would be stripped of carbon dioxide, leaving a hydrogen-rich gas.

The hydrogen rich gas would either be combined with air and used as fuel in a combustion turbine combined cycle facility to produce electricity (similar to a natural gas fired combined cycle) or sent to an integrated manufacturing complex to produce over 1,000,000 tons per year of nitrogen-based fertilizer. The manufacturing complex would manufacture anhydrous ammonia and nitric acid to produce urea ammonium nitrate (UAN) and urea pastilles. The anhydrous ammonia and nitric acid would only be intermediate products used to produce fertilizers and would not be sold as stand-alone products.

The project would capture up to 90 percent of the carbon dioxide in the syngas stream, which would then be piped a little over 3 miles to the Elk Hills Oil Field, where it would be used by Occidental of Elk Hills, Inc. (OEHI) for enhanced oil recovery (EOR). This use of captured CO_2 could result in the eventual sequestration of approximately 2.6 million tons of CO_2 per year. Some of the captured CO_2 and nitrogen from the air separation unit would be used to manufacture urea fertilizer and other nitrogenous compounds. While OEHI has stated that it can use as much carbon dioxide as HECA can produce, the stated lifespan of the OEHI operation (20 years) is shorter than the length of time HECA proposes to operate (25 years).

The project proposes to generate between 405 and 431 MW gross or an average of 416MW gross electrical power and between 151 to 266 MW net after accounting for onsite auxiliary power loads. The lower values apply during the periods of maximum fertilizer production and the higher values apply during periods of maximum electricity production. When considering the air separation unit and the electricity used by OEHI during enhanced oil recovery operations, which are both part of the project as described by the applicant, the net electricity generation available to California consumers drops to 52.5 MW of new electrical capacity added to the grid during periods of maximum electricity production. The project would be a net consumer of 61.8 MW from the grid during periods of maximum fertilizer production. These net power values include all project-wide power generation and power consumption sources, including the power consumption of the third-party owned air separation unit and the power consumption required by OEHI for CO_2 compression/injection/recovery/re-injection for EOR and, ultimately, carbon sequestration.

The coal would be transported from New Mexico via rail. The applicant has requested certification of two options for final transport to the project site. One option would be to construct a 5-mile long rail spur so that trains could go directly to the project site. The other option would be to offload the coal at the Wasco Transloading Facility into trucks for 400 round trips each day for the final 27 miles to the project site. In either case, the petroleum coke would be trucked in from the Santa Maria refinery or other refineries located in Southern California.

In addition to electricity and CO_2, other produced products would include degassed liquid sulfur, gasification solids and nitrogen-based fertilizers. HECA is expected to generate a maximum of 850 tons per day of gasification solids, 200 tons per day of sulfur, 2,800 tons per day of UAN and 1,670 tons per day of urea pastilles. The actual production rates of these intermediate and final products are likely to vary as market conditions dictate.

The gasification solids would accumulate onsite (up to 7 days worth could be stored on site) and made available for appropriate recycling or beneficial use into roofing shingle aggregate and concrete pozzolanic admixtures. If these options are not available, HECA would dispose of these solids in accordance with applicable laws. The sulfur in the feed stocks would be removed and converted to a salable product, which would be transported offsite by truck or rail. The UAN and urea pastilles would also be exported offsite by truck or rail.

A portion of the hydrogen-rich fuel would be used as a feedstock for the ammonia synthesis unit, which would have a capacity of 2,000 tons per day of ammonia. The ammonia would be used as an intermediate for the production of urea for sale. The project's urea production unit would use pastillation technology, which converts urea melt into high quality urea pastilles (small solid pellets). The unit would have a capacity of about 1,670 tons per day.

The applicant proposes to use up to 7,500 acre feet per year of groundwater purchased from the Buena Vista Water Storage District, which is significantly more water per megawatt than other projects recently licensed by the Energy Commission. While the applicant and district refer to this water as brackish, there is evidence that it could be used for other more beneficial purposes.

For more detailed information about the project and its components, please see **Project Description**.

CUMULATIVE EFFECTS

Staff conducted an extensive search of past, present, and reasonably foreseeable "probable" future projects (see **Cumulative Project List Table 14** in the **Socioeconomics** section). Staff reviewed project tracking information and available environmental reports and notices through various resources, including websites of local, regional and state jurisdictions. Additionally, staff queried project managers from various California public agencies to compile a comprehensive list of past, present and probable future projects that resulted in its list of Cumulative Projects. **Table 1** below presents a master list of the projects considered part of the HECA cumulative setting.

CEQA Guidelines define cumulative impacts as "two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts." (Cal. Code Regs., tit. 14, § 15355.) The Guidelines continue: (a) "[t]he individual effects may be changes resulting from a single project or a number of separate projects" and (b) "[t]he cumulative impact from several projects is the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time." (*Ibid*.)

Accordingly, staff in each technical section of this PSA determined which of the projects from the Cumulative Projects list could create impacts specific to their technical area.

Using unique sets of criteria specific to each area, staff then evaluated whether the cumulative effects were significant, and if so, whether the project's contribution to that combined effect would be "cumulatively considerable". Therefore, this PSA/DEIS will identify and analyze the impacts of all aspects and phases of HECA, including the combined effect the proposed project will have in conjunction with other projects.

Table 1 -- HECA Master List of Cumulative Projects

Project Name	Location	Description
Abajo Transmission	Kern County	Installation of 18-inch diameter pipeline along Abajo Avenue connecting Sage Land and Santa Lucia water tanks.
Barren Ridge Transmission	Kern County; Los Angeles County	Expansion of Barren Ridge Switching Station; and construction of Haskell Canyon Switching Station; construction of 230 kV transmission lines and reconductoring of existing lines.
Berry Petroleum Steam Injection	Kern County	Construction of cyclic steam injection facilities for enhanced oil recovery.
Biodiesel Refinery	City of Fresno	Three phase construction of industrial biodiesel refining facility.
Borax Co-gen Plant Replacement	Kern County	Construct replacement co-generation plant with two natural-gas-fired turbine generators and steam recovery system.
California High Speed Rail	Fresno County; Kern County; Los Angeles County	Construction of dedicated, electrified high-speed rail system. If developed, Merced to Palmdale sections may utilize area labor.
Calnev Pipeline Expansion	San Bernardino County	Construction of a new 233-mile 16-inch diameter pipeline.
Crystal Geyser Bottling Plant	Inyo County	Construct water-bottling facility with associated warehouse and 8.3-acre solar photovoltaic power array.
Fremont Valley Preservation	Kern County	Construction of tertiary wastewater treatment and disinfection facility.
Fresno Tertiary Water Treatment	City of Fresno	Construct tertiary wastewater treatment and disinfection facility.
Lehigh Alternative Fuels	Kern County	Install equipment necessary to use alternative fuels to provide heat for cement production.
Liberty Energy Center	Kern County	Construct 19.5-megawatt gasification facility to supplement existing composting operation.
Northern Area Water	Kern County	Convert 18-miles of earthen canals to 25-miles of pipeline in Buttonwillow Service Area.
Red Rock Bridge Replacement	Kern County	Replace existing bridge on SR 14 at Red Rock Canyon Wash.
Sierra View Hospital Laboratory	City of Porterville	Construct new hospital laboratory facility.
Tulare County Sherriff Detention Facility	Tulare County	Construct new Tulare County detention facility.

Sources: Fresno County 2012, Kern County 2012b, Kern County 2012c, Kern County 2012d, OPR 2012.

In addition to the projects listed above, staff identified 132 solar photovoltaic power projects and 11 wind power projects that are planned, proposed, or under development in the defined labor market area for staff's socioeconomics analysis. Over half of the solar projects are proposed in Kern County, while the remaining projects are primarily in Fresno County. The photovoltaic projects range in size from one MW or less, to over 1,000 MW, in the case of the Kern Solar Ranch project. The majority of the proposed wind power projects are located in eastern Kern County. They range in size from 40 to 750 MW.

PUBLIC AND AGENCY COORDINATION AND OUTREACH EFFORTS

Energy Commission certification is in lieu of any permit required by state, regional, or local agencies, and federal agencies to the extent permitted by federal law (Pub. Resources Code, §25500). However, the Energy Commission seeks comments from and works closely with other regulatory agencies that administer LORS that may be applicable to proposed projects. These agencies may include, but are not limited to, the U.S. Environmental Protection Agency, U.S. Fish and Wildlife Service, U.S. Army Corps of Engineers, State Water Resources Control Board, Central Valley Water Quality Control Board, California Department of Fish and Wildlife, the California Air Resources Board, California Public Utilities Commission, California Department of Conservation (including the Division of Oil, Gas, and Geothermal Resources), California Department of Parks and Recreation (including the Office of Historic Preservation), California Department of Toxic Substances Control, the San Joaquin Valley Air Pollution Control District, Buena Vista Water Storage District, and Kern County.

On May 15, 2012, the Energy Commission staff sent a notice of receipt and a copy of the HECA Amended Application for Certification to a comprehensive list of all local, state, and federal agencies that administer LORS applicable to the project, as well as to other agencies that may have an interest in the proposed project and public libraries. Additionally, the notice of receipt of the Amended AFC was sent to property owners within 1,000 feet of the proposed project and those located within 500 feet of the linear facilities. In addition to providing notice of receipt of the AFC, the notices provided a brief description of the project, discussion of the Energy Commission's siting certification process, and information on how agencies and the public can comment and participate in the proceeding. Staff continues to seek cooperation and comments from regulatory agencies that administer LORS that are applicable to the proposed project as well as comments from the public. Staff also mailed notices on May 15, 2012, informing elected officials of the Commission's receipt and availability of the application 08-AFC-8A. Each notice contained a link to the Commission-maintained HECA project website (http://www.energy.ca.gov/sitingcases/hydrogen_energy/index.html).

On June 19, 2012 the U.S. Department of Energy placed in the *Federal Register* an Amended Notice of Intent Modifying the Scope of the Environmental Impact Statement for the Hydrogen Energy California's Integrated Gasification Combined Cycle Project.

LIBRARIES

On May 11, 2012, (08-AFC-8A) the Energy Commission staff sent the HECA Amended AFC to libraries in the city of Taft, Tehachapi, Boron, Bakersfield, and Buttonwillow. In addition, the Amended AFC was also sent to state libraries in Eureka, Fresno, Los Angeles, Sacramento, San Diego, and San Francisco.

PUBLIC WORKSHOPS

Energy Commission staff conducted several public workshops to facilitate public, agency, and intervenor participation. Furthermore, these workshops allowed a transparent and comprehensive discussion of several technical issues related to the proposed project and allowed for further staff, agency, and public understanding. The Energy Commission issued notices for all these workshops at least 10 days prior to each meeting. These workshops were conducted on the following dates:

On June 20, 2012, Energy Commission staff facilitated a workshop on the Amended AFC (08-AFC-8A), data requests, and the revised Monitoring, Reporting and Verification Plan (MRVP). The purpose of the workshop was to allow staff, the applicant, intervenors, interested agencies, and the public to discuss several technical disciplines related to the HECA Amended AFC, including but not limited to the project description, air quality, carbon capture and storage, coordination between local, state and federal agencies, traffic and transportation, water resources and other topics as needed.

On July 12, 2012, DOE and CEC held a joint publicly noticed meeting at the Elk Hills Elementary School, 501 Kern Street, Tupman, CA 93276. For the Energy Commission, this meeting constituted its Site Visit and Informational Hearing, which provided an opportunity for members of the community in the project vicinity to obtain information about the project and included a site visit and brief presentation at the proposed project site.

On September 27, 2012, staff conducted a publicly noticed data response workshop in Sacramento and discussed the topics of air quality, greenhouse gas, carbon capture and storage, land use, biology, cultural resources, socioeconomics, traffic and transportation, public health and safety, visual resources, public health, hazardous materials, hazardous waste, and soil and water resources. Participating in the workshop were the applicant, US DOE, California Department of Fish and Wildlife, U.S. Fish and Wildlife Service, Sierra Club, and the public.

On November 7, 2012, staff conducted a publicly noticed data response workshop in Bakersfield with the applicant, intervenors and public with discussions on air quality, greenhouse gas, carbon capture and storage, land use, biology, public health and safety and hazardous materials. Participating agencies in the workshop included the California Department of Fish and Wildlife, California Department of Conservation - Division of Oil, Gas, and Geothermal Resources (DOGGR), and Kern County.

On February 20, 2013, Energy Commission staff conducted a water supply issues resolution workshop at the California Energy Commission office in Sacramento, California. The applicant, Buena Vista Water Storage District staff, intervenors, interested agencies, and public where in attendance.

After the PSA/DEIS has been published, PSA/DEIS Workshops (CEQA)/Public Meetings (NEPA) will be held in Buttonwillow (Kern County, California).

CONSULTATION WITH LOCAL NATIVE AMERICAN COMMUNITIES

The following is intended as a narrative record of Native American consultation for the project. Updates will be added as appropriate and dated. A separate list of participants in the Native American consultation process is kept by the Energy Commission team and U.S. Department of Energy.

Consultation with local Native American communities regarding the proposed HECA project was initiated by three entities: URS Corporation (consultant to the applicant), the U.S. Department of Energy (DOE), and Energy Commission staff.

URS contacted the California Native American Heritage Commission on four occasions from 2008 through 2009, requesting a records search of the Sacred Lands File, and a list of local Native American contacts (individuals and/or organizations) that might have knowledge of cultural resources within the project area of analysis. The Native American Heritage Commission provided lists of individuals and organizations that might have knowledge of cultural resources in the project area of analysis. URS sent letters to the listed contacts; the letters described the proposed project and contained a map depicting the proposed project. Letters were sent to the identified parties on March 14, 2008; June 24, 2008; and April 1, 2009. The letters inquired whether the recipients had any concerns regarding the proposed project or wished to provide input regarding cultural resources in the project area of analysis. URS also corresponded with Native American contacts by telephone between 2008 and 2010. Native American input consisted of recommendations for cultural resources monitoring during construction and preparation of a monitoring plan and burial agreement.

On May 10, 2012, DOE mailed consultation letters to three federally recognized Indian tribes in partial fulfillment of its obligations to consult with Indian tribes under Section 106 of the National Historic Preservation Act, among other federal laws, orders, regulations, and guidelines. These tribes were the Tejon Indian Tribe, Santa Rosa Rancheria of Tachi Yokuts, and Tule River Indian Tribe. The Tejon Indian Tribe responded by letter on June 5, 2012, indicating that it had no knowledge of specific cultural resources in the project area nor any conflict with the proposed project. Tejon Indian Tribe later indicated that it was interested in more information about the proposed project (see below).

Energy Commission staff consulted with Native American tribes and individuals regarding the proposed HECA project. Staff obtained a list of local Native American contacts from the State of California's Native American Heritage Commission on June 13, 2012. Staff mailed letters to these 10 contacts (representing eight tribes and Native American organizations) on June 21, 2012. The letters briefly described the proposed project, outlined the Energy Commission's siting review process, and requested comments and information concerning cultural resources. On July 17, 2012, staff met with Dr. Donna Begay, then-tribal chairwoman of the Tubatalabals of Kern Valley, to discuss tribal concerns with the proposed project. Staff also had telephone conversations with several Native Americans and DOE staff.

Correspondence between staff, tribes, and DOE culminated in a September 26, 2012 meeting to examine the enhanced oil recovery area in Elk Hills. The meeting was attended by Energy Commission staff, members of the Tejon Indian Tribe, DOE personnel, and personnel from Occidental of Elk Hills. The purpose of the meeting was to acquaint the Tejon Indian Tribe with the setting of the proposed enhanced oil recovery facilities, the proposed HECA project as a whole, and discuss tribal concerns. Although the Tejon Indian Tribe did not share information about specific cultural resources in the project area of analysis, the tribe indicated that it is concerned about the proposed project's potential to damage Native American archaeological sites and human remains. All parties present discussed the level of effort needed to identify cultural resources in the proposed Occidental of Elk Hills enhanced oil recovery area, and the Tejon Indian Tribe requested information about how it can continue to participate in the siting review process.

During the weeks of October 8 and 15, 2012, staff mailed packets of information to the tribes and individuals that asked to participate further in the siting review process. Packets were sent to the Tejon Indian Tribe, Santa Rosa Rancheria of Tachi Yokuts, Kitanemuk & Yowlumne Tejon Indians, and Ron Wermuth. These packets contained information on how to participate in the siting process, project descriptions and associated maps.

DOE had a follow-up telephone conversation with the Tejon Indian Tribe on October 3, 2012, during which the tribe stated that it would be requesting confidential archaeological resource maps from the Energy Commission. Staff has not yet received the specific requests.

Participants in the meetings are on file with the Energy Commission and DOE.

ENERGY COMMISSION'S PUBLIC ADVISER'S OFFICE

The Energy Commission's outreach program is also facilitated by the Public Adviser's Office (PAO), which conducts an ongoing, consistent outreach process apart from the efforts of the applicant or other parties. The PAO ensures full and adequate public participation in the HECA project through a variety of activities, including:

- advising interested groups and the public about how to participate;
- requesting that organizations post public service announcements;
- distributing notices about the Energy Commission's receipt of the HECA Amended Application for Certification (AFC); and

- placing advertisements in local newspapers and distributing bilingual notices regarding the Public Site Visit and Informational Hearing/DOE Scoping Meeting held on July 12, 2012 at the Elk Hills School in Tupman (Kern County), California.

RESPONSE TO COMMENTS

Energy Commission staff endeavored to respond to all comments pertaining to the proposed project received to date. As this document was being finalized for publication, however, it could not be continually updated to respond to comments still coming in. Therefore, any comments already made but not addressed in this document will be addressed in the appropriate technical section in the FSA/FEIS. All comments received in response to DOE's Notice of Intent have been addressed as a standard part of the analyses or considered, called out and addressed within the PSA/DEIS. Please see the attached, Appendix 1 of the Executive Summary, for a list of all comments received and addressed within the PSA/DEIS. Responses can be found in the "Response to Comments" subsection of most technical sections. The FSA/FEIS will also contain staff responses to all comments filed on the PSA/DEIS up to the end of the noticed public comment period.

ENVIRONMENTAL JUSTICE

California law defines environmental justice as "the fair treatment of people of all races, cultures, and income with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies" (Government Code Section 65040.12 and Public Resources Code Section 72000).

All Departments, Boards, Commissions, Conservancies and Special Programs of the California Natural Resources Agency must consider environmental justice in their decision-making process if their actions have an impact on the environment, environmental laws, or policies. Such actions that require environmental justice consideration may include:

- adopting regulations;
- enforcing environmental laws or regulations;
- making discretionary decisions or taking actions that affect the environment;
- providing funding for activities affecting the environment; and
- interacting with the public on environmental issues.

In considering environmental justice in energy facility siting cases, staff uses a demographic screening analysis to determine whether a low-income and/or minority population exists with the potentially affected area of the proposed site. The demographic screening is based on information contained in two documents: Environmental Justice: Guidance Under the National Environmental Policy Act (Council on Environmental Quality, December, 1997) and Guidance for Incorporating

Environmental Justice Concerns in EPA's Compliance Analyses (U.S. Environmental Protection Agency, April, 1998). Due to the change in the sources and methods of collection used by the U.S. Census Bureau, the screening process relies on Year 2010 U.S. Census data to determine the number of minority populations and data from the 2007-2011 American Community Survey (ACS) to calculate the population below-poverty-level. Staff's demographic screening is designed to determine the existence of a minority or below-poverty-level population or both within the area of the proposed project.

Environmental Justice: Guidance Under the National Environmental Policy Act, defines minority individuals as members of the following groups: American Indian or Alaskan Native; Asian or Pacific Islander; Black, not of Hispanic origin; or Hispanic. A minority population is identified when the minority population of the potentially affected area is:

1. greater than 50 percent;
2. or when the minority population percentage of the area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis.

In addition to the demographic screening analysis, staff and DOE follow the steps recommended by the U.S. EPA's guidance documents in regard to outreach and involvement; and if warranted, a detailed examination of the distribution of impacts on segments of the population.

Staff and DOE have followed each of the above steps for the following thirteen sections in the PSA: **Air Quality, Cultural Resources, Hazardous Materials Management, Land Use, Noise and Vibration, Public Health, Socioeconomics, Soil and Water Resources, Water Supply, Traffic and Transportation, Transmission Line Safety and Nuisance, Visual Resources,** and **Waste Management**. Over the course of the analysis for each of these technical disciplines, staff considered potential impacts and mitigation measures, and whether there would be a significant impact on an environmental justice population.

To assess the potential presence of an environmental justice population in the project area, staff first estimated two radii encompassing areas equal to 6-miles from the center points of the HECA power plant site and the CO_2 processing facility site, respectively. Staff then merged the two radii to create a combined buffer area. **Socioeconomics Table 2** presents data on the minority population within the buffer area, as well as for a variety of surrounding communities and for an assortment of comparison geographies.

According to the latest decennial census, the 2010 resident population of the census blocks located within the buffer area was 3,663 persons. The minority population was 1,850 persons, which equaled roughly 51 percent of the total population.

Notable population centers located within the buffer area include Buttonwillow, Dustin Acres, Tupman, and Valley Acres. Buttonwillow had a total population of 1,508 and a minority population of 1,254, equal to nearly 83 percent minority. Dustin Acres had a total population of 652, with a minority population of 159, or around 24 percent. Tupman had a smaller population with 161 residents, and a minority population of 22 residents, equal to around 14 percent. Valley Acres had a total population of 527, with a minority population of 148, or around 28 percent.

Other notable communities located in the general project area include Bakersfield, Derby Acres, Fellows, Ford City, Maricopa, McKittrick, South Taft, Taft, Taft Heights, and Wasco. Of these, Bakersfield had a 62 percent minority population, while Ford City was 50 percent minority and Wasco was nearly 86 percent minority. Kern County as a whole showed a minority population equal to more than 61 percent of the total population. The HECA project site and the CO_2 processing site are located within two different Census County Divisions (CCDs). The Buttonwillow CCD had a minority population of nearly 67 percent, while the West Kern CCD had a minority population of only around 36 percent. **Socioeconomics Table 2** provides additional data for these geographies for comparison purposes.

Below-Poverty-Level-Populations as discussed in the **Socioeconomics** section - **Socioeconomics Table 3** shows estimates of the population living below-poverty-level from the 2007-2011 ACS Five-Year Estimates. According to this data, approximately 1,390 people in the combined census tracts intersecting the project buffer area, about 21 percent, lived below the federal poverty threshold between 2007 and 2011.

Because the minority population located within the buffer area was greater than 50 percent of the total population, staff and DOE conclude that the minority population located within the buffer area does constitute an environmental justice population, as defined above. Construction and operation of the proposed HECA project, including the associated EOR operation, could therefore have adverse or disproportionate impacts on an environmental justice population. Please refer to each technical section to identify whether the project has significant, unmitigated impacts on the above identified environmental justice population.

DEPARTMENT OF ENERGY'S SUMMARY STATEMENT

Preamble

The National Environmental Policy Act (NEPA)

PURPOSE AND NEED FOR DEPARTMENT OF ENERGY ACTION

This chapter introduces the Proposed Action of the Department of Energy (DOE), describes the purpose and need for DOE's action, and outlines the scope of the DOE's NEPA analysis contained in this Preliminary Staff Assessment and Draft Environmental Impact Statement (PSA/DEIS) . This section also summarizes DOE's process, project objectives, and the public scoping process undertaken for this PSA/DEIS.

INTRODUCTION

DOE proposes to provide federal financial assistance to Hydrogen Energy California, LLC (HECA) for its proposed project (the “project”), which would demonstrate integrated gasification combined cycle (IGCC) technology with carbon capture in a new electricity generating plant in Kern County, California. DOE has prepared this PSA/DEIS in accordance with NEPA (42 United States Code [U.S.C.] §§ 4321 et seq.), regulations implementing NEPA promulgated by the Council on Environmental Quality (Title 40, Code of Federal Regulations [C.F.R.] Parts 1500–1508), and DOE’s NEPA procedures (10 C.F.R. Part 1021). This PSA/DEIS describes the potential environmental impacts associated with DOE’s proposed action (providing financial assistance), the project itself (including aspects of the project that DOE would not fund), and alternatives to and options for the project, including the No Action Alternative. DOE will use this PSA/DEIS to inform its decision on whether to provide financial assistance for construction and demonstration of the project and, if so, whether it should impose environmental mitigation measures as a condition of its financial assistance for these activities.

HECA would construct its electricity and fertilizer production facility on a site currently used for agriculture in Kern County. The 1,106 acre site (453 acres of which would be used for the project and 653 acres for a controlled buffer area) is in south-central California near the unincorporated community of Tupman, approximately 7 miles west of the western border of the city of Bakersfield. The site’s topography is relatively flat, low-lying terrain that gently slopes from southeast to northwest. The site and surrounding areas are used for agricultural purposes, including cultivation of cotton, alfalfa, and onions. HECA’s facility would capture about 90 percent of the carbon dioxide (CO_2) produced by the gasification process. Most of this captured CO_2 would be transported via a new pipeline to a nearby oil field owned by Occidental of Elk Hills, Inc. (OEHI), where it would be sequestered through its use for enhanced oil recovery (EOR). HECA would use a small portion of the captured CO_2 to produce urea fertilizer and other nitrogenous compounds.

CLEAN COAL POWER INITIATIVE

Since the early 1970s, DOE and its predecessor agencies have pursued research and development programs that include large, technically complex projects in order to spur innovation in a wide variety of coal technologies through the proof-of-concept stage. However, helping a technology reach the proof-of-concept stage does not ensure its continued development or commercialization. Before a technology can be considered seriously for commercialization, it must be demonstrated at a sufficient scale to prove its reliability and economic competitiveness. The financial risk associated with such large-scale demonstration projects is often too high for the private sector to assume in the absence of strong incentives.

The Clean Coal Power Initiative (CCPI) program was established in 2002 as a government and private sector partnership to implement the recommendation in President Bush's National Energy Policy to increase investment in clean coal technology. Through cooperative agreements with its private sector partners, the program advances clean coal technologies to commercialization. These technologies involve combustion improvements, control systems advances, gasifier design, pollution reduction (including greenhouse gas reduction), efficiency increases, fuel processing, and others.

Congress established criteria for projects receiving financial assistance under this program in Title IV of the Energy Policy Act of 2005 (Pub. L.109-58) (EPACT 2005). Under this statute, CCPI projects must "advance efficiency, environmental performance, and cost competitiveness well beyond the level of technologies that are in commercial service" (Pub. L. 109-58, § 402(a)). In February 2009, the American Recovery and Reinvestment Act of 2009 (Pub. L. 111-5, 123 Stat. 115 (Feb. 17, 2009)) (ARRA) appropriated $3.4 billion to DOE for "Fossil Energy Research and Development;" the Department is using a significant portion of these funds to provide financial assistance to CCPI projects.

DOE's CCPI program selects projects for its government-private sector partnerships through an open and competitive process. Potential private sector partners may include developers of technologies, utilities and other energy producers, service corporations, research and development firms, software developers, academia and others. DOE issues funding opportunity announcements that specify the types of projects it is seeking, and invites submission of applications. Applications are reviewed according to the criteria specified in the funding opportunity announcement; these criteria include technical, financial, environmental, and other considerations. DOE selects the projects that demonstrate the most promise when evaluated against these criteria, and enters into a cooperative agreement with the applicant. These agreements set out the project's objectives, the obligations of the parties, and other features of the partnership. Applicants must agree to provide at least 50 percent of their project's cost; for most CCPI projects, the applicant's cost share will be much greater if the project proceeds to completion.

To date, the CCPI program has conducted three rounds of solicitations and project selections. The first round sought projects that would demonstrate advanced technologies for power generation, improvements in plant efficiency, economics, and environmental performance. Round 2 requested applications for projects that would demonstrate improved mercury controls and gasification technology. Round 3, which DOE conducted in two phases, sought projects that would demonstrate advanced coal-based electricity generating technologies which capture and sequester (or put to beneficial use) carbon dioxide emissions. DOE's overarching goal for Round 3 projects was to demonstrate technologies at commercial scale in a commercial setting that would: (1) operate at 90 percent capture efficiency for CO_2; (2) make progress towards capture and sequestration at less than a 10 percent increase in the cost of electricity for gasification systems and a less than 35 percent increase for combustion and oxycombustion systems; and (3) make progress toward capture and sequestration of 50 percent of the facility's CO_2 output at a scale sufficient to evaluate the full impacts of carbon capture technology on a generating plant's operations, economics and performance.

The HECA project was one of two selected in the first phase of Round 3. DOE entered into a cooperative agreement with HECA on September 30, 2009, and began the NEPA process. HECA had already begun to seek the regulatory authorizations needed for the project, including certification by the Energy Commission and environmental permits from other agencies before its project was selected to receive financial assistance from DOE. It continued to seek these approvals and permits until September 2, 2011, when SCS Energy California LLC (SCS Energy) acquired HECA from BP Alternative Energy North America Inc. (BP), and Rio Tinto Hydrogen Energy LLC (Rio Tinto). Because SCS Energy intended to make several modifications to the project – including the addition of fertilizer production capabilities – the NEPA and regulatory processes were suspended until HECA submitted an Amended Application for Certification (AFC) to the Energy Commission on May 2, 2012.

DOE'S NEPA STRATEGY

In compliance with NEPA, this PSA/DEIS will be used by DOE decision-makers to inform their decision on whether to provide financial assistance for detailed design, construction, and operation of the project. This PSA/DEIS evaluates the environmental impacts of alternatives and connected actions and provides a means for the public to participate in the decision-making process.

DOE developed an overall strategy for compliance with NEPA for its CCPI program consistent with CEQ regulations (40 CFR 1500 through 1508) and DOE regulations (10 CFR 1021). The strategy has two principal steps. The first step consists of an open solicitation and competitive selection process to obtain a set of projects that best meets program needs. Applications are screened for compliance with a number of basic eligibility requirements that are defined by the program. The set of applications that meet the mandatory eligibility requirements constitutes the range of reasonable alternatives available to DOE to meet the program's purpose and needs. Recognizing that the range of reasonable alternatives in the context of competitive financial assistance programs is in large part determined by the number and nature of the proposals submitted to DOE for consideration, section 216 of DOE's NEPA regulations requires the Department to prepare an "environmental critique" that assesses the environmental impacts and issues relating to each of the proposals that the DOE selecting official considers for an award. See 10 C.F.R. § 1021.216. This official considers these impacts and issues, along with other aspects of the proposals (such as technical merit and finance ability) and the program's objectives, in making awards. DOE prepared a critique of the proposals that were deemed suitable for selection in this round of awards for the CCPI program. Because the critique contains confidential business information, it is not made available to the public; a synopsis of the critique is included as **U.S. Department of Energy Documents**, **Appendix 1**, located in section 7-1 of the PSA/DEIS.

The second element of DOE's NEPA strategy consists of preparing a more detailed NEPA evaluation for each selected project. For this project, DOE determined that providing financial assistance for the proposed project would constitute a major federal action that may significantly affect the quality of the human environment. Therefore, DOE has prepared this PSA/DEIS to assess the potential impacts on the human environment of the proposed action and reasonable alternatives. DOE has used information provided by HECA for the proposed project, as well as information provided by state and federal government agencies, subject-matter experts, and others. This PSA/DEIS has been prepared in accordance with Section 102(2)(C) of NEPA, as implemented under regulations promulgated by CEQ (40 CFR 1500 through 1508) and as provided in DOE regulations for compliance with NEPA (10 CFR 1021).

The original Notice of Intent (NOI) to prepare an EIS for this project was published by DOE in the Federal Register on April 6, 2010 (75 FR 17397). The Amended Notice of Intent (ANOI) was published by DOE in the Federal Register on June 19, 2012 (77 FR 36519). A public scoping meeting was conducted on July 12, 2012, at the Elk Hills Elementary School in Tupman, California, and comments were accepted through August 3, 2012 (one week after July 27, 2012, the date the comment period closed).

Scope of DOE's NEPA Analysis

The PSA/DEIS will inform DOE's decision on whether to provide financial assistance under its CCPI Program for the construction and demonstration of HECA's project, which has an estimated capital cost of over $4 billion. DOE's financial assistance (or "cost share") would be limited to $408 million, about 10 percent of the project's total cost. DOE's financial assistance is also limited to certain aspects of the power and manufacturing plants, carbon capture, and sequestration. The PSA/DEIS evaluates the potential impacts of DOE's proposed action, the project proposed by HECA and any connected actions, cumulative impacts, and reasonable alternatives to DOE's proposed action.

Connected and Cumulative Actions

Under the cooperative agreement between DOE and HECA, DOE would share the costs of the gasifier, syngas cleanup systems, combustion turbine, steam generator, steam turbine, fertilizer production facilities, supporting facilities and infrastructure, and a demonstration phase in which the project would use captured CO_2 for EOR. Under this agreement, DOE would not share in the cost of the air separation unit, CO_2 EOR and sequestration facilities, or certain other facilities. Accordingly, DOE's NEPA process considers these aspects of HECA's project as connected actions. The impacts of these connected actions are evaluated in the same manner as the impacts of the parts of the project funded by DOE.

In addition to the impacts of the project and its connected actions, DOE's analysis of cumulative impacts such as greenhouse gas emissions and global warming, other air emissions, and other incremental impacts that, when added to past, present, and reasonably foreseeable impacts, may have significant effects on the human environment are separately discussed in the Carbon Sequestration and Green House Gas section of this document.

PURPOSE AND NEED

The purpose and need for DOE action – providing limited financial assistance for the construction and operation of HECA's project – is to advance DOE's CCPI program by funding projects that have the best chance of achieving the program's objective as established by Congress. The objective of the CCPI program is the commercialization of clean coal technologies that improve efficiency, environmental performance, and cost competitiveness well beyond those of technologies that are currently in commercial service.

DOE selected HECA's proposed project under the CCPI program as one in a portfolio of projects. That portfolio represents the most appropriate mix of projects to achieve CCPI program objectives and meet legislative requirements. Specifically, DOE's purpose and need for selecting the HECA project is to promote the commercialization of IGCC technologies that improve efficiency, environmental performance, and cost competitiveness.

PROPOSED ACTIONS

DOE's proposed action is to provide financial assistance for the detailed design, construction and operation of HECA's project, which would produce and sell electricity, carbon dioxide and fertilizer.

OVERVIEW OF HECA'S PROPOSED PROJECT

HECA's project would use integrated gasification combined cycle (IGCC) and carbon capture technology to meet market demands for producing and selling electricity, carbon dioxide, and fertilizer. The basic components and attributes of the project include:

- The use of an IGCC power system to demonstrate pre-combustion carbon dioxide capture and sequestration technology on a commercial scale that provides dependable, low-carbon electricity from a plant whose output can be adjusted so as to back up intermittent renewable power sources, increasing the reliability of the grid;
- capture of 90 percent of the CO_2 generated by the facility;
- transportation of most of the CO_2 to the Elk Hills Oil Field for use in EOR, resulting in its sequestration;
- advanced air emissions controls;
- use of brackish water for process water needs;
- zero liquid discharge;
- an integrated manufacturing plant producing approximately 1 million tons per year of nitrogenous compounds such as urea, urea ammonium nitrate (UAN) and anhydrous ammonia to be used in agricultural, transportation and industrial applications;
- use of a single Mitsubishi Heavy Industries' (MHI) oxygen-blown dry feed gasifier and an MHI 501 GAC© combustion turbine;

- use of a blend of 75 percent coal and 25 percent petcoke as fuel throughout the life of the facility;
- use of natural gas for start-up, shut down and equipment outages only, not for routine operation of the turbine.

The project would capture approximately 3 million tons per year of CO_2; 2.6 million tons would be permanently sequestered as a result of its use for EOR. While most of the captured CO_2 (about 90 percent of the amount captured) would be used for EOR at the nearby Elk Hills Oil Field, about 0.4 million tons per year of the captured CO_2 would be used to manufacture fertilizer; DOE does not considered this CO_2 to be sequestered.

Proposed Generating Plant

The HECA project would demonstrate IGCC and carbon capture technology on a commercial scale in a new power plant consisting of a single gasifier with gas cleanup systems, a hydrogen-rich fired combustion turbine, a heat recovery steam generator, a steam turbine, and associated facilities.

The plant would gasify coal and petcoke to produce syngas, which would then be processed and purified to produce a hydrogen-rich fuel. The hydrogen would be used to drive the gas combustion turbine. Hot exhaust gas from the gas combustion turbine would generate steam from water in the heat recovery steam generator to drive the steam turbine; both turbines would generate electricity. At full capacity, the plant is expected to use about 4,580 tons of coal and about 1,140 tons of petcoke per day (about 162 million tons and 400,000 tons per year, respectively).

Combined, the gas combustion and steam turbines would have the capacity to generate between 405 and 431 MW (gross) of electricity, compared to the 390 MW gross and 288 MW net anticipated from the plant as originally proposed by British Petroleum (BP) and Rio Tinto. However, the net new capacity added to the electrical grid is lower due to the additional products generated by the current design. This combined-cycle approach (using gas and steam turbines in tandem) increases the amount of electricity that can be generated from the feedstock, but the additional products reduce the net generation.

The proposed facility would minimize emissions of sulfur dioxide, nitrogen oxides, mercury, and particulates compared to conventional coal-fired power plants. The local air pollution control district is requiring additional mitigation in the form of emissions reductions with the intent that the facility would emit no more nitrogen oxide pollution than a natural gas fired power plant.

The facility would incorporate state-of-the-art air emission controls that reflect or exceed Best Available Control Technology. It is expected that these controls would remove in excess of 99 percent of the sulfur dioxide produced by the plant and would also limit emissions of nitrogen oxides, carbon monoxide and volatile organic compounds. In addition, over 99 percent of the mercury in the feedstock would be removed and over 99 percent of the particulates in the syngas would be removed using liquid scrubbing. Solids generated by the gasifier would be accumulated onsite (up to 7 days worth) and made available for appropriate recycling or beneficial use. If these options were not available, HECA would dispose of these solids in accordance with applicable laws. Unlike the gasifiers that BP and Rio Tinto originally planned to use, the MHI gasifier would not produce solids with fuel value, and therefore solids would not be returned to the gasification process as had been originally planned.

In addition to the gasifier and turbines, the power plant's equipment would include exhaust stacks, mechanical-draft cooling towers, syngas cleanup facilities, and particulate filtration systems. The height of the tallest proposed structure would be approximately 305 feet above ground (a flare stack). Flares are designed for combusting emissions resulting from startups or outages, or during emergencies. The plant would also require systems for feedstock handling and storage, as well as on-site roads, administration buildings, water and wastewater treatment systems, and facilities for handling gasification solids.

Proposed Fertilizer Production Facilities

A portion of the clean hydrogen-rich fuel would be used as a feedstock for the ammonia synthesis unit, which would have a capacity of 2,000 tons per day of ammonia. The ammonia would be used as an intermediate for the production of urea for sale. The project's fertilizer manufacturing complex would convert urea into urea ammonium nitrate and urea pastilles (small solid pellets). The pastilles unit would have a capacity of about 1,700 tons per day.

Proposed Linear Facilities

Linear facilities are the pipelines, electrical lines, and railways used to transport materials and power to and from the plant. The plant's process water would be brackish groundwater supplied by the Buena Vista Water Storage District; approximately 4,600 gallons per minute (average annual basis) would be required for cooling water makeup, steam cycle makeup, and other processes. The process water pipeline would be approximately 15 miles in length. Potable water for drinking and sanitation would be supplied by the West Kern Water District. The potable water line would be approximately 1 mile in length. The project would recycle water and would incorporate zero liquid discharge (ZLD) technology for process and other wastewater from plant operations. Therefore, there would be no industrial wastewater discharge. Sanitary wastewater would be disposed of in an onsite leach field (e.g., a septic system) in accordance with applicable law.

HECA would connect to the PG&E Midway Substation via a 230 kV Midway-Wheeler Ridge transmission line and a new PG&E switching station. A 230 kV, single pole, double circuit capacity transmission line would be built to transmit the plant's electricity. The line would be approximately 2 miles in length.

An approximately 13-mile natural gas pipeline would connect with an existing PG&E pipeline north of the project site, and an approximately 3-mile CO_2 pipeline would extend from the site to the Elk Hills Oil Field. HECA has proposed two alternatives for coal transportation to the site. Alternative 1 consists of an approximately 5-mile new railroad spur that would connect the site to the San Joaquin Railroad's Buttonwillow line. Alternative 2 would use the 27-mile truck route proposed by BP and Rio Tinto to transport coal using 400 round trips each day from an existing coal transloading facility in Wasco, California.

Proposed Use of CO_2 for EOR and Sequestration

The project would result in the sequestration of about 2.6 million tons of CO_2 per year during the demonstration phase that DOE would fund rather than the two million tons originally proposed by BP and Rio Tinto. HECA anticipates this rate of sequestration would continue for the operational life of the power plant due to the requirements of California law and the value created by the use of the CO_2 for EOR. The captured CO_2 would be compressed and transported via pipeline to the Elk Hills Oil Field approximately 3 miles from the power plant. The CO_2 would enhance domestic oil production, contributing to the nation's energy security. An additional small amount of the CO_2 produced by the facility would be used to manufacture urea.

The EOR process involves the injection and reinjection of CO_2 to reduce the viscosity and enhance other properties of trapped oil in order to facilitate its flow through the reservoir, improving extraction. During EOR operations, the pore space left by the extracted oil is occupied by a portion of the injected CO_2, sequestering it in the geologic formation. The remainder of the CO_2 is produced with the oil, and it must be separated from the oil, recompressed, and then re-injected into the formation.

Proposed Project Schedule

The project proposed by HECA includes engineering and design, permitting of the plant and associated facilities, equipment procurement, construction, startup, operations, and demonstration of the IGCC technology and CO_2 sequestration. HECA anticipates that it would take about four years to construct, commission, and commence operation of the plant. The estimated project schedule would be start of construction activities in January 2014 and commencing commercial operation by February 2018. This schedule is contingent upon HECA receiving the necessary regulatory authorizations (which would be preceded by the hearings and other events mandated by the regulatory agencies' procedures) and upon DOE deciding to provide financial assistance for the construction and demonstration phases of the project (a decision that would occur after completion of DOE's NEPA and Energy Commission's certification processes).

PROPOSED PROJECT AND ALTERNATIVES

PROPOSED PROJECT

DOE's proposed action is to provide financial assistance for the construction and operation of HECA's project, which would produce and sell electricity, carbon dioxide and fertilizer. DOE selected this project for an award of financial assistance through a competitive process under the Clean Coal Power Initiative (CCPI) program.

HECA's project would demonstrate integrated gasification combined cycle (IGCC) technology with carbon capture in a new electricity generating plant in Kern County, California. The plant would use a blend of 75 percent coal and 25 percent petroleum coke (petcoke) and would capture, sell and sequester carbon dioxide on a commercial scale. It would also produce and sell fertilizer and other nitrogenous compounds.

The project would gasify the coal and petcoke to produce synthesis gas (syngas), which would then be purified to produce a hydrogen-rich fuel for a combustion turbine that would generate electricity while minimizing emissions of sulfur dioxide, nitrogen oxides, mercury, and particulates compared to conventional coal-fired power plants. In addition, the project would achieve a carbon dioxide (CO_2) capture efficiency of approximately 90 percent at steady-state operation. The captured CO_2 would be compressed and transported via pipeline to the adjacent Elk Hills Oil Field (owned and operated by Occidental of Elk Hills, Inc. (OEHI)) for injection into deep underground oil reservoirs for enhanced oil recovery (EOR), resulting in geologic sequestration.

Project Site Location and General Description

HECA would construct its electricity and fertilizer production facility on a site currently used for agriculture in Kern County, California. The 1,106 acre site (453 acres of which would be used for the project and 653 acres for a controlled buffer area) is in south-central California near the unincorporated community of Tupman, approximately 7 miles west of the western border of the city of Bakersfield. The site's topography is relatively flat, low-lying terrain that slopes very gently from southeast to northwest. The site and surrounding areas are used for agricultural purposes, including cultivation of cotton, alfalfa, and onions.

ALTERNATIVES

NEPA requires that a federal agency evaluate the range of reasonable alternatives to its proposed action. The range of reasonable alternatives encompasses those alternatives that would satisfy the underlying purpose and need for agency action. The purpose and need for DOE action – providing limited financial assistance to the HECA IGCC project – are to advance the CCPI program by selecting projects that have the best chance of achieving the program's objective as established by Congress: the commercialization of clean coal technologies that advance efficiency, environmental performance, and cost competitiveness well beyond the level of technologies that are currently in service.

DOE's NEPA regulations include a process for identifying and analyzing reasonable alternatives in the context of providing financial assistance through a competitive selection of projects proposed by entities outside the federal government. The range of reasonable alternatives in competitions for grants, loans and other financial support is defined in large part by the range of responsive proposals DOE receives. Unlike projects undertaken by DOE itself, the Department cannot mandate what outside entities propose, where they propose to do it, or how they propose to do it beyond establishing requirements in the funding opportunity announcement that further the program's objectives. DOE's decision is limited to selecting among the applications submitted by project sponsors that meet CCPI's goals.

Recognizing that the range of reasonable alternatives in the context of financial assistance and contracting is in large part determined by the number and nature of the proposals submitted, section 216 of DOE's NEPA regulations requires the Department to prepare an "environmental critique" that assesses the environmental impacts and issues relating to each of the proposals that the DOE selecting official considers prior to making a selection. See 10 C.F.R. § 1021.216. This official considers these impacts and issues, along with other aspects of the proposals (such as technical merit and financial ability) and the program's objectives, in making awards. DOE prepared a critique of the proposals that were deemed suitable for selection in this round of awards for the CCPI program.

Once DOE selects a project for an award, the range of reasonable alternatives becomes the project as proposed by the applicant, any alternatives still under consideration by the applicant or that are reasonable within the confines of the project as proposed (e.g., the particular location of the generating plant on the 1,106-acre site or the rights-of-way (ROWs) for linear facilities), and a no action alternative. Regarding the no action alternative, DOE assumes for purposes of the PSA&DEIS that, if it were to decide to withhold financial assistance for construction and operation of the project, it would not proceed. DOE currently plans to analyze the project as proposed by HECA (with and without any mitigating conditions that DOE or the Energy Commission may identify as reasonable and appropriate); alternatives to HECA's project that it is still considering (e.g., the rights of way for linear facilities or methods of transporting coal to site); and the no action alternative.

DOE'S No-Action Alternative

Under the no action alternative, DOE would not provide funding to HECA for construction and operation of its project. In the absence of financial assistance from DOE, HECA could reasonably pursue two options. It could build the project without DOE funding; the impacts of this option would be essentially the same as those of DOE's proposed action. Or, HECA could choose not to pursue its project, and there would be no impacts from the project. This option would not contribute to the goal of the CCPI program, which is to accelerate commercial deployment of advanced coal technologies that provide the United States with clean, reliable, and affordable energy. However, as required by NEPA, DOE analyzes this option as the no action alternative in order to have a meaningful comparison between the impacts of DOE providing financial assistance and withholding that assistance.

CALIFORNIA ENVIRONMENTAL QUALITY ACT (CEQA) ALTERNATIVES SUMMARY

Staff evaluated a number of potentially feasible alternatives, ruled out most in the initial screening process, carried others forward and continues to further develop those alternatives to reach conclusions under CEQA.

- Alternative sites evaluated in the subsection "Alternatives Eliminated from Detailed Consideration" focused on locations proximate to the EHOF.

- As described in the subsection "Alternatives Eliminated From Detailed Consideration," staff has eliminated the Natural Gas Project Alternative which consists of a conventional natural gas-fired electric generation facility that would generate electricity but would not meet the DOE goal of demonstrating an advanced coal-based electricity generating technology which would include CO_2 capture or storage, EOR at the Elk Hills Oil Field, or the applicant's goals of production of any fertilizer or other nitrogen-based products. A natural gas alternative with CO_2 capture and storage will be analyzed in the FSA/FEIS.
- A Dry Cooling or Wet-Dry Hybrid Cooling Alternative will be evaluated in the FSA/FEIS to determine if it can reduce HECA's water consumption.
- Staff is considering an alternative that would consist of a biomass-fired boiler that would provide the same net new electrical capacity and energy as HECA. This alternative may not provide carbon capture and storage, but would provide a new, local renewable energy facility with a low-carbon footprint, depending on how far the biomass would have to be transported to the facility site.
- Based upon staff's analysis, the No Project Alternative would eliminate potentially significant environmental impacts associated with the HECA project, while the No Fertilizer Manufacturing Complex Alternative (Reduced Project Alternative) would lessen impacts in a number of environmental issue areas.
- The HECA project includes both rail and truck options for coal delivery from the rail transfer point. These options are analyzed in the **Traffic and Transportation** and **Land Use** sections of this PSA/DEIS.
- The identification of a CEQA environmentally superior alternative and NEPA environmentally preferred alternative will be identified in the FSA/FEIS.

NOTEWORTHY PUBLIC BENEFITS

Noteworthy public benefits that would result from the HECA project are as follows:

SOCIOECONOMICS

Public benefits include the changes in local economic activity and tax revenue that would result from project construction and operation.

The applicant estimated that the total construction cost for the whole of the project would be around $4 billion. The total direct labor costs for construction would equal roughly $1.37 billion. The remaining $1.78 billion includes other non-labor expenditures, such as project engineering and materials procurement. Note that these are gross figures, which do not account for economic leakage. Based on these direct expenditures, the applicant anticipates that the project would generate roughly $843 million in indirect and induced economic output, as well as $294 million in additional labor income.

For operations, the applicant estimated that the project as a whole would generate around $30 million in direct labor income. The indirect and induced impacts of project operations, including both HECA and the OEHI EOR projects, would reportedly include the annual maintenance of 430 jobs, $21 million in labor income, and $68 million in economic output.

Property Tax

Staff estimates that the capital cost attributable to the construction of the HECA power plant would equal roughly $2.6 billion. At the applicable 1.09 percent property tax rate, this would generate nearly $28.7 million in annual property tax revenue. The rail spur, likewise, would account for around $26 million in capital costs, which would translate to between $278,000 and $285,900 in annual property tax revenue. Together, the HECA power plant and rail spur could generate upwards of $28.9 million in annual property tax revenue.

According to the California Department of Conservation (CDC), the State of California does not levy severance taxes on oil and natural gas production (CDC 2012a). The state does levy an assessment on the value of oil and natural gas produced. The Oil and Gas Assessment rate for fiscal year 2012-2013 is 14.06207 cents per barrel of oil or 10 million cubic feet (Mcf) of natural gas produced (CDC 2012b). An increase in the amount of oil produced due to implementation of the EOR project would correlate to an increase in the assessed value of oil and natural gas production and in the revenues received by the CDC's Division of Oil, Gas, and Geothermal Resources.

PRELIMINARY CONCLUSIONS

Energy Commission staff briefly highlights those technical sections that have identified potential significant, unmitigated impacts or those sections requiring additional information below.

Air Quality

The Hydrogen Energy California Project should comply with all applicable air quality laws, ordinances, regulations, and standards and should not result in significant air quality impacts provided the recommended conditions of certification are adopted by the Commission and implemented by the project owner. The project has secured emission reduction credits in sufficient quantity to meet San Joaquin Valley Air Pollution Control District requirements. The applicant has also agreed to provide funding to the San Joaquin Valley Air Pollution Control District's Emission Reduction Incentive Program to create additional emissions reductions necessary for General Conformity.

These emission reduction credits and emissions reductions created from the mitigation agreement funding would fully offset all onsite project emissions of nonattainment pollutants and their precursors that occur within the San Joaquin Valley Air Basin at a minimum offset ratio of 1:1, and would fully offset the offsite NOx emissions as required for General Conformity. If built and operated as described in the Amended AFC, and if the permitting authority implements construction and operating conditions equivalent to those recommended by Energy Commission staff, the Occidental Petroleum Carbon Dioxide Enhanced Oil Recovery component would also comply with all applicable air quality laws, ordinances, regulations, and standards. Energy Commission staff is requesting additional information from the applicant prior to publishing the FSA/FEIS.

Carbon Sequestration and Greenhouse Gas Emissions

HECA's likely operating profile is not known although the applicant has described the facility's expected operation using more than one potential operating profile. Different operating profiles may need to be evaluated to determine which set of operating conditions represent actual operations and worst case impacts. Some operating profiles may result in the facility not complying with certain regulatory requirements. For example, a profile provided by the applicant indicated reduced electricity production for eight hours each day, reducing the portion of the hydrogen-rich gas used to produce electricity and increasing that used to produce fertilizer. Under this operating profile, the project may not comply with California's Greenhouse Gases (GHG) Emission Performance Standard (EPS) during early operating years. Staff has asked for additional information in order to resolve this issue.

Assuming the above issue is resolved, the project could meet the EPS that applies to long-term utility purchases of base load power from power plants (Title 20, California Code of Regulations, section 2900 et seq.), if the majority of HECA's CO_2 emissions are permanently sequestered. Staff is in the process of designing conditions of certification that would enforce the carbon sequestration that is necessary for this project to comply with this regulation. Staff has provided preliminary conditions of certification that outline the type of requirements that will be recommended by staff; however, significant additional detail will be added to these conditions in the FSA and additional conditions may be required for the facility to comply with the EPS so they could sell electricity to a California electric utility under a long-term contract.

BIOLOGICAL RESOURCES

Blunt-nosed leopard lizard (BNLL) is a California fully protected species under California Fish and Game Code Section 5050 and therefore, incidental take of the species is not legally permitted as defined by Section 86 of the Fish and Game Code. This species is present at the Elk Hills Oil Field and has a high potential to occupy the proposed carbon dioxide pipeline route as well as disturbed allscale scrub areas along the natural gas pipeline. The construction of the project would impact approximately 192 acres of natural allscale scrub and disturbed lands which provide small mammal burrow habitat for BNLL; this poses a threat to BNLL in the form of mortality from vehicles and equipment on roadways, entrapment in construction-related trenches or pipes, burial in burrows by equipment, avoidance of certain habitats, modification to breeding and/or foraging behaviors, and reduced carrying capacity of natural scrub habitat and neighboring lands known to be occupied by BNLL. Staff has proposed a condition of certification to mitigate this impact to the extent feasible, but even with the implementation of staff's proposed take avoidance and minimization measures, incidental take of blunt-nosed leopard lizard would likely occur over the life of the project. Therefore, staff considers this impact significant and unavoidable under CEQA even with the incorporation of mitigation. It is also unclear whether the project would comply with Fish and Game Code Section 5050 relating to Fully Protected Reptile and

Amphibian Species and the California Endangered Species Act since avoiding take of this species cannot be guaranteed for the life of the project.

During protocol-level surveys performed for Swainson's hawk, 12 active raptor nests were found within the survey area, six of which were confirmed Swainson's hawk nests. All six Swainson's hawk nests appear to be within a 0.25 mile of either the project site or a proposed linear facility and therefore could be affected by construction noise or other construction disturbances during the nesting season. The majority of these nest trees occur along canal levees of the Kern River Flood Control Channel, West Side Canal and other smaller unnamed agricultural canals and ditches and are likely supplied to some extent by irrigation runoff that accumulates in irrigation canals as well as groundwater. In addition, valley sink scrub, a sensitive vegetation community identified by the California Natural Diversity Database, potentially occurs in these same areas in association with the Kern River Flood Control Channel. Staff believes that a more definitive analysis is needed on the water source of the nest trees that occur in the project area and pre- and post-project groundwater drawdown around the proposed well field.

Staff also believes the loss of approximately 571 acres of agricultural lands including alfalfa, wheat, onion fields, and other low-growing crop types that provide forage value is a significant loss of foraging habitat for Swainson's hawk. More definitive analysis is needed on the baseline groundwater levels and water source of the nest trees and sensitive vegetation communities that occur in the project area. Until additional data is provided regarding the project's impacts and overall mitigation strategy, staff cannot determine if the project's impacts to Swainson's hawk habitat would be reduced to below a level of significance. If groundwater drawdown from HECA's proposed well field and along the 15-mile processed water pipeline is consistent enough over the course of several years, staff believes the decrease in water supply to the root system of the trees could result in gradual decline and eventually nest tree failure which may constitute take under the California Endangered Species Act, the Migratory Bird Treaty Act, and California Fish and Game Code 3503; therefore, it is unknown if HECA complies with these LORS at this time.

The applicant has proposed to mitigate for permanent and temporary habitat impacts to federally and state listed species at a 0.1:1 and 2.1:1 ratio, respectively, which staff believes would not suffice as adequate habitat compensation for project impacts to special-status species (HECA 2012b, URS 2013b). The applicant has also proposed to purchase habitat credits from the Kern Water Bank as mitigation for the project, which the wildlife agencies have indicated is not a feasible option for mitigating HECA's impacts to special-status wildlife species. The CDFW and USFWS have indicated that while it may be possible to purchase some mitigation credits for a portion of the listed species that would be impacted, it is not feasible to mitigate HECA entirely at the Kern Water Bank, given the nature of the project's impacts to listed wildlife species from project traffic road mortality and habitat loss.

During May 2013, the applicant submitted a Section 2081 Incidental Take Permit application for project impacts to state-listed wildlife species for which the applicant would be seeking incidental take coverage which staff has preliminarily reviewed (URS 2013d). Staff has inserted Condition of Certification BIO-20 (Compensatory Habitat Mitigation for Upland Species) as a placeholder. Staff will continue to work with the applicant, CDFW, and USFWS to develop an appropriate mitigation strategy for HECA that is consistent with the goals and objectives of the Recovery Plan for Upland Species of the San Joaquin Valley. Additional conditions of certification, and modifications to currently proposed conditions of certification including Condition of Certification BIO-20, are likely to be necessary based on further consultation with the wildlife agencies and information provided by the applicant. With the implementation of staff's proposed Conditions of Certification BIO-1 through BIO-20, impacts to special-status species would be reduced; however, without an adequate mitigation proposal, staff cannot make a determination whether the project would comply with all applicable LORS or that project impacts to sensitive biological resources would be reduced to less than significant levels in accordance with CEQA.

CULTURAL RESOURCES

Staff tentatively concludes that the proposed HECA project would have a significant direct impact on historical resources and historic properties, as defined by the California Environmental Quality Act and Section 106 of the National Historic Preservation Act. Significant impacts may be incurred upon as many as 21 known, significant archaeological resources and as many as four known, significant historic built environment resources. Additionally, the proposed project could result in significant adverse changes to an unknown number of as-yet-unidentified, buried archaeological resources. Field work and limited archeological excavations are ongoing at this time.

Staff believes HECA and related OEHI components would result in direct and indirect impacts to National Register of Historic Places/California Register of Historical Resources (NRHP/CRHR)-eligible cultural resources. However, staff requires additional information about cultural resources in order to complete its analysis.

LAND USE

While the project would be a conditionally permitted use pursuant to the county zoning ordinance, one finding that must be made by the Energy Commission's Committee is that "the proposed use will not be detrimental to the health, safety, and welfare of the public or to property and residents in the vicinity" (19.104.040(E)). Staff cannot recommend whether this finding should be made by the Committee, until the outstanding information identified in other technical areas is provided. Staff also needs additional information to determine project compliance with Sections 19.12.070 (setbacks) and 19.12.100 (parking) of the Kern County Zoning Ordinance.

POWER PLANT EFFICIENCY

There is a discrepancy in the applicant's documents concerning the gross output of the project. The AFC indicates it will be 405 MW while later filed documents appear to assume it will be 431 MW. Staff has requested additional information from the applicant to clarify.

POWER PLANT RELIABILITY

The applicant predicts an equivalent power block availability factor of at least 91.3 percent, which staff believes is possible upon the successful completion of the requisite one to two years of pilot to mature operations. The applicant has failed to: 1) demonstrate adequate reliability of the project's industrial water supply, and 2) assign availability to the gasification system and ancillary systems upon which the power block is dependent. Staff has requested additional information to address these issues.

TRAFFIC AND TRANSPORTATION

Although potentially significant impacts associated with implementation of the proposed HECA project can be reduced with recommended conditions of certification, staff has concerns that the project has the potential to substantially increase traffic levels on farming roads not currently intended for heavy truck traffic and heavy load capacities. This substantial increase in traffic also has the potential to impact traffic associated with existing farming activities (e.g., tractors traveling on public roadway) thereby potentially resulting in safety issues and increased accidents to the public. Based on a recent Board of Supervisor's meeting held on February 26, 2013, the Board instructed the Public Works Department to review the roadways intended for heavy truck and worker traffic and report back at their June 2013 Board meeting as to recommendations for improvements to the local roadway system. Staff will address the concerns and/or recommendations by Kern County in the FSA.

Staff has also requested additional information from the applicant concerning the capacity of the Wasco transloading facility to handle the amount of coal anticipated, the applicant's recent proposal to truck in limestone fluxant, and information necessary to analyze the proposed at-grade rail crossings.

TRANSMISSION SYSTEM ENGINEERING

The Transition Cluster Phase II Interconnection Study Report (Phase II Study) for HECA is scheduled to be issued by early July, 2013. Staff expects to analyze the Phase II Study to determine the downstream distribution impacts and any required mitigation. The Phase I study indicated that no additional new transmission facilities that would require a CEQA review other than those proposed by the applicant are needed for the interconnection of the HECA project.

VISUAL RESOURCES

The HECA project would cause a significant visual impact at Key Observation Point (KOP) 1 (HECA). KOP 1 is located on Station Road, approximately 2,600 feet east of the middle of the HECA project site. Viewers at or near KOP 1 include residents at two adjacent properties near the intersection of Station Road and Tule Park Road and motorists on Station Road. The applicant intends to prepare and submit an off-site conceptual landscape plan to mitigate the significant impact at KOP 1, but staff is uncertain whether an offsite plan would be sufficient to mitigate to less than significant.

WASTE MANAGEMENT

The HECA project would produce thousands of tons per year of waste during the operation of the facility. The majority of the waste would be gasification solids. HECA is expected to generate a maximum of 850 tons per day of gasification waste (vitrified slag). HECA is currently investigating three potential markets for beneficial reuse of this material; 1) roofing granules, 2) blasting grit, 3) pozzolanic admixtures in cement manufacture. The large quantity of waste would significantly impact Kern County landfills and possibly compromise the county's compliance with Public Resources Code section 40000 et seq. and Senate Bill (SB) 1016 (Stats. 2008, ch. 343.) and implementing regulations (requiring jurisdictions such as Kern County to divert 50 percent of their waste from landfill disposal).

The gasification waste could be excluded from hazardous waste regulations (i.e., 40 C.F.R. § 261.4 (b) (7) (ii) (F) and Cal. Code Regs, tit. 22, § 66261.4(b) (5) (A)). However, prior to acceptance of the gasification solids into a Kern County owned and operated landfill the solids must be analyzed and classified as non-hazardous or hazardous waste. The HECA project owner has not produced a comprehensive plan for the reuse and disposal of the gasifier solids. HECA tested the gasification solids and they are considered non-hazardous according to federal standards. California testing standards should be used to determine if the HECA gasification solids are non-hazardous.

If the solids are determined to be hazardous, the amount of hazardous waste would be burdensome to the State of California and disposal would be costly to the applicant. If they are determined to be non-hazardous according to Title 14 regulations, nonhazardous waste quantities generated and/or disposed of in Kern County would count against the county's waste diversion goals. The expected volume of waste would likely result in the Kern County exceeding their state mandated waste diversion goals. The applicant has proposed to export waste for disposal so the diversion goals can be met. However, CalRecycle has indicated Kern County would still be responsible for the waste generated in the county. To avoid significant waste management impacts the project owner would have to work with Energy Commission, Kern County and CalRecycle staff to establish an operational waste diversion program. This plan must be completed and approved by the coordinating agencies prior to staff's publication of the Final Staff Assessment.

The results of soil sampling and analytical testing at the HECA project site indicate there are elevated concentrations of petroleum hydrocarbons and other contaminants affected by previous site activities. Staff is recommending the site be appropriately characterized prior to the Final Staff Assessment.

Staff has reviewed the waste management aspects of the Occidental of Elk Hills, Inc. CO_2 Enhanced Oil Recovery (OEHI CO_2 EOR) component of the project for construction and operation, as described in the Supplemental Environmental Information (SEI) report (HECA 2012e, Volume II). Nonhazardous and hazardous waste would be generated during construction and operation of the OEHI CO_2 EOR. In order to verify that Kern County has enough landfill capacity to accommodate the project's solid waste disposal needs, staff requires the project owner to provide information on the quantity of project waste that would be disposed of in local landfills.

WATER SUPPLY

Staff has preliminarily concluded the following regarding the project's proposed water use:

1. The project pumping could result in well interference and lower water levels in neighboring wells.
2. The proposed industrial supply wells may induce the inflow of relatively poor quality groundwater into a zone of relatively higher water quality within the water-supply aquifer beneath the Buttonwillow Service Area.
3. The project's pumping could exacerbate overdraft in the Kern County subbasin.
4. The project pumping could reverse local water level increases and increase the threat to the California Aqueduct from subsidence.
5. The project use of the proposed water supply may not be consistent with Energy Commission and other state water policies.
6. Staff cannot verify a persistent source of saline water flowing eastward towards the Buttonwillow Service Area.
7. Applicant dismisses potentially feasible water alternatives because proposed use is so high.

Therefore, staff proposes to investigate in more detail alternative cooling options in the FSA/FEIS.

The **Executive Summary Table 2** below illustrates Energy Commission staff's preliminary assessment of the proposed HECA project and also identifies the areas where staff has requested additional information. These preliminary conclusions are subject to change in the FSA/FEIS depending upon additional information received.

Executive Summary - Table 2
Environmental and Engineering Assessment

Technical Area	Complies with LORS	Impacts Mitigated	Additional Information Requested
Air Quality	Yes	Yes	**Yes**
Biological Resources	Undetermined	Undetermined	**Yes**
Carbon Sequestration and GHG Emission	Undetermined	Undetermined	**Yes**
Cultural Resources	Undetermined	Undetermined	**Yes**
Hazardous Materials	Yes	Yes	No
Land Use	Undetermined	Undetermined	**Yes**
Noise and Vibration	Yes	Yes	**Yes**

Technical Area	Complies with LORS	Impacts Mitigated	Additional Information Requested
Public Health	Yes	Yes	No
Socioeconomics	Yes	Yes	No
Soil and Surface Water Resources	Yes	Yes	**Yes**

ADDITIONAL INFORMATION THAT ENERGY COMMISSION STAFF REQUIRES FROM THE APPLICANT IN ORDER TO COMPLETE THE FINAL STAFF ASSESSMENT

Below is a list, arranged by technical area, of outstanding information staff requires prior to issuing an FSA/FEIS. Please refer specifically to each technical section for a detailed discussion and the context for which the information is required.

AIR QUALITY

A revised emissions estimate for HECA that matches the current project description, including but not necessarily limited to: the removal of the ammonia product shipping emissions; and the addition of the limestone fluxant. The revised emissions estimate should include the shipping, handling, and storage emissions from the fluxant and should address the shipping emissions for potential alternative shipping locations for the gasifier solids that have been provided to staff in other data responses.

Carbon Sequestration and Greenhouse Gas Emissions

A binding contract between SCS Energy LLC and Occidental of Elk Hills, Inc., provided to the Energy Commission, that:

1. Identifies the responsibilities of each party to demonstrate and document permanent sequestration of the supplied carbon dioxide.
2. Documents Hydrogen Energy California's rights to the entire carbon dioxide sequestration emissions reductions as necessary for SB 1368 EPS and other regulatory compliance.

3. Clearly states that the carbon dioxide sequestration emissions reductions shall not be used for any other purpose than providing for the compliance obligation needs for HECA.
4. Requires Occidental of Elk Hills, Inc. to provide a Carbon Dioxide Emissions Sequestration Plan to the Energy Commission for review and approval as detailed under the preliminary staff Condition of Certification **GHG-3**.
5. Clearly states the duration of the contract agreement.

Additionally, the applicant needs to provide:

1. A complete electrical energy balance estimate for HECA that includes the complete gross electrical production and complete parasitic load for the plant by major functional area, including the air separation unit, in MWh for both hydrogen rich fuel and natural gas operation. Staff cannot complete its determination of compliance with the SB 1368 EPS without this information.
2. A revised greenhouse gases emissions estimate for HECA that matches the current project description, including but not necessarily limited to: the removal of the ammonia product shipping emissions; the addition of the limestone fluxant shipping and use; and that addresses the shipping emissions for potential alternative shipping locations for the gasifier solids.
3. The District's FDOC that addresses staff's comments on the PDOC, specifically revising the combined-cycle power generating permit unit condition 86 to be based on the District's CO_2 BACT determination rather than the SB 1368 EPS.
4. Further information describing how OEHI would abate CO_2 if it leaks to the surface and escapes into the atmosphere.
5. Information detailing how the applicant would comply with the proposed allowable CO_2 venting hours without a back-up CO_2 injection zone.
6. Provide all of the following (some of the terms below such as "Power", Fertilizer" and "Common" refer to computations in the new material presented in spreadsheets provided by e-mail on May 10, 2013.):
    a. A carbon balance for HECA demonstrating the complete flow of carbon from the introduction of feedstock to the coal dryer to the products (including carbon dioxide [CO_2]) and waste streams. Please provide this carbon balance for both the oon- and ooff-Peak operating cases. This carbon balance should be more detailed than what was previously provided in the Amended AFC and data responses, clearly identifying the carbon in all the streams between major processes and process units where carbon flows changes.
    b. Detailed background information supporting the latest applicant- sponsored SB 1368 calculations. Please provide the following:
        - A detailed list of the project equipment indicating each piece of equipment's power consumption value; and

- Project equipment allocation (Power, Fertilizer or Common) for each listed piece of project equipment.

c. The gross and net megawatt (MW) assumptions for the three available ambient cases (39, 65 and 97 degrees F). Include the on-Peak, off-Peak and Daily Average categories.

d. Describe how the fertilizer power generation values, which appear to be different than the previously presented 5 MW value, were determined for the on-Peak and off-Peak cases.

e. Detailed calculations and rationale for the syngas allocation percentages allocated to power block and fertilizer in the HECA Power Generation for SB 1368 Emission Performance Standard Table for each project case (on-peak, off-peak, and Daily Average).

f. Detailed calculations and rationale for the calculations used to determine the syngas allocation to power and fertilizer that were used to determine the CO_2 emissions by emissions source. Please confirm this value is for the daily average case, and provide the values for the on-peak and off-peak cases.

g. Additional background information explaining the syngas allocation method used to determine CO_2 emissions from the fertilizer plant. This additional detail should explain the methodology sufficiently to ensure that CO_2 emissions from the fertilizer plant are not double counted when CO_2 emissions are sequestered in the urea produced.

h. The syngas allocation by section (see spreadsheet provided by applicant for May 10, 2013 meeting, attached to TN 70829) does not include a value for the common allocation. The CO_2 emissions from components identified elsewhere in the spreadsheet designated as "Common" are calculated using the power allocation percentage in the spreadsheet. Confirm or provide the correct common allocation percentage.

i. The air separation unit's power consumption value expected for the on-peak, off-peak on-peak, off-peak, and daily average cases. This can be presented with apportionment to the power block and fertilizer plant if detailed calculations and rationale for that apportionment basis (based on use of the produced oxygen and nitrogen and its later products, hydrogen and CO_2, used for power and fertilizer production) are provided.

j. The applicant stated that the power consumption for initial CO_2 compression that is completed at the HECA site was sufficient to provide CO_2 at a pressure necessary for geologic sequestration.

   - Confirm that means that the compression completed at the HECA site and the power consumed by the compressors on the HECA site is adequate to provide a level of compression that is sufficient to provide pressure necessary for geologic sequestration, or if the power consumption calculations include additional compression power consumption beyond that which is actually done at the HECA site that would be needed to obtain the desired pressure.

- Indicate if the assumed pressure necessary for geologic sequestration is the same pressure that is required by Oxy Elk Hills (OEHI) to inject the CO_2 into the Stevens formation.
- Indicate how much pressure is lost in terms of equivalent power consumption from the CO_2 custody transfer point to the point of receipt at the OEHI central EOR facility for initial injection into the oil reservoir.

k. A review of the emissions tables indicates that there are changes to some of the emissions calculation assumptions provided in Appendix E, such as the fuel consumption in the gas turbine and duct burners.

- Update Appendix E as necessary to include all of these changes as well as the other recent changes to the project (addition of fluxant, removal of ammonia export).
- Provide emissions calculations (AQ and GHG) for both the on-peak and off-peak cases clearly showing fuel flow to the combustion turbine and duct burners for each case.
- Show how HECA off-peak operations would impact other emission sources and provide information on changes to the major component stream flows that may occur during these operating conditions (such as, does amount of CO_2 shipped to OEHI go up during off-peak operations, or does the CO_2 concentration in the hydrogen rich fuel go up to maintain a constant CO_2 emissions profile for the HRSG and coal dryer stacks for on- and off-peak operations?).

l. Based on Table 2-10 provided in the Amended AFC, during maximum ammonia production, referred to as off-peak operation, production of the other fertilizer components do not increase.

- Provide data/calculations confirming the plant will have adequate ammonia storage facilities capable of handling the increased ammonia that would be produced during off-peak operations.
- Indicate if the rate of ammonia consumed by the plant varies with respect to the fertilizer products during on-peak and off-peak operations, and if so please provide the on- and off-peak operation case production rates for nitric acid, urea, and UAN production.
- Clearly indicate if HECA's ammonia use is higher than its production rate during on-peak operations, or if other components of fertilizer production, including the intermediate products like nitric acid, would increase with the increase in ammonia production during off-peak periods of operation.

m. Provide a detailed list of the monitoring and recordkeeping methods and procedures that are proposed to be used to demonstrate ongoing compliance with the SB 1368 emission performance standard (EPS) during facility operations. This should include:

- Monitoring methods and locations to establish CO_2 emissions from all onsite project sources, including fugitive emissions sources.
- Monitoring methods and locations to establish net electricity generation values for all electricity consumed and generated.
- Recordkeeping measures to ensure completeness and accuracy of data collected.
- Coordination with OEHI to obtain necessary data on carbon sequestration to support the value of the sequestered CO_2 that can be used to account for the amount of CO_2 shipped to OEHI.

n. As an adjunct to GHG, confirm the current planned and unplanned outage as the basis for reliability. Currently, our understanding is as follows:

- Planned: Two 1-week planned maintenance outages with 15-hour ramping allowance for 351 hours
- Planned: Two cold-start cycles, each 4 days long for a total of 192 hours
- Unplanned: 219 hours of outage based on 91.3% equivalent availability factor (EAF), calculated as follows: (1-0.913) x 8760 = 762 hours of total outage. 762 (hours of total outage) –351 (maintenance outage hours) – 192 (cold start-up hours) = 219 hours (unplanned outage hours).

BIOLOGICAL RESOURCES

1. Comprehensive mitigation strategy for project impacts to San Joaquin kit fox, giant kangaroo rat, Tipton kangaroo rat, San Joaquin antelope squirrel, blunt-nosed leopard lizard, Swainson's hawk, burrowing owl and HECA's incremental contribution to cumulative effects to these species that are covered in the *Recovery Plan of Upland Species of the San Joaquin Valley*. Specifically, identify which species and acreage the applicant is proposing to mitigate through purchase of mitigation credits from the Kern Water Bank and which species and acreages would be mitigated through offsite land acquisition. For offsite land acquisition, please identify the species-specific habitat criteria for offsite mitigation lands and cost estimates for determining security (eg. cost estimates for land acquisition, start-up activities and initial habitat improvements, funding during the three-year interim management period, and long-term management).
2. Additional focused protocol-level botanical surveys (CDFG 2009) along all linear routes and additional baseline botanical data, primarily the proposed carbon dioxide pipeline route;
3. Jurisdictional determination from CDFW regarding state waters (ephemeral drainages) in the project area, including all linear routes and ephemeral drainages that may occur along the proposed carbon dioxide pipeline route;

4. Jurisdictional determination from the U.S. Army Corps of Engineers Section 404 for the project area, including all linear routes and ephemeral drainages that may occur along the proposed carbon dioxide pipeline route;
5. Habitat mitigation strategy for habitat loss impacts from OEHI component of HECA at the Elk Hills Oil Field. Please identify whether species impacts including habitat loss for the OEHI component would be included under the Section 10 Habitat Conservation Plan currently under preparation or if habitat loss for the OEHI component of HECA would be mitigated under separate consultations with CDFW and USFWS;
6. Western spadefoot toad habitat assessment along project linear routes including upland refugia and aquatic habitats preferably during the wet season (defined as October 15 to April 15 of any given year) and following sufficient winter or spring rains in order to identify potential depressional areas and upland refugia that may provide habitat for western spadefoot toad. All potential ponding areas should be identified and mapped with a GPS unit including the single pond where this species was identified previously. Information to be collected at each mapped potential breeding area includes, but is not limited to: the specific numbering system of each potential breeding area, presence of tadpoles and species (if any), habitat community, microhabitat features, observed plant species, observed wildlife species including invertebrates, water temperature, approximate depth and surface area, and level of disturbance;
7. Vehicle-fox strike and incidental take analysis considering the project's contribution to existing traffic volumes and intersections of the proposed construction and operation routes with other linear right-of-ways that occur within and outside of San Joaquin kit fox core recovery areas. The applicant should calculate vehicle mortality rates to kit fox and other mammals over the life of the project; and
8. Water supply analysis and the effects of groundwater pumping to the sensitive vegetation communities and raptor nest trees which occur in the project area. The applicant must provide an analysis of the baseline groundwater levels and water source of raptor nest trees and alkali sink scrub habitat along HECA's linear routes, primarily the natural gas pipeline, processed water pipeline, and well field.

CULTURAL RESOURCES

For the EOR components: all of the information required for cultural resources in the Energy Commission Siting Regulations, Appendix B (20 Cal. Code Regs., §1704(b)(2), App. B).

1. Complete pedestrian survey results for all of HECA's linear alignments.
2. Results of test excavations and evaluations of CRHR/NRHP eligibility for all archaeological sites that staff has identified as having the potential to be directly impacted by HECA or OEHI.
3. Results of geoarchaeological field sampling.

LAND USE

A site plan drawn to scale of all proposed structures demonstrating compliance with the sections of the zoning ordinance cited above.

NOISE

Due to potential noise impacts to receptors from project-related traffic, soundwalls may be necessary along the truck route. Prior to preparing the FSA/FEIS, the applicant needs to inform staff of the potential locations of the soundwalls.

SOILS AND SURFACE WATER

Additional Information for the draft DESCP:

- Show all potential locations of horizontal directional drilling (HDD) activities in the DESCP and update the disturbed soil estimates of entry/exit pits. If HDD sites are not yet finalized, please be conservative and include all potential sites.
- Staff notes that some of the lined retention basins at the HECA site are calculated to have drawdown times that exceed the Kern County maximum of seven days (Kern County Hydrology Manual – Section 408.08.01). Please adjust the basin design and/or operations to comply with the Kern County basin standard. Also revise the DESCP and hydrology report to reflect these changes.

Proposed Rail Spur Impacts to Offsite Flooding:

- Maps and drawings that show locations where construction would cross drainages, canals, and other water bodies. Identify what local and/or permits would be required for these crossings.
- Description of typical methods proposed for accommodating flows under or around the rail bed. Include maps that show locations of drainage features and indicate what flows they would be designed to handle.
- Identify whether the rail bed would be constructed in or near a FEMA 100-year floodplain Zone A. If so, discuss the measures that would be required to ensure no upstream or downstream impacts.

TRAFFIC AND TRANSPORTATION

The applicant recently proposed adding storage of limestone and ammonium nitrate at the project site. These revisions would change the number of truck trips to and from the project site. Staff needs additional information from the applicant regarding how this revision in the number of truck trips could also change the potential impacts related to traffic and transportation. Specifically, staff requests the applicant provide revised truck trip numbers for both with the rail spur and without the rail spur and identify changes to the level of service (LOS) at intersections and roadway segments that would occur with the revised truck trips. This issue will be addressed in the FSA/FEIS.

Along with the revision to the on- site storage of limestone and ammonia nitrate used for the HECA project, staff has raised a question regarding the need to expand the Wasco coal servicing facility to serve the project's demand. Potential components of the coal servicing facility initially considered by staff include the possible need for additional storage silos and/or receiving lane for trains and/or haul trucks. Staff requests the applicant identify specific components that would need to be expanded at the coal servicing facility in Wasco. The project's potential demand for expanding the Wasco coal servicing facility will be addressed in the FSA/FEIS.

Under a proposed alternative, HECA would construct and operate a rail spur for delivery of fuel and products to and from the project site. Because the CPUC traditionally has jurisdiction over such facilities, staff will continue to coordinate closely with the CPUC to ensure appropriate design of the rail line for safe operation. In order to ensure that CPUC staff has sufficient information in order to assist in analyzing the proposal, the applicant must submit all the information otherwise required for a formal application pursuant to Title 20, California Code of Regulations, section 3.1 for all public at-grade rail crossings needed for the proposed rail spur. This information is outlined in the CPUC Rules of Practice and Procedure 3.7 to 3.11 under Section 1001 of the Public Utilities Code and should be submitted, to both the CPUC and Energy Commission staff.

Additionally, the applicant must provide an analysis discussing the need for each of the private at-grade crossings proposed, the potential risks involved in proposing this many private crossings in such a small area, and whether, upon further examination, any crossings can be eliminated. This analysis should also discuss potential impacts to the movement of farm machinery and equipment due to reducing the crossings, and should identify to what extent lands on either side of the proposed spur are owned and maintained by the same person or entity, and, thus, could possibly be impacted by reduced connectivity.

Waste Management

- Staff was not provided a breakdown of types and quantities of nonhazardous and hazardous waste that will be generated from the OEHI component of HECA to confirm that the project will not have an impact on Kern County landfills. This data would be needed for staff to complete an assessment of potential impacts
- Staff needs the results of waste characterization tests in accordance with Title 22, California Code of Regulations, Division 4.5, section 66262.10 on coal and petcoke mixes using the Mitsubishi gasifier in Japan using processing methods representative of those to be used for project operation. The purpose of the testing is to determine whether the gasification solids would be hazardous or non-hazardous. This information is needed to further evaluate how the waste can be disposed of and whether it is feasible to market the solids for other uses. The information should include a description of the waste stream, an evaluation of where the residual material is suitable for disposal, identification of facilities that would accept the volume of waste generated, a letter from the facility demonstrating they would accept the waste, and evidence the disposal of the waste would be in compliance

with Kern County waste disposal requirements. If the project owner proposes to market the solids for use as supplementary cementitious materials or other purposes, then a detailed report indicating what uses can be marketed and letters of intent from prospective purchases should be included.

- The project owner should enter into an agreement with DTSC for the purpose of fully characterizing and if necessary remediating the site property so that it is in the appropriate condition to allow for future use. In addition based on the type of agreement with DTSC the applicant should conduct the necessary site characterization to determine if site remediation is needed and if so what the scope of remediation would be prior to the FSA.

Staff needs information on additional waste streams that would result from the addition of the limestone fluxant such as total tons and cubic yards. The applicant shall also provide information on the increased amount of gasification solids in tons and cubic yards.

GEOLOGY AND PALEONTOLOGY

Limestone would be mined and transported to the site to be used as a fluxant to reduce sulfur emissions. Currently it is unknown where the limestone is being mined, the entity that permitted the mine's operation, the capacity of the mine's resource and the estimated consumption of limestone during the project's design life. Staff requests that this information be provided as its evaluation is necessary to complete the analysis for the completion of the FSA/FEIS.

POWER PLANT EFFICIENCY

1. Reconciliation of the 405 MW gross power generation originally submitted in the AFC and the 431 MW power level currently under discussion elsewhere in this document;
2. Update of the mass and energy balance for the *entire* project boundary that uses *all* contemporaneous conditions, including the enhanced oil recovery (EOR) field, air separation (ASU), and the introduction of calcium carbonate to the feedstock blend, based on the various MW ratings.
3. Identification and description of the major power block components, including the gasifier, based on the various MW ratings.

POWER PLANT RELIABILITY

The applicant has failed to assign an AF (availability factor) to the gasification system and ancillary systems upon which the power block is dependent. The applicant needs to assign this AF, demonstrate how it was derived, and explain how it affects the 91.3 percent AF assigned to the power block.

TRANSMISSION SYSTEM ENGINEERING

The Transition Cluster Phase II Interconnection Study Report (Phase II Study) for HECA.

Appendix 1 of Executive Summary
Response to Comments

INTRODUCTION

PURPOSES OF THIS DOCUMENT

This Preliminary Staff Assessment and Draft Environmental Impact Statement (PSA/DEIS) is a joint document presenting the California Energy Commission and Department of Energy staffs' independent review and analysis of the Hydrogen Energy California project (HECA). The Energy Commission uses this document along with other information obtained during the course of the proceeding to decide whether to certify the HECA project; this certification is in lieu of any permit required by state, regional, or local agencies, and federal agencies to the extent permitted by federal law (Pub. Resources Code, §25500). The Warren-Alquist Act (Pub. Resources Code §25500 et seq.), Title 20, California Code of Regulations section 1701 et seq., and the California Environmental Quality Act (CEQA) (Pub. Resources Code, §21000 et seq.) guide Energy Commission staff in its analysis.

The U.S. Department of Energy (DOE) will use this document to inform its decision on whether to provide financial assistance for the construction and demonstration of the project; it must comply with the National Environmental Policy Act (42 United States Code [U.S.C.] §§ 4321 et seq.) in making this decision.

As the CEQA and NEPA processes are similar, the Energy Commission and DOE decided to cooperate in complying with the requirements applicable to each agency to the extent practicable in order to facilitate public involvement and conserve agency resources. CEQA encourages state agencies to combine environmental documents with federal agencies where possible and appropriate and Executive Order 13604 (Obama, March 22, 2012) directs federal agencies to avoid environmental reviews that are duplicative of reviews conducted by state agencies or other entities whenever possible. Preparation of a combined Preliminary Staff Assessment and Draft Environmental Impact Statement is consistent with this objective. Energy Commission staff and DOE also believe that this combined effort is in the best interest of stakeholders and interested parties, as it allows them to participate in a single, coordinated process, avoiding their needing to review multiple documents that contain similar information about the project. Accordingly, this document constitutes Energy Commission staff's PSA and DOE's DEIS. The Energy Commission and DOE worked closely with other agencies in preparing this PSA/DEIS – the U.S. Environmental Protection Agency, U.S. Fish and Wildlife Service, U.S. Army Corps of Engineers, California State Lands Commission, State Water Resources Control Board/Regional Water Quality Control Board, California Department of Fish and Wildlife, the California Air Resources Board, and Kern County.

While each agency has distinct missions and regulatory requirements, the proposed project, the affected environment, and the potential impacts are the same. Accordingly, the sections of this document that deal with these topics do not contain specific reference to a particular agency. On the other hand, this document contains separate sections discussing each agency's mission, the alternatives it must consider, the regulatory requirements applicable to it, and the decisions it will make based on the information in this document, as these are different for the Energy Commission and DOE. Both NEPA and CEQA share the goal of ensuring government agencies make informed decisions regarding proposed actions subject to their jurisdiction.

For the Energy Commission, this PSA/DEIS is a staff document; it is neither a Committee document, nor a draft decision. The Energy Commission Committee overseeing the project will hold evidentiary hearings, then prepare a Presiding Member's Proposed Decision, which will be presented to the full Energy Commission for a vote to approve or deny that proposed decision. For DOE, this PSA/DEIS serves as a NEPA document; it will be followed by a Final Environmental Impact Statement. At this time, DOE anticipates that the Final Environmental Impact Statement would be issued in conjunction with the Energy Commission's Final Staff Assessment. If DOE decides to provide financial assistance for construction of the HECA project, this will be followed by a Record of Decision (ROD).

The PSA/DEIS describes the following:

- the proposed project;
- the project alternatives (which may be somewhat different for each agency as a result of their differing roles and statutory regimes);
- the existing environment;
- whether the project's facilities can be constructed and operated safely and reliably in accordance with applicable laws, ordinances, regulations and standards (LORS);
- the environmental consequences (impacts) of the project including potential public health and safety impacts;
- the potential cumulative impacts of the project in conjunction with other existing and reasonably foreseeable developments;
- mitigation measures proposed by the applicant, Energy Commission staff, DOE, other interested agencies, local organizations, the public, and intervenors that may lessen or eliminate potential impacts; and
- the proposed conditions under which the project should be constructed and operated if it is certified by the Energy Commission and provided financial assistance by DOE.

The analyses in this PSA/DEIS are based upon information from the: (1) Amended Application for Certification (AFC), (2) responses to data requests, (3) supplementary information from local, state, and federal agencies, interested organizations and individuals, (4) existing documents and publications, (5) independent research, and (6) comments from the public. The analyses for most technical areas include proposed conditions of certification; some may also include mitigation measures DOE could impose as a condition of it providing financial assistance. Each proposed condition of certification is followed by a proposed means of "verification." This document presents preliminary conclusions about potential environmental impacts and conformity with

LORS, as well as proposed conditions that apply to the design, construction, operation and closure of the facility.

This document was prepared in accordance with Public Resources Code section 25500 et seq. and Title 20, California Code of Regulations section 1701 et seqCEQA (Pub. Resources Code, § 21000 et seq.), NEPA (42 U.S.C. § 4321 et seq.), the regulations implementing NEPA promulgated by the Council on Environmental Quality (CEQ) (Title 40, Code of Federal Regulations [C.F.R.] Parts 1500–1508), and DOE's NEPA procedures (10 C.F.R. Part 1021).

ORGANIZATION OF THE DOCUMENT

Resource areas are examined in individual sections and are followed by a discussion of project construction, operation, and required conditions of certification for each resource analyzed. In addition there are a set of standard Energy Commission requirements that apply to the project called "General Conditions". These contain the facility closure plans. At the end of the document there is also a list of the Energy Commission staff that assisted in preparation of the document.

Each of the resource assessments includes section authors and a discussion of:

- laws, ordinances, regulations and standards (LORS);
- the regional and site-specific setting;
- project specific and cumulative impacts;
- mitigation measures;
- conclusions and recommendations; and
- conditions of certification (and perhaps mitigation measures) for both construction and operation (if applicable).

ENERGY COMMISSION SITING PROCESS

The Energy Commission has the exclusive authority to certify the construction, modification and operation of thermal electric power plants 50 megawatts (MW) or larger in California. The Energy Commission certification is in lieu of any permit required by state, regional, or local agencies, and federal agencies to the extent permitted by federal law (Pub. Resources Code, § 25500). The Energy Commission must review power plant AFCs to assess potential environmental impacts including potential impacts to public health and safety, potential measures to mitigate those impacts [Pub. Resources Code, § 25519), and compliance with applicable governmental laws or standards (Pub. Resources Code, § 25523 (d)].

The Energy Commission's siting regulations require staff to independently review the AFC and assess whether the list of environmental impacts contained is complete, and whether additional or more effective mitigation measures are necessary, feasible and available [Cal. Code Regs., tit. 20, §§ 1742 and 1742.5(a)]. In addition, staff must assess the completeness and adequacy of the measures proposed by the applicant to ensure compliance with health and safety standards, and the reliability of power plant operations [Cal. Code Regs., tit. 20, § 1743(b)]. Staff is required to develop a compliance plan (coordinated with other agencies) to ensure that applicable laws, ordinances, regulations and standards are met [Cal. Code Regs., tit. 20, § 1744(b)].

Staff conducts its environmental analysis in accordance with the requirements of CEQA. No additional Environmental Impact Report (EIR) is required because the Energy Commission's site certification program has been certified by the California Resources Agency as meeting all requirements of a certified regulatory program [Pub. Resources Code, § 21080.5 and Cal. Code Regs., tit. 14, § 15251 (j)]. The Energy Commission is the CEQA lead agency.

The staff prepares a PSA that presents for the applicant, intervenors, organizations, agencies, other interested parties and members of the public, the staff's analysis, conclusions, and recommendations. Where it is appropriate, the PSA incorporates comments received from agencies, the public and parties to the siting case, and comments made at the workshops.

Staff will provide a comment period to resolve issues between the parties and to narrow the scope of adjudicated issues in the evidentiary hearings. During the period after the publishing of the PSA, staff will conduct one or more community workshops to discuss its findings, proposed mitigation, proposed compliance-monitoring requirements, and acquire the missing information needed for a final analysis. Based on the workshops and written comments, staff may refine its analysis, correct errors, and finalize conditions of certification to reflect areas where agreements have been reached with the parties, and publish a Final Staff Assessment (FSA).

The FSA is only one piece of evidence that will be considered by the Committee (two Commissioners who have been assigned to this project) in reaching a decision on whether or not to recommend that the full, five-member Energy Commission approve the proposed project. At the public hearings, all parties will be afforded an opportunity to present evidence and to rebut the testimony of other parties, thereby creating a hearing record on which a decision on the project can be based. The hearing before the Committee also allows all parties to argue their positions on disputed matters, if any, and it provides a forum for the Committee to receive comments from the public and other governmental agencies.

Following the hearings, the Committee's recommendation to the full Energy Commission on whether or not to approve the proposed project will be contained in a document entitled the Presiding Member's Proposed Decision (PMPD). Following publication, the PMPD is circulated in order to receive written public comments. At the conclusion of the comment period, the Committee may prepare a revised PMPD if necessary. At the close of the comment period for the revised PMPD, the PMPD is submitted to the full Energy Commission for a decision.

DOE NEPA PROCESS

DOE proposes to provide federal financial assistance to the applicant for its proposed project ("HECA" or "the project"), which would demonstrate integrated gasification combined cycle (IGCC) technology with carbon capture in a new electricity generating plant. DOE does not have regulatory jurisdiction over the project, nor would it own or operate the project. Its decisions are limited to whether and under what circumstances it would provide financial assistance for the construction and demonstration of the project. After the demonstration period called for in DOE's financial assistance agreement with the applicant -- which would last for two years once the project is in operation – DOE would have no further role in funding or other aspects of the project.

This DEIS describes the potential environmental impacts associated with DOE's proposed action (providing financial assistance), the project itself (including aspects of the project that DOE would not fund), and alternatives to and options for the project, including the No Action Alternative. Public comments will be solicited and considered prior to the development of the final environmental impact statement (FEIS).

DOE will use the NEPA process to inform its decision on whether to provide financial assistance for construction and demonstration of the project and, if so, whether it should impose environmental mitigation measures as a condition of its financial assistance for these activities. DOE's decisions will be announced in a Record of Decision (ROD). The Council on Environmental Quality's (CEQ) NEPA regulations require that DOE wait at least 30 days after the publication of an FEIS before it issues a ROD. DOE anticipates that it would not issue a ROD for HECA until after the Energy Commission's Presiding Member's Proposed Decision has been published, and possibly until the full Energy Commission votes to determine whether the project will be approved.

INTEGRATION OF THE NEPA AND CEQA PROCESSES

Energy Commission staff and DOE have integrated the environmental review processes required under CEQA with those required under NEPA. This PSA/DEIS is one aspect of that coordination. The agencies anticipate that they will prepare and issue a second coordinated document that would constitute the FSA and FEIS. After that the agencies anticipate that they will proceed independently in making their respective decisions regarding the HECA project. As noted above, DOE anticipates it will wait for the Energy Commission's Presiding Member's Proposed Decision, or possibly the final Commission Decision, before issuing a Record of Decision.

PROJECT DESCRIPTION

John Heiser

INTRODUCTION

In September of 2011, SCS Energy California LLC (SCS Energy) acquired the Hydrogen Energy California (HECA) project from BP Alternative Energy North America Inc., and Rio Tinto Hydrogen Energy LLC. Because SCS Energy intended to make several modifications to the project – including the addition of fertilizer production capabilities – the National Environmental Policy Act (NEPA) and the California Energy Commission's regulatory processes were suspended until HECA submitted the Amended Application for Certification to the Energy Commission on May 2, 2012.

HECA, if approved, would be partially funded by the U. S. Department of Energy (DOE) as a demonstration project under the Clean Coal Power Initiative Round 3 (CCPI-3). The CCPI-3 solicitation sought projects that would demonstrate advanced coal-based electricity generating technologies which capture and sequester (or put to beneficial use) carbon dioxide emissions. The HECA project was selected in the first phase of Round 3. The agreement with DOE includes possible funding support through the design, construction and the first two years of commercial operations.

SCS Energy California, LLC, the new owner of Hydrogen Energy California, LLC, submitted an Amended Application for Certification (AFC) to the Energy Commission on May 2, 2012. Public Resources Code section 25540.6 exempts certain types of projects from filing a notice of intention prior to filing an application for certification. This project qualifies for such an exemption as a "thermal powerplant designed to develop or demonstrate technologies which have not previously been built or operated on a commercial scale" pursuant to subsection 25540.6(a)(5). Pursuant to this exemption, the project may not exceed 300 megawatts unless the Energy Commission has authorized a greater capacity pursuant to regulation. As of the date of publication of this document, the Energy Commission has not authorized a greater capacity. HECA LLC is proposing to construct and operate a polygeneration project. HECA would use Western sub-bituminous coal, most likely from New Mexico mines, and petroleum coke (petcoke) from southern California refineries as the basis for producing the synthetic gas (syngas) fuel source for the project. HECA would comprise an advanced integrated gasification combined cycle (IGCC) power plant. The gasification process would rely on a Mitsubishi Heavy Industries oxygen-blown dry feed gasifier, designed to convert petroleum coke and coal into a carbon dioxide and hydrogen-rich synthesis gas (syngas) which would fuel a combustion turbine unit. Through a complex process, mercury, sulfur, hydrogen sulfide and carbon dioxide would be removed from the syngas leaving a hydrogen rich fuel for the combustion turbine. By directing steam produced in this process to a heat recovery steam generator (HRSG) that is connected to the shaft powering the generator, HECA would produce up to 300 megawatts of net electrical output to the grid. The proposed manufacturing complex would produce approximately one-million tons per year of ammonia and nitrogen-based fertilizer products. The plant would produce low carbon ammonia-based agricultural fertilizers by diverting hydrogen and carbon dioxide produced from the gasification process, and nitrogen from the air separation unit, to the manufacture of urea pastilles and urea-ammonium nitrate; both products are agricultural fertilizers. Intermediate products produced to make fertilizer products, but not be sold as products, include anhydrous ammonia and nitric acid.

Additionally, approximately 90 percent of the carbon dioxide ($C0_2$) produced by HECA, estimated to be about 3 million tons per year, would be captured. Approximately 2.6 million tons would be compressed and sent through a three-mile long, 12” diameter pipeline to the Occidental Elk Hills Oil Field $C0_2$ enhanced oil recovery (EOR) Processing Facility where it will be conditioned, and distributed to satellite locations and then to injection wells as part of an on-going enhanced oil recovery project. The CO_2 would be a key component of a water-alternating-gas process that displaces and moves oil and gas from the pore-spaces to the production wells and would result in the eventual sequestration (permanent geologic encapsulation) of the injected CO_2 within the reservoir’s vacated pore-spaces. Approximately 0.4 million tons of CO_2 per year would be used in fertilizer production and not considered to be sequestered. HECA would be expected to have a 25 year life span, and Occidental Elk Hills, Incorporated (OEHI) EOR project would use the CO_2 from HECA for the life of the HECA project (see the **Sequestration and Greenhouse Gas** section of this document).

HECA has proposed two coal transportation alternatives: Alternative 1 is a proposed 5-mile private railroad spur that would connect with the existing San Joaquin Valley Railroad at Buttonwillow to HECA. Alternative 1 would allow for the delivery of coal and the possible transportation of the proposed manufactured products to commercial markets. Alternative 2 would involve transportation of the coal to HECA from the coal transloading facilities in Wasco using trucks, an approximately 27-mile route. Manufactured product would also require truck transport from the project site under Alternative 2. (**Project Description Figures 6, 7,** and **9**).

During construction traffic would range as high as 1230 vehicle round trips per day, with an additional 50 truck deliveries, and 60 soil deliveries to the site. During operations (post-construction) expected traffic levels were estimated for each of the two alternatives. Alternative 1, would likely have 154 vehicle round trips per day for operations staff, 213 truck round trips for process material (fertilizers) and 175 truck round trips for feed stock deliveries (predominantly petcoke and fluxant). Alternative 2 would have 154 vehicle round trips, 399 truck round trips for process materials, and 910 truck round trips delivering feed stock (coal, petcoke and fluxant). The **Traffic and Transportation** and the **Land Use** sections of this document discuss these elements in more detail. Staff also analyzes the associated impacts from each transportation alternative further in the **Air Quality**, **Public Health**, and **Noise** sections of this document.

HECA proposes to use Mitsubishi Heavy Industries equipment to gasify petroleum coke (petcoke) from southern California refineries, bituminous coal from mines in New Mexico and limestone fluxant from California sources, producing a hydrogen-rich synthesis gas (syngas) to be used in a combustion turbine and a steam turbine to drive a single-shaft generator producing between 405 and 431 megawatts (MW) of gross base-load electricity, with up to 300 MW net electrical output, and would connect to the Pacific Gas and Electric (PG&E) 230kV transmission network at a new switchyard to be constructed approximately 2 miles east of the project site. The proposed transmission line would be approximately 2.8 miles in length from the on-site switchyard at the northwest portion of the project, with 0.8 miles of the line traversing eastward across the HECA site and buffer area.

HECA would gasify an approximately 75 percent coal and 25 percent petcoke fuel blend to produce synthesis gas (syngas) that would be processed and purified to produce a hydrogen-rich gas; the syngas would be used to fuel the combustion turbine and the burners that provide supplemental fire to the heat recovery steam generator (HRSG). The HRSG produces steam from the combustion turbine exhaust heat.

The Mitsubishi Heavy Industries (MHI) gasification system selected for this project produces a synthetic gas that is further processed and cleaned to produce both CO_2 and a hydrogen-rich fuel used for power generation and ammonia synthesis to be used at the manufacturing complex, where the syngas would also be used in the manufacturing of low-carbon ammonia-based agricultural fertilizer products in the integrated manufacturing complex. **Project Description Figure 3** displays the principal features of the gasification, power generation, and manufacturing facilities proposed for HECA.

HECA would capture up to 90 percent of the CO_2 produced from these processes, then compress and send this via an approximately 3-mile pipeline to a facility to be developed by Occidental Petroleum Elk Hills, Inc. (OEHI) for use in a planned enhanced oil recovery (EOR) project. HECA would capture approximately 3 million tons sequestering about 2.6 million tons of CO_2 annually for aiding in increasing oil production and eventual geologic sequestration in the Stevens Reservoir of the Occidental Elk Hills Oil Field (EHOF). The EHOF is owned and operated by Occidental Elk Hills, Inc. (OEHI) (**Project Description Figures 4 and 10**). The OEHI EOR project would apply separately for the required permits through the Department of Conservation, Division of Oil, Gas, and Geothermal Resources (DOGGR), and has provided initial information and begun discussions with that agency. Additional permits may also be required for certain project elements, such as roads, through Kern County requirements.

The CO_2 EOR Processing Facility would be located approximately 3-miles south of the HECA property, inside the EHOF (**Project Description Figure 10**). The Processing Facility and 13 satellites would be expected to occupy approximately 136 acres within the EHOF and located approximately 3-miles south of the HECA property. The facility would use approximately 720 producing and injection wells, 570 existing wells and 150 new well installations. Approximately 652 miles of new pipeline would also be installed in the EHOF during the 20-year proposed phase of the EOR project. Should HECA be approved, and begin operations, OEHI could extend the planned use of CO_2 in the EHOF's EOR process (HECA 2012a, Vol. I, Appendix A).

PROPOSED CONSTRUCTION TIMELINES

Project construction milestones have been affected by delays in the application process. The projected milestones below are based upon an approximately 7-month delay from those projected by the applicant in the May 2, 2012, AFC (Vol. I, page 2-11):

Table 1: Proposed HECA Construction and Commercial Operation Timeline

Commence preconstruction, construction activities	January 2014
Commence truck deliveries and ground disturbance	March 2014
Completion of construction	September 2017
Commence pre-commissioning activities	September 2016
Commencement of commercial operation	April 2018

PROJECT LOCATION AND JURISDICTION

As proposed, HECA would be located on a total of approximately 1,106 acres of privately-owned land in western unincorporated Kern County, California. The IGCC and the manufacturing complex and storage facilities, as well as the proposed coal, petcoke and fluxant storage facilities would be on 453-acres, with 653 acres adjacent to the project site allowing for a large buffer area with controlled access (**Project Description Figures 2, 3, 5** and **8**).

HECA would be located 20 miles west of the city of Bakersfield. It is 1.5 miles northwest of the unincorporated community of Tupman, and approximately 4 miles southeast of the unincorporated community of Buttonwillow. The project site address is 7361 Adohr Road, Buttonwillow CA 93106 (**Project Description Figure 1**).

The California State Water Project aqueduct lies to the south, and the Elk Hills Oil Field boundary is located approximately 1 mile south of the project site (**Project Description Figure 4**).

The western border of the Tule Elk State Natural Reserve (California state park) is located approximately 1,700 feet to the east of the project site. The nearest single-family dwellings are currently located approximately 370 feet to the northwest, 1,400 feet to the east, 3,300 feet to the southeast, and 4,000 feet to the north of the proposed project site (**Project Description Figure 5**). HECA has an option to purchase the dwelling in the northwest area of the project site (noted as 370 feet to the northeast).

The HECA site is located within Section 10 of Township 30 South, Range 24 East in Kern County. The project site Assessor's Parcel Numbers (APNs) are part of 159-040-02, part of 159-040-16, and part of 159-040-18.The proposed controlled area APNs consist of all of 159-040-04, all of 159-040-11, all of 159-040-17, all of 159-190-09, remnant part of 159-040-02, remnant part of 159-040-16 and remnant part of 159-040-18.

Kern County would require merging the parcels for the proposed project as part of the county's approval process, the Energy Commission would require compliance with this requirement (see the **Land Use** Section of this document).

Current and Adjacent Land Use

The proposed facility site is currently in agricultural production including cultivation of cotton, alfalfa and onions and an approximately 72-acre tract is currently subject to a Williamson Act agricultural land preservation contract; the applicant is pursuing a contract cancellation with Kern County and a hearing scheduled for June 13, 2013, regarding this parcel. The buffer area is proposed to remain in agricultural use. Land use in the vicinity of the project site is primarily agricultural with almond, pistachio, grapes, tomatoes, corn, onions and alfalfa crops.

The West Side Canal (and the Outlet Canal, Kern River Flood Control Channel (KRFCC), and the California Aqueduct (State Water Project) are approximately 500, 700, and 1,900 feet south of the project site, respectively (See **Project Description Figures 5 and 10**).

State and Federal Jurisdiction

The Energy Commission has exclusive permitting jurisdiction for the siting of thermal power plants of 50 MW or more and related facilities in California. The Energy Commission also has responsibility for ensuring compliance with the California Environmental Quality Act (CEQA) through the administration of its certified regulatory program and is the lead agency under CEQA. Additionally, under CEQA, the Energy Commission must conduct an environmental review of the "whole of the action," which may include facilities not licensed by the Energy Commission (California Code of Regulations, title 14, §15378). As a result, the Energy Commission analysis includes an environmental analysis of the proposed Occidental Elk Hills, Incorporated (OEHI) enhanced oil recovery (EOR) project that would be located within the Elk Hills Oil Field (EHOF). This EOR project and the related infrastructure would be the responsibility of the Department of Conservation, Division of Oil, Gas and Geothermal Resources (DOGGR) as Lead Agency. This PSA/DEIS analyzes the proposed EOR as a part of the project, or the whole of the action, pursuant to CEQA.

This PSA/DEIS provides initial analysis of these elements and facilities as part of its CEQA responsibility. The analysis regarding the EOR process and the permitting expectations is discussed in **Land Use, Air Quality, Sequestration and Greenhouse Gas, Socioeconomics, Biological Resources**, and other technical sections of this document.

This Preliminary Staff Assessment/Draft Environmental Impact Statement (PSA/DEIS) is being prepared as part of the coordinated Energy Commission and Department of Energy joint review process. Comments on this document, along with new information gathered by staff, will be included in a Final Staff Assessment/Final Environmental Impact Statement (FSA/FEIS).

Agency Coordination

Energy Commission staff, in cooperation with the Department of Energy, are coordinating with a wide range of federal and state agencies for the analysis of HECA. A brief summary of these efforts follows:

The Department of Energy (DOE) will issue joint documents with Energy Commission staff through the Final Staff Assessment and Final Environmental Impact Statement (FSA/FEIS) prior to issuing the federally-required Record of Decision (ROD) for the proposed HECA. The Amended Notice of Intent (ANOI) was published by DOE in the *Federal Register* on June 19, 2012 (77 FR 36519).

The U.S. Fish and Wildlife Service (USFWS), and the California Department of Fish and Wildlife (CDFW) are working with staff and with the DOE, and HECA, LLC regarding the biological analysis as well as the development of the required Biological Opinion, which will cover HECA and also the OEHI enhanced oil recovery project (EOR) that is planned within the OEHI's Elk Hills Oil Field (EHOF). The EOR would utilize approximately 3 million tons per year of the CO_2 produced by HECA, expecting that the project will result in sequestration of the CO_2 in permanently in the pore space vacated by the produced oil and gas. (See the **Biological Resources** and the **Sequestration and Greenhouse Gas** sections of this PSA/DEIS).

The DOE also has a responsibility under Section 106 of the National Historic Preservation Act to consult with the Native American tribes affected by HECA. This required effort parallels the requirement of the Energy Commission under the terms of the California Environmental Quality Act (CEQA). Efforts include coordination with the California State Historic Preservation Office (SHPO) to insure identification of the appropriate tribal entities, interested Native American individuals, and the possible location of important cultural resources in the vicinity of the proposed project. For detailed information on the process and the status of these efforts please see the **Cultural Resources** section of this document.

Coordination with Kern County will continue through this process, and through construction and operations should the project be approved. Through the efforts of the Kern County Planning and Community Development Department (PCDD) the Energy Commission staff and the applicant have independently sought clarification of the laws, ordinances, regulations and standards (LORS) which would govern the permitting of HECA but for the exclusive jurisdiction of the Energy Commission for powerplant applications proposing capacity of 50 MW or greater. The PCDD continues to provide input to staff, attending Energy Commission workshops and working with the Kern County Board of Supervisors to provide information on the County's LORS and recommended mitigation necessary to insure protection of the health and safety of the County residents. This input to date is reflected in the **Socioeconomics, Land Use, Traffic and Transportation**, and the **Worker Safety and Fire Protection** sections of this document.

The San Joaquin Valley Air Pollution Control District (SJVAPCD) issued a Preliminary Determination of Compliance (PDOC) on February 7, 2013, held a public workshop in Bakersfield on April 2, 2013, and scheduled a second PDOC workshop held in Buttonwillow on May 17, 2013, with a comment period closing on May 30, 2013. Work with the SJVAPCD continues throughout the process, and this also requires coordination with the California Air Resources Board (CARB) and the U.S. Environmental Protection Agency (EPA). For a complete description of these efforts please see the **Air Quality** and the **Sequestration and Greenhouse Gas** sections of this document.

The Department of Conservation, Division of Oil, Gas, and Geothermal Resources (DOGGR) is coordinating with OEHI to review OEHI's Class II permit applications for the first phase of its CO_2 EOR proposal. DOGGR is still in the process of obtaining sufficient information regarding the proposal in order to deem the application complete and begin substantive evaluation. It is not likely that DOGGR will have made substantial permitting progress prior to Energy Commission and DOE action on a final Decision and Record of Decision. (See the **Sequestration and Greenhouse Gas** section of this PSA/DEIS).

California State Department of Parks and Recreation, Tehachapi District, Tule Elk State Natural Reserve is monitoring the project, and has provided staff with initial comments and planning its participation as the process moves forward. (See the **Biological Resources** section of this document).

The California State Water Board and the Regional Water Quality Control Board continue to provide information to staff, both agencies participated in the water supply workshop that was held in Sacramento on February 20, 2013.

General Agency Coordination: Staff continues to work with U.S. Environmental Protection Agency (U.S.EPA) staff to host a monthly agency roundtable discussion regarding HECA. The goal is to insure that agencies are kept apprised of the schedule for the project and that agencies may discuss regulatory and process concerns within the agency context. State and federal agencies have continued to make this forum a valuable source for information.

PROJECT DESCRIPTION, DESIGN AND OPERATION

This section describes HECA's conceptual design and various aspects of its proposed operation; **(Project Description Figure 3** shows the Site Plan and on-site project components**).**

FEEDSTOCK STORAGE, DRYING AND THE GASIFICATION UNIT

The petroleum coke and coal feedstock would be stored in separate piles inside a large storage building where it would be blended at a set rate and sent via an enclosed transfer conveyor system to the gasification system. The MHI oxygen-blown gasifier is a two stage design resulting in the production of syngas composed of mainly of (hydrogen and carbon monoxide. A complex syngas treatment system further refines the product prior to its use as fuel for the turbine and chemical plant. Steam produced as the syngas is cooled in this process is directed to the heat recovery steam generator (HRSG) to assist in power generation. The gasification system consists of equipment used to grind and dry the feedstock prior to its entering the two-stage MHI gasifier. The limestone fluxant is added to the feedstock as it moves to the gasifier. Feedstock would enter the gasifier at two stages. One stream is fed into the first stage of the gasifier and oxygen is added. In this lower first stage the feedstock and oxygen are gasified at high heat, sufficient to melt the coal ash, and producing carbon monoxide (CO), H_2, CO_2 and other trace components. The molten coal ash flows down a protective membrane and is quenched in a water bath and then removed via a lock hopper system. The gas produced in the first stage rises to the second stage where the second stream of feedstock enters but no additional oxygen is added. In this second stage the gasification of char to CO occurs. The syngas produced in this stage exits through a syngas cooler, generating steam. This steam is directed to the heat recovery steam generator (HRSG) and used for power generation. Downstream a cyclone and a filter collect the char and recycle the char back to the lower stage of the gasifier to increase the overall carbon conversion efficiency.

The syngas leaving the second stage is at approximately 2200 degrees Fahrenheit, which helps insure that negligible hydrocarbon gases and liquids are formed. This raw syngas would now go through an additional complex series of treatment processes including scrubbing to remove chlorides, minimizing potential for forming ammonium chloride inside downstream equipment as the syngas cools.

There are several complex downstream systems associated with processing the raw syngas so that it would become suitable to fuel the combustion turbine. Processes downstream remove sulphur, and in a Sour Shift Unit, the remaining CO and water go through a water-gas shift reaction which produces CO_2 and hydrogen (H_2). Additional systems remove mercury, acid gases (in a patented Rectisol® system) including hydrogen sulfide and CO_2.

POWER BLOCK CTG AND THE HRSG UNIT

A cold startup of the coal gasifier and transitioning to start up of the combustion turbine and electrical generation system would begin with processing (grinding and drying) of the coal and blending with the petcoke and loading to the gasifier for production of the syngas. The syngas would be routed to the CTG and the HRSG. During startup operations the combustion turbine generator (CTG)/heat recovery steam generator (HRSG) would be fired on natural gas and would transition to the hydrogen-rich fuel (syngas) approximately two and a half hours into the transition process. A startup sequence of the CTG and HRSG operating on natural gas is estimated to require approximately 4.5 hours. A complete system (CTG, HRSG, and gasification system) shutdown sequence is estimated to take 9 hours. The combined cycle power block would generate between 405 and 431 MW. The applicant's engineering team continues to work with the MHI engineering group and results of the final design may increase the efficient use of process excess heat, which may result in increasing the gross CTG output to the higher value. The applicant expects that HECA would be providing baseload electricity using the syngas produced from the project's gasification unit. The power generation equipment is similar to conventional natural gas power plants; however, there is substantial heat integration with the gasification process where heat is recovered as useful energy for additional power generation. The combined cycle block would include a single-shaft MHI 501GAC® G-class, air-cooled combustion turbine/steam turbine generator configured to operate using hydrogen-rich fuel.

The power block also would include a heat recovery steam generator (HRSG) and a water cooled surface condenser. Exhaust gas from the turbine as well as supplemental hydrogen-rich fuel and other process off-gas for duct-firing would be sent to the HRSG to generate additional electricity. The HRSG would be equipped with emission control technology to reduce stack emissions. The HRSG would include a selective catalytic reduction system (SCR) to meet best available control technology (BACT) requirements for nitrogen oxides (NOx). The SCR system would use ammonia injected upstream of the SCR catalyst. The SCR catalyst would be used to convert NOx and ammonia into nitrogen and water.

Proposed Operation of HECA

HECA is designed to balance power production, CO_2 capture and use, and fertilizer manufacturing plant output. The electrical output and availability of maximum electricity production is, in part, balanced with the maximum manufacturing output. HECA, in the AFC, has proposed that the balance would be approximately 16 hour per day at 405 MW, (per amended AFC application) when maximum electricity production may be needed; and 8 hours per day at 295 MW during hours when maximum fertilizer and ammonia production would be possible due to lessened demand for the electrical output.

The HECA assumption is that this variability provides an optimum balance for the combined operations. HECA also assumes that products that would result from operations of the above systems may have commercial value. These include the electricity produced (between 267 MW and 300 MW), the CO_2 (2.6 million tons), the degassed liquid sulphur (up to 100 short tons per day (stpd) and the gasification solids (938 stpd dry basis). Additionally, bi-products from these processes would be diverted to the fertilizer manufacturing facility for the production of fertilizer products, these are discussed in that section.

COOLING TOWERS

The power block cooling tower

The power block cooling tower would be used to facilitate removal of the waste heat from the steam power cycle portion of the combined cycle CTG/HRSG. Approximately 95,500 gallons per minute (gpm) of water would be circulated in the power block cooling tower.

The process block cooling tower

The process block cooling tower would be used for heat rejection from the CO_2 compressor and an acid gas removal (AGR) refrigeration unit. The process block cooling tower circulation rate would be approximately 163,000 gpm of water.

The air separation unit (ASU) cooling tower

The ASU cooling tower would reject waste heat from the ASU. The ASU cooling tower circulation rate would be approximately 45,000 gpm of water and would be equipped with a high efficiency drift eliminator. The ASU, including the ASU cooling tower, would be designed, built, owned, and operated by third party. However, for purposes of the analysis staff considers this unit as part of the HECA facility.

Zero Liquid Discharge System

HECA would rely on a zero liquid discharge system (ZLD) to minimize the discharge of waste water. Plant wastewater, cooling tower blowdown, water treatment reject, evaporative cooler blowdown, and water from plant drains would be evaporated and concentrated using a conventional mechanical vapor recompression brine concentrator followed by a brine crystallizer. Resulting filter cake would be dispose of appropriately. Additional discussion of waste will be found in the **Waste Management** section of this document.

MANUFACTURING PLANT

The proposed manufacturing complex includes an ammonia synthesis unit. The ammonia synthesis unit manufactures ammonia (NH_3) for urea pastilles and urea-ammonium nitrate (UAN) solution production. The ammonia synthesis unit uses nitrogen from the ASU and high purity hydrogen from the Pressure Swing Adsorption unit (PSA) to convert the nitrogen and hydrogen to ammonia. This exothermic conversion occurs over an iron-based catalyst. The effluent is used to generate steam in the waste heat boiler. Cold liquid ammonia is stored in two vertical steel tanks housed in a second vessel and equipped with a vapor recovery system to prevent losses. A leak detection and repair (LDAR) program has been proposed by the applicant to limit fugitive emission from the NH_3 streams.

The proposed urea unit would be used to produce a concentrated urea solution by combining a purified stream of CO_2 recovered in the Acid Gas Removal system with ammonia from the ammonia synthesis resulting in a concentrated urea solution. This solution would be used as feed to produce UAN solution and urea pastilles, commercial agricultural fertilizers. **(**See **Project Description Figure 3)**

LINEAR FACILITIES

Construction of proposed linear facilities would include installation of approximately 32 miles total of underground pipelines, as well as construction of a 2-mile long transmission line and a proposed 5-mile industrial railroad spur that would be built and owned by the applicant (see **Project Description Figure 4, 5, 6, 7, 9** and **10)**.

Construction of the underground pipelines would consist primarily of crews performing the following typical pipeline construction activities: hauling and stringing of the pipe along the route; welding; radiographic inspection; coating of the pipe welds; trenching; lowering of the pipe into the trench; backfill of the trench; hydrostatic testing of the pipeline; purging the pipeline; and cleanup and restoration of construction areas. Grade cuts would be restored to their original contours and affected areas would be restored to their original state to minimize erosion (HECA 2012bb, §A116).

At areas where pipes would cross certain watercourses and roadways, the applicant proposes to use horizontal directional drilling (HDD) to avoid direct disturbances at these locations. HDD involves drilling from the ground surface adjacent to the area of concern, such as a stream, using a technique that guides the direction of the drill to pass under the stream and emerge on the ground surface on the opposite side without disturbing the streambed. Staging areas are required at the entry and exit points of the drill, with each “entry pit” requiring a temporary disturbance area of approximately 120 feet by 100 feet and each “exit pit” requiring an area of approximately 75 feet by 100 feet (HECA 2012bb, §A116).

Construction and installation of the approximately 2.8-mile electrical transmission line would follow a sequence similar to that of underground facilities, with trench excavation being replaced by the augering of holes to facilitate placement of the reinforced concrete foundations for the tubular-steel transmission structures, followed by backfilling and compaction. Grade cuts would be restored to their original contours, and affected areas would be restored to their original state to minimize the potential for erosion. To the extent possible, the material excavated from trenches and auger holes would be used to backfill around the foundations and in the trenches. Additional excess material that cannot be reused along the easement corridor would be transported to another reuse area or disposed of at an offsite landfill facility (HECA 2012bb, §A116).

The means for delivery of coal (200 rail cars per day would require staff to evaluate the applicant's proposal for two Transportation Alternatives: Alternative 1, rail transportation would entail construction of an approximately 5-mile new industrial railroad spur that would connect the project site to the existing San Joaquin Valley Railroad (SJVRR), Buttonwillow railroad line located north of the project site. This railroad spur would also be used to transport HECA manufactured fertilizer products, gasified solids, limestone fluxant and coal from the coal transloading facility located in Wasco, northeast of the project site. The truck route distance is approximately 27 miles. (HECA 2012bb, §A116). Staff and the applicant have initiated discussions with the California Public Utilities Commission (CPUC) staff regarding the appropriate measures for the permitting of two roads that would require lights, signals and other required safety measures, as well as the disruption of several agricultural crossings which would require either developing an alternative routing or a private crossing of the rail line. Staff, the applicant and CPUC continue working on the appropriate means of permitting this spur. Alternative 2 requires use of trucks for these transport needs.

Water Supply

The project would use approximately 6.6 million gallons per day (mgd) of water on a calendar year average basis, or approximately 7,427 acre-feet per year for process water needs. Water usage in the project can be divided into six categories: power block cooling tower, process cooling tower, air separation unit cooling tower, manufacturing complex, gasification solids, and heat recovery steam generator stack. This process water would be supplied from the Buena Vista Water Storage District (BVWSD). Potable water would be supplied by Westland Kern Water District (WKWD) located east of the project site, along Morris Road north of Station Road. (**Project Description Figure 4**). A complete analysis of the proposed water supply is located in the **Water Supply** section of this document.

Electrical Transmission System

An approximately 2.8-mile (0.8 miles are on the HECA site) electrical transmission line using approximately 15 steel poles outside of the project site, would interconnect the HECA switch yard to the future PG&E switching station and then to the first point of interconnection with the 230 kilovolt PG&E grid. The electrical transmission line extends east from the proposed switch yard within the northwest portion of the project site, across Tupman Road, then Morris Road and then eastward to the proposed new PG&E switching station. The majority of the approximately 2-mile route is adjacent to road shoulders and within areas of active agriculture. (**Project Description Figure 4** and **5**).

At this time, HECA does not have a power purchase agreement (PPA), but is in negotiations with PG&E.

Carbon Dioxide Pipeline to Elk Hills Oil Field CO_2 Processing Facility

CO_2 resulting from the above processes would be compressed at HECA and transported by an approximately 3-mile pipeline south to the EHOF CO_2 Processing Facility. The CO_2 pipeline would pass under the Kern River Flood Control Channel, the Buena Vista Water Storage District West Side Canal and the California Aqueduct. (**Project Description Figures 4, 6** and **10**).

Natural Gas Supply System

HECA would complete an approximately 13-mle natural gas interconnection with an existing PG&E pipeline north of the project. The interconnection will consist of one tap as well as a 100-foot by 100-foot metering station. This facility will be surrounded by a chain link fence. Also associated with this natural gas pipeline will be an additional metering station at the receiving end, located on the southwest side of the HECA project site (see **Project Description Figure 8**).

Industrial Rail Spur and Truck Route for Coal Transportation

Two alternative coal transportation routes would be evaluated: Alternative 1 would be a 5-mile private rail spur; Alternative 2 would be the truck route from the Wasco coal facility to HECA.

An approximately five-mile private rail spur, to be owned and maintained by HECA, is proposed to connect with the San Joaquin Valley Railroad in Buttonwillow. This rail spur, if constructed, would greatly reduce truck trips from the coal facility in Wasco to the project, approximately 27-miles one way using existing roads. This rail spur could also transport the fertilizer products from the proposed manufacturing facility to markets. The HECA site would also have a rail loop that would be capable of on-site holding of trains up to 1-mile in length prior to either unloading feed stock or on loading of manufacturing plant products (see **HECA Site Plan, Figure 6 and 9**).

Water Supply Pipelines

The raw water supply pipeline would be approximately 15-miles in length, connecting to to five new BVWSD groundwater wells. Potable water would be supplied by the West Kern Water District, through an approximately one-mile pipeline to the east of HECA **(see Project Description figures 4 and 9).**

SUPPORT INFRASTRUCTURE

Emergency Engines

The facility would have several emergency engines, all would be fueled using ultra-low sulfur diesel fuel. These would include two emergency standby diesel generators, each 2,000-kilowatt unit would be in an outdoor enclosure and connected by a stepdown transformer to supply emergency power to critical infrastructure including lube oil pumps, cooling pumps, gasification and auxiliary steam systems in the event of power loss from the project's generation equipment. Key infrastructure support would include the station battery chargers, uninterruptable power supply, heat tracing, control room, and other critical plant loads. An approximately 600-horsepower standby diesel-driven firewater pump would be located next to the firewater tank (HECA, 2012a).

Fire Protection

A detailed fire protection program is described in the AFC (HECA, 2012a, pps 2-41).The proposed program is evaluated in the **Worker Safety and Fire Protection** section of this PSA/DEIS. The proposed program includes design elements including conservative spacing between project elements. Discreet fire areas are used to identify potential hazards, protect personnel, and to control fire incidents within a confined area. Hard systems including a firewater storage tank, and distribution system, a dedicated fire loop with hydrants, and automatic fire-suppression systems would be in place. The system would include inert gas suppression systems, sprinker and water spray systems depending on the type of risk associated with the fire area. In addition a variety of alarms and personnel training would be utilized to insure fire safety. All elements would be consistent with National Fire Protection Association recommendations. Please refer to the **Worker Safety and Fire Protection** section of this PSA/DEIS for more specifics related to fire response and emergency services proposed for HECA construction and operations.

Hazardous Materials

There would be a variety of hazardous materials used and stored during construction and operation of HECA.

Hazardous materials that will be used during construction include gasoline, diesel fuel, oil, lubricants, and small quantities of solvents and paints, compressed gas cylinders including oxygen, acetylene and argon. All hazardous materials used during construction and operation would be stored on site in storage tanks, vessels and containers that are specifically designed for the characteristics of the materials to be stored; as appropriate, the storage facilities would include the needed secondary containment in case of tank/vessel failure. As part of a risk management plan (RMP), Material safety data sheets (MSDS) for each chemical in use would be required to be on site during construction and operations, and all contractors and staff would be instructed in their use in avoiding associated materials accidents and responding appropriately should an accident or material related incident occur. Maintenance of up to date MSDS books and locations would be the responsibility of each contractor on the site.

Hazardous materials routinely used and stored on site during operation would include methanol, petroleum products, flammable and compressed gases, acids and caustics, ammonia, water treatment and cleaning chemicals. Storage of all hazardous materials would be in appropriately designed storage areas. All bulk tanks would be provided with secondary containment in case of spills or leaks.

The **Hazardous Materials Management** section of this PSA/DEIS provides additional data on the hazardous materials that would be used during construction and operation, including quantities, associated hazards and permissible exposure limits, storage methods, and special handling precautions.

Waste Management

While waste management is primarily the process whereby all wastes produced at the project site are properly collected, treated (if necessary), and disposed of; the technical area is also responsible for evaluating past activities on a proposed site, and the potential impacts associated with additional proposed actions at that site. For the HECA proposed property a series of Environmental Site Assessments (ESAs) were completed for the proposed project site. The last Phase I ESA was dated April 2012, prepared by URS for the 453 acre project proposed HECA site. The results of the preliminary soil sampling and analytical testing indicate that there are elevated concentrations of petroleum hydrocarbons and other contaminants affected by previous site activities on a former wash area immediately north of the HECA site. There is soil staining in various areas on the project site that is likely caused by handling of fuel, lubricating oils, and pesticides. Residual contaminants at the site include organochlorine pesticides, dieldrin, endrin, and endosulfan (HECA 2012e, page 5.13-3). Soil samples taken at the site indicate that concentrations of the pesticides dieldrin, endrin, and endosulfan exceed the Regional Water Quality Control Board (RWQCB) Environmental Screening Levels, but did not exceed the California Human Health Screening Levels (CHHSLs) (HECA 2012e, page 5.13-3)). The Department of Toxic Substances Control (DTSC) has indicated that additional site characterization is required to further define the level of contamination at the proposed site. Energy Commission staff is currently working with the applicant and DTSC to develop the necessary characterization information and a plan for addressing the potential issues associated with the past contamination.

Waste management for the proposed project would also insure that all wastes produced at the project site are properly collected, treated (if necessary), and disposed of. Wastes include process and sanitary wastewater, nonhazardous waste, and hazardous waste, both liquid and solid. These include the gasification solids comprised of vitrified (glass-like) material produced by melting the mineral matter in the feedstock with small amounts of unconverted carbon. These gasification solids would be stored for off-site transportation by rail or truck. The applicant is exploring potential markets for this material which would reduce the impact of landfilling, the associated transport and disposal costs. Among the potential uses being explored are uses in cement production, as sand blasting grit and possibly as roofing granules. The **Soils and Surface Water** section of this PSA/DEIS discusses process wastewater and sanitary wastewater. For all other wastes, the **Waste Management** section of this PSA/DEIS would detail the process by which both hazardous and nonhazardous wastes from HECA construction and operation would be appropriately stored, transferred and disposed.

HECA AND THE ELK HILLS ENHANCED OIL RECOVERY AND CO_2 SEQUESTRATION PROJECT

As noted above, HECA is dependent upon the sale of CO_2 to Occidental of Elk Hills (OEHI), who plans to utilize CO_2 resulting from HECA operations to increase the effectiveness of its enhanced oil recovery program (EOR) by adding an injected CO_2 component to its existing waterflood method of sweeping the oil shale to increase oil production. HECA CO_2 production and delivery to OEHI, utilized in a water alternating gas (WAG) process, would potentially result in the permanent geologic sequestration of substantial quantities of CO_2, and important greenhouse gas. (see the **Sequestration**

and Greenhouse Gas section): Some key features of the proposed EOR program that would utilize the CO_2 from HECA are noted below.

The proposed HECA sequestration and enhanced oil recovery project would:

- Utilize CO_2 from HECA for enhanced oil recovery and carbon sequestration purposes;
- Utilize a water-alternating gas (WAG) technique for oil recovery;
- Develop a CO_2 EOR processing facility connecting with 13 satellite injection facilities that would be expected to occupy approximately 135.6 acres;
- Utilize an estimated total length of phased new pipeline of 652 miles, located in existing pipeline corridors and sited on disturbed acreage. At-grade pipelines would be up to 26 inches in diameter;
- The EOR may include approximately 720 producing and injection wells;
- Require well installation footprints of 130' x 280' (36,400 square feet or 0.84 ac.);
- The EOR proposes to use 107 million standard cubic feet/day (mmscfd) of CO_2 delivered from HECA (up to approximately 2.6 million tons per year from HECA);
- This process would require OEHI to seek approval from DOGGR for the miscible gas injection project to use methane/ethane recovered gases from oil production combined with the CO_2 mixture;
- The project would employ injection wells drilled to approximately 5,000 feet below ground surface, sealed by the "Reef Ridge Shale" and within the "Monterey Formation" 4,500 to 10,000 feet below surface.
- The project proposes at least 20 years of CO_2 capture/delivery from HECA. This is equivalent to less than 5 percent of the useable reservoir pore volume above the free water level.
- The project would employ a closed loop fluid and gas recycle/reuse/reinjection process.

Energy Commission staff evaluates the EOR program in this PSA/DEIS as a part of the whole project (CEQA reference). It is an integral part of the HECA planned project, and the means by which geologic sequestration of a greenhouse gas (CO_2) is potentially accomplished. The actual permits associated with the EOR project will be issued by other agencies, including The Department of Conservation, Division of Oil, Gas and Geothermal Resources (DOGGR), Kern County, and the San Joaquin Valley Air Pollution Control District (SJVAPCD), each agency with specific regulatory authorities over the activities on the EHOF.

DOGGR would separately permit the wells, pipelines and associated structures, including the proposed CO_2 handling facility, with the OEHI EOR project. DOGGR has statutory responsibility under Division 3 of the Public Resources Code to regulate all oilfield operations in the state of California. DOGGR is authorized by law to approve the injection and extraction wells and associated well facilities, to regulate down-hole operations, and to be responsible for appropriate regulation of surface activities relating to the OEHI CO_2 EOR. The wells to be used for injection of the CO_2 would be permitted as Class II injection wells under the Underground Injection Control (UIC) program in the Federal Safe Drinking Water Act (SDWA), 42 United States Code § 300h-4. DOGGR has primacy to approve Class II injection wells in the state of California under Section 1425 of the SDWA, see U.S. Environmental Protection Agency (USEPA, 1983). The wells and associated well facilities for the OEHI CO_2 EOR will be permitted pursuant to authority provided to DOGGR in the Public Resources Code and the SDWA and in accordance with applicable DOGGR regulations.

PROJECT CONSTRUCTION AND CLOSURE

An Engineering, Procurement, and Construction (EPC) contractor would be responsible for the engineering, procurement, and construction of the project. The EPC contractor would select subcontractors for certain specialty work as required.

Mobilization: The EPC contractor would be expected to commence truck deliveries and ground disturbance as soon as possible should the project secure Energy Commission approval and a final Record of Decision (ROD) from the DOE. Project site preparation work would include site grading and storm water/erosion control. Gravel and road base material would be used for temporary roads, laydown, parking, and work areas. Construction planning would include the evaluation of existing county roads. The roads would be upgraded as necessary to handle the increased loads and traffic.

Project Site Construction: Construction activities for the project would occur throughout the 42-month construction period. All construction laydown and parking areas would be located within the project site and the controlled area. On-site construction activities include clearing and grubbing, grading, hauling, layout of equipment, delivery and handling of materials and supplies, and Project construction and testing operations.

Commencement of commissioning activities would occur beginning at 34 months, and commercial operation would be expected at approximately 51 months.

Site Access: Construction site access would be via Dairy Road for truck deliveries and Adohr Road for construction craft vehicles arriving and departing the site. Dairy Road currently ends at Adohr Road, but would be extended during project construction. This extension would be permanent and would also be used for personnel access during operations. The peak construction site workforce levels and operations workforce estimates can be reviewed in the **Socioeconomics** section of this **PSA/DEIS.**

PROJECT CONSTRUCTION

General Grading, Leveling and Construction Facility Installation

The project site occurs in an area of relatively flat topography. Site grading would occur as necessary to form level building pads for major process units. Initial site preparation operations would include construction of temporary access roads, craft parking, laydown areas, office and warehouse facilities, installation of erosion control measures, and other improvements necessary for construction.

Storm Drainage System

Existing drainage patterns outside the site boundary would remain undisturbed. No runoff from outside the site boundary would flow onto the project site. All surface runoff during and after construction would be controlled in accordance with the requirements of the Drainage, Erosion, and Sedimentation Control Plan, and all other applicable LORS.

Erosion and Sediment Control Measures

Protection of soil resources would be an important factor in the design of the erosion and sedimentation controls. Erosion control measures would include construction of storm water retention basins and related site drainage facilities to control runoff within the site boundary. Additional project site erosion control would be accomplished during construction through the use of strategically placed berms, swales, and culverts to redirect runoff toward the storm water retention basins. Sandbags, filter bales, silt fences, and/or temporary dams would be installed, as needed, to minimize the volume of sediment carried by storm runoff and to prevent the erosion of slopes and temporary drainage facilities. Grades would be designed to prevent the effects of ruts and ponding.

Following each significant precipitation event, a site review of the effectiveness of the erosion control plan would take place. Storm water would be retained on site for impoundment in the storm water retention basins (please see the **Soils and Surface Water** section of this **PSA/DEIS** for full analysis).

Restoration of Temporary Disturbance

As proposed, temporarily disturbed areas will be restored to their preconstruction conditions. Temporary access roads used during construction will also be re-graded and restored to pre-existing function and grade.

PROJECT CLOSURE

At some point in the future, the project will cease operation and close down. At that time, it will be necessary to ensure that the closure occurs in such a way that public health and safety and the environment are protected from adverse impacts. Although the setting for this project does not appear, at this time, to present any special or unusual closure problems, it is impossible to foresee what the situation will be in 30 years or more when the project ceases operation. Therefore, provisions must be made that provide the flexibility to deal with the specific situation and project setting that exist at the time of closure. Laws, Ordinances, Regulations and Standards (LORS) pertaining to facility closure are identified in the sections dealing with each technical area. Facility closure will be consistent with LORS in effect at the time of closure. Facility closure of the project can be either temporary or permanent. Facility closure would include plans for all structures on the 453 surface acres, underground objects, and associated linear facilities such as transmission lines, pipelines, and the railroad spur previously described.

The project closure process is described in detail in the **Compliance Conditions** section of this PSA/DEIS. This section describes at least three circumstances in which a facility closure can take place: planned closure, unplanned temporary closure and unplanned permanent closure. The section also details what would be required by the Energy Commission to protect public health and safety and the environment from adverse impacts in each of the above instances.

Recent Information Affecting the Project

As is often the case in a complex proceeding, ongoing project design produces features and information that could not be included in the Application for Certification, or was being developed in the ongoing process of project refinement. Recent information that staff has attempted to incorporate into this PSA/DEIS, but may require additional information from the applicant and a fuller discussion in the Final Staff Assessment/Final Environmental Impact Statement (FSA/FEIS), is noted below:

Proposed addition of limestone fluxant

- Limestone fluxant will be added to the coal and petroleum coke feedstock; on average 175 ton/day or 59,000 tons/year of fluxant would be used;
- The average gasification solids flow rate increases from 850 tons/day to 938 tons/day. The properties of the gasification solids will not change. The options for eventual disposition of the gasification solids will not change due to the addition of fluxant;
- Fluxant will be delivered by truck and would be either tarped or enclosed, to eliminate potential fugitive dust from the material as it travels to the site;
- The fluxant will be stored in a silo that will be approximately 30 feet in diameter and 80 feet tall, to be located to the north of the proposed feedstock barn;
- The fluxant unloading and silo area would have a baghouse to control dust.
- The flux would be added to the feedstock on the conveyor at the point where it exits the feedstock storage barn;
- In the gasifier the limestone splits into two components, calcium oxide and carbon dioxide. The calcium oxide becomes part of the gasification solids. The carbon dioxide becomes part of the syngas stream and is captured in the Rectisol Unit;
- The additional CO_2 would flow to the EHOF enhanced oil recovery stream from HECA, and the CO_2 emitted from the turbine/feedstock dryer and CO_2 vent would also increase proportionally.
- Carbon capture would be expected to remain at 90 percent or greater of the CO_2 in the syngas exiting the gasifier;
- Maximum daily trucks increase by 10 fluxant trucks and 2 gasification solids trucks under Alternative 1-with the rail spur;
- Maximum daily trucks increase by 10 fluxant trucks and 9 gasification solids trucks under Alternative 2-no rail spur.

Inclusion of electrical demand for the Air Separation Unit

The Air Separation Unit (ASU) is proposed by the applicant to be owned and operated by a separate company, and as such, the applicant did not originally provide detailed information about its electrical demand. Staff considers the ASU to be part of the proposed project, subject to the Energy Commission's jurisdiction, and therefore included in staff's evaluation of project impacts and LORS conformance. On April 10, 2013, the applicant provided staff with the unit's electrical demand. Technical staff have incorporated the new information and developed preliminary assumptions that are reflected in the **Powerplant Efficiency** and the **Sequestration and Greenhouse Gas** sections. Staff now assumes that the proposed ASU power use should be factored into the project's anticipated parasitic load. The following information is being evaluated by staff:

- ASU On-Peak Power Demand: 109 MW
- ASU Off-Peak Power Demand: 103 MW

Final Design Criteria for the Electrical Generation Equipment

Staff will need final design criteria and a clear statement regarding the equipment's heat rate and a complete listing of all parasitic loads to be attributed to the project. The applicant's statement of the gross and net electrical production from HECA continues to fluctuate based on continued design refinement by the applicant and the equipment manufacturer, Mitsubishi Heavy Industries. The information is reflected in a variable assessment of the gross and net electrical output for HECA. Gross output may vary as noted in information provided to the SJVAPCD and in the April 10, 2013 email to Energy Commission staff (URS, 2013):

- Gross electrical output 405 MW as noted in the AFC, and 431 MW in other documents;
- Net electrical output may vary from 300 MW as noted in the AFC, and 267 MW.

No information on the overall project heat rate and breakdown of auxiliary loads based on the 431MW figure has been provided to staff at this time. Staff evaluation of this preliminary information has a variable affect on the analysis contained in the **Powerplant Efficiency**, **Sequestration and Greenhouse Gas** and the **Air Quality** sections of this PSA/DEIS. A clear statement of the project information will be required prior to completion of the Final Staff Assessment/Final Environmental Statement. (See the sections noted above for additional analysis).

ENVIRONMENTAL ASSESSMENT

AIR QUALITY

Prepared by William Walters, P.E.
and Nancy Fletcher

SUMMARY OF CONCLUSIONS

The Hydrogen Energy California Project (HECA)[1] should comply with all applicable air quality laws, ordinances, regulations, and standards (LORS) and should not result in significant air quality impacts provided the recommended conditions of certification are adopted by the Commission and implemented by the project owner. The project has secured emission reduction credits in sufficient quantity to meet San Joaquin Valley Air Pollution Control District (SJVAPCD or District) requirements. The applicant has also agreed to provide funding to the District's Emission Reduction Incentive Program (ERIP) to create additional emission reductions necessary for General Conformity and California Environmental Quality Act (CEQA) compliance purposes as determined necessary by the District. Additionally, these emission reduction credits would fully offset all onsite project emissions of nonattainment pollutants and their precursors that occur within the San Joaquin Valley Air Basin (SJVAB) at a minimum offset ratio of 1:1. The Occidental Petroleum Carbon Dioxide Enhanced Oil Recovery component would also comply with all applicable air quality LORS.

Staff has assessed the potential for localized impacts and regional impacts for both the project's construction and operation. As a product of this analysis staff has recommended mitigation and monitoring requirements sufficient to reduce the potential adverse construction and operating emission impacts to less than significant.

Staff has reviewed the District's Preliminary Determination of Compliance (PDOC) and finds that it is generally complete and accurate, but notes that there are a number of consistency and continuity issues in the District conditions. Staff has provided a comment letter on the PDOC addressing these issues and staff expects that the District will implement revisions to the PDOC and the PDOC conditions to address these issues in the Final Determination of Compliance (FDOC) that will be presented in the Final Staff Assessment/Final Environmental Impact Statement (FSA/FEIS).

The District developed a sulfur oxides (SOx) for particulate matter (both particulate matter less than 10 microns [PM10] and particulate matter less than 2.5 microns [PM2.5]) interpollutant trading ratio of one-to-one and concluded that this would be adequate to manage regional particulate matter impacts and progress towards attainment. However, staff notes that the one-to-one interpollutant trading ratio is lower than what has been historically required by the District on similar past power plant cases. In addition, the District's recently adopted air quality management plan for fine particulate identifies a 4.1:1 SOx for PM2.5 interpollutant trading ratio. Therefore, in a formal comment letter regarding the PDOC dated March 28, 2013, staff has asked the District to provide additional information on why a 1:1 SOx for PM10 and PM2.5 interpollutant trading ratio for this project would be allowed, and whether that value would truly provide a net air quality benefit. Staff's final determination on whether the

---

[1] A comprehensive acronym list is provided at the end of this section.

proposed mitigation meets CEQA requirements, or whether additional mitigation may be required, will in part be based on the answers to these questions received from the District, as well as, additional review and consideration of the other mitigation measures proposed for the project; including the applicant's funding of the District's ERIP.

Staff has also considered the potential for adverse air quality impacts to the minority population surrounding the site. With the adoption of the recommended conditions of certification, the project's direct and cumulative air quality impacts would be reduced to less than significant. Therefore, the project will not result in a significant or adverse impact to an identified environmental justice population.

The applicant has made recent revisions to the project, including removing ammonia as an export product and adding a limestone fluxant to the gasifier feedstock that would impact transportation emissions and stationary source emissions and District permitting requirements. Staff is also aware of very recent but apparently very minor revisions to the gas turbine fuel consumption estimates. Staff will obtain revisions to the project emissions estimates, as well as the related project description information updates, and will provide the revised information in the FSA/FEIS. Staff's air quality conclusions for the project based on the evaluation of the information provided in the Amended AFC and the subsequent formal data responses provided by the applicant and do not include evaluation of these most recent project revisions.

INTRODUCTION

On May, 5, 2012, Hydrogen Energy California, LLC (applicant) submitted an amended Application for Certification (AFC) to construct and operate an integrated gasification combined cycle (IGCC) power generating facility near the community of Tupman in Kern County, California. The applicant originally submitted an AFC on July 31, 2008 and a revised AFC on May 28, 2009 for a change in the project site. The project was acquired by SCS Energy LLC in 2011. The project was redesigned and key components were modified including the addition of an integrated fertilizer manufacturing complex. The Amended AFC filed on May 2, 2012 includes the power generating facility, the fertilizer manufacturing complex, and the capture, transport and use of carbon dioxide (CO_2) for enhanced oil recovery (EOR).

The proposed project is designed to operate on a fuel blend of western sub-bituminous coal and petroleum coke. The proposed feedstock blend is 75 percent coal, sourced from mines located outside the State of California, and 25 percent petroleum coke (pet coke), a product from California refineries. The majority of California's petcoke production is currently shipped overseas. However, a small portion is used in existing California power plants. The feedstock fuel would be gasified to produce a synthetic gas (syngas) which would be further processed to generate a hydrogen-rich fuel. The hydrogen-rich fuel would be the primary fuel for the combined cycle gas turbine and fertilizer manufacturing complex. In addition, CO2 from this process would be captured and used for EOR at an oil production field, Elk Hills Oil Field (EHOF), located approximately four miles south of the proposed HECA site. EHOF is owned and operated by Occidental of Elk Hills, Inc. (OEHI).

The U.S. Department of Energy has selected HECA for financial assistance under the Clean Coal Power Initiative Round 3 (CCPI) program. The project is therefore subject to the National Environmental Policy Act (NEPA). The NEPA and CEQA review for this project will be combined in this analysis. As discussed in the Introduction Section of this Preliminary Staff Analysis, this document analyzes the project's impacts pursuant to both NEPA and CEQA. The two statutes are similar in their requirements concerning analysis of a project's impacts. Therefore, unless otherwise noted, staff's use of, and reference to, CEQA criteria and guidelines also encompasses and satisfies NEPA requirements for this environmental document.

The project proposes to generate between 405 and 431 MW gross or an average of 416MW gross electrical power and between 151 to 266 MW net after accounting for onsite auxiliary power loads. The lower values apply during the periods of maximum fertilizer production and the higher values apply during periods of maximum electricity production. When considering the air separation unit and the electricity used by OEHI during enhanced oil recovery operations, which are both part of the project as described by the applicant, the net electricity generation available to California consumers drops to 52.5 MW of new electrical capacity added to the grid during periods of maximum electricity production. The project would be a net consumer of 61.8 MW from the grid during periods of maximum fertilizer production. These net power values include all project-wide power generation and power consumption sources, including the power consumption of the third-party owned air separation unit and the power consumption required by OEHI for CO_2 compression/injection/recovery/re-injection for EOR and, ultimately, carbon sequestration.

The EHOF is approximately 48,000 acres and is located southwest of Bakersfield and south of the City of Buttonwillow in Western Kern County. The EHOF is immediately south of the Lakern Area of Critical Environmental Concern (ACEC), including 3,111 acres controlled by the Bureau of Land Management. Approximately 2,050 acres of this surrounding area is managed as various conservation areas by the Center for Natural Lands Management and OEHI Habitat Management Lands. The remainder is owned by Chevron Corporation and other companies. McKittrick Valley and portions of Buena Vista Valley are to the west. Ten miles west of the site is another ACEC approximately 199,030 acres in size. To the south is the Buena Vista Valley the majority of which is another oil field. The city of Taft is approximately seven miles south of the EHOF. Land to the east includes the Coles Levee Ecological Preserve (6,059 acres), Kern Water Bank Authority (19,900 acres), Tule Elk Reserve State Park and the Kern River.

This analysis evaluates the expected air quality impacts from the emissions of criteria air pollutants from both the construction and operation of HECA including the use of CO_2 for enhanced oil recovery and sequestration at the EHOF. Criteria air pollutants are defined as air contaminants for which the state and/or federal governments, per the California Clean Air Act and federal Clean Air Act respectively, have established ambient air quality standards to protect public health.

The criteria pollutants analyzed within this section are nitrogen dioxide (NO_2), sulfur dioxide (SO_2), carbon monoxide (CO), ozone (O_3), particulate matter (PM) and lead (Pb). Additional pollutants are regulated under federal and state programs, including hazardous air pollutants (HAPS) and toxic air contaminants (TACS). Therefore emissions from HAPS and TACS such as mercury (Hg) and hydrogen sulfide (H_2S) will be quantified to determine compliance with regulatory requirements. Potential health impacts from these pollutants will be analyzed in the **Public Health** Section of this document.

Particulate matter is categorized into two subsets, inhalable particulate matter less than 10 microns in diameter (PM10) and fine particulate matter less than 2.5 microns in diameter (PM2.5). Nitrogen oxides (NOx, consisting primarily of nitric oxide [NO] and NO_2) and volatile organic compound (VOC) emissions readily react in the atmosphere as precursors to ozone and, to a lesser extent, particulate matter. SOx readily react in the atmosphere to form particulate matter and are major contributors to acid rain. The terms nitrogen oxides (NOx) and SOx are also used when discussing these two pollutants.

In carrying out the analysis, the California Energy Commission (Energy Commission) staff evaluated the following three major issues:

- Whether HECA is likely to conform with applicable federal, state and SJVAPCD air quality laws, ordinances, regulations and standards (Title 20, California Code of Regulations, section 1744 (b));
- Whether HECA is likely to cause significant air quality impacts, including new violations of ambient air quality standards or contribute to existing violations of those standards (Title 20, California Code of Regulations, section 1742 (b)); and
- Whether the mitigation measures proposed for HECA are adequate to lessen the potential impacts to a less than significant level (Title 20, California Code of Regulations, section 1742 (b)).

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

The applicable laws, ordinances, regulations and standards for HECA and the associated OEHI CO_2 EOR component are both detailed below.

HECA

The federal, state, and local laws and policies applicable to the control of criteria pollutant emissions and mitigation of air quality impacts for HECA are summarized in **Air Quality Table 1**. Staff's analysis examines the project's compliance with these requirements.

Air Quality Table 1
HECA
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable Law	Description
Federal	**U.S. Environmental Protection Agency**
40 CFR 50	National Ambient Air Quality Standards (NAAQS).
40 CFR 51	New Source Review (NSR) – Requires NSR permit(s) for new stationary sources. This requirement is addressed through SJVAPCD Rule 2201, with the exception of PM2.5 NSR (100 ton/year trigger), that is not currently included in SJVAPCD Rule 2201.

40 CFR 52.21	Prevention of Significant Deterioration (PSD) – Requires dispersion modeling to demonstrate there is no violation of NAAQS or PSD increments, for pollutants that attain the NAAQS.
40 CFR 60, Subpart A	General Provisions - Outlines general requirements for facilities subject to standards of performance including, notification, work practice, monitoring and testing requirements.
40 CFR 60, Subpart Db	Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units [40 CFR Part 60 - New Source Performance Standards (NSPS)] - Requires monitoring, notification, and reporting of emissions and operation of the proposed natural gas fired auxiliary boiler.
40 CFR 60, Subpart Ga	Standards of Performance for Nitric Acid Plants for Which Construction, Reconstruction, or Modification Commenced After October 14, 2011 - Limits exhaust nitrogen oxide content based on production.
40 CFR 60, Subpart Y	Standards of Performance for Coal Preparation and Processing Plants - Requires dust collector particulate matter source testing, visual emissions testing and visual monitoring of equipment, and recordkeeping for coal handling, storage, and emission control equipment.
40 CFR 60, Subpart IIII	Standards of Performance for Stationary Compression Ignition Internal Combustion Engines - Requires the proposed emergency engines to achieve specific emission standards depending on the size and model year of the engine.
40 CFR 60, Subpart KKKK	Standards of Performance for Stationary Combustion Turbines - Replaces Subparts Da and GG for the proposed combustion turbines and duct burners with heat recovery steam generators. Requires proposed combined cycle units to achieve 15 ppm NOx and achieve fuel sulfur standards.
40 CFR 63, Subpart ZZZZ	National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines - Establishes emission limitations and operating limitations for internal combustion (IC) engines located at major and area sources of HAP emissions.
40 CFR 63, Subpart UUUUU	National Emission Standards for Hazardous Air Pollutants: Coal-And Oil-Fired Electric Utility Steam Generating Units - Establishes emission limitations, work place standards for hazardous air pollutants as well as compliance requirements.
40 CFR 70, CAA Sec 401, 42 USC 7661	Federal Title V Operating Permit Program - Consolidates federally-enforceable operating limits. An application is required within one year following the start of operation. This program is within the jurisdiction of the SJVAPCD with U.S. EPA oversight [SJVAPCD Rule 2520].
40 CFR 72, CAA Sec 401 42 USC 7651	Title IV Acid Rain – Applicable to electrical generating units greater than 25 MW. Requires a Title IV permit and compliance with acid rain provisions, implemented through the Title V program. This program is within the jurisdiction of the SJVAPCD with U.S. EPA oversight [SJVAPCD Rule 2540].
40 CFR Part 93 General Conformity	Requires a determination of conformity with State Implementation Plans for projects requiring federal approvals if a project's annual emissions are above specified levels.

State	**California Air Resources Board and Energy Commission**
Health and Safety Code (HSC) Section 44300-44384; Title 17 of The California Code of Regulations (17 CCR 93300-93300.5) Toxic "Hot Spots"	Requires preparation and biennial updating of facility emission inventory of hazardous substances; health risk assessments.

Acts	
Health and Safety Code (HSC) Section 40910-40930	Permitting of source needs to be consistent with approved clean air plans. The SJVAPCD New Source Review (NSR) program is consistent with regional air quality management plans.
California Health & Safety Code Section 41700	Public Nuisance Provisions. Outlaws the discharge of air contaminants that cause nuisance, injury, detriment, or annoyance.
California Public Resources Code 25523(a); 20 CCR 1752, 2300, 2309 and DIV. 2, Chap. 5, Art. 1, Appendix B, Park (k)	Requires that the Energy Commission decision on the Application For Certification (AFC) include requirements to assure protection of environmental quality; AFC is required to address air quality protection.
California Code of Regulations (CCR) 17 CCR § 93115	Airborne Toxics Control Measure for Stationary Compression Ignition Engines. Limits types of fuels allowed, establishes maximum emission rates and establishes recordkeeping requirements for stationary compression ignition engines, including emergency generator and fire water pump engines.
California Code of Regulations (CCR) 13 CCR § 2485	Airborne Toxics Control Measure to Limit Diesel-Fueled Commercial Motor Vehicle Idling. Generally prohibits idling longer than five minutes for diesel-fueled commercial motor vehicles.
California Code of Regulations (CCR) 13 CCR § 2449	In-Use Off-road Diesel Vehicle Regulation. Imposes idling limits of five minutes, requires a plan for emissions reductions for medium to large fleets, requires all vehicles with engines greater than 25 horsepower to be reported to the California Air Resources Board (CARB) and labeled, and restricts adding older vehicles into fleets.

Local	**San Joaquin Valley Air Pollution Control District**
Regulation I, General Provisions	Establishes the requirements and standards for stack monitoring (Rule 1080), source sampling (Rule 1081), and breakdown events (Rule 1100) and identifies penalties.
Regulation II, Permits	Establishes the regulatory framework for permitting new and modified sources. Included in these requirements are the federally-delegated requirements for NSR, the Title V Operating Permit Program, and the Title IV Acid Rain Program.
Rule 2010, Permits Required	Requires any person constructing, altering replacing or operating any source operation which emits, may emit, or may reduce emissions to obtain an Authority to Construct or a Permit to Operate, unless exempted by Rule 2020.
Rule 2201, New and Modified Stationary Sources	Establishes the pre-construction review requirements for new, modified or relocated emission sources, in conformance with NSR to ensure that these facilities do not interfere with progress in attainment of the ambient air quality standards and that future economic growth in the San Joaquin Valley is not unnecessarily restricted. Establishes the requirement to prepare a Preliminary Determination of Compliance (PDOC) and Final Determination of Compliance (FDOC) during District review of an application for a power plant for power plants under Energy Commission jurisdiction. This regulation establishes Best Available Control Technology (BACT) and emission offset requirements.
Rule 2410, Prevention of Significant Deterioration	Incorporates federal Prevention of Significant Deterioration (PSD) program requirements for new major sources in areas that are in attainment or unclassified for a criteria pollutant. The PSD requirements will be incorporated into the Determination of Compliance.
Rule 2520, Federally Mandated Operating Permits	Establishes the permit application and compliance requirements for the federal Title V federal permit program. HECA qualifies as a Title V facility and must submit a Title V application within twelve months after starting operation.
Rule 2540, Acid Rain Program	Implements the federal Title IV Acid Rain Program, which requires

	subject facilities to obtain emission allowances for SOx emissions and requires fuel sampling and/or continuous monitoring to determine SOx and NOx emissions.
Rule 2550, Federally Mandated Preconstruction Review for Major Sources of Air Toxics	Establishes requirements for new or reconstructed facilities classified as a major air toxics source.
Rule 4001, New Source Performance Standards	Specifies that a project must meet the requirements of the Federal New Source Performance Standards (NSPS), according to Title 40, Code of Federal Regulations, Part 60. The specific NSPS subparts that are applicable to HECA include: • Subpart A - General Provisions • Subpart Db - Standards of Performance for Small Industrial-Commercial Institutional Steam Generating Units • Subpart Ga - Standards of Performance for Nitric Acid Plants for Which Construction. Reconstruction, or Modification Commenced After October 14, 2011 • Subpart GG – Standards of Performance for Stationary Gas Turbines • Subpart Y - Standards of Performance for Coal Preparation and Processing Plants • Subpart IIII - Standards of Performance for Stationary Compression Ignition Internal Combustion Engines • Subpart KKKK - Standards of Performance for Stationary Combustion Turbines
Rule 4002, National Emission Standards for Hazardous Air Pollutants	Incorporates the National Emission Standards for Hazardous Air Pollutants from Part 61 and Part 63, Chapter I, Subpart C, Title 40 CFR and applies to major sources of HAPs. Subpart UUUUU applies to the electrical generating unit, and Subpart ZZZZ applies to the emergency engines.
Rule 4101, Visible Emissions	Prohibits visible air emissions, other than water vapor, of more than No. 1 on the Ringelmann chart (20 percent opacity) for more than three minutes in any one-hour.
Rule 4102, Nuisance	Prohibits any emissions which cause injury, detriment, or public nuisance.
Rule 4201-4202, Particulate Matter	Limits particulate emissions from any source that emits or may emit dust, fumes, or total suspended particulate matter.
Rule 4301, Fuel Burning Equipment	Limits the concentrations of combustion contaminants and specified emission rates from any fuel burning equipment.
Rule 4304, Equipment Tuning Procedure for Boilers, Steam Generators and Process Heaters	Provides equipment tuning procedures for boilers, steam generators and process heaters to control visible emissions and emissions of both NOx and CO.
Rule 4351, 4305-4306, Boilers, Steam Generators and Process Heaters –Phase 1, 2 & 3	Limits NOx, CO, SO_2, and PM10 from gaseous/liquid fueled boilers, steam generators, and process heaters.
Rule 4311, Flares	Limits NOx, VOC, and SOx from the operation of flares.
Rule 4320, Advanced Emission Reduction Options for Boilers, Steam Generators, and Process Heaters Greater than 5.0 MMBtu/Hr	Limits NOx, CO, SO_2, and PM10 from gaseous/liquid boilers, steam generators, and process heaters.
Rule 4701-4702, Internal Combustion Engines – Phase 1 & 2	Limits emissions of NOx, CO, and VOC from internal combustion engines. However, as emergency units, the proposed emergency engine-generator set and emergency fire water pump engine are exempt from emission limits, subject to monitoring and

	recordkeeping.
Rule 4703, Stationary Gas Turbines	Limits the proposed stationary gas turbine emissions of NOx to 3 ppmv and CO to 25 ppmv over a 3-hour averaging period. Provided certain demonstrations are made, the emission limits do not apply during startup, shutdown, or reduced load periods (defined as "transitional operation periods").
Rule 4801, Sulfur Compounds	Limits SOx emissions to no greater than 0.2 percent by volume calculated as SO_2 on a dry basis averaged over 15 consecutive minutes.
Rule 7012, Hexavalent Chromium	Limits emissions of hexavalent chromium from circulating water in cooling towers.
Regulation VIII, Fugitive PM10 Prohibition	Sets forth the requirements and performance standards for the control of emissions from fugitive dust causing activities.
Rule 9110, General Conformity	Specifies criteria and procedures for determining the conformity of federal actions with the SJVAPCD's air quality implementation plan.

OEHI CO_2 EOR Component

The federal, state, and local laws and policies applicable to the control of criteria pollutant emissions and mitigation of air quality impacts for the OEHI CO_2 EOR component are summarized in **Air Quality Table 2**. Staff's analysis provides a preliminary examination of the proposed OEHI CO_2 EOR component's compliance with these requirements in order to determine whether there are any potentially significant adverse impacts.

Air Quality Table 2
OEHI CO_2 EOR Component

State	**California Air Resources Board and Energy Commission**
Health and Safety Code (HSC) Section 44300-44384; Title 17 of The California Code of Regulations (17 CCR 93300-93300.5) Toxic "Hot Spots" Acts	Requires preparation and biennial updating of facility emission inventory of hazardous substances; health risk assessments.

Health and Safety Code (HSC) Section 40910-40930	Permitting of source needs to be consistent with approved clean air plans. The SJVAPCD New Source Review (NSR) program is consistent with regional air quality management plans.
California Health & Safety Code Section 41700	Public Nuisance Provisions. Outlaws the discharge of air contaminants that cause nuisance, injury, detriment, or annoyance.
California Code of Regulations (CCR) 17 CCR § 93115	Airborne Toxics Control Measure for Stationary Compression Ignition Engines. Limits the types of fuels allowed, establishes maximum emission rates, and establishes recordkeeping requirements on stationary compression ignition engines, including emergency generator and fire water pump engines.
California Code of Regulations (CCR) 13 CCR § 2485	Airborne Toxics Control Measure to Limit Diesel-Fueled Commercial Motor Vehicle Idling. Generally prohibits idling longer than five minutes for diesel-fueled commercial motor vehicles.
Local	**San Joaquin Valley Air Pollution Control District**
Regulation I, General Provisions	Establishes requirements and standards for stack monitoring (Rule 1080), source sampling (Rule 1081), and breakdown events (Rule 1100) and identifies penalties.
Regulation II, Permits	Establishes the regulatory framework for permitting new and modified sources. Included in these requirements are the federally-delegated requirements for NSR, the Title V Operating Permit Program, and the Title IV Acid Rain Program.
Rule 2201, New and Modified Stationary Sources	Establishes the pre-construction review requirements for new, modified or relocated emission sources, in conformance with NSR to ensure that these facilities do not interfere with progress in attainment of the ambient air quality standards and that future economic growth in the San Joaquin Valley is not unnecessarily restricted. This regulation establishes Best Available Control Technology (BACT) and emission offset requirements.
Rule 2250, Permit Exempt equipment Registration	Provides a mechanism to determine compliance of permit-exempt equipment with applicable rules and regulations.
Rule 2280, Portable Equipment Registration	Establishes standards for registrations of certain portable emission units for operation.
Rule 2520, Federally Mandated Operating Permits	Establishes the permit application and compliance requirements for the federal Title V federal permit program. HECA qualifies as a Title V facility and must submit the Title V application within twelve months after starting operation.
Rule 2530, Federally Enforceable Potential to Emit	Restricts potential to emit of a stationary source so the source may be exempt from the requirements of Rule 2520 (Federally Mandated Operating Permits).
Rule 2550, Federally Mandated Preconstruction Review for Major Sources of Air Toxics	Establishes requirements for new or reconstructed facilities classified as a major air toxics source.
Rule 4001, New Source Performance Standards	Specifies that a project must meet the requirements of the Federal New Source Performance Standards (NSPS), according to Title 40, Code of Federal Regulations, Part 60. The specific NSPS subpart that is applicable to the OEHI CO_2 EOR component is Subpart IIII - Standards of Performance for Stationary Compression Ignition Internal Combustion Engines.
Rule 4002, National Emission Standards for Hazardous Air Pollutants	Incorporates the National Emission Standards for Hazardous Air Pollutants from Part 61 and Part 63, Chapter I, Subpart C, Title 40 CFR. Applies to major sources of HAPs, and Subpart ZZZZ applies to the emergency engines.
Rule 4101, Visible Emissions	Prohibits visible air emissions, other than water vapor, of more than No. 1 on the Ringelmann chart (20 percent opacity) for more than three minutes in any one-hour.
Rule 4102, Nuisance	Prohibits any emissions which cause injury, detriment, or public

	nuisance.
Rule 4201-4202, Particulate Matter	Limits particulate emissions from any source that emits or may emit dust, fumes, or total suspended particulate matter.
Rule 4301, Fuel Burning Equipment	Limits the concentrations of combustion contaminants and specified emission rates from any fuel burning equipment.
Rule 4304, Equipment Tuning Procedure for Boilers, Steam Generators and Process Heaters	Provides equipment tuning procedures for boilers, steam generators and process heaters to control visible emissions and emissions of both NOx and CO.
Rule 4351, 4305-4308, Boilers, Steam Generators and Process Heaters –Phase 1, 2 & 3	Limits NOx, CO, SO_2, and PM10 from gaseous/liquid fueled boilers, steam generators, and process heaters.
Rule 4311, Flares	Limits NOx, VOC, and SOx from the operation of flares.
Rule 4320, Advanced Emission Reduction Options for Boilers, Steam Generators, and Process Heaters Greater than 5.0 MMBtu/Hr	Limits NOx, CO, SO_2, and PM10 from gaseous/liquid boilers, steam generators, and process heaters.
Rule 4701-4702, Internal Combustion Engines – Phase 1 & 2	Limits emissions of NOx, CO, and VOC from internal combustion engines. However, as emergency units, the proposed emergency engine-generator set and emergency fire water pump engine are exempt from emission limits, subject to monitoring and recordkeeping.
Rule 4801, Sulfur Compounds	Limits SOx emissions to no greater than 0.2 percent by volume calculated as SO_2 on a dry basis averaged over 15 consecutive minutes.
Regulation VIII, Fugitive PM10 Prohibition	Sets forth the requirements and performance standards for the control of emissions from fugitive dust causing activities.

Air Quality Table 2 above presents staff's current understanding of the OEHI CO_2 EOR component and the related applicable air quality regulations. Any EOR project using CO_2 from HECA is expected to undergo a separate CEQA analysis and would undergo a separate air quality permitting analysis, assuming that HECA is granted a license by the Energy Commission.

SETTING

METEOROLOGICAL CONDITIONS

The climate in California is typically dominated by the eastern Pacific high-pressure system centered off the coast of California. In the summer, this system results in low inversion layers and clear skies inland and typically early morning fog by the coast. In winter, this system promotes wind and rainstorms originating in the Gulf of Alaska and striking Northern California.

The climate of the southern San Joaquin Valley where the proposed project would be located is characterized by hot dry summers and mild winters with precipitation almost exclusively in the winter. Very little precipitation occurs during the summer months because the Pacific high-pressure ridge blocks migrating storm systems. Beginning in the fall and continuing through the winter, the storm belt and zone of strong westerly winds begins to greatly influence California. Temperature, winds, and rainfall are variable during fall and winter months, and stagnant conditions occur more frequently than during summer months.

Wind speeds are generally higher in summer than in winter and are typically north-northwesterly winds. During the spring, summer, and fall, the stronger winds are caused by a combination of offshore and thermal low pressure resulting from high temperatures in the Central Valley. During the winter months, winds are more variable. Calm conditions occur more during winter, but are relatively infrequent throughout the year. Valley fog often occurs during these calm, stagnant atmospheric conditions, when temperature inversions trap a layer of cool, moist air near the surface. The annual rainfall in the Tupman area is less than 7 inches and over 90 percent of the precipitation occurs during October through April. Summers are very warm with average daily peak high temperatures of 97°F and 96°F for the months of July and August, respectively. During December and January, the average daily low temperatures are 35°F and 37°F, respectively (WC 2013).

Along with the wind flow, the atmospheric stability and mixing heights are important factors in the determination of pollutant dispersion. Atmospheric stability is an indicator of the air turbulence and mixing. During the daylight hours of the summer when the earth is heated and air rises, there is more turbulence, more mixing, and thus less stability. During these conditions there is more air pollutant dispersion and therefore usually reduced air quality impacts near any single air pollution source. However, during the winter months between storms very stable atmospheric conditions with lower mixing heights and lower mean wind speeds can occur, resulting in very little mixing. Under these conditions, minimal air pollutant dispersion occurs, and consequently higher air quality impacts may result near air pollution emission sources.

SENSITIVE RECEPTORS

The general population includes many sensitive subgroups that may be at greater risk from exposure to emitted pollutants. These sensitive subgroups include the very young, the elderly, and those with existing illnesses. In addition, the location of the population in the area surrounding a project site may have a large bearing on health risk. The nearest non-residential sensitive receptor (Elk Hills Elementary School) for the HECA site is located approximately 2.5 miles southeast of the project site in Tupman. There are a few farm residences that surround the site location. Two residences and the Tule Elk Preserve State Park (which can attract visits by potentially sensitive subpopulations including people of advanced age and children) are located within one mile of the IGCC main complex on the project site, with the closest residence being approximately 1,400 feet east of the project site.

EXISTING AMBIENT AIR QUALITY

The Federal Clean Air Act and the California Clean Air Act both require the establishment of standards for ambient concentrations of air pollutants, called ambient air quality standards (AAQS). The state AAQS, established by the California Air Resources Board, are typically lower (more protective) than the federal AAQS, which are established by the United States Environmental Protection Agency (U.S. EPA). The current state and federal air quality standards are listed in **Air Quality Table 3**. The averaging times for the various air quality standards, the times over which they are measured, range from one-hour to an annual average. The standards are read as a concentration, in parts per million (ppm), or as a weighted mass of material per a volume of air, in milligrams or micrograms of pollutant in a cubic meter of air (mg/m^3 or $\mu g/m^3$, respectively). The U.S. EPA revised the PM2.5 annual standard from 15 $\mu g/m^3$ down to 12 $\mu g/m^3$ in December 2012, but the former NAAQS remains applicable for the analysis of this project because U.S. EPA allows the grandfathering of permit applications that were deemed complete prior to December 2012 However, the area is classified as nonattainment as described more fully below, regardless of whether the 12 or at 15 $\mu g/m^3$ standard is used.

In general, an area is designated as attainment if the concentration of a particular air contaminant does not exceed the standard. Likewise, an area is designated as nonattainment for an air contaminant if that contaminant standard is violated. Exceptional events that are out of human control that create very high pollutant concentrations such as wind storms and fires are generally excluded from attainment designations. In circumstances where there is not enough ambient data available to support designations as either attainment or nonattainment, the area can be designated as unclassified or unclassifiable. The unclassified area is normally treated the same as an attainment area for regulatory purposes. In addition, an area could be designated as attainment for one air contaminant and nonattainment for another, or attainment for the federal standard and nonattainment for the state standard for the same air contaminant.

The project site is located in western Kern County within the SJVAB and is under the jurisdiction of the SJVAPCD. Western Kern County in the SJVAB is designated as nonattainment for the federal and state ozone standards, the state PM10 standard, and the federal and state PM2.5 standards. This area is designated as attainment or unclassified for the state and federal CO, SO_2, lead (particulate), federal PM10 and NO_2, and state NO_2, H_2S, SO_4, visibility reducing particulates and vinyl chloride standards. **Air Quality Table 4** summarizes the area's attainment status for various applicable state and federal standards. The ambient air quality standards that staff uses as a basis for determining project significance are health-based standards. They are set at levels to adequately protect the health of all members of the public, including those most sensitive to adverse air quality such as the aged, people with existing illnesses, and infants and children, while providing a margin of safety.

The determination of appropriate and representative background concentrations needs to consider the location of the project site, the regional context of the site, the location of available monitoring stations, and the data available from those monitoring stations. Background concentrations are not used to categorize the general air quality of an air basin. Instead, the general air quality in an air basin is based on worst-case monitoring data in that air basin. This worst case monitoring data is the basis for the SJVAB designations presented in **Air Quality Table 4**. Background concentrations are used to determine the worst-case air quality concentrations in the local vicinity where the proposed project may cause an impact. These background concentrations are used in impact analyses to allow a determination of the additive impacts of a project that would occur at and downwind of the project's site fence or otherwise in the near-field where the general public has access. The proposed site for the HECA facility is a predominantly agricultural area in western Kern County, approximately 2.5 miles northwest of the unincorporated community of Tupman and approximately 7 miles from the western border of the city of Bakersfield. This project site is located on the western side of the San Joaquin Valley in a rural area that is not located downwind of a major urban area. Therefore, the use of monitoring stations that are both more distant from the project site and that exist in a different regional context than the project site, such as the Arvin monitoring station that is on eastern side of the valley and is immediately downwind of Bakersfield, the largest urban area in the southern San Joaquin Valley, would not be representative for the determination of background values for the area that would be impacted by this project.

Air Quality Table 3
Federal and State Ambient Air Quality Standards [a, b]

Pollutant	Averaging Time	Federal Standard	California Standard
Ozone (O_3)	8 Hour	0.075 ppm (147 μg/m^3)	0.070 ppm (137 μg/m^3)
	1 Hour	--	0.09 ppm (180 μg/m^3)
Carbon Monoxide (CO)	8 Hour	9 ppm (10 mg/m^3)	9.0 ppm (10 mg/m^3)
	1 Hour	35 ppm (40 mg/m^3)	20 ppm (23 mg/m^3)
Nitrogen Dioxide [c] (NO_2)	Annual	0.053 ppm (100 μg/m^3)	0.03 ppm (57 μg/m^3)
	1 Hour	0.100 ppm	0.18 ppm (339 μg/m^3)
Sulfur Dioxide [d] (SO_2)	24 Hour	--	0.04 ppm (105 μg/m^3)
	3 Hour	0.5 ppm (1,300 μg/m^3)	--
	1 Hour	0.075 ppm	0.25 ppm (655 μg/m^3)
Particulate Matter (PM10)	Annual	--	20 μg/m^3
	24 Hour	150 μg/m^3	50 μg/m^3
Fine Particulate Matter (PM2.5)	Annual	15 [h] μg/m^3	12 μg/m^3
	24 Hour	35 μg/m^3	--
Lead [e,f]	30 Day Average	--	1.5 μg/m^3
	Calendar Quarter	1.5 μg/m^3	--
	Rolling 3-Month Average	0.15 μg/m^3	--
Visibility Reducing Particulates	8 Hour	--	See footnote g
Sulfates (SO_4)	24 Hour	--	25 μg/m^3
Hydrogen Sulfide (H_2S)	1 Hour	--	0.03 ppm (42 μg/m^3)
Vinyl Chloride [e] (chloroethene)	24 Hour	--	0.01 ppm (26 μg/m^3)

Source: ARB 2013b.

Notes: [a] California standards for ozone, carbon monoxide, sulfur dioxide (1 and 24 hour), nitrogen dioxide, and particulate matter (PM10, PM2.5 and visibility reducing particles are values that are not to be exceeded. All others are not to be equaled or exceeded.)

[b] National standards (other than ozone, 1-hour NO_2, particulate matter and those based on annual arithmetic mean) are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest 8-hour concentration measured at each site in a year averaged over three years is equal or less than the standard. For PM10, the 24-hour standard is attained when the expected number of days per calendar year with a 24-hour average concentration above 150 μg/m^3 is equal or less than one. For PM2.5, the 24-hour standard is attained when 98 percent of the daily concentrations, averaged over three years are equal or less than the standard.

[c] To attain the 1-hour national standard, the 3-year average of the annual 98th percentile of the 1-hour daily maximum concentrations at each site must not exceed 100 ppb (0.100 ppm).

[d] On June 2, 2010, a new 1-hour SO_2 standard was established and the existing 24-hour and annual primary standards were revoked. To attain the 1-hour standard, the 3-year average of the annual 99th percentile of the 1-hour daily maximum concentrations at each site must not exceed 75 ppb (0.075 ppm). The 1971 SO_2 national standards (24-hour and annual) remain in effect until 1 year after the area is designated for the 2010 standard, except that in areas designated non-attainment for the 1971 standards. The 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standards are approved by U.S. EPA.

[e] The ARB has identified lead and vinyl chloride as “toxic air contaminants” with no threshold level exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.

[f] The national standard for lead was revised on October15, 2008 to a rolling 3-month average. The 1978 lead standard (1.5 μg/m^3 as a quarterly average) remains in effect until 1 year after an area is designated for the 2008 standard, except that in areas designated non-attainment for the 1978 standard, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 are approved.

[g] In 1989, the ARB converted both the general statewide 10-mile visibility standard and the Lake Tahoe 30-mile visibility standard to instrumental equivalents, which are “extinction of 0.23 per kilometer” and “extinction of 0.07 per kilometer” for the statewide and Lake Tahoe Air Basin standards, respectively.

[h] The current federal annual standard is 12 μg/m$^{3.}$ However, this project will be evaluated for compliance with the previous federal annual standard of 15 μg/m^3 due to the date the HECA application was deemed complete by the SJVAPCD.

Air Quality Table 4
Federal and State Attainment Status for the San Joaquin Valley

Pollutant	Attainment Status	
	Federal	**State**
Ozone – 1 hour	No Federal Standard [a]	Nonattainment/Severe
Ozone – 8 hour	Nonattainment/Extreme [b]	Nonattainment
PM10	Attainment [c]	Nonattainment
PM2.5	Nonattainment	Nonattainment
CO	Attainment/Unclassified	Attainment/Unclassified
NO_2	Attainment/Unclassified [d]	Attainment
SO_2	Attainment/Unclassified	Attainment
Lead (particulate)	No Designation/Classification	Attainment
H_2S	No Federal Standard	Unclassified
SO_4	No Federal Standard	Attainment
Visibility Reducing Particulates	No Federal Standard	Unclassified
Vinyl Chloride	No Federal Standard	Nonattainment

Source: SJVAPCD 2013b, U.S. EPA 2013a
Notes:
[a] Effective June 15, 2005, the U.S. EPA revoked in the federal 1-hour ozone standard, including associated designations and classifications. However, U.S. EPA had previously classified the SJVAB as extreme nonattainment for this standard. EPA approved the 2004 Extreme Ozone Attainment Demonstration Plan on March 8, 2010 (effective April 7, 2010). Many applicable requirements for extreme 1-hour ozone nonattainment areas continue to apply to the SJVAPCD.
[b] Initially classified as serious nonattainment for the 1997 8-hour ozone standard, EPA approved a reclassification to extreme nonattainment in the Federal Register on May 5, 2010 (effective June 4, 2010).
[c] On September 25, 2008, U.S. EPA redesignated the San Joaquin Valley to attainment for the PM10 National Ambient Air Quality Standard (NAAQS) and approved the PM10 Maintenance Plan.
[d] On February 17, 2012, U. S. EPA designated the entire United States as "unclassifiable/attainment" for the new federal 1-hour NO_2 standard, effective February 29, 2012.

The monitoring station located closest to the proposed project site is the Shafter-Walker Street (Shafter) station, which is approximately 13 miles northeast of the project site. The Shafter station is operated by the ARB and is 18 miles northwest of Bakersfield. This station monitors ozone, NO_2 and VOCs (non-methane organic compounds (NMOCs) and non-methane hydrocarbons [NMHC]). The monitoring site is classified as a Type 1 Photochemical Assessment Monitoring Station (PAMS). The objective of this type of site is to provide background ozone concentrations. Therefore, the monitor is located upwind from Bakersfield to establish concentrations that are presumed to not be influenced by nearby urban emissions (SJVAPCD 2011).

The Bakersfield-5558 California Avenue monitoring station is located approximately 20 miles east of the project site. This station monitors ozone, PM10, PM2.5, NO_2, toxics and hexavalent chromium (Cr^{6+}). This station is closer to the southern end of the San Joaquin Valley and has mountains to the east, west and south. The mountains impede air flow so pollutants can get trapped and accumulate in the area. This station is operated by ARB and is located in the Bakersfield metropolitan area. The objective of this site is to monitor representative pollutant concentrations in an urban area.

The Bakersfield Golden Highway monitoring station is located approximately 21 miles east of the project site, but was closed early in 2010. This station measured CO. Data is available until 2010; however 2010 only includes limited data from January. There is data from the Bakersfield-5558 California Avenue station spanning 2002-2005 and also limited data in 2011. The 2011 data includes preliminary data from October only.

The Fresno First Street monitoring station, located approximately 100 miles to the north northwest, is the only ambient pollutant monitoring station within the SJVAB which currently measures SO_2. This station is operated by ARB and is located in Fresno. The purpose of this site is to monitor representative pollutant concentrations in an urban area. Historical SO_2 data exists from other stations in Kern County; however, the latest data collected dates back to 2001 and before.

Air Quality Table 5 summarizes the historical air quality data that staff determined is

Air Quality Table 5
Criteria Pollutant Summary
Maximum Ambient Concentrations (ppm or µg/m^3)

Pollutant	Averaging Period	Units	2006	2007	2008	2009	2010	2011	AAQS
ARB Website Data									
Ozone	1 hour	ppm	0.106	0.111	0.131	0.105	0.106	0.097	0.09
Ozone	8 hour	ppm	0.100	0.103	0.111	0.084	0.095	0.087	0.07
PM10 [a]	24 hour	µg/m^3	159	118	263	99	238	154	50
PM10 [a]	Annual	µg/m^3	48.4	48.5	55.3	41.2	32.6	44.2	20

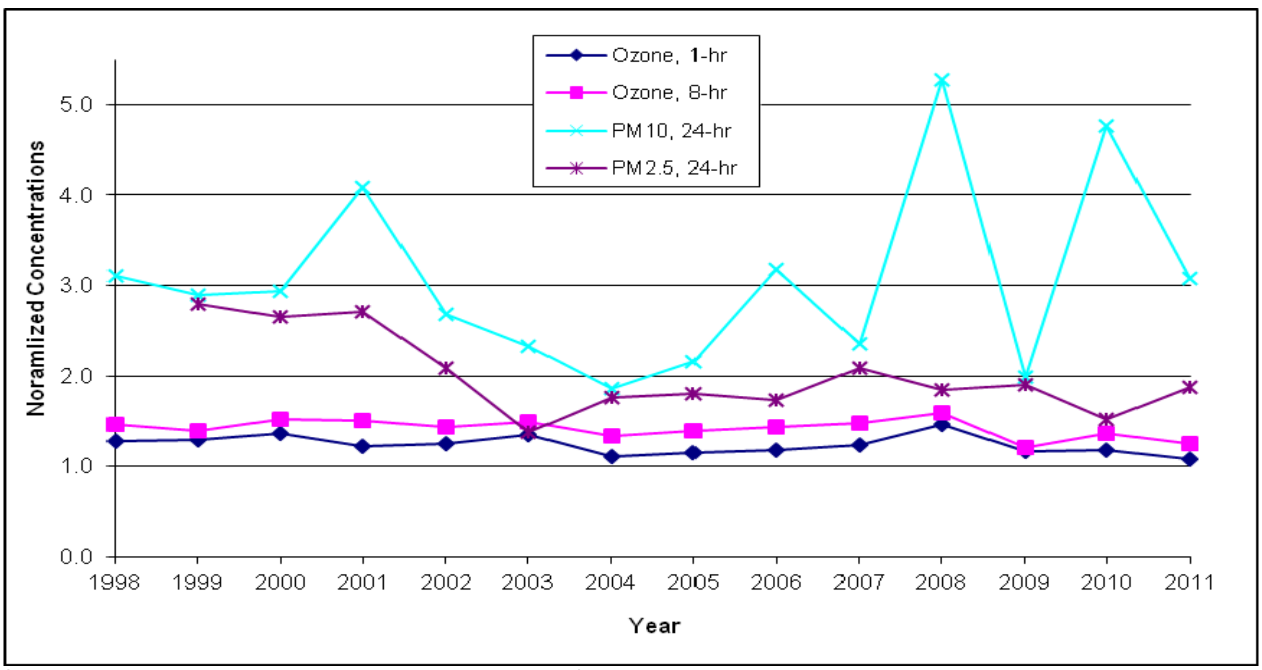
ND = No data or insufficient data.
Notes:
[a] Exceptional PM concentration events, such as those caused by wind storms are not shown in the U.S.EPA data but are still included in the state data presented in the upper portion of this table.
[b] 24-hour PM2.5 data shown are the 98th percentile concentrations.
[c] Annual average PM2.5 data shown are National annual average for those years when state annual average data are not available.
[d] 1-hour federal NO_2 data are 98th percentile of daily 1-hour maximums.
[e] 1-hour federal SO_2 data are 99th percentile of daily 1-hour maximums.

most representative of the project location, recorded at Shafter-Walker Street station for ozone (2006-2011) and NO_2 (2006-2011), Bakersfield-5558 California Avenue for PM10 (2006-2011), PM2.5 (2006-2011), and CO (2006-2011). CO concentrations for the years 2006-2010 were recorded at the Bakersfield-Golden State Highway monitoring station. However, the availability of 2010 data from this station is limited. SO_2 data are collected from the Fresno-1st Street station for 2007-2011. Concentrations are provided based on ARB website summary data and U.S.EPA website summary data. The U.S.EPA website summary data that is provided in the table excludes exceptional events and also provides data that is relevant to the form of the NAAQS standard, such as 98th percentile of daily hourly maximum concentrations for the 1-hour NO_2 standard that is not available in the ARB website data.

In **Air Quality Figure 1**, short term normalized values are provided from 1998 to 2009. Normalized values represent the ratio of the highest measured concentrations in a given year to the most-stringent applicable national or state ambient air quality standard. Normalized values lower than one indicate that the measured concentrations were lower than the most-stringent ambient air quality standard while values above one indicate that concentrations from the monitoring station exceed the corresponding AAQS.

Air Quality Figure 1
Normalized Maximum Short-Term Historical Air Pollutant Concentrations*



Source: ARB 2013A. Normalized concentration is the ratio of the highest measured concentration to the applicable most stringent ambient air quality standard. For example, in 1999 the highest one-hour average ozone concentration measured at the Shafter Walker Street station was 0.116 ppm. Since the most stringent ambient air quality standard is the state standard of 0.09 ppm, the 1999 normalized concentration is 0.116/0.09 = 1.289.
* Shafter Walker Street monitoring station data (1998-2011) was used for all ozone values and Bakersfield-5558 California Avenue monitoring station (1998-2011) was used for PM10 and PM2.5.

Ozone (O_3)

Ozone is a colorless gas found in two regions of the atmosphere. In the upper region, it protects the earth from harmful rays from the sun. In the lower region, ozone is near the ground and forms what is generally called smog. Ozone is not directly emitted from stationary or mobile sources, but is formed as the result of chemical reactions in the atmosphere between nitrogen oxides (NOx) and hydrocarbons (Volatile Organic

Compounds [VOC]) in the presence of sunlight. Low precipitation levels, high temperatures and light winds are all conducive to elevated ozone levels.

Air Quality Table 4 and **Air Quality Figure 1** clearly show that ozone concentrations measured near the project site continue to violate the applicable standards. SJVAPCD is designated as extreme nonattainment for federal 8-hour ozone standard, severe nonattainment for the state 1-hour standard and nonattainment for the state 8-hour standard. The peak 1-hour and 8-hour ozone concentrations typically occur between May and September when ambient conditions are most favorable for the photochemical reactions that form ozone.

Nitrogen Dioxide (NO_2)

NO_2 is a component of a group of highly reactive gasses collectively known as NOx. NO_x is formed from the reaction of nitrogen and oxygen during combustion. Approximately 90 percent of the NOx emitted from combustion sources is in the form of nitric oxide (NO), while the balance is NO_2. NO is oxidized in the atmosphere by ozone to form NO_2, but some level of photochemical activity is needed for this conversion to occur. The highest concentrations of NO_2 typically occur during the fall. The winter atmospheric conditions can trap emissions near the ground level, but lacking significant photochemical activity (sun light), NO_2 levels are relatively low. In the summer the in-plume conversion rates of NO to NO_2 are high, but the relatively high temperatures and windy conditions disperse pollutants, preventing the accumulation of larger concentrations of NO_2.

The entire San Joaquin Valley Air Basin is classified as attainment for the state 1-hour NO_2 standard, unclassifiable/attainment for the 1-hour federal NO_2 standard and attainment for the annual federal NO_2 standard. EPA strengthened the ambient air quality standard for 1-hour NO_2 levels, effective April 12, 2010 and classified the entire United States as “unclassifiable/attainment” based upon data collected from 2008 to 2010, with the designation effective February 29, 2012. Once new, near-roadway monitoring stations based on population and traffic counts are in place and operational (expected in 2013) and sufficient data are collected, redesignation will be considered. The NO_2 concentrations in the project area continue to be well below both the state and federal ambient air quality standards.

Carbon Monoxide (CO)

Carbon monoxide (CO) is a colorless, odorless gas emitted from combustion processes. CO is a product of incomplete combustion primarily from mobile sources. The project site area within the SJVAB is classified as attainment for the state 1-hour and 8-hour CO standards. Past monitoring has indicated compliance and there are currently no minimum requirements for monitoring CO within the SJVAPCD. The highest concentrations of CO occur when low wind speeds and a stable atmosphere trap the pollution emitted at or near ground. The project area has a lack of significant mobile source emissions and based on Bakersfield monitoring stations, the local area has CO concentrations that are well below both the state and federal ambient air quality standards.

Particulate Matter (PM10) and Fine Particulate Matter (PM2.5)

Particulate matter with an aerodynamic diameter of less than 10 microns (PM10) and particulate matter with an aerodynamic diameter of less than 2.5 microns (PM2.5) can be emitted directly or it can be formed many miles downwind from emission sources when various precursor pollutants interact in the atmosphere.

The area is nonattainment of the state PM10 standards, attainment of the federal PM10 standards, and nonattainment of the state and federal PM2.5 standards. **Air Quality Figure 1** shows recent PM10 and PM2.5 concentration trends. The figure shows fluctuating concentration patterns, and shows clear exceedances of the state PM10 and state PM2.5 standards. It should be noted that an exceedance does not necessarily mean a violation or nonattainment, as exceptional events such as those caused by high winds or large wildfires may be determined by the regulatory community to not be violations.

Fine particulate matter, or PM2.5, is derived mainly from either the combustion of materials, or from precursor gases (SOx, NOx, and VOC) through complex reactions that form PM2.5 in the atmosphere. PM2.5 consists mostly of sulfates, nitrates, ammonium, elemental carbon, and a small portion of other organic and inorganic compounds.

Sulfur Dioxide (SO_2)

The SJVAB is classified as attainment for both state and federal SO_2 standards. The sulfur dioxide attainment status could change due to the new federal 1-hour standard; although a staff review of the air basin’s monitoring data suggest this would not occur for the SJVAB.

Sulfur dioxide is typically emitted as a result of the combustion of fuel containing sulfur; such as coal, oil, and to a much less extent natural gas and motor vehicle fuels. This project uses a high sulfur content fuel feedstock but the gasification process separates most of this into elemental sulfur which is not combusted and this greatly reduces the SO_2 pollution potential from this project’s emission sources.

Lead (Pb)

Lead is a naturally occurring metal that is soft and resistant to chemical corrosion. Lead forms compounds with both organic and inorganic substances. Lead has been used for many purposes for thousands of years and has accumulated in the environment. As an air pollutant, lead is present in small particles. Sources of lead emissions include industrial processes and emission from sources using coal and lead-based fuels such as aviation gas. In 1970, the ARB set the CAAQS for lead. In addition, the ARB has identified lead as a toxic air contaminant and is therefore involved in risk management activities for lead. In 1978, EPA set the NAAQS for lead. The NAAQS was substantially strengthened in 2008. Lead is monitored as a toxic substance at the Bakersfield-California site. The Bakersfield-California site is the most representative for lead concentrations for the proposed site due to the proximity of the Bakersfield-California monitor. However, the available lead concentration data is provided as 24-hour concentrations and not 30-day average, three-month rolling average, or quarterly average concentrations that are the basis of the AAQS, so that data has not been presented.

Lead is released from coal during combustion or gasification. Formation of lead is dependent on variables such as the lead species present in the coal, pretreatment of coal, gasification temperature and reaction time. Lead can be removed in plant particulate and acid gas cleanup systems. Due to the very low concentrations shown in the available ambient monitoring data and the low amount of lead emissions from this project it is assumed that the project would not create significant impacts based on the ambient lead standards. The Public Health Section provides additional information regarding the quantity of emissions and the health risks of the lead emissions from this project.

Hydrogen Sulfide (H_2S)

Hydrogen sulfide (H_2S) is a colorless, flammable gas that smells like rotten eggs. It is an impurity associated with natural gas and also results from the breakdown of organic matter in anaerobic conditions. During high temperature gasification of coal, sulfur is released and converted to H_2S. HECA proposes to remove the sulfur found in the feedstock with an acid gas removal system. H_2S concentrations have not been monitored in the San Joaquin Valley, other than at the former Bakersfield-Rio Bravo monitoring station for a short period at the end of 1983, so background concentrations for H_2S are not available for the San Joaquin Valley.

Other Toxics

Toxic air contaminants (TACs) and hazardous air pollutants (HAPS) include pollutants that are known or suspected to cause cancer or result in other serious health effects such as reproductive effects or birth defects. These include both metals and organic compounds. The inorganic pollutants of greatest environmental concern are metals such as arsenic, boron, cadmium, mercury, molybdenum and selenium; and for this project other TACs of concern are the reduced sulfur compounds formed in the gasification process: H_2S, carbon disulfide (CS_2) and carbonyl sulfide (COS). Mercury is of particular concern for coal gasification systems. The proposed system includes an activated carbon control system to reduce mercury emissions both from the hydrogen-rich gas stream before it is combusted in the CTG/HRSG and for the coal dryer exhaust to remove mercury volatilized in the upstream coal-drying process. Organic pollutants of concern include compounds such as formaldehyde and other incomplete products of combustion. Emissions of these categories of pollutants are expected to be in line with emissions from combustion-based plants. Please see the Public Health Section for a more thorough discussion of the toxic air pollutants and their emissions estimates and public health effects.

Summary

In summary, staff recommends the background ambient air concentrations in **Air Quality Table 6** for use in the modeling and impacts analyses. The maximum criteria pollutant concentrations from the past three years of available data collected at the monitoring stations near the proposed project site, excluding exceptional events, are used to determine these recommended background values.

Air Quality Table 6
Staff Recommended Background Concentrations (μg/m^3)

Pollutant	Averaging Time	Recommended Background	Limiting Standard	Percent of Standard
NO_2	1 hour CAAQS	140	339	56%
	1 hour NAAQS	83.3	188	44%
	Annual	24.7	57	47%
PM10	24 hour	238	50	**476%**
	24 hour NAAQS	97	150	65%
	Annual	44.2	20	**221%**
PM2.5	24 hour	67	35	**191%**
	Annual	21.2	12	**177%**
CO	1 hour	4,025	23,000	18%
	8 hour	2,411	10,000	24%
SO_2	1 hour CAAQS	42	655	6%
	1 hour NAAQS	24	197	12%
	3 hour	26	1,300	2%
	24 hour	13	105	12%

Source: ARB 2013b, U.S. EPA 2013b, and Energy Commission Staff Analysis
Note: PM2.5 24-hour data shown in **Air Quality Table 5** are the 98th percentile values, 1-hour NAAQS NO_2 data is a three year average of the 98th percentile of maximum daily values for the past three years of data, and 1-hour NAAQS SO_2 are 99th percentile of maximum daily values.

Where possible, staff prefers that the recommended background concentrations come from nearby monitoring stations with site characteristics similar to the proposed site. For this project, staff determined that these are the Shafter-Walker Street monitoring station, providing the ozone and NO_2 background concentration data, the Bakersfield-5558 California Avenue station and the Bakersfield-Golden State Highway monitoring station providing PM10, PM2.5 and CO background concentration data and the Fresno-1st Street monitoring station providing background SO_2 concentration data.

The background concentrations for PM10 and PM2.5 are above the most restrictive existing ambient air quality standards and are identified in **Air Quality Table 6** by bold font in the percent of standard column, while the background concentrations for the other pollutants are all well below the most restrictive existing ambient air quality standards.

The pollutant modeling analysis was limited to the pollutants listed above in **Air Quality Table 6**; therefore, recommended background concentrations were not needed nor determined for the other criteria pollutants (ozone, lead, visibility, etc.).

PROJECT DESCRIPTION AND EMISSIONS

Hydrogen Energy California LLC (HECA), owned by SCS Energy California, LLC, has proposed to build an Integrated Gasification Combined Cycle (IGCC) polygeneration project (hereafter referred to as HECA or the project) in Kern County, California. The project involves the conversion of a feedstock via gasification to a synthetic gas used for both power production and the manufacturing of nitrogen-based fertilizer products at an integrated manufacturing complex. The proposed feedstock is a 75 percent coal and 25 percent petroleum coke (petcoke) fuel blend as measured by the thermal input to the gasifier on a higher heating value (HHV) basis. Carbon dioxide (CO_2) produced during this process would be captured and used by the manufacturing complex and for enhanced oil recovery (EOR) at a nearby oil production field.

The facility developer is proposing to gasify a 75 percent coal and 25 percent petcoke fuel blend to produce the syngas. The proposed coal is a western sub-bituminous coal from New Mexico. The coal would be transported to Kern County by rail. The coal would then be transported to the site either by a new railroad spur or by truck from Wasco. Under Transportation Alternative 1, a new five mile railroad spur would be constructed to connect the project site to the existing San Joaquin Valley Railroad Buttonwillow line. This rail spur would allow the rail transport of coal all the way to the project site, and would also allow products to be shipped by rail directly from the manufacturing complex at the project site. Under Transportation Alternative 2, trucks would be used to transport the coal 27 miles from an existing coal transloading facility in Wasco to the project site. Additionally, all products would be trucked from the site to various locations within and outside of the San Joaquin Valley. It is estimated that 4,580 short tons of coal would be used per day. Petroleum coke, also called “petcoke” is a byproduct of the oil refining process. Currently, petcoke produced from California refineries is generally exported overseas. The applicant anticipates the petcoke for the project would be supplied from refineries located in the Los Angeles or Santa Maria area. The petcoke would be transported to the site by truck. It is estimated that 1,140 short tons of petcoke would be used per day. Several coal mines and petroleum refineries have been identified as potential coal and petcoke feedstock suppliers.

The feedstock would be gasified and processed at the facility to produce a hydrogen-rich syngas. Gasification is a chemical conversion process to convert the solid feed stock to syngas. The applicant is proposing the use of an oxygen-blown, dry-feed gasification technology incorporating a two stage operation. The Mitsubishi Heavy Industries (MHI) gasification system selected for this project incorporates equipment that grinds and dries the feedstock prior to gasification. The syngas produced in the gasifier is further processed and cleaned to produce both CO_2 and a hydrogen-rich fuel used for power generation and ammonia synthesis at the manufacturing complex.

The manufacturing complex would produce 1 million tons per year of nitrogen-based fertilizer products such as urea and urea ammonium nitrate (UAN). Intermediate products that are produced to make these fertilizer products, but that will not be sold as products, include anhydrous ammonia and nitric acid. A pressure swing adsorption unit would purify the hydrogen-rich syngas produced in the gasification process. The high purity hydrogen stream and a nitrogen stream from the air separation unit would be the feedstocks for the ammonia synthesis unit. The ammonia would be used onsite to produce urea pastilles and UAN solution. Recovered CO_2 from the gasification process would be purified and combined with the ammonia for urea synthesis. The UAN solution would be produced from nitric acid, ammonium nitrate and urea.

The CO_2 recovered from the project would also be used by Occidental of Elk Hills, Inc. (OEHI) for enhanced oil recovery at the nearby Elk Hills Oil Field. The CO_2 would be compressed and delivered by pipeline to OEHI’s enhanced oil recovery (EOR) production facility. The CO_2 would be distributed to injection wells in patterns designed to optimize crude oil recovery. Recovered fluids would be pumped to the surface at nearby production wells and transported to the EOR processing facility. The recovered fluid would contain liquids (crude oil) and gases (natural gas and CO_2). The natural gas can include CO_2 from break through at the production well. The CO_2 would be separated from the natural gas and recompressed for reinjection into the underground oil reservoir. Each time CO_2 is injected, a percentage of the CO_2 remains trapped in the reservoir and is unrecoverable. This unrecoverable CO_2 would be permanently trapped underground over time via three trapping mechanisms: physical, residual and geochemical. The physical trapping mechanism is expected to eventually sequester all the CO_2 delivered by HECA and used in the EOR process. Please see the **Carbon Sequestration and Greenhouse Gas Emissions** section of the PSA/DEIS for a complete discussion of the carbon sequestration and CO_2 emissions impacts for HECA and the OEHI EOR component.

Staff requested the applicant to respond to a number of data requests regarding the construction and operations emission estimates and air dispersion modeling analysis. The applicant responded to these requests in a number of separate data response documents[2] by providing additional project description and revised emissions estimates. Staff has compiled the latest information from the AFC (HECA 2012e), and the air quality data responses in this Preliminary Staff Assessment/Draft Environmental Impact Statement (PSA/DEIS) section. Staff has reviewed the revised emission estimates and air dispersion modeling analysis[3] and finds them to be reasonable considering the level of emissions mitigation now stipulated to by the applicant.

EQUIPMENT DESCRIPTION

The project is evaluated by breaking it into separate sections: the power generating facility including the integrated manufacturing complex and EOR operations. The Energy Commission has jurisdiction over the power generation and manufacturing complex while other entities have jurisdiction over the EOR operations. However, EOR operations are evaluated in this document as part of the whole of the project. A separate EOR operations discussion, including the equipment description, will follow the power generating facility and integrated manufacturing complex discussion.

The power generation element includes an integrated gasification combined cycle facility (IGCC), which includes solids handling, gasification and gas treatment, power generation, manufacturing complex and auxiliary equipment.

For emission calculation purposes, the emission sources are summarized as follows:

Feedstock Delivery, Handling & Storage	• Feedstock handling System: Bulk material unloading (including fluxant), loading, belt conveying, belt transfer points, silo loading; controlled by various baghouses.

[2] This includes the following: AFC, ATC, and data response references: HECA 2012d, HECA 2012e, HECA 2012j, HECA 2012q, HECA 2012s, HECA 2012z, HECA 2012dd, HECA 2012ff, HECA 2012hh, HECA 2012pp, HECA 2013a, HECA 2013b, OXY 2013c and OXY 2013e. The latest updated emissions estimates are summarized for all HECA emissions sources in HECA 2013a and HECA 2013b. Staff also reviewed the data responses that were provided to address intervenor data requests.

[3] This includes a review of the emission source inputs, including the type of source (point, volume, area) and the variables used to describe each source (emissions, height, location, temperature, etc. as appropriate).

Gasification	• Feedstock Grinder & Dryer • Gasifier • Syngas Treatment Equipment • Gasification Flare • Sulfur Recovery Unit (SRU) Flare • Rectisol® Flare • Tail Gas Thermal Oxidizer • Process Cooling Tower • Air Separation Unit (ASU) Cooling Tower • Carbon Dioxide Vent
Power Block	• Combined Cycle Combustion Turbine (MHI 501GAC®) • Power Block Cooling Tower
Other Equipment	• Auxiliary Boiler
Emergency Equipment	• Emergency Diesel Generator 1, 2,922 brake horsepower (bhp) • Emergency Diesel Generator 2, 2,922 bhp • Emergency Diesel Firewater Pump, 565 bhp
Manufacturing Complex	• Ammonia synthesis (including ammonia heater) • Urea Unit • Urea Pastillation • Pastillation Handling • Nitric Acid Unit • Ammonium Nitrate Unit • Urea Ammonium Nitrate (UAN) Unit

Solids Handling

Feedstock Delivery, Handling and Storage

As noted above, there are two different alternatives for feedstock delivery, handling and storage. Under Transportation Alternative 1, coal is brought to the project site via rail. The coal is unloaded from the trains and conveyed to a storage barn through a rail unloading and transfer system. The transfer conveyor is fully enclosed and all related coal feedstock buildings are fully enclosed. Petcoke would be delivered to the site by truck. A truck unloading station would be used to unload the trucks and convey the petcoke to storage.

Under Transportation Alternative 2, coal would be brought to the site in the same manner as petcoke. The feedstocks would be delivered to the project site via bottom dump haul truck. The truck unloading station would receive the petcoke or coal and a transfer system would convey the feedstock to storage.

Both the coal and petcoke unloading stations consist of buildings that would be fully enclosed with roofing and siding. Dust suppression spray systems and dust collection systems would be used as needed to control dust from these operations.

The coal and petcoke would be stored in separate piles in an enclosed storage building. The feedstock piles would have a 30 day total storage capacity consisting of approximately 140,000 tons of coal and 35,000 tons of petcoke. The feedstock would be blended as 75 percent coal and 25 percent petcoke on a British Thermal Unit (BTU) heat input basis and then placed on a conveyor to transfer the material from the storage building to the gasification system for further processing. Feedstock fed to the gasifier would be consistently blended to this level. The transfer system would be fully enclosed.

Fluxant Delivery, Handling and Storage

The applicant has indicated that after additional testing of the coal and petcoke, a limestone fluxant would need to be added to the gasifier feedstock. The fluxant would be trucked to the facility using enclosed or covered trucks, then unloaded and stored in a silo located just north of the feedstock building. The particulate emissions from the fluxant unloading and storage silo would be controlled by a baghouse. A total of 59,000 tons per year of fluxant would be used.

Gasification

Feedstock Grinding and Drying

The MHI gasification system includes equipment used to grind and dry the feedstock prior to gasification. Blended feedstock, including the limestone fluxant, is stored in intermediate bins prior to transport to the dryer. The coal/petcoke dryer receives the blended feedstock, grinds and dries it before entering the gasifier. The heat source for the drying is a portion of the turbine exhaust gas. Emissions from the HRSG exhaust gas are controlled by the oxidation catalyst and the SCR prior to the diversion of the exhaust gas to the dryer. Emissions from the dryer are controlled by a baghouse and activated carbon is used to facilitate the removal of mercury.

Gasifier

The MHI oxygen-blown gasifier is a two stage design and the feed enters the gasifier at two separate points. In the first stage, the feedstock is fed to the gasifier with O_2. The high temperatures in this stage produce CO_2 and water vapor. The temperatures are high enough to melt the coal ash. The coal ash is quenched in a water bath to facilitate removal of the gasification solids, which are eventually transported offsite. The remaining feedstock is added to the second stage without additional O_2. At this stage the char created through the pyrolysis of the feedstock in the second stage produces CO, and the CO and water form hydrogen and CO_2. The syngas leaves the gasifier through a syngas cooler for further processing. A cyclone and filter remove char from the stream to recycle it in the gasifier. Steam produced in this process is directed to the HRSG to assist in power generation.

The gasifier unit is a source of fugitive emissions from piping components such as valves and connectors from the gasification stream. The fugitive emissions from the syngas stream are mainly CO and CO_2 but also include methane, hydrogen sulfide, carbonyl sulfide and ammonia.

Syngas Treatment Equipment

Syngas from the gasifier is further treated prior to the CO_2 removal and treated further before its use in the manufacturing facility and its use for electricity generation. After leaving the gasifier the syngas is treated in a scrubber to remove chlorides. The syngas then enters the sour shift unit (SSU) where a water-gas reaction is used to convert the CO and water to CO_2 and hydrogen. The catalyst used in this reaction also facilitates the hydrolysis of carbonyl sulfide to hydrogen sulfide. The gas is then cooled and sent to an ammonia wash column to remove ammonia from the syngas. The shifted, cooled ammonia free syngas is then sent to the mercury removal unit. The mercury removal unit is needed to remove trace amounts of mercury occasionally found in petcoke and typically contained in western sub-bituminous coal. Mercury is removed from the stream using activated carbon. After the mercury is removed the syngas is treated in the acid gas removal (AGR) unit. Acid gas is a term used to describe a gas containing significant quantities of acidic gasses such as H_2S and CO_2. The facility is proposing to use a Rectisol® unit that utilizes a methanol solvent to absorb the H_2S, other sulfur compounds and CO_2. The resulting hydrogen-rich fuel is then sent to the combustion gas turbine (CTG) or to the pressure swing adsorption unit for further purification. CO_2 is separated from the stream where it is compressed and transported to OEHI for oil recovery operations and the manufacturing facility. The gasification and syngas treatment processes utilize three flares to control emissions during startup or upset conditions.

The pressure swing adsorption (PSA) unit generates a high-purity hydrogen gas stream from a portion of the syngas from the AGR unit. This high purity gas is sent as a feedstock to the ammonia synthesis unit. The off-gas from the PSA unit is compressed and sent as duct burner fuel to the heat recovery steam generator (HRSG).

Gasification Flare

The gasifier would be equipped with a 4,000 MMBtu/hr emergency elevated flare with a 0.5 MMBtu/hr natural gas pilot flame. Flaring from the gasifier would only occur during startup and shutdown or upset conditions. The flare would be used to safely dispose of gasifier startup gases, syngas (also called unshifted and shifted gases[4]) and hydrogen-rich fuel. The proposed MHI gasifier design minimizes flaring events. The MHI gasifier is a 100 percent-capacity gasifier with an internal membrane wall which eliminates rotations and requires less maintenance. During startup and shutdown flaring events the maximum firing rate for the flare would range from 2,386 MMBtu/hr for the flaring of unshifted gas, to 2,413 MMBtu/hr for the flaring of shifted syngas and to 2,926 lbs/hr for the flaring of natural gas. The applicant is proposing two startup/shutdown events per year.

---

[4] Shifted gas sent to the flare would contain large amounts of hydrogen and carbon dioxide but would still contain sulfur, as H_2S, and other impurities, such as low levels of mercury, not yet removed in the process. Unshifted gas sent to the flare would contain large amounts of carbon monoxide, carbon dioxide and hydrogen and would also contain sulfur compounds, as carbonyl sulfide (COS), and the other impurities contained in the shifted gas.

Sulfur Recovery Unit (SRU) Flare

The sulfur recovery unit (SRU) would be equipped with an 800 MMBtu/hr elevated flare with a 0.3 MMBtu/hr natural gas pilot flame. Flaring would only occur during startup and shutdown or upset conditions. The flare's function would be to safely dispose of acid-gas streams containing sulfur from the acid gas removal (AGR) unit, gasification unit, and sour water stripper unit during startup or during emergency or upset events. The acid gas would be first vented through an emergency caustic scrubber and knockout drum to remove sulfur compounds and entrained liquids and then vented to the flare for oxidation of the remaining acid gas. During startup and shutdown the flare would be operated at a firing rate of approximately 36 MMBtu/hr. The applicant is proposing 40 hours per year of flare venting for the SRU flare.

Rectisol® Flare

The Rectisol® unit would be equipped with a 5,500 MMBtu/hr elevated flare with a 0.3 MMBtu/hr natural gas pilot flame. Flaring would only occur during startup and shutdown or upset conditions. The flare would be used as an emergency flare to safely dispose of low temperature gas streams from the acid gas removal (AGR) unit and its associated refrigeration unit during startup, shutdown, and unplanned upsets or emergency events. These gases, which would be first vented through a knockout drum to remove any entrained liquids prior to introduction to the flare header, would be below the freezing point of water and would require segregation from the other flared gases. During startup and shutdown the flare would be operated at a firing rate of approximately 430 MMBtu/hr. The applicant is proposing 40 hours per year of flare venting for the Rectisol® flare.

SRU/Tail Gas Thermal Oxidizer

The facility would utilize a sulfur recovery system to recover sulfur from the processing facility and convert it to a usable sulfur byproduct. The sulfur recovery system would consist of a sulfur recovery unit (SRU) and a tail gas unit (TGU). Acid gas from the AGR unit would be sent to a SRU where H_2S is first oxidized to SO_2 followed by an SO_2 conversion to elemental sulfur in a reaction furnace. SRU effluent gases would then be sent to a tail gas unit (TGU) to convert the remaining sulfur compounds in the gas back to H_2S. The tail gas unit would be equipped with a natural gas fired thermal oxidizer rated at 96 MMBtu/hr to combust 16 MMBtu/hr of natural gas from the assist burner and 80 MMBtu/hr from the waste gas burner. The SRU tail gas thermal oxidizer would be operated to oxidize H_2S and other vent gas components that would be generated during startup, shutdown, and other miscellaneous gasification unit streams (tank and equipment vents) during normal operation to prevent nuisance odors during operation. The recovered sulfur would be in the form of liquid elemental sulfur that would be trucked offsite as a secondary product. The overall sulfur recovery is estimated to range from 99.8 to 99.9+ percent.

The emissions calculated from the unit were originally based on a 13 MMBtu/hr natural gas assist burner. However due to recent changes in project design, the natural gas burner capacity was increased to 16 MMBtu/hr. However, the applicant intends to limit emissions to the level proposed in the application. The SRU unit also would have fugitive emissions from the piping components from various VOC and CO laden streams, including the sulfur and the tail gas treatment unit processes.

Process Cooling Tower

The process block cooling tower would be used for heat rejection from the CO_2 compressor and AGR refrigeration unit. The process block cooling tower circulation rate would be approximately 163,000 gpm of water and it would operate 8,322 hours annually. The cooling tower would operate with a maximum total dissolved solids (TDS) concentration of 9,000 ppmw[5] and the cooling tower's particulate emissions would be controlled with a high efficiency drift eliminator designed to reduce the drift to less than 0.0005 percent of circulation.

Air Separation Unit (ASU) Cooling Tower

The ASU cooling tower would be in the ASU unit and reject waste heat from the ASU. The ASU, including the ASU cooling tower, would be designed, built, owned, and operated by another party. However, for permitting purposes it is considered part of the HECA facility. The ASU cooling tower circulation rate would be approximately 45,000 gpm of water and it would operate up to 8,322 hours annually. The cooling tower would operate with a maximum total dissolved solids (TDS) concentration of 2,000 ppmw[6] and the cooling tower's particulate emissions would be controlled with a high efficiency drift eliminator designed to reduce the drift to less than 0.0005 percent of circulation.

Carbon Dioxide Vent

The carbon dioxide vent would be used to release the produced CO_2 vent stream, which would contain small amounts of CO, VOC, and H_2S when the exhaust compression, pipeline, or injection systems are unavailable. The OEHI component as currently envisioned does not include a back-up enhanced oil recovery CO_2 injection zone. However the CO_2 vent would be limited to 504 hours per year, which is the worst case venting assumption during early operation (first two years). CO_2 venting is expected to occur no more than 120 hours per year during mature operations. Carbon dioxide emissions estimates in the **Carbon Sequestration and Greenhouse Gas Emissions** PSA/DEIS section include these emissions.

Power Block

Power Block CTG/HRSG Unit

The combined cycle power block would generate approximately 431 MW of gross power and would provide low-carbon baseload electricity primarily using hydrogen-rich fuel generated from the project's gasification unit. The power generation equipment is similar to conventional natural gas power plants; however, there is substantial heat integration with the gasification process where heat is recovered for useful energy in the

---

[5] The TDS levels could range from 3,000 to 9,000 ppmw for the project's cooling towers, depending on the raw water quality and operating cycles of concentration for each cooling tower. For permitting purposes the maximum level of 9,000 ppmw has been assumed.

[6] The applicant has indicated that this cooling tower requires a lower TDS level than the power block and process cooling towers; that is why it is assumed to have a TDS level of 2,000 ppmw versus the 9,000 ppmw TDS levels assumed for the other two cooling towers.

form of additional power generation. The combined cycle block would include a single-shaft MHI 501GAC® G-class, air-cooled combustion turbine/steam turbine generator configured to burn hydrogen-rich fuel. The block also includes a HRSG and water cooled surface condenser. The exhaust gas from the turbine as well as supplemental hydrogen-rich fuel and PSA off-gas for duct-firing would be sent to the HRSG to generate additional electricity.

The combustion equipment would also be equipped with separate fuel nozzles for natural gas. The facility would be permitted for limited natural gas operation during startup, shutdown and equipment outages. The combustion turbine generator (CTG) would use natural gas during periods of unplanned equipment outages but not during normal operation. When operating on natural gas, water would be injected to control NOx emissions. During startup operations the CTG/heat recovery steam generator (HRSG) would be fired on natural gas and would transition to hydrogen-rich fuel two and a half hours into the startup sequence. A startup sequence is estimated to require 4.5 hours and the shutdown sequence is estimated to take 9 hours. A total of two startup/shutdown sequences are expected to be needed per year. The maximum expected operating schedule for the CTG/HRSG is provided in **Air Quality Table 7**. These hours reflect early operations when the facility owners are learning how to use the facility efficiently. These conditions are used to establish permit operating limits. More mature operations would require less use of natural gas, and fewer startup/shutdown cycles and less CO_2 venting (not shown in the table).

Air Quality Table 7
Maximum Annual CTG/HRSG Operating Schedule (Early Operations)

Operating Conditions	Early Operations (Maximum Permitted)
Total Hours of Operation	8,363
Hydrogen-Rich Fuel Operation	8,000
Natural Gas	336
Startup/Shutdown	27

Source: HECA 2013a, HECA 2013b

For permitting purposes the duct burner operation has been assumed to operate 100 percent of the time the turbine is operating, except during startup and shutdown periods. The applicant assumes that during early operations, natural gas firing would occur up to two weeks per year, or 336 hours per year for unplanned equipment outages.

The HRSG would be equipped with emission control technology to reduce stack emissions. The HRSG would include an SCR system used to meet BACT requirements for NOx. The SCR system would use ammonia injected upstream of the SCR catalyst. The SCR catalyst would be used to convert NOx and ammonia into nitrogen and water. An oxidation catalyst would be used upstream of the SCR ammonia injection location to oxidize CO and VOC to reduce their emissions. A portion of the treated exhaust gas would be sent to the gasification unit to dry the feedstock. The HRSG stack would be equipped with a continuous emissions monitoring system (CEMS) to verify compliance with applicable emission limits. The CEMS would be used to monitor NOx, CO and O_2 and would be certified to comply with the applicable SJVAPCD and U.S. EPA standards.

Power Block Cooling Tower

The largest heat rejection load would be the steam turbine surface condenser in the power block. The power block cooling tower would be used to facilitate removal of the waste heat from the steam power cycle portion of the combined cycle CTG/HRSG. Approximately 95,500 gallons per minute (gpm) of water would be circulated in the power block cooling tower, which would operate 8,668 hours annually. The cooling tower would operate with a maximum total dissolved solids (TDS) concentration of 9,000 parts per million by weight (ppmw)[7] and the cooling tower's particulate emissions would be controlled with a high efficiency drift eliminator designed to reduce the drift to less than 0.0005 percent of circulation.

Other Equipment

Auxiliary Boiler

The auxiliary boiler, fired exclusively on natural gas, would be used to provide steam to facilitate CTG startup and for other miscellaneous purposes when steam from the gasification block or HRSG is not available. During typical operation the auxiliary boiler would be in either warm standby or cold standby. The proposed boiler was originally rated at 213 MMBtu/hr when operated on natural gas. Due to recent changes in project design, the currently proposed boiler would have a maximum heat input of 230 MMBtu/hr; however, HECA intends to limit the boiler operation to 213 MMBtu/hr equivalent to keep emissions at the same level as proposed in the application. Annual emissions from the auxiliary boiler were calculated based on full-time operation at a 23 percent annual capacity factor[8]. The auxiliary boiler would be equipped with an ultra-low NOx burner and selective catalytic reduction to further reduce NOx emissions. Emergency Equipment.

Emergency Diesel Generator

The proposed project includes two diesel-fired emergency internal combustion engines powering emergency generators. The generators would be used to supply emergency service power to critical components as needed during an electric grid power outage. The proposed engines would be Tier 4 certified and rated at 2,922 bhp each. Other than emergency operation, the engines would be operated up to 50 hours per year each for maintenance and readiness testing purposes.

Emergency Firewater Pump

The proposed project includes a Tier 4, 556 bhp diesel-fueled emergency internal combustion engine powering a firewater pump that would only be used in an emergency to put out fires, maintenance and readiness testing. Other than emergency operation, the engine could be operated up to 100 hours per year for maintenance and readiness testing purposes.

---

[7] The TDS levels could range from 3,000 to 9,000 ppmw for the project's cooling towers, depending on the raw water quality and operating cycles of concentration for each cooling tower. For permitting purposes, the maximum level of 9,000 ppmw has been assumed.

[8] Originally the calculations used a 25 percent annual capacity factor for the 213 MMBtu/hr rated boiler, however 23 percent is the equivalent annual capacity factor for the higher 230 MMBtu/hr rated boiler.

Manufacturing Complex

Ammonia Synthesis

The proposed manufacturing complex includes an ammonia synthesis unit. The ammonia synthesis unit manufactures ammonia for urea pastilles and UAN solution production. After consideration, the applicant has determined that the ammonia would not be shipped as a separate product; however, the transportation emissions estimates still include ammonia transportation. The ammonia synthesis unit uses nitrogen from the ASU and high purity hydrogen from the PSA to convert the nitrogen and hydrogen to ammonia. This exothermic conversion occurs over an iron-based catalyst. The effluent is used to generate steam in the waste heat boiler. Cold liquid ammonia is stored in two vertical steel tanks housed in a second vessel and equipped with a vapor recovery system to prevent losses.

A natural gas fired startup heater rated at 55 MMBtu/hr would be used to raise the catalyst bed temperature during plant commissioning and startup. The operation of the unit would be equivalent to 140 hours per year of full capacity operation.

A leak detection and repair (LDAR) program has been proposed by the applicant to limit fugitive emission from the NH_3 streams.

Urea Unit

A proposed urea unit would be used to produce a concentrated urea solution. The urea unit would combine a purified stream of CO_2 recovered in the AGR with ammonia from the ammonia synthesis unit to produce the concentrated urea solution. This solution would be used as feed to the UAN solution and urea pastilles.

The off-gas from the urea synthesis would consist of CO_2, nitrogen, water feed, process air, and unreacted ammonia. The off-gases would be scrubbed to remove the ammonia from the stream. Ammonia emissions from the urea absorbers are estimated based on plant capacity. A LDAR program has been proposed by the applicant to limit fugitive emission from the NH_3 and CO_2 streams.

Urea Pastillation Unit and Pastille Handling System

The concentrated urea would be converted to high-quality pastilles. The process would occur in an enclosed area with a hood and baghouse to control the urea dust. The urea pastilles would then be conveyed to urea storage and a rail/truck load out facility. All conveyors and the handling system building would be fully enclosed and equipped with dust collection systems. The dust collectors from the material handling system and urea pastillation unit would be designed to limit PM emissions (PM10 and PM2.5) to 0.001 grains per dry standard cubic feet.

Nitric Acid Unit

Nitric acid production is an intermediate step in urea ammonium nitrate (UAN) production. Ammonia from the ammonia synthesis unit would be oxidized by high temperature air over a platinum-based catalyst. Nitric oxide formed during the ammonia oxidation would also be oxidized in a non-catalytic reaction with O_2 to form nitrogen dioxide. The nitrogen dioxide is cooled and sent into an absorption tower with water where nitric acid is formed. Tail gas from the absorber column would be cleaned prior to venting by catalytic decomposition and reduction of N_2O and NOx. Primary and secondary reduction of N_2O would occur without a catalyst. Tertiary reduction would occur with a catalyst under high temperatures to reduce 95 percent of the remaining N_2O. NOx emissions would be reduced using SCR with injected ammonia as a reducing agent. NOx emissions would be limited to 0.2 lb/ton of nitric acid (approximately 15 ppmv). To adequately control the NO_2 emissions, sufficient ammonia must be injected into the SCR system. Based on information from the manufacturer, ammonia emissions would be limited to 10 ppm or 1.0 lbs/hour.

Ammonium Nitrate Unit

Ammonium nitrate production is another intermediate step in UAN production. Ammonia and nitric acid would be combined to produce an ammonium nitrate solution. The vent stream would contain water vapor and residual ammonium nitrate solution that would be routed to a water scrubbing system to reduce particulate emissions. The vent scrubber would condense the vapor into a condensate which would absorb the mist droplets. Emissions of PM from the condensing vent scrubbing system and the scrubber vent particulate emissions would be limited to less than 0.2 lb per hr, assumed to all be PM2.5 or smaller.

Urea Ammonium Nitrate Unit

The ammonium nitrate solution and the urea solution are metered, mixed and cooled in the urea ammonium nitrate (UAN) unit. The final product may contain water depending on final product specifications. The UAN solution would be stored in tanks and then loaded into railcars or trucks for shipment. An LDAR program has been proposed by the applicant to limit fugitive emission from the NH_3, CO_2 and HNO_3 streams.

CONSTRUCTION

Emission sources during construction of HECA would include on-site sources, linear construction sources, and off-site sources. On-site emission sources would include combustion and fugitive emissions from construction equipment and activity, delivery trucks entering the site and commuter vehicles. Construction activities would include clearing and grubbing of vegetation, grading, hauling and payout of equipment, hauling materials and supplies, and project facility construction and testing. Linear sources would include the construction equipment required for linear construction, specifically construction activities associated with the water supply pipeline, carbon dioxide pipeline, natural gas supply, electrical transmission line, and potential rail spur. Construction of the on-site rail spur and rail unloading facility would only be required under Transportation Alternative 1. Off-site emissions sources would include combustion and fugitive emissions from delivery trucks and worker commuter vehicles while traveling off-site. The trip distances for the off-site sources were all assumed to be within Kern County.

The construction/commissioning period would last approximately 49 months. This includes 42 months of site preparation and construction and up to 18 months of commissioning and startup. The commissioning and startup period would partially overlap with the construction period. During the construction and commissioning period, emissions would vary depending on the specific scheduled activities and conditions. The applicant provided a detailed schedule including the quantity of equipment needed and expected usage. This list served as the basis for estimating emissions and determining periods of maximum short-term construction emissions.

Onsite and offsite construction particulate emission estimates include emissions from both fuel combustion and fugitive sources. Fugitive particulate emissions can result from areas that are disturbed due to grading, excavating and construction of project structures. Various areas within the project site would be disturbed at different times during the 42 month construction period. Additionally, paved and unpaved road travel creates fugitive dust emissions. Combustion emissions result from exhaust sources, including diesel-fired construction equipment used for site preparation and building/structure construction, water trucks used to control dust emissions, welders, heaters, portable generators, air compressors, pumps, diesel trucks for deliveries and vehicles used by workers to commute to and from the construction site. Construction activities were assumed to occur approximately 22 days per month (Monday-Friday) with a single shift each day.

The applicant's emissions estimates from the construction vehicles incorporated several conservative (over predictive) assumptions. Emissions from the on-road vehicles are based on 2010 emission factors using the ARB EMFAC2007 model and the off-road vehicle emissions are based on the ARB OFFROAD2007 model. These models were updated by ARB in 2011. The older EMFAC2007 and OFFROAD2007 models are used in the emission estimates because the U.S.EPA has not yet approved the use of the new ARB models for Transportation Conformity analyses. While this project requires a General Conformity analysis and not a Transportation Conformity analysis, to be conservative the applicant decided to use the U.S.EPA-approved ARB emission factor models. The EMFAC2007 and EMFAC2011 model emissions factors are very similar for the same vehicles and model years, but there are some minor differences including revisions to the tire wear and brake wear emission assumptions. The major difference in the OFFROAD2007 and OFFROAD2011 model's emissions factors is the large reduction in the assumed engine capacity factor. The OFFROAD2011 model has reduced the assumed capacity factor by one-third resulting in a major difference in the calculated emission factor. Another conservative assumption for both the on-road and off-road equipment emissions estimates is the use of a 2010 baseline to develop the emissions factors rather than the years 2013 through 2016 when construction is expected to occur if the project is licensed. This assumption does not reflect model year improvements that are driven by federal and state regulation (i.e. nonroad equipment emissions standards) that cause an ongoing reduction of emissions from diesel-fired equipment. Therefore, using these older models and input assumptions would result in conservative on-road vehicle emissions estimates and very conservative off-road equipment emissions estimates.

The applicant determined that the short-term maximum construction emissions occur during the third month of construction for PM10 and PM2.5, when the fugitive dust generating mass grading activities are being conducted and before the internal site road is constructed, and during the 24th month of construction for other criteria pollutant emissions when there are extensive structure construction activities under way. The maximum annual emissions, which are based on the peak 12 consecutive months of emissions during the construction period, occur during months 1 through 12 for PM10 and PM2.5 emissions and during months 20 through 31 for the other criteria pollutant emissions. The Applicant's estimates for the highest emissions during construction are provided in **Air Quality Table 8** (daily emissions) and **Air Quality Table 9** (annual emissions).

Air Quality Table 8
Maximum Daily Construction Emissions

Activity (lbs/day)	NOx	CO	SOx	VOC	PM10	PM2.5

Notes:
a. Worst-case onsite daily emissions would occur during Months 1-12 of construction for PM10 and PM2.5 and Months 20-31 of construction for the other pollutants.

INITIAL COMMISSIONING

The initial commissioning of a power plant refers to the time between the completion of construction and the reliable production of electricity for sale on the market. For most power plants, normal operating emission limits usually do not apply during the initial commissioning activities due to the need to test individual components during commissioning, often before emission controls are operational.

The commissioning and initial startup is currently scheduled to require 18 months to complete. The commissioning for the project would require four distinct phases which are described as follows:

1. Power block commissioning on natural gas

2. Power block commissioning on hydrogen-rich fuel

3. Gasification block and balance of plant (BOP)

4. Manufacturing Complex

Commercial operation would start when the commissioning and startup activities are completed and the licensor/contractor guarantees and milestones have been achieved.

The commissioning activities would occur in several phases. They would begin with the utility and support systems, which includes electric power, water treating, natural gas supply, auxiliary boiler, cooling tower, and safety systems.

The fertilizer manufacturing process units would be commissioned in the general order of the manufacturing process, with the feed producing units commissioned before the product producing units. This commissioning process includes several plants and support systems with an estimated 3,388 total hours of commissioning operations.

The power block would be commissioned before commissioning the gasification block to ensure the reliability of the power block to supply substantial amounts of electrical power to be consumed by the gasification block. The power block would be commissioned only on natural gas during this period. This commissioning phase is estimated to require 1,129 hours of commissioning operations, during which emissions would be partially abated since the commissioning of the emissions control devices, including the SCR unit, is part of this commissioning phase. This phase of commissioning would be followed by gasification block commissioning.

The gasification, Rectisol®, and sulfur recovery unit (SRU) flares would be tested with natural gas and nitrogen. The tail gas thermal oxidizer would also be commissioned on natural gas. Included in the gasification block initial commission emissions are the balance of plant (BOP) operations not otherwise included in the CTG/HRSG initial commissioning emission estimate.

The last commissioning phase is to commission the power block on hydrogen-rich fuel. The hydrogen-rich fuel and nitrogen blending systems would be commissioned, and the CTG combustors would be tuned for different fuel types. Unlike during the natural gas commissioning phase, the emission control devices would be operating at all times when operating within their normal operating temperature range. The CTG would be performance-tested on hydrogen-rich fuel at the end of this commissioning phase.

Emissions estimates for each commissioning phase are shown in **Air Quality Table 10**.

Air Quality Table 10
Summary of Commissioning Emissions

Phase	NOx	CO	VOC	SOx	PM10/PM2.5
Max Hourly Commissioning Event Emissions (lb/hr)[a]					
CTG/HRSG on Natural Gas	391.20	2,270.00	65.00	4.80	15.00
CTG/HRSG on Hydrogen-Rich Fuel	99.04	1,622.60	35.12	5.13	15.00
Gasification Block and BOP	140.00	4,000.00	5.50	11.03	1.85
Manufacturing Complex	81.20	1.52	0.16	0.08	0.32
Total Commissioning Emissions (tons)[a]					
CTG/HRSG on Natural Gas	61.03	199.35	4.75	2.06	8.32
CTG/HRSG on Hydrogen-Rich Fuel	20.83	132.79	4.41	1.83	8.51
Gasification Block and BOP	52.53	614.40	2.73	6.04	12.40
Manufacturing Complex	4.00	0.18	0.03	0.01	0.24
Total Commissioning Emissions	**138.39**	**946.72**	**11.92**	**9.94**	**29.47**

Source: HECA 2012e
Notes:
[a] – The maximum hourly emissions for the gasification block and BOP are for the largest single commissioning event and do not include concurrent commissioning activities.
[b] - The annual cooling tower emissions associated with the CTG/HRSG commission are shown with the Gasification Block and BOP emissions.

OPERATIONAL PHASE

Project Operating Emissions

The operational emissions from the project include both the power generating facility and integrated manufacturing complex. The most significant emission source would be emissions from combustion of the hydrogen-rich syngas in the combined cycle power block. Other significant sources of emissions would be the combined emissions generated from on-site and off-site mobile sources, the coal dryer, tail gas thermal oxidizer and nitric acid plant. Minor emission sources would include the auxiliary boiler, flares, cooling towers, two emergency diesel-fired engines powering emergency generators, emergency firewater pump engine, CO_2 vent and miscellaneous operations for the manufacturing complex. Emissions from the project would include normal operating conditions as well as emissions from startup and shutdown events that are considered normal operation for the equipment. One to two plant startup/shutdown events are anticipated annually to perform major maintenance. Emissions from startup and shutdown operations are often higher than normal operating conditions as many control systems are optimized to parameters associated with normal operations and not startup/shutdown.

CTG HRSG Emissions

The emissions from the proposed project's CTG/HRSG include both startup and shutdown events and normal operations. The differences in the emission rates are due in part to the chemical and physical differences of the fuel types, and also because the combustor is tuned to operate on a hydrogen-rich fuel/nitrogen mixture and therefore it does not meet the same emissions guarantees when operating on natural gas. The CTG/HRSG would be fired on natural gas during the first two and a half hours of a startup event and last five hours of a shutdown event. **Air Quality Table 11** presents the total startup and shutdown emissions per event.

Air Quality Table 11
Summary of HRSG/Coal Drying Startup and Shutdown Emissions, lbs/event

Pollutant	NOx	CO	VOC	SOx	PM10/PM2.5
Startup (4.5 hrs)	429.9	3,702.7	73.0	12.2	63.7
Shutdown (9 hrs)	804.6	8,482.8	196.7	23.4	131.4

Source: HECA 2013a, HECA 2013b

The applicant's estimated average normal hourly CTG/HRSG and coal dryer operating emissions for each fuel type are presented in **Air Quality Table 12**.

Air Quality Table 12
Summary of Normal Hourly HRSG/Coal Dryer Operating Emissions, lbs/hr

Pollutant	NOx	CO	VOC	SOx	PM10/PM2.5
Hydrogen-Rich Fuel					
HRSG	25.0	18.3	3.5	4.1	12.9
Coal Dryer	4.4	3.2	0.6	0.9	1.4
Combined Maximum	29.4	21.5	4.1	5.0	14.3
Natural Gas	34.1	26.0	5.9	4.7	15.0

Source: HECA 2013a, HECA 2013b

Maximum short-term operational emissions from the CTG/HRSG and coal dryer were determined from a comparative evaluation of potential emissions corresponding to normal operating conditions, and CTG startup/shutdown conditions. **Air Quality Table 13** presents worst case hourly emissions regardless of fuel type. The maximum hourly CTG/HRSG and coal dryer emissions generally occur during startup or shutdown, but the maximum SOx and PM10 emissions occur during normal operations for hydrogen-rich fuel and natural gas fuel operations, respectively.

Air Quality Table 13
Summary of Worst Case Hourly CTG/HRSG Emissions, lbs/hr

Pollutant	NOx	CO	VOC	SOx	PM10/PM2.5
HRSG	122.0	2270.0	64.8	4.7	15.0
Coal Dryer	15.1	147.4	1.9	0.9	1.5
Combined Maximum [a]	122.3	2270.0	64.8	5.0	15.0

Source: HECA 2013a, HECA 2013b
Note: a – This summary includes startup and shutdown and both fuels. The worst case hourly HRSG and coal dryer emissions do not always happen concurrently. For example the worst case PM10/PM2.5 emissions for the coal dryer occur during maximum normal operation, while the worst case PM10/PM2.5 emission from the HRSG and the total for the HRSG and coal dryer combined occur during the last seven hours of a shutdown.

Transportation Emissions

Mobile emissions from the project would occur from several different types of sources, including; trucks for the transport of petcoke and products, trains for the transport of coal and products, dedicated site trucks for onsite maintenance, and employee vehicles. Transportation Alternative 1 assumes that a rail spur would be built to the site and that the trains would be unloaded at the project site, while Transportation Alternative 2 assumes that the trains would be unloaded in Wasco and the coal would be trucked from Wasco to the project site. The applicant completed emissions estimates for both transportation alternatives. The annual mobile source emissions estimates for the emissions that occur within the SJVAB under each option are presented in **Air Quality Table 14**.

Air Quality Table 14
Summary of Annual Mobile Source Emissions (SJVAB), tons/yr

Pollutant	NOx	CO	VOC	SOx	PM10	PM2.5
Transportation Alternative 1						
On-site trucks	0.99	0.63	0.16	0.01	0.15	0.05

Off-site trucks	23.42	14.22	1.98	0.17	6.43	1.94
Off-site trains	13.48	3.49	0.37	0.25	0.22	0.21
Total	**40.14**	**23.30**	**2.89**	**0.44**	**7.98**	**2.52**

Source: HECA 2013a, HECA 2013b

A feedstock and product transportation emission estimate was also performed by the applicant for the other air quality jurisdictions within California and the other states affected by the coal feedstock and product transportation emissions. It is assumed that the coal would be transported by rail from a mine in northwestern New Mexico and that petcoke would be shipped by truck from Los Angeles area refineries. The project's products, including sulfur, coal ash, and the fertilizer manufacturing plant products would be shipped by truck or rail to various locations within and outside of California depending on the transportation alternative. The estimated emissions for each of the two transportation alternatives are presented in the **Air Quality Table 15**.

Project Total Emissions

Air Quality Table 16 presents worst case daily emissions for each of the stationary sources within the facility. The worst case daily emissions presented in the table include all the equipment from the entire facility. These worst-case daily emissions do not directly correlate to worst-case operating conditions because the worst-case conditions from the individual sources do not all occur concurrently. Therefore, this table indicates how many hours a day each of these sources operates when emitting their peak daily emissions and the summation of these individual worst-case conditions would not be representative of the worst cast operating scenarios.

The following assumptions are used to derive the worst case daily emissions.

- The CTG/HRSG emissions estimate assumes a worst case for each pollutant which is either normal operation with natural gas (SOx and PM10/PM2.5), or a 9 hour shutdown preceded by 15 hours of normal operation with natural gas (NOx, CO, and VOC).

Source: HECA 2013a, HECA 2013b
Note: [a] – The transportation emissions estimates include ammonia shipping which has since been removed from the project description and do not include the fluxant shipping which was a late addition to the project description. The emissions from fluxant shipping would be lower than the emissions from ammonia shipping due to the higher quantity of ammonia that was assumed to be shipped from the site. Therefore, the emissions presented above are slightly conservative for the current project description.

- The coal dryer emissions estimate assumes a worst case for each pollutant which is either normal operation at the worst-case ambient condition (SOx and PM10/ PM2.5), or a 4 hour startup followed by 20 hours of normal operation at the worst-case ambient condition (NOx, CO, and VOC).
- The three cooling towers, the auxiliary boiler, the CO_2 vent, nitric acid unit, urea pastillation unit, ammonium nitrate unit, and ammonia startup heater are assumed to operate 24 hours/day.

- The tail gas thermal oxidizer is assumed to operate in startup mode for 24 hours.
- The SRU and Rectisol® flares are conservatively assumed to operate with pilot and vented gas 24 hours.
- The Gasification Flare is assumed to operate through one 10 hour startup sequence with the pilot on for 24 hours.
- Each emergency generator is assumed to operate 1 hour per day.
- The fire pump is assumed to operate 2 hours per day.
- Feedstock, urea, and gasification solids materials handling occurs 6 to 24 hours per day depending on the specific material handling source (there are 18 separate sources with emissions calculations). The emissions estimate provided is for the solids material handling associated with Transportation Alternative 1, which forms the permitted emissions basis for the project that Alternative 2 would also have to achieve.
- Fugitive emissions are assumed to occur 24 hours/day.

Air Quality Table 16
Summary of Worst Case Daily Emissions – Stationary Sources, lbs/day

Pollutant	Maximum Hours Per Day	NOx	CO	VOC	SOx	PM10	PM2.5

Notes:
[a] – The value in this table reflects the assumption of both the applicant and District that PM2.5 emissions are 60 percent of the total cooling tower emissions. Staff has issues with the technical validity of this assumption, and staff will be asking U.S. EPA to provide comment on this issue given the significance of PM2.5 health effects. However, this assumption does not affect whether the project would be deemed a major PM2.5 emissions source under PSD permitting regulations.
[b] – This represents 10 hours of flaring during a gasifier start-up and 24 hours of the flare pilot operation.
[c] – There are multiple material handling sources and the maximum daily use varies from 6, 8, 12, and 24 hours depending on the material handling source. The values shown assume all of these material handling sources operate on the same day.
[d] – The fluxant handling emissions are not included in these totals. The FSA will provide an updated table that includes the fluxant handling emissions.

Annual facility emission estimates, including the non-stationary source and net SJVAB feedstock transportation emissions, are provided in **Air Quality Table 17**, and are based on the following assumptions:

- The CTG/HRSG power block would have two startups/shutdown cycles per year, 8,000 hours per year of hydrogen-rich fuel operation, and 336 hours of natural gas operation.
- The coal dryer would have two startup/shutdown cycles per year and 8,000 hours per year of normal operation.
- The process block and ASU cooling towers are assumed to operate 8,322 hours/year, and the power block cooling tower is assumed to operate 8,668 hours/year.
- The auxiliary boiler is assumed to operate 2,190 hours/year based on a 213 MMBtu/hr heat input.
- Each of the emergency generator engines would operate 50 hours/year and the fire pump would operate for 100 hours/year.
- All three flares would have their natural gas fueled pilots operating 8,760 hours per year and each flare would operate with vented gases as follows: gasification flare – 2,386 to 2,926 MMBtu/hr heat input for a total of 10 hours during a startup and 2,413 MMBtu/hr for 4 hours during a shutdown with two startup/shutdown cycles occurring in a year; SRU Flare – 40 hours @ 36 MMBtu/hr heat input, and Rectisol® Flare – 40 hours @ 430 MMBtu/hr heat input pilot emissions only.
- Tail gas oxidizer would have normal full load operations for 8,318 hours/year with two startup events lasting a total of 48 hours per year.
- The CO_2 vent use is limited to 504 hours/year.
- The nitric acid unit and the urea pastillation unit are assumed to operate 8,052 hours per year.
- The ammonium nitrate unit is assumed to operate 8,000 hours per year.
- The ammonia startup heater is assumed to operate 140 hours per year at full capacity.
- Feedstock, urea, and gasification solids materials handling would occur from 1,248 to 8,760 hours per year depending on the specific material handling source (there are 18 separate sources with emissions calculations). The emissions estimate provided is for the solids material handling associated with Transportation Alternative 1, which forms the permitted emissions basis for the project that Alternative 2 would also have to achieve.
- Fugitive emissions are assumed to occur 8,760 hours per year.

OEHI CO_2 EOR COMPONENT

The OEHI CO_2 EOR component is considered part of the whole of the project proposed. This subsection provides information on the air pollutant emissions sources and the current emission source estimates for the OEHI CO_2 EOR component. It should be noted that the OEHI CO_2 EOR component is expected to be evaluated in a separate CEQA document and will require a separate District air quality permitting action sometime after a decision is made on HECA by the Energy Commission. All of the information presented at this time on the OEHI CO_2 EOR component is preliminary and subject to change during those later formal regulatory evaluations.

Construction

Construction of the OEHI CO_2 EOR component would include the initial stationary facility construction and ongoing well drilling and construction requirements for moving the injection/production well grids over time, so construction occurs throughout the assumed 20-year CO_2 injection project life. The maximum annual and total estimated construction emissions during the 20-year construction period for the OEHI CO_2 EOR component are provided in **Air Quality Table 18**.

Air Quality Table 18
Total Estimated OEHI CO_2 EOR Component Construction Emissions, tons

	NOx	CO	SOx	VOC	PM10	PM2.5
Maximum Tons per Year [a]	59.11	47.62	0.06	2.39	6.68	6.68
Total (20-year period)	418.87	352.44	0.48	19.70	47.18	47.18
Annual Average (tons/year)	20.94	17.62	0.02	0.98	2.36	2.36

Source: HECA 2012s
Notes:
a. The maximum emissions for the criteria pollutants occur in different horizon years. The maximum emissions for NOx, VOC, CO and SOx are estimated to occur in 2023, while the maximum emission for PM10/PM2.5 is estimate to occur in 2015.

Operation

Air pollutant emissions during operation would occur from three general categories: permitted stationary sources, other stationary activities, and mobile sources. The operating emissions sources are described as follows:

CO_2 Injection Heater

The natural gas fired CO_2 injection heater would be used to maintain desired operating temperatures.

Triethlylene Glycol (TEG) Reboiler

The natural gas fired triethlylene glycol (TEG) reboiler would be used to dehydrate the recovered gases to the CO_2 water content specification. This early dehydration step would allow for the use of standard carbon steel material throughout the reinjection compression facility.

Amine Unit

The amine unit would remove the CO_2 and the sulfur compounds and would contain the natural gas fired nitrogen reinjection unit (NRU) heater.

Regeneration Gas Heater

The regeneration gas heater would be used to heat up the regeneration gas from the molecular sieve bed where the gas would be dehydrated to prevent ice or hydrate formation in the cold sections of the fractionation system.

Flares

OEHI proposes to use flares for the Central Tank Battery (CTB) and the Reinjection Compression Facility (RCF). These intermittent sources would operate only a few hours per year and would primarily have combustion emissions from the natural gas flame pilot gas.

Fire Pump Engines

The project is proposing two fire pump engines (175 hp each), one associated with the CTB and one associated with the RCF. The primary emissions from the fire pump engines would occur from diesel fuel combustion during routine readiness testing.

Fugitive and Tank Emissions

Fugitive emissions of VOC would occur due to minor leaks in the piping components and venting losses from storage tanks that service gases and liquids with a VOC content.

The maximum annual operating emissions for the OEHI CO_2 EOR component are provided in **Air Quality Table 19**.

The emissions presented above in **Air Quality Table 19** are based on the maximum CO_2 recycle rate identified by OEHI (685 MMscfd) based on OEHI's current estimates for the permitted and other expected emission sources but do not include emissions from upset flaring events.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Energy Commission staff assesses four kinds of primary and secondary[9] impacts: construction, operation, closure and decommissioning, and cumulative. Construction impacts result from the onsite and offsite emissions occurring during site preparation and construction of the proposed project. Operation impacts result from the emissions of the proposed project during operation, which include all of the onsite equipment emissions (gas turbine, auxiliary boiler, flares, cooling towers, emergency engines, etc.), the onsite maintenance vehicle emissions, and the offsite employee and fuel delivery trip emissions. Closure and decommissioning impacts occur from the onsite and offsite emissions that would result from dismantling the facility and restoring the site. Cumulative impacts analysis assesses the impacts that result from the proposed project's incremental effect viewed over time, together with other closely related past, present, and reasonably foreseeable future projects whose impacts may compound or increase the incremental effect of the proposed project. (Pub. Resources Code § 21083; Cal. Code Regs., tit. 14, §§ 15064(h), 15065(c), 15130, and 15355.)

METHOD AND THRESHOLD FOR DETERMINING SIGNIFICANCE

As discussed in the Introduction, this document analyzes the project's impacts pursuant to both NEPA and CEQA. The two statutes are similar in their requirements concerning analysis of a project's impacts. Therefore, unless otherwise noted, staff's use of, and reference to, CEQA criteria and guidelines also encompasses and satisfies NEPA requirements for this environmental document.

Energy Commission staff evaluates potential impacts per Appendix G of the CEQA Guidelines (AEP 2012). A significant adverse impact is determined to occur if potentially significant impacts cannot be mitigated through the adoption of conditions of certification. Specifically, Energy Commission staff uses health-based ambient air quality standards (AAQS) established by the ARB and the U.S. EPA as a basis for determining whether a project's emissions will cause a significant adverse impact under CEQA. The ambient air quality standards are set at levels that include a margin of safety and are designed to adequately protect the health of all members of the public, including those most sensitive to adverse air quality impacts such as the aged, people with existing illnesses, children, and infants. Staff evaluates the potential for significant adverse air quality impacts by assessing whether the project's emissions of criteria pollutants and their precursors (NOx, VOC, PM10 and SO_2) could create a new AAQS exceedance (emission concentrations above the standard), or substantially contribute to an existing AAQS exceedance.

Staff evaluates both direct and cumulative impacts. Staff will find that a project or activity will create a direct adverse impact when it causes an exceedance of an AAQS. Staff will find that a project's effects are cumulatively considerable when the project emissions in conjunction with ambient background, or in conjunction with reasonably foreseeable future projects, substantially contribute to ongoing exceedances of an

[9] Primary impacts potentially result from facility emissions of NOx, SOx, CO and PM10/PM2.5. Secondary impacts result from air contaminants that are not directly emitted by the facility but formed through reactions in the atmosphere that result in ozone, and secondary formation of PM10/PM2.5.

AAQS. Factors considered in determining whether contributions to ongoing exceedances are substantial include:

1. the duration of the activity causing adverse air quality impacts;

2. the magnitude of the project emissions, and their contribution to the air basin's emission inventory and future emission budgets established to maintain or attain compliance with AAQS;

3. the location of the project site, i.e., whether it is located in an area with generally good air quality where non-attainment of any ambient air quality standard is primarily or solely due to pollutant transport from other air basins;

4. the meteorological conditions and timing of the project impacts, i.e., do the project's maximum modeled pollutant impacts occur when ambient concentrations are high (such as during high wind periods, or seasonally);

5. the modeling methods, and how refined or conservative the impact analysis modeling methods and assumptions were and how that may affect the determined adverse impacts;

6. the project site location and nearest receptor locations; and whether the identified adverse impacts would also occur at the maximum impacted receptor location; and,

7. the potential for future cumulative impacts; and whether appropriate mitigation is being recommended to address the potential for impacts associated with likely future projects.

DIRECT/INDIRECT IMPACTS AND MITIGATION - HECA

The estimated project emissions represent the mass of pollutants emitted from the project, whereas the impacts are the concentration of pollutants from the project that reach the ground level. Total project emissions are a compilation of the emissions released from all the different emission points. When pollutants are released they are then subject to different physical and chemical forces that affect the way the pollutant travels through the atmosphere. For example, emissions that are expelled at high temperatures and velocity through relatively tall stacks will be significantly diluted by the time they reach ground level. The emissions from the proposed project are analyzed through the use of air dispersion models to determine the probable impacts at ground level.

Air dispersion models provide a means of predicting the location and ground level magnitude of the impacts of a new emissions source. These models consist of several complex series of mathematical equations, which are repeatedly calculated by a computer for many ambient conditions to provide theoretical maximum offsite pollutant concentrations for short-term (1-hour, 3-hour, 8-hour, and 24-hour) and annual periods. The model results are generally described as maximum concentrations, often described as a unit of mass per volume of air, such as micrograms per cubic meter ($\mu g/m^3$).

The applicant is required to use air dispersion modeling to demonstrate compliance with all CAAQS and NAAQS. The required analysis is determined by the attainment status of the project region and the expected annual emissions from the project. Modeling protocols were submitted by the applicant to the Energy Commission, SJVAPCD and U.S. EPA Region IX prior to the submittal of the AFC.

SJVAPCD District Rule 2201, NSR, requires an analysis of the impacts on ambient air quality from a new project. Any project that triggers public notice must include an analysis for all project units. Air quality modeling is used to demonstrate a project's regulated air pollutants would not cause or contribute to a violation of the applicable NAAQS or CAAQS. The analysis includes the impacts of the project in addition to the representative background concentrations of the regulated pollutants for all regulated criteria pollutants regardless of the attainment status. SJVAPCD can take into consideration mitigation of emissions through offsets when making the determination of compliance with the AAQS; however HECA did not take any credit for emission offsets in their modeling analysis.

SJVAPCD District Rule 2410, PSD, requires impacts on ambient air quality from a new PSD Major Stationary Source be examined. PSD requirements are applicable to major sources in areas that are designated in attainment of NAAQS. PSD for the project is triggered for CO, NO_2, PM10 and CO_2 however there are no NAAQS for CO_2. Therefore the applicable air pollutants for this demonstration are CO, NO_2 and PM10. Modeling is required to demonstrate that the facility's applicable air pollutant emissions will not cause or contribute to a violation of the applicable NAAQS, PSD increments, air quality related values (AQRV), visibility and soil and vegetation degradation.

For the PSD NAAQS compliance demonstration, a project's impacts can be compared to significant impact levels (SILs) established by U.S. EPA to determine if the project will cause or contribute to a NAAQS violation. SILs are screening tools used to determine whether a proposed source's emissions will have a significant impact on the ambient air quality in a region. A facility's air quality impacts are determined to be insignificant if the impacts are less than the corresponding SIL. More comprehensive, cumulative modeling analysis is not required for emission impacts below the corresponding SIL. Only stationary sources are included for comparison to the SILs.

The Energy Commission requires modeling for both the construction and operational phases of the project for compliance with CEQA. The modeling performed for the operational phase includes emissions from stationary sources, in addition to exhaust and fugitive dust from mobile sources that would be part of normal facility operations. Mobile sources include feedstock delivery, shipment of products, operations, and maintenance. The EMFAC 2007 model developed by CARB was used to calculate the emission rates from on-road vehicles. The EMFAC 2007 model is used instead of the updated EMFAC2011 model because the project is subject to NEPA as well as CEQA and EMFAC2011 has not yet been approved for federal projects. For CEQA compliance, project impacts in addition to representative background data are compared to the CAAQS.

Per U.S. EPA and SJVAPCD guidance, all modeling performed for PSD and NAAQS compliance includes permitted source emissions and does not include emissions from mobile sources. However, for CEQA compliance all modeling for compliance with CAAQS includes both the permitted source emissions and mobile source emissions.

The permitted sources are modeled using maximum potential emission rates from either normal or startup/shutdown operations to demonstrate compliance for all CAAQS and NAAQS with the exception of the NO_2 and SO_2 1-hour NAAQS modeling analysis. The applicant predicted NO_2 1-hour impacts from the project to be over the SIL. Therefore, a refined analysis was performed to demonstrate compliance with the NO_2 1-hour NAAQS. This refined analysis is a cumulative analysis that includes HECA's stationary sources and 371 existing permitted units within a 10 kilometer radius of the project site. In-stack NO_2/NOx ratios were developed for all of the HECA emissions sources and the cumulative emissions units using available regulatory guidance, and were approved by the SJVAPCD.

The applicant used the U.S. EPA guideline ARMS/EPA Regulatory Model (AERMOD) to estimate ambient impacts from project construction, commissioning and operation to demonstrate compliance with all CAAQS and NAAQS. AERMOD is able to model emission plumes from multiple point, area, or volume sources in flat, simple, and complex terrain using hourly meteorological data. The inputs to the model include stack information (exhaust flow rate, temperature, and stack dimensions), specific source emission data, meteorological data (wind speed and atmospheric conditions), and site elevation. The meteorological data used for the model included hourly wind speeds and directions measured at the Bakersfield Airport meteorological station from 2006 to 2010, located within 20 miles of the project site to the east northeast.

Emission sources from construction and operation were modeled as both point and area sources. The construction emission sources for the site were grouped into two categories: equipment (off-road equipment); and vehicles (on-road equipment). Emissions from the exhaust and fugitive dust for each group were calculated and impacts were modeled. The equipment exhausts were modeled as point sources and fugitive dust emissions were modeled as areas sources. Similar modeling procedures were used by the applicant to determine impacts from the operating emissions stationary sources, maintenance vehicle exhaust, and fugitive dust emissions.

For the determination of one-hour average and annual average construction, commissioning and annual operational NOx concentrations, the Plume Volume Molar Ratio Method (PVMRM) was used to determine worst-case near field NO_2 impacts. The NOx emissions from internal combustion sources, such as diesel engines, are primarily in the form of nitric oxide (NO) rather than NO_2. NO converts into NO_2 in the atmosphere, primarily through the reaction with ambient ozone. The PVMRM option determines the conversion rate for NO to NO_2 based on a calculation of the NO moles emitted into the plume and the amount of ozone moles contained within the volume of the plume.

Hourly meteorological data, hourly ozone data and in-stack NO_2/NOx ratios are required to conduct a PVMRM modeling analysis. The applicant obtained the meteorological data and hourly ozone data from SJVAPCD, and confirmed appropriate in-stack NO_2/NOx ratios through correspondence with SJVAPCD. The development of appropriate in-stack NO_2/NOx ratios is an ongoing science, with new information and understanding being developed over time. The default value was formerly 0.1; however, U.S. EPA has raised the default in-stack NO_2/NOx ratio to 0.5[10]. The use of other ratios is allowed by U.S. EPA if those values can be justified. The applicant has used in-stack NO_2/NOx ratios that range from 0.1 to 0.5 depending on the emissions source (HECA 2012e, Appendix E-7). Staff's review of the proposed in-stack NO_2/NOx ratios did not find any significant issues with the values used for the HECA emissions sources and, as noted above, these ratios were approved by the SJVAPCD.

The applicant followed U.S. EPA and SJVAPCD modeling guidelines in their air dispersion modeling analysis. The land immediately adjacent to the project site within approximately 2 miles is classified as rural. Therefore the AERMOD rural mode was used in the analysis. In addition, all HECA exhaust stacks would be less than or equal to the good engineering practice (GEP) default height of 65 meters except for the coal dryer, SRU Flare and CO_2 Vent. The actual coal dryer, CO_2 vent stacks and flare stacks are below the calculated GEP height values for these stacks. The stack heights of the flares used in the modeling were calculated based off of the GEP default height of 65 meters.

The applicant performed screening modeling with maximum emissions and conservative stack parameters in order to determine conservative worst case off-site impacts. The modeling assumed maximum emissions from each source regardless of whether the equipment modeled would actually be operating at these maximum conditions simultaneously. This methodology was used in order to determine conservative impacts without having to perform sensitivity modeling for each piece of equipment. Sensitivity modeling describes a more refined modeling that takes into account the actual operating parameters of the equipment and sequencing rather than using worst-case parameters and scenarios that may not represent actual operation. If the most conservative impact scenario complies with the AAQS then more in-depth modeling is not needed. Therefore if modeling assumes simultaneous worst case operations from all equipment and complies with the AAQS, then modeling using more realistic operating parameters and emissions is not needed to demonstrate compliance.

Staff reviewed the background concentrations provided by the applicant, replacing them where appropriate with the available highest ambient background concentrations from the last three years (2009 through 2011) at the most representative monitoring stations as shown in **Air Quality Table 6**. Staff's background data are different than the background values identified by the applicant for all pollutants except 1-hour NO_2, 1-hour SO_2, and 24-hour SO_2. The primary reason for the difference in background concentrations is that the applicant used background concentrations from 2008 through 2010 to determine background, while staff is using more recent background data that became available after the applicant completed their analysis. Staff added the modeled impacts to these background concentrations and then compared the results with the ambient air quality standards for each respective air contaminant to determine whether the proposed project's emission impacts would cause a new exceedance of an ambient air quality standard or would contribute to an existing exceedance.

[10] Higher in-stack NO_2/NOx ratios result in higher modeled impacts. Therefore, it is important not to underestimate these ratios when performing refined modeling analyses that use these in-stack ratios.

For construction emissions, the mitigation that is considered is limited to controlling both construction equipment tailpipe emissions and fugitive dust emissions to the maximum extent feasible. For operating emissions, the mitigation considered includes both feasible emission controls called best available control technology (BACT) and the use of emission reduction credits (ERCs) to offset emissions of nonattainment criteria pollutants and their precursors.

The following sections discuss the proposed project's short-term direct construction and operation ambient air quality impacts as estimated by the applicant, and describes appropriate mitigation measures.

Construction Impacts and Mitigation

Construction Modeling Analysis

The applicant modeled the construction emissions of the proposed project and evaluated the impacts within 10 kilometers using AERMOD (version 12060). Fugitive dust emissions from vehicles, on-site equipment and earthmoving equipment are modeled as area sources. Combustion exhaust emissions from vehicles and other on-site equipment are modeled as a series of point sources. The PVMRM option in AERMOD was used to determine NO_2 impacts. Data from the Shafter-Walker Street monitoring station was used to provide the hourly ozone concentration data used by the model. An initial in-stack NO_2/NOx ratio of 0.11 was assumed for the diesel-fueled construction equipment and heavy duty diesel truck NOx emissions and an initial NO_2/NOx ratio of 0.25 was assumed for the worker vehicle NOx emissions[11].

To determine the construction impacts on short-term ambient standards (i.e. 1-hour through 24 hours) the worst-case daily on-site construction emission levels shown in **Air Quality Table 8** were modeled. For pollutants with annual average ambient standards, the applicant used the summation of overall construction activities for the consecutive 12-month period that would produce the highest emissions of all pollutants. Modeling assumed that all of the equipment would operate 10 hours, from 6 am to 4 pm, daily. **Air Quality Table 20** provides the results of this modeling analysis of construction impacts.

The applicant's modeling results indicate that the project's construction impacts would not create violations of NO_2, SO_2 or CO standards, but could further exacerbate existing violations of the PM10 and PM2.5 standards. In light of the existing PM10 and PM2.5 nonattainment status for the project site area, staff considers the modeled impacts of PM and PM precursors to be significant and, therefore, require mitigation.

[11] These in-stack NO_2/NOx ratios are CAPCOA recommended values (CAPCOA 2011) for on-road heavy duty diesel trucks (0.11) and on-road light and medium duty gasoline vehicles (0.25), respectively. Staff notes that the applicant also used the 0.11 ratio for the off-road diesel equipment, although the CAPCOA recommendations for off-road equipment are either a default value of 0.2, or a value of 0.1564 presented for a 322 horsepower water pump. Staff may re-run the 1-hour NO_2 modeling analysis using the higher CAPCOA default off-road diesel equipment NO_2/NOx ratio, and if so will present those modeling results in the FSA.

[a] Background values have been adjusted per staff recommended background concentrations shown in **AIR QUALITY Table 5**.
[b] Results for NO_2 during construction used PVMRM with ambient ozone data.
[c] U.S. EPA does not require evaluation of NAAQS for short-term impacts such as construction. Therefore, the 1-hour NO_2 and SO_2 construction impacts are compared to the 1-hour CAAQS standards. The PM2.5 24-hour modeled impact results compared against the NAAQS are shown only for informational purposes.

Construction Mitigation

As described in the “Laws, Ordinances, Regulations, and Standards” section, District Regulation VIII (i.e. Series 8000) limits fugitive dust emissions during the construction phase of a project. Staff recommends that construction emission impacts be mitigated to the greatest feasible extent including all feasible measures from the LORS, as well as other measures considered necessary by staff to fully mitigate the construction emissions.

Applicant’s Proposed Mitigation

The applicant has proposed the following emissions mitigation measures during construction (HECA 2012e).

Fugitive Dust Emissions Mitigation (applicant proposed measure AIR-1)

- Stabilize the main access roads through the facility with crushed rock or gravel for dust control;
- Use either water application, chemical dust suppressant application, or other suppression technique to control dust emissions from on-site unpaved road travel and unpaved parking areas;
- Cover all trucks hauling soil, sand, and other loose materials or require all such trucks to maintain at least two feet of freeboard;
- Limit traffic speeds on all unpaved site areas to 15 miles per hour;
- Install sandbags or other erosion control measures to prevent silt runoff to roadways;
- Replant vegetation in disturbed areas as quickly as possible;

- Inspect and wash as necessary vehicle tires prior to exiting construction site onto paved roadways; and
- Mitigate fugitive dust emissions from wind erosion on areas disturbed by construction activities (including storage piles) by application of either water, chemical dust suppressant, or other suppression techniques.

Exhaust Emissions Mitigation (applicant proposed measure AIR-2)

- Properly maintain and tune engines to the engine manufacturer's specifications;
- Limit the engine idle time to no more than five minutes for heavy diesel construction equipment that does not need to idle as part of their normal operation;
- Use low sulfur and low aromatic fuel meeting California standards for motor vehicle diesel; and
- Use low-emitting gas and diesel engines meeting state and federal emissions standards (Tiers 2 and 3) for construction diesel engines with a rating of 50 horsepower or higher.

The applicant's construction emissions estimates in **Air Quality Tables 8** and **9** and construction modeling results in **Air Quality Table 20** include the effect of all of the emissions reduction measures noted above except the use of higher tier off-road engines. The off-road equipment emission estimates were based on the OFFROAD model's fleet average emission factors for Kern County in 2013, which includes some lower tier (i.e., higher emitting) engines.

Adequacy of Proposed Mitigation

The applicant's fugitive dust emission mitigation measures are not as comprehensive or as restrictive as they could be to control fugitive dust emission from all activities during construction. For example the applicant's proposed measure doesn't have street sweeping requirements, doesn't restrict speed to be as low as possible on unpaved roads, doesn't require paving of the onsite roads as soon as possible, and has no compliance assurance requirements. Staff believes that all reasonable construction emission mitigation measures with adequate compliance assurance measures should be implemented to mitigate the potentially significant construction PM10 and PM2.5 impacts.

The applicant's proposed off-road engine emissions mitigation is very similar to the mitigation measure that staff has recommended in the past, particularly in terms of required off-road engine tier requirements. However, staff updates its engine mitigation measure periodically to include higher off-road engine tier requirements as reasonable based on the dates when higher engine tier standards become effective for new model year engines. Staff considers the applicant's engine emissions mitigation to be a bit dated, and based on engine availability it does not provide adequate ozone precursor (NOx and VOC) and diesel particulate matter (DPM) mitigation.

Staff Proposed Mitigation

Staff is recommending construction emissions mitigation measures that are more stringent than those proposed by the applicant. However, staff's proposed measures do not include certain emission reduction measures (such as use of ARB low sulfur diesel) that are explicitly required already by existing state regulations. Staff's recommended Conditions of Certification **AQ-SC1** through **AQ-SC5** include several additional or more stringent construction fugitive dust PM10 emission mitigation measures and more stringent off-road equipment mitigation to assure maximum feasible fugitive dust control performance and construction equipment exhaust emissions control, as well as adding compliance assurance requirements.

Staff recommends **AQ-SC1** to require the applicant to have an onsite construction mitigation manager who would be responsible for the implementation and compliance of the construction mitigation program. The documentation of the ongoing implementation and compliance with the construction mitigation program would be provided in the monthly construction compliance report that is required in staff's recommended Condition of Certification **AQ-SC2**.

Staff incorporated and augmented the applicant's proposed fugitive dust mitigation measures and recommends that the fugitive dust mitigation measures be formalized in Condition of Certification **AQ-SC3**. **AQ-SC3** includes several additional mitigation measures to control fugitive dust emissions and requires that District Regulation VIII rule requirements apply when they are more stringent.

Staff recommends Condition of Certification **AQ-SC4** to require visible dust plume response requirements that would limit the potential offsite impacts from visible dust emissions from the construction activities.

Staff recommends Condition of Certification **AQ-SC5** to require the use of new off-road equipment that would meet the highest level of emissions reductions available for the engine family of the equipment being used by requiring the use of the latest available U.S. EPA/ARB Tier level including Tier 4 or Tier 4i engines or when Tier 4 engines are not available requiring add-on emissions controls where feasible, which would significantly reduce the NOx and diesel particulate emissions from off-road equipment.

Based on the relatively short-term nature of the worst-case construction impacts, which would occur during the initial grading phase of the first few months of construction, and staff's recommendation of requiring all feasible construction emission mitigation measures, staff believes that the construction air quality impacts would be less than significant with the implementation of staff-recommended mitigation measures contained in the conditions of certification.

Operation Impacts and Mitigation

The following section discusses the project's direct ambient air quality impacts as estimated by the applicant and evaluated by staff. Additionally, this section discusses the recommended mitigation measures.

Operational Modeling Analysis

The applicant performed direct impact modeling analyses, including normal operations, fumigation (see text below for definition), and initial commissioning impact modeling.

A refined dispersion modeling analysis was performed to identify off-site criteria pollutant impacts that would occur from routine operational emissions throughout the life of the project. This impact analysis includes both maximum operating and startup/shutdown scenarios to determine worst-case air quality impacts on both a short-term and an annual basis. The operating profiles are shown in **Air Quality Table 11** to **Air Quality Table 17**. These conditions were modeled to determine the worst case short term impacts. The predicted maximum concentrations of these pollutants are summarized in **Air Quality Table 21**.

Air Quality Table 21
HECA Operating Impacts, (µg/m³)

Pollutant	Averaging Period	Project Impact (µg/m³)	Background (µg/m³) [a]	Total Impact (µg/m³)	Limiting Standard (µg/m³)	Type of Standard	Percent of Standard
NO_2	1 hour state	185	140	325	339	CAAQS	96%
	1 hour fed	-- [c]	83.3 [b]	126 [c]	188	NAAQS	67%
	Annual state	1.5	24.7	26.1	57	CAAQS	46%
	Annual fed [d]	0.6	24.7	25.3	100	NAAQS	25%

Source: HECA 2012d, HECA 2012e
[a] Background values have been adjusted per staff recommended background concentrations shown in **Air Quality Table 6**.
[b] The background is provided for informational purposes only as it is a statistical background that cannot be directly added to determine impacts for this standard.
[c] The project impacts and hourly NO_2 background values are a combined, or paired, cumulative modeling analysis which predicts the total cumulative impacts of the project's emissions sources and the other 371 cumulative permit units within 10 kilometers of the project site that were included in the modeling analysis based on the statistical 98th percentile of the maximum daily 1-hour values.
[d] The difference between the state and federal impacts are that the state impacts include mobile source emissions.
[e] This provides an addition of the 99th percentile background plus the maximum hourly facility impact, which overstates a combined, or paired, 99th percentile value. However, this conservative approach clearly shows compliance with the NAAQS.

The applicant's modeling results combined with staff-recommended background concentrations indicate that the project's normal operational impacts would not create violations of the NO_2, SO_2 or CO standards. Results indicate the project could further exacerbate existing violations of the PM10 and PM2.5 standards. In light of the existing PM10 and PM2.5 nonattainment status for the project site area, staff considers the modeled impacts of PM and PM precursors to be significant and, therefore, require mitigation.

Fumigation Modeling Impact Analysis

Fumigation describes a meteorological condition where a plume is released below an inversion layer. Plume pollutants can be rapidly transported to ground-level during these conditions as the inversion layer begins to become unstable. High, short-term concentrations may potentially occur during fumigation conditions. In the early morning hours before sunrise, the air is usually very stable. During stable meteorological conditions, emissions from elevated stacks rise through the stable layer and are dispersed aloft. When the sun first rises, the air at ground level is heated, resulting in a vertical mixing of air. Stack emissions entering this vertically mixed layer of air will also be vertically mixed, resulting in a transport of emissions down to ground level. Later in the day, as the sun continues to heat the ground, this vertical mixing layer becomes higher and higher, allowing emissions plumes to disperse. The early morning fumigation event is a transitory condition usually lasting approximately 30 to 90 minutes.

A fumigation analysis was performed using U.S. EPA model SCREEN3. Due to the transitory nature of fumigation, a given receptor may only be impacted for a brief time. Therefore hourly impact model predictions are used for fumigation modeling. The applicant analyzed the maximum one-hour air quality impacts under fumigation conditions from the CTGs/HRSG unit, coal dryer, tail-gas thermal oxidizer and nitric acid plant. The results of the analysis, as shown in **Air Quality Table 22**, indicate that the maximum one-hour fumigation impacts would be lower than the maximum operating emission impacts under normal meteorological conditions, as shown above in **Air Quality Table 21**.

Air Quality Table 22
Maximum HECA Fumigation Impacts, (μg/m³)

Pollutant	Averaging Period	Project Impact (μg/m³)	Background (μg/m³) [a]	Total Impact (μg/m³)	Limiting Standard (μg/m³)	Type of Standard	Percent of Standard
NO_2	1 hour	42.9	140	183	339	CAAQS	54%
SO_2	1 hour	2.7	42	45	655	CAAQS	7%
CO	1 hour	282	4,025	4,307	23,000	CAAQS	19%

[a] Background values have been adjusted per staff recommended background concentrations shown in **Air Quality Table 6**.

Initial Commissioning Short-Term Modeling Impact Analysis

The applicant modeled the commissioning emissions to determine worst-case short-term operating impacts for the project. Emissions from individual pieces of equipment during initial commissioning can be significantly higher than normal operations. For example, the maximum hourly emissions of NOx and CO from the CTG/HRSG are elevated during certain initial commissioning steps. However, there would be limited pieces of equipment operating during each commissioning step, so the resulting total project impacts during commissioning may or may not be greater than those that would occur under normal operations. The applicant presented several initial commissioning scenarios that represent worst-case emission combinations that could occur prior to meeting normal emission limits. The scenarios analyzed are described below as labeled by the applicant.

- Case 1: Modeling analysis for SO_2 (1-hour and 24-hour), NO_2 (1-hour), CO (1-hour and 8-hour) and PM10 (24-hour) for testing of either of the emergency diesel generator engines while cooling tower is at reduced or no load. This occurs early in the commissioning sequence during utility and support system commissioning.
- Case A: Modeling analysis for CO only during initial first fire operation of the combustion turbine on natural gas at 20 percent load prior to the operation of the SCR and oxidation catalyst. The power block cooling tower is also operating at a reduced load during this scenario.
- Case B: Modeling analysis for SO_2 and NO_2 during tuning the water injection rates, operation of the combustion turbine on natural gas at 80 percent load prior to the operation of the SCR and oxidation catalyst.
- Case A2: Modeling NO_2, CO and PM10 during initial operation of the gasifier at 50 percent load while flaring sweet unshifted syngas in the gasification flare. The HRSG and coal dyer would be operated on natural gas at 80 percent load, operation of the three cooling towers and the tail gas thermal oxidizer.
- Case B2: Modeling of SO_2 during late in the start-up sequence when shifted syngas is sent to the gasification flare while all three cooling towers are operational. This scenario anticipates a brief excursion in the SO_2 emissions from the tail gas thermal oxidizer before the tail gas is recycled to the shift converters.
- Case C2: Modeling CO during gasifier operation at 50 percent load while flaring hydrogen-rich fuel gas in the gasification flare. This occurs during the transition period prior to the gas turbine switching to hydrogen rich fuel and CO_2 is vented prior to the CO_2 compressor being ready to send CO_2 to OEHI. Power block operation is at 80 percent load fired on natural gas; thermal oxidizer and cooling towers are operational.
- Case D2: Modeling NO_2 during gasifier operation at 50 percent load while commissioning the PSA unit. Hydrogen rich gas and off-gas is sent to the gasification flare, CO_2 is being sent offsite, power block operation is at 80 percent load fired on natural gas, the thermal oxidizer and all three cooling towers are operational.
- Case E2: Modeling NO_2 and CO during gasifier operation at 50 percent load and gas turbine operation at 40 percent load with surplus hydrogen rich fuel being sent to the gasification flare. This follows the turbine transition from natural gas to hydrogen rich gas. CO_2 may be vented during this period; thermal oxidizer and all three cooling towers are operational.
- Case A3: Modeling was not analyzed for this scenario because all the pollutants are overlapped or covered in other scenarios. The scenario included the commissioning of the ammonia and urea units when hydrogen is flared and purified CO_2 is vented prior to the conversion to products. The gasification block, thermal oxidizer and all three cooling towers are operational, and power block operation is at 100 percent load fired on hydrogen-rich gas.
- Case B3: Modeling SO_2, NO_2 and CO under Case A3 with the ammonia synthesis start-up heater operating.

- Case C3: Modeling NO_2 and PM10 during commissioning of the nitric acid unit. The gasification block, ammonia and urea units, three cooling towers and thermal oxidizer are operational. Power block operation is at 100 percent load fired on hydrogen-rich fuel.

These emission scenarios were modeled using the AERMOD model to determine maximum commission impacts. The modeling conducted does not include any overlap from construction activities. Since the commissioning operations are limited term activities, impacts are not compared to the federal NO_2 and SO_2 1-hour standards which are based on long-term statistical averaging periods. The results of the commissioning emissions modeling analysis are shown in **Air Quality Table 23.** As shown in the table below, the worst-case emissions would not cause an exceedance of the one-hour NO_2 standard or the one-hour and eight-hour CO standards. Therefore, the modeling results indicate that the commissioning emissions, and by comparison the startup emission impacts, do not have the potential to cause significant short-term ambient air quality impacts.

Air Quality Table 23
Maximum HECA Initial Commissioning Impacts

Pollutant	Averaging Period	Project Impact ($\mu g/m^3$)	Background ($\mu g/m^3$) [a]	Total Impact ($\mu g/m^3$)	Limiting Standard ($\mu g/m^3$)	Type of Standard	Percent of Standard
CO (Case A)	1 hour	1,975	4,025	6,000	23,000	CAAQS	26%
	8 hour	801	2,411	3,212	10,000	CAAQS	32%
NO_2 (Case B)	1 hour	150	140	290	339	CAAQS	86%
PM10 (Case A2)	24-hour	3.4	238	241	50	CAAQS	483%
SO_2 (Case B2)	1 hour	97.4	42	139	655	CAAQS	21%
	3 hour	37.5	24	62	1300	NAAQS	5%
	24 hour	7.5	13	21	105	CAAQS	20%

Source: HECA 2012d, HECA 2012e
[a] Background values have been adjusted per staff recommended background concentrations shown in **Air Quality Table 6**.

Odor Impacts

HECA would emit several substances in high enough concentrations that they could possibly cause offensive odors. Specifically, the substances of concern for HECA would be hydrogen sulfide (H_2S), carbonyl sulfide (COS), carbon disulfide (CS_2), and ammonia (NH_3). The project would also have minimal emissions of a few other odorous compounds (acetaldehyde, naphthalene, phenol); however, given their emission levels, odor thresholds, and release/dispersion characteristics, staff concludes that no adverse odor impacts are likely to occur from these other substances. The applicant modeled H_2S emissions to determine the potential for H_2S odor impacts. This substance has a higher emissions rate and a lower odor threshold than the other reduced sulfur compounds so it provides a worst-case odor potential of the reduced sulfur compounds.

The odor thresholds for the four substances of concern are as follows:

Odorous Compound	Odor Threshold
Hydrogen sulfide	0.0005 ppm

Carbon disulfide	0.0081 ppm
Carbonyl sulfide	0.1 ppm
Ammonia	17 ppm

The applicant completed modeling to determine the maximum concentration of H_2S beyond the property fence line. This modeling showed that the concentrations predicted were less than the CAAQS, which is approximately the mean odor threshold. The modeling results showed a worst-case hourly impact of 23 $\mu g/m^3$ versus the 1-hour CAAQS of 42 $\mu g/m^3$ (0.03 ppm).

Staff believes that the use of 1-hour average concentrations for odor impact determination is problematic because odor impacts can occur over a much shorter duration than a 1-hour period with concentrations above the odor threshold for a short period even if the impact is below the mean odor threshold when averaged over a full hour. Additionally, the H_2S odor threshold for sensitive individuals is much lower than the mean odor threshold (i.e., the 0.0005 ppm lower odor threshold for H_2S identified above is much lower than 0.03 ppm mean odor threshold used to set the CAAQS). Therefore, staff believes that there is the potential for H_2S odors from HECA emissions sources to be perceived beyond the fence line. It is very important to note that there is a difference between perceiving an odor and for that odor to become a public nuisance. While staff does not believe that the H_2S CAAQS provides a clear demarcation for perceiving H_2S odors, we acknowledge that ARB's stated purpose for this standard is to protect public health and to significantly reduce odor annoyance. Additionally, the potential for public exposure to these concentrations is limited given the low population immediately surrounding the project site. Therefore, while staff believes that H_2S odors may be able to be perceived beyond the fence line during worst-case meteorological conditions, these odors per the CEQA Guidelines Appendix G part III. Air Quality e) are not likely to "create objectionable odors affecting a substantial number of people" and thus they are not likely to be significant problematic odors.

Comparing the odor thresholds and the emissions (see the Public Health Table 6) of the other reduced sulfur compounds with H_2S, staff concludes that there is not likely to be adverse odor impacts from the normal operating emissions of CS_2 and COS.

Ammonia would be emitted in much higher quantities than the reduced sulfur compounds, but it also has a much higher odor threshold. Ammonia emissions from the stationary and fugitive sources were included in the Health Risk Assessment (HRA) modeling for the project, which is presented in the **Public Health** section of the DEIS/PSA. The Office of Environmental Health Hazard Assessment acute reference exposure level for ammonia is lower than the odor detection threshold for ammonia (3,200 $\mu g/m^3$, or 4.6 ppm), and staff found that the maximum concentrations under normal operations were well below the acute reference exposure level. Therefore, ammonia concentrations from the HECA emissions sources would be well below the odor detection level and would not be detectable under normal operating conditions.

In conclusion, while staff believes that during normal operations HECA would not create odor impacts that would create a public nuisance, there is the potential for H_2S odors to be perceived beyond the fence line. Additionally, there would be the potential for odor impacts during equipment upset events. However, HECA would be required to correct equipment upsets expeditiously in compliance SJVAPCD rules and regulations.

Air Quality Related Values (AQRVs)

The analysis of air quality related values (AQRVs) concerns impacts to resources that are sensitive to air pollution, and includes the analysis of impacts to soils and vegetation and visibility. The Federal Land Manager (the representative of the agency of jurisdiction) reviewed the applicant's initial emissions over distance (Q/d) analysis and determined that the project would have less than significant impacts for all AQRVs (HECA 2012q). However, the applicant completed analysis related to impacts to soils and vegetation and visibility per the request of U.S. EPA Region 9. Each is described next.

Soils and Vegetation

A soils and vegetation impact analysis is required under the federal Prevention of Significant Deterioration (PSD) permitting program. The analysis includes both a screening analysis to determine if maximum modeled ground-level concentrations of the project impact plants and a discussion of soils and vegetation that may be affected by proposed project emissions and associated impacts. The applicant provided an analysis in the PSD application submitted to SJVAPCD. The applicant followed a U.S. EPA established screening procedure for determining impacts to plants, soils, and animals from emissions of NO_2, SO_2, PM10, H_2S and CO from the project. In addition HECA provided a detailed discussion on the surrounding vegetation. The modeled impacts of NO_2, SO_2, PM10, H_2S and CO emissions combined with background concentration data are below the screening concentrations identified in the screening procedures. The results are summarized in **Air Quality Table 24**.

Air Quality Table 24
Soils and Vegetation Results

Pollutant	Modeled Averaging Time	Predicted Impact ($\mu g/m^3$)	Background ($\mu g/m^3$) [b]	Total Impact ($\mu g/m^3$)	U.S. EPA AQRV Screening Concentration ($\mu g/m^3$)	U.S. EPA AQRV Screening Averaging Time	Percent of Screening
SO_2	1 hour	50	42	92	917	1 hour	10%
	3 hour	29	26	55	786	3 hour	7%
	Annual	0.1	13	13.1	18	Annual	73%
NO_2	1 hour	185	140	325	3,760	4-hour & 8-hour	9%
					564	Weekly	58%
	Annual	1.5	24.7	26.2	94	Annual	27%
PM10	24 hour	4.9	97	102	N/A	N/A	N/A
	Annual	0.8	44.2	45.0	N/A	N/A	N/A
CO	8 hour	371	2,411	2,782	1,800,000	Weekly	0.15%
H_2S	1 hour	23	N/A	23	28,000	4 hour	0.08%

Source: HECA 2012j and PDOC (SJVAPCD 2013a)
[a] Background values have been adjusted per staff recommended background concentrations shown in **Air Quality Table 6**.

The modeling results summarized in **Air Quality Table 24** show impacts that are well under the U.S. EPA AQRV screening concentrations. Therefore, it is concluded that emissions associated with the project would not generally result in adverse impacts to soils or vegetation.

Visibility Impacts

A visibility analysis of the project's gaseous emissions is required under the federal Prevention of Significant Deterioration (PSD) permitting program. The potential for visibility impairment is characterized for Class I areas located within 50 km of the proposed site and Class II areas identified as potentially sensitive state or federal parks, forests, monuments or recreation areas. The nearest Class I area is San Rafael Wilderness which is approximately 60 km away from the project, which is beyond the 50 km threshold for analysis. Therefore, the applicant did not evaluate visibility impacts to Class I Areas. U.S. EPA Region 9 requested that a Class II visibility analysis for Sequoia National Forest and Los Padres National Forest be performed. Sequoia National Forest is 54 kilometers away and Los Padres National Forest is 49 kilometers away from the project site. The applicant proposed a methodology and threshold similar to Class I areas because the EPA has not established a quantitative visibility impairment threshold for Class II areas. This visibility screening modeling analysis compares the project's impacts against visual screening criteria for total color contrast (Delta E) and plume contrast. The results of the applicant's VISCREEN analysis are shown **Air Quality Table 25.**

Air Quality Table 25
Class II Visibility Results

Maximum Visual Impacts Inside Area Screening Criteria Are Not Exceeded								
Background	Theta	Azimuth	Distance	Alpha	Delta E		Contrast	
					Criteria	Plume	Criteria	Plume
SKY	10	142	15	27	2	1.765	0.05	0.013
SKY	140	142	15	27	2	0.532	0.05	-0.012
TERRAIN	10	84	11	84	2	1.932	0.05	0.019
TERRAIN	140	84	11	84	2	0.291	0.05	0.01

Source: HECA 2012ff and PDOC (SJVAPCD 2013a)

The modeling results summarized in **Air Quality Table 25** show plume impacts for the two Class II areas that are below the Delta E and Contrast screening criteria for Class I areas. Staff concludes that emissions associated with the project would not generally result in adverse impacts to visibility.

Growth

A growth impact analysis is required under the federal Prevention of Significant Deterioration (PSD) permitting program. The analysis includes a discussion of general commercial, residential, industrial, and other growth associated with the project. The applicant provided a discussion of potential growth impacts that would likely occur to support the project. Topics include population, housing, economic base and employment. The SJVAPCD determined that the project would not cause any significant population increases or associated growth. In the **Socioeconomics** section of the

PSA/DEIS staff also concluded that the project would not induce substantial population growth, displacement of population, or demand for housing and public services.

Operations Mitigation

As described in the "Laws, Ordinances, Regulations, and Standards" section, District NSR Rule 2201 establishes emission and operation requirements. Staff recommends operating emission impacts be mitigated to the greatest feasible extent including all feasible measures from the LORS, as well as other measures considered necessary by the District and staff to fully mitigate the emissions.

BACT requirements for this project are triggered on a per pollutant basis for each emissions unit with a potential to emit greater than 2 lbs/day. BACT is not required for ammonia emissions resulting from the operation of the SCR unit since the SCR unit is a control device used to meet BACT for NOx. Ammonia emissions are quantified and limited according to the applicants proposed slip limits[12]. The following reflects measures to meet both BACT requirements and applicant-proposed mitigation.

Proposed Mitigation

Emissions Control Mitigation for Each Process Unit

CTG/HRSG Combustion Turbine (excluding Startup/Shutdown conditions)

NOx: The PDOC identifies selective catalytic reduction limiting emission levels to 2.5 ppmvd (1-hour average) and 4 ppmvd (3-hour average) @ 15 percent O_2 for hydrogen-rich and natural gas fuel respectively as BACT. The applicant has proposed a 3-hour averaging period when operating on hydrogen-rich fuel, and they are proposing SCR technology to meet these limits.

CO: The PDOC identifies an oxidation catalyst achieving emission levels of 3.0 ppmvd and 5.0 ppmvd @ 15 percent O2 (3-hour average) for hydrogen-rich and natural gas fuels, respectively as BACT. The applicant is proposing an oxidation catalyst to meet these limits.

VOC: The PDOC identifies an oxidation catalyst achieving emission levels of 1.0 ppmvd and 2.0 ppmvd @ 15 percent O2 (3-hour average) for hydrogen-rich and natural gas fuels, respectively as BACT. The applicant is proposing an oxidation catalyst to meet these limits.

PM10: The PDOC identifies an air inlet cooler/filter tube, lube oil vent coalescer and 0.003 lb SOx/MMBtu when firing on hydrogen-rich fuel exclusively, or either PUC-regulated natural gas or non-PUC regulated natural gas with no more than 0.75 grains sulfur (S)/100 dry standard cubic feet (dscf) as BACT. The applicant is proposing to meet these limits with the necessary equipment or equivalent, meet 0.003 lb SOx/MMBtu when firing on hydrogen-rich fuel and the use of PUC-regulated natural gas.

[12] Quantification of the proposed project's ammonia emissions are presented in the Public Health section of this document, in **Public Health Tables 5** and **6**.

SO_X: The PDOC identifies PUC –regulated natural gas, non-PUC regulated natural gas with no more than 0.75 grain S/100 dscf or 0.003 lb SOx/MMBtu when firing on hydrogen-rich fuel as BACT. The applicant is proposing to meet these limits through the use of PUC-regulated natural gas and hydrogen-rich fuel meeting 0.003 lb SOx/MMBtu.

NH_3: The applicant is proposing 5 parts per million by volume, dry (ppmvd) at 15 percent O_2 on hydrogen-rich fuel and natural gas fuel.

Railcar Unloading and Transfer System, Truck Unloading and Transfer System, Feedstock Grinding/Crushing and Drying System, Gasification Solids Handling System and Urea Storage and Handling Operation

PM10: The PDOC identifies storage, mixer, augers, elevators, and conveyors to all be enclosed and vented to a fabric filter baghouse as BACT for dry material handling storage and conveying. The baghouse particulate emissions are not to exceed 0.001 grains/dscf. Visible emissions from transfer points are limited to 5 percent opacity.

In addition the PDOC requires water spray dust suppression in the coal/petcoke unloading stations and the storage enclosure when unloading.

The applicant is proposing to use water spray and other dust suppression techniques to control emissions during train and truck unloading of coal and petcoke. The applicant is also proposing to fully enclose handling, conveying and storage system and vent emissions to be controlled with fabric filter baghouses to meet these BACT requirements.

Fugitive Emissions from Gasification System, and Sulfur Recovery System

VOC: The PDOC defines leaks as a reading of methane in excess of 100 ppmv above background for valves and 500 ppmv above background for pump and compressor seals when measured using EPA Method 21 and an inspection and maintenance program pursuant to District Rule 4455 as BACT. The applicant is proposing a leak detection and repair program for valves and connectors with VOC above 100 ppmv and pumps and seals with VOC above 500 ppmv.

Sulfur Recovery System

SOx: The PDOC identifies the use of a sulfur recovery unit with tail gas treating unit to limit the sulfur recovery system to 10 ppmv H_2S (three hour moving average) or less and a standby incinerator, except during startup and shutdown as BACT. The applicant is proposing this equipment and would meet the limit.

CO_2 Recovery and Vent System

CO and VOC: The PDOC identifies capture, compression and transportation of the exhaust stream in a pipeline for injection (during normal operation): venting due to upset condition up to 504 hours (or equivalent) per rolling 12 month period as BACT. The applicant is proposing equipment and would meet the limit.

Auxiliary Boiler

NOx: The PDOC identifies limiting emission levels to 5 ppmvd @ 3 percent O_2 as project specific BACT. The applicant is proposing SCR technology to meet this limit.

VOC, SOx, CO, PM10: The PDOC identifies using natural gas with LPG backup as BACT. The applicant is proposing to use PUC-quality natural gas.

Cooling Towers

PM10: The PDOC identifies a cellular type drift eliminator as BACT. The applicant is proposing a cellular type drift eliminator with a 0.0005 percent drift as percent of the amount of recirculating water, total dissolved solids limit and good operating practices.

Flares

NOx: The PDOC identifies an engineered flare or enclosed burner with air or stream assisted combustion, staged combustion and/or equivalent District approved controls and demonstrated NOx emissions of less than 0.068 lb/MMBtu equipped with a flare gas recovery system for non-emergency releases as BACT.

CO: The PDOC identifies an engineered flare with air or steam assisted combustion, staged combustion, and/or equivalent District approved controls and a flare gas recovery system as BACT.

VOC: The PDOC identifies an enclosed ground level flare or any other engineered flare designed with a VOC destruction efficiency of 98.5 percent or greater.

PM10: The PDOC identifies an engineered flare with air or steam assisted combustion, staged combustion, and/or equivalent District approved controls and a flare gas recovery system as BACT.

SO_X: The PDOC identifies a flare with a flare gas recovery system for non-emergency releases, and natural gas as the pilot and purge gas as BACT.

The applicant is proposing a natural gas piloted flare with good combustion practices, and limited operations, that would meet the other emission limit and destruction efficiency requirements listed above for the Gasification, Rectisol®, and SRU flares. Additionally, the applicant is proposing the use of a caustic scrubber to remove sulfur from the gases prior to their destruction in the SRU flare.

Ammonia Synthesis Startup Heater

NOx: The PDOC identifies 9 ppmvd @ 3 percent O_2 as BACT. The applicant is proposing a low NOx burner to meet these requirements, CO, VOC, SOX, PM10: The PDOC identifies PUC- quality natural gas firing as BACT. The applicant is proposing PUC-quality natural gas.

Nitric Acid Unit

NOx: The PDOC identifies extended absorption and/or catalytic reduction limiting NOx emission to 0.20 lb/ton of nitric acid produced (expressed as 100 percent nitric acid on a 24 hour rolling average basis) as BACT. The applicant is proposing a low NOx burner to meet these requirements.

Ammonium Nitrate Unit

PM10: The PDOC identifies a wet scrubber limiting emissions to 0.0075 lb-PM10/ton of ammonium nitrate produced. The applicant is proposing a wet scrubber to meet this limit.

Two Emergency Diesel Generators, 2,922 hp and One Emergency Firewater Pump Engine, 565 hp

NOx/CO/VOC/PM10: The PDOC identifies the latest EPA Tier Certification level for the applicable horsepower range as BACT.

SO_X: The PDOC identifies very low sulfur diesel of 15ppmv or less as BACT.

The applicant is proposing the use of interim Tier 4 engines fueled by low sulfur diesel fuel to meet these BACT requirements. The applicant would be required to obtain equipment meeting final Tier 4 emissions standards if that tier level is applicable at the time of installation.

Emission Offsets

As documented in **Air Quality Table 4**, the SJVAPCD is in non-attainment with AAQS for O_3, PM10, and PM2.5. The California Energy Commission requires mitigation for the emissions of pollutants and/or their precursors that are in non-attainment with state and federal air quality standards or may result in any violation of any air quality standard. Precursors of O_3, PM10, and PM2.5 include VOC, SOx, and NOx. Therefore mitigation is required for PM10, PM2.5, SOx, NOx, and VOC emissions in areas designated as non-attainment for O_3, PM10, and PM2.5 standards. Worst case 1-hour and 8-hour CO impacts modeling runs performed by the applicant and the SJVAPCD indicated CO emissions from the project would not cause a violation to the CO AAQS. Therefore, offset mitigation is not required for CO.

Emission offsets are used to mitigate project impacts. Offsets are reductions in emissions in one place that compensate for an increase in emissions elsewhere. Emission reduction credits (ERCs) are credits that are issued for a specific reduction in emissions that can be used as emission offsets. In the San Joaquin Valley Air Basin, ERCs are generated by voluntary reductions in emissions from stationary and area sources. ERCs can be generated from the shutdown of emission sources, adding control equipment to existing sources, or by a change in operating conditions. ERCs are issued or ‘banked’ by the District after the reductions have been analyzed to verify they are real, surplus, quantifiable, permanent and enforceable. Reductions in emissions are only eligible if the decrease in emissions can be verified and the decrease goes beyond any emissions reductions required by the District.

The SJVAPCD NSR rule, District Rule 2201, requires new facilities with emissions above certain levels to provide ERCs as mitigation. The mitigation required by the District is quantified separately from the mitigation required by the California Energy Commission. Mitigation required by SJVAPCD is outlined in the District NSR rule and does not necessary reflect the mitigation required by the California Energy Commission under CEQA. Therefore this document includes a comparison of the emission offsets quantified to satisfy the local District Rules and Regulations and with the recommendations by Energy Commission staff for additional CEQA mitigation.

The SJVAPCD NSR rule does not exactly match federal requirements in all respects; some requirements are more stringent in some areas and less stringent in others. ERCs generated in the SJVAPCD are credited as surplus at the time they are banked. However, federal requirements stipulate ERCs are to be surplus at the time of use. Because the SJVAPCD NSR rule does not require discounting of ERCs at the time of use, ERCs are tracked and adjusted on a programmatic basis. In addition, SJVAPCD offsetting thresholds are lower than federal offsetting requirements. Therefore, SJVAPCD is required to demonstrate to the U.S. EPA that on an annual basis their ERC tracking and adjustment program is equivalent to federal requirements. This demonstration includes both review of the offsets required for new and modified sources in comparison to the direct implementation of federal requirements and a review of the reductions required by SJVAPCD from new and modified sources after discounting to ensure mitigation equals or exceeds the ERCs required under federal regulations. Since SJVAPCD offsets are tracked, and adjusted if necessary on a programmatic basis, additional reasonably available control technology (RACT) adjustments are not imposed. RACT adjustments are used to reduce ERCs to account for District rules that impose emissions reductions that would have been required if the equipment were still in operation. This ensures that the emissions reductions are truly surplus to regulatory actions.

District Rule 2201 requires that the applicant provide emission offsets, in the form of banked ERCs, but only for the portion of a project’s stationary source emissions that exceed SJVAPCD Rule 2201 offset thresholds. HECA would require offsets for VOC, NOx, SO_2, and PM10 based on District Rule 2201.

District Rule 2201 does not require emissions to be offset for non-major sources of pollutants. District Rule 2201 defines the threshold for a major source of PM2.5 emissions as 100 tons per year. The project is expected to be below this threshold for PM2.5. However, the modeled impacts of PM2.5 emissions exceed the 24 hour and annual AAQS and SIL thresholds. Therefore the District is also requiring HECA to fully offset PM2.5 emissions. The District determined the full mitigation of PM2.5 emissions would not cause or make worse a violation of the PM2.5 AAQS.

Air Quality Table 26 shows the District’s summary of the emission liabilities that need to be offset.

Air Quality Table 26
HECA District Offset Calculations (lb/year)

Offset Need Determination	NOx	CO	VOC	SO_2	PM10	PM2.5
HECA Total Emissions	317,310	544,421	75,376	59,436	178,863	158,151
Offset Threshold	20,000	200,000	20,000	54,750	29,200	200,000
Offsets Triggered?	**Yes**	**Yes** [a]	**Yes**	**Yes**	**Yes**	**Yes** [b]

Source: PDOC (SJVAPCD 2013a), staff analysis.
Notes:
[a] – Although the proposed project's estimated emissions would be above the offset threshold, offset requirements for CO are exempted in attainment areas where ambient air quality standards are not violated. The project's modeling analysis provided sufficient proof to the District that CO ambient air quality standards would not be violated by this project, so CO offsets are not required.
[b] – Required because the modeled impacts of PM2.5 emissions exceed the 24 hour and annual AAQS and SIL thresholds.

The quantities of emission offsets required are calculated according to District Rule 2201 on a quarterly basis. The applicant is proposing several sources of emission reduction credits to offset the project's permitted emissions, which are described below and summarized in **Air Quality Tables 27** through **29**. Calculations of the offsets required take into consideration the distance of the project from the source of the emission reduction. This is done by the application of a distance offset ratio. For VOC and NOx from new major sources, the District requires a distance offset ratio of 1.5:1. For other pollutants the District requires a distance offset ratio of 1.3:1 for off-site ERCs created from sources that are located within 15 miles of the HECA site, and a distance offset ratio of 1.5:1 for ERCs created from sources that are located more than 15 miles from the HECA site. The applicant's proposed ERCs are from sources located more than 15 miles away, except for the VOC ERCs that come from sources located within 15 miles of the HECA project site. Therefore, a distance ratio of 1.5:1 is used for District offset purposes for all pollutants (SJVAPCD 2013a).

In addition, offsets are not required for emergency equipment that would be used exclusively as standby equipment and that would not operate more than 200 hours per year for non-emergency purposes such as testing and maintenance. Therefore emissions from the two emergency engines and emergency fire pump are subtracted from the facility total emissions prior to the application of the distance offset ratio in the offset determination calculations.

The applicant is proposing to satisfy their offset requirements for both PM10 and PM2.5 through interpollutant offsets. The use of interpollutant offsets is approved by the District on a case by case basis. Approval is based on a demonstration that the emission increases would not cause or contribute to a violation of an AAQS. Per District Rule 2201, interpollutant offsets between PM2.5 and PM2.5 precursors are allowed at specific ratios established by U.S. EPA or as approved in the SIP. The District approved a 1:1 interpollutant ratio of SOx offsets for PM10/PM2.5. This ratio is based on chemical mass balance modeling and speciated rollback modeling performed for the 2008 PM2.5 attainment plan.

As shown in **Air Quality Table 27** through **Air Quality Table 30**, the applicant has demonstrated, per District requirements and Energy Commission policy, that it owns ERCs in quantities sufficient to offset the project's NOx, VOC, SO_2 and PM10 emissions.

NOx Emission Offsets

Air Quality Table 27 provides a summary of the total project NOx emissions subject to District offsets and identifies the offset emission reduction credit sources owned by the applicant. Credit S-3273-2 was created in November 1983 from the shutdown of a catalytic cracker, fluid coker, and CO boiler. Credits C-1058-2 were created in January 2008 through the installation of a SCR unit, a scrubber, and a conversion from fuel oil to natural gas.

Air Quality Table 27
NOx Offsets Available for HECA

Offset Source Location	Distance (miles)	Credit Number	Total Q1 (lb)	Total Q2 (lb)	Total Q3 (lb)	Total Q4 (lb)
Emissions Above Threshold [a]		---	74,201	74,201	74,201	74,201
6500 Refinery Ave., Bakersfield	> 15	S-3273-2	120,500	120,500	120,500	120,500
11535 E. Mountain Ave., Kingsburg	> 15	C-1058-2	10,100	10,100	10,100	10,100
Total ERC Holdings		---	130,600	130,600	130,600	130,600
Total HECA Offsets required @ 1.5:1		---	111,302	111,302	111,302	111,302
Surplus		---	19,299	19,299	19,299	19,299

Sources: PDOC (SJVAPCD 2013).
Note: [a] – The offset emission thresholds are provided in **Air Quality Table 26**, and the quarterly threshold is one quarter of the annual threshold shown in that table after subtracting the emergency equipment emissions provided in **Air Quality Table 17**.

The applicant has sufficient offset credits to comply with the District's NOx offset requirements for this project. The applicant could retain or sell the surplus ERCs they own that are not needed to offset this project.

VOC Emission Offsets

Air Quality Table 28 provides a summary of the total project VOC emissions subject to District offsets and identifies the offset emission reduction credit sources owned by the applicant. Credits S-3305-1, S-3557-1 and S-3605-1 are all from the same emission reduction event that occurred in September 1979 through the shutdown of an entire stationary source. The applicant is proposing to surrender ERC certificate S-3305-1 and a portion of S-3605-1 to offset the VOC emissions from the project.

The applicant has sufficient offset credits to comply with the District's VOC offset requirements for this project. The applicant could retain or sell the surplus ERCs they own that are not needed to offset this project.

SOx and PM10/PM2.5 Emission Offsets

The applicant has proposed the use of SOx emissions offsets to mitigate PM10 and PM2.5 emissions as a form of interpollutant offsets to complete the PM10 offset package. **Air Quality Table 29** provides a summary of the total project SO_2 and PM10 emissions subject to District offsets and identifies the offset emission reduction credit sources owned by the applicant. Credit S-3275-5 was created in March of 1992 through the shutdown of a tail gas incinerator. Credit C-1058-5 was created in January 2008 through the installation of a scrubber and a conversion from fuel oil to natural gas.

Air Quality Table 28
VOC Offsets Available for HECA

Offset Source Location	Distance (miles)	Credit Number	Total Q1 (lb)	Total Q2 (lb)	Total Q3 (lb)	Total Q4 (lb)

Total HECA Offsets required [b]		---	61,062	61,062	61,062	61,062
Surplus		---	5,438	5,438	5,438	5,438

Sources: PDOC (SJVAPCD 2013a).
Notes:
[a] – The offset emission thresholds are provided in **Air Quality Table 26**, and the quarterly threshold is one quarter of the annual threshold shown in that table after subtracting the emergency equipment emissions provided in **Air Quality Table 17**.
[b] – Total offsets include the SOx offsets and PM2.5 offsets. The PM10 offsets required include PM2.5 emission. However, since the facility is fully offsetting the PM2.5 emissions they exceed the PM10 offset contribution.

The applicant has proposed the use of SOx for PM10 interpollutant offsets. SOx is accepted as one of the major precursors of PM10 and PM2.5 through reaction with ammonia to form ammonium sulfates. Reductions in SOx, particularly in areas that are ammonia rich such as the SJVAB, will reduce secondary particulate formation. Therefore, interpollutant offsets of SOx for PM10 can be used to reach the goal of mitigating a project's impacts to regional ambient particulate concentrations. The key issue is the determination of an appropriate interpollutant offset ratio, which depends on the existing levels of PM precursors and the general air chemistry of the area in question. The District has determined that an offset ratio of 1:1 is adequate for SOx for

PM10 interpollutant ERC trading. However, the SJVAPCD's Governing Board approved the District's 2012 PM2.5 Plan for inclusion in the State Implementation Plan (SIP) in December 2012, which was then approved by the California Air Resources Board (ARB) on January 24, 2013. That plan calls for a 4.1 to 1 sulfur oxides (SOx) for PM2.5 interpollutant offset ratio for the San Joaquin Valley, and use of the 1:1 offset ratio was rejected by the U. S. EPA. Additionally, there is no reason that the SOx for PM2.5 interpollutant offset ratio should be different than the SOx for PM10 interpollutant offset ratio. However, both the applicant and SJVAPCD are still using a 1:1 SOx for PM interpollutant offset ratio. Staff has provided a comment to the District regarding the appropriateness of this offset ratio and the Final Staff Assessment (FSA) will provide additional information based on the comment response provided by the District in the FDOC.

The applicant does not currently have sufficient offset credits to comply with the District's SOx and PM10 offset requirements for this project if the SOx to PM10 offset ratio is increased from 1:1 to 4.1:1.

CEQA Offsets

Energy Commission staff have long held that for fossil fuel power plants, the annual operation emissions for all nonattainment pollutants and their precursors need to be fully offset at a minimum 1:1 ratio, not just the portion of a facility's emissions that exceed offset trigger levels, such as allowed by SJVAPCD Rule 2201. For this project, as shown in **Air Quality Table 30**, the District's offset requirements would exceed that minimum 1:1 offsetting goal for NOx, VOC, SOx, PM10 and PM2.5.

Air Quality Table 30
Total Operations Offset Ratio for HECA's SJVAB Emissions

Pollutant	Annual Emissions[a]	District Required ERCs	Offset Ratio
NOx	317,310 lbs/year	445,206 lbs/year	1.40:1
VOC	75,379 lbs/year	82,672 lbs/year	1.10:1
SOx + PM10/PM2.5[b]	238,299 lbs/year	244,248 lbs/year [c]	1.02:1

Source: Compilation of data from **Air Quality Tables 17**, and **27** through **29**
Notes:
[a] **– Total facility emissions, not just the portion that exceeds Rule 2201 thresholds**
[b] – PM10/PM2.5 offset requirements are the larger of the two. In this case PM2.5.
[c] – SO_2 ERCs.

Staff notes that with the assumption that an interpollutant offset ratio of SOx for PM[13] of 1:1 is appropriate, the applicant's offset proposal would meet staff's CEQA offset recommendation of a minimum offset threshold of 1:1 for all non-attainment pollutants and their precursors. However, if a SOx for PM interpollutant offset ratio of 4.1:1 is determined to be appropriate then the applicant does not currently have enough SOx credits to offset the combined HECA SOx and PM emissions. The final evaluation of the adequacy of this interpollutant offset ratio will in part be based on the District's response to staff's questions on this issue. Staff will determine, based on that response and the rest of the evidence provided, whether recommended adjustments need to be made to

[13] Staff evaluation of CEQA mitigation for PM2.5 impacts is the same as for PM10.

this interpollutant offset ratio for CEQA mitigation purposes. Staff will provide this final determination in the FSA/FEIS.

Mitigation Agreements

The applicant has entered into two separate Governing Board approved mitigation agreements with the District. The first agreement covers providing VOC and NOx emissions reductions for General Conformity compliance and additional PM10 emissions reductions for District CEQA compliance purposes. This agreement covers providing emission reduction funding of over $7,500,000 to address 243.6 tons of NOx, 39.5 tons of VOC, and 61.3 tons of PM10 emissions during project construction and ten years of project operating NOx transportation emissions, totaling 436 tons of NOx emissions (SJVAPCD 2013c, Attachment A, Exhibit C). The monies obtained by this agreement would be used by the District to fund emissions reductions within the air basin. However, the applicant would be required to provide additional funding or emission reduction credits from the District bank to cover any shortages in the emission reductions obtained versus the amount of necessary emissions reductions identified in this agreement until sum of the emissions reductions obtained equals the amount of emission reductions required by this agreement.

The second voluntary emissions reduction agreement (VERA) addresses excess NOx emissions from the project due to the fact that the NOx emissions efficiency for this project is lower than for natural gas fired combined cycle projects. The District has determined that this lower efficiency results in an additional 16.7 tons per year of NOx emissions as compared with other combined cycle projects and requires the fee for this agreement to be based on the current average NOx ERC cost of $67,492 per ton. The total amount required to be paid to the District under this voluntary agreement, including a 5 percent administrative fee, is $1,181,135. Unlike the other mitigation agreement, this is a one-time fee that has no stipulations in regards to the final amount of emissions reductions achieved by the emissions reduction projects funded with the monies obtained from this agreement.

Staff recognizes that the first agreement would be used to satisfy General Conformity offset requirements, and is subject to approval by DOE. Additionally, staff recognizes the additional air quality benefits that the first agreement and the second voluntary agreement would provide, including the associated reduction of pollutants (PM10, PM2.5, air toxic pollutants), other than VOC and NOx. Staff supports the applicant and the District in their efforts to provide these additional air quality benefits to the region. However, staff would prefer that these agreements include an additional implementation requirement that these emission reductions would occur as close to the project site as feasible.

Adequacy of Proposed Mitigation

Staff concurs with the District's determination that the project's proposed emission controls/emission levels for criteria pollutants meets BACT requirements and that the proposed emission levels are reduced to the lowest technically feasible levels.

Staff has made a preliminary determination that the applicant's offset proposal meets both District requirements and meets CEQA mitigation requirements for the project's stationary sources. Additionally, staff agrees with most of the mitigation measures that the applicant has proposed to reduce emissions from the project's mobile sources that are not regulated by the District. However, there are two issues that need to be resolved prior to the issuance of the FSA in order for staff to finalize this determination. These two issues are as follows:

1) SO_2-for-PM10 offset ratio.

Staff is still evaluating the appropriateness of the 1:1 offset ratio for interpollutant trading of SO_2 for PM10 in terms of providing adequate and SIP-required mitigation for the project's potential PM10 impacts and adequate mitigation for the project's PM2.5 impacts. Staff and U.S. EPA have previously provided comments regarding this issue to the District (CEC 2010, U.S. EPA 2010), and staff has provided another comment on this issue in staff's PDOC comment letter to the SJVAPCD, dated March 28, 2013. Staff will be evaluating the District's response and additional comments from other parties, such as U.S. EPA, as part of our final conclusion regarding this issue.

2) Mercury and Air Toxics Standards (MATS) Compliance

The District has not included any MATS compliance conditions in the PDOC. Staff acknowledges that the MATS regulation has been stayed but U.S. EPA published the amended MATS rule on March 28, 2013. Therefore, the District should assume that by the time the project begins operation, the MATS regulation will be in force and provide necessary permit conditions for MATS rule compliance. The affected sources are the combustion turbine generator/heat recovery steam generator (CTG/HRSG) and coal dryer that need to meet the particulate, mercury, and hydrogen chloride emission limitations of this rule. For the time being, staff has added Condition of Certification **AQ-SC13** to address the project's MATS compliance requirements.

Additionally, in the March 28, 2013 letter to SJVAPCD, staff has provided several other comments to the District on the PDOC that staff feels need to be resolved for clarity of the analysis findings and the permit condition requirements.

Staff Proposed Mitigation

Staff is proposing several staff conditions of certification (**AQ-SC6** through **AQ-SC14**), some of which memorialize mitigation commitments made by the applicant for mobile source emissions, and others to fill gaps in the emissions mitigation proposed by the applicant and the District in the PDOC.

To reduce the project's on-road and off-road emissions, staff is proposing Conditions of Certification **AQ-SC6** and **AQ-SC7**. Condition of Certification **AQ-SC6** requires that when the applicant purchases vehicles for feedstock (coal and petcoke) transport during facility operations, they must purchase new model year dedicated on-road and off-road equipment. This will reduce potential operating period maintenance and on-site fuel handling emissions by ensuring that only new equipment meeting the latest emissions standards are purchased. Staff Condition of Certification **AQ-SC7** requires that when the applicant contracts out for these services, the contractor must use vehicles with engines that meet post-2010 emissions standards.

Due to the large project site, much of which will not be paved or otherwise controlled, staff is proposing Condition of Certification **AQ-SC9** that would require the applicant provide and implement a fugitive dust control plan during operations.

In response to concerns regarding fugitive particulate emissions and spillage from the transport of coal, the applicant has agreed to either use covered railcars or dust suppressants to control the fugitive dust from rail based coal transportation. Therefore, staff has included Condition of Certification **AQ-SC10** to memorialize this applicant stipulation and has expanded it to include the control of fugitive dust emission from all transported bulk materials to and from the site. This condition of certification also includes right of way inspection requirements along the transportation routes to ensure mitigation measure effectiveness (i.e. no observed spillage). For the rail transportation this is currently limited to the length of the HECA rail spur for several reasons, including; right of access to the right of way, and issues of attribution where rail transport of coal would include other end users. Staff will consider increasing the inspection requirements if access and spillage source attribution can be assured.

To reduce air pollutant emissions from rail transportation, staff is proposing Condition of Certification **AQ-SC12**. This condition memorializes the applicant's proposed measure to require the contracted rail provider to use Tier 3 or better locomotives. However, given the fact that Tier 4 standards will be in effect for new locomotive and switching engines by 2015, which would be before the project could start operation if approved, staff is proposing that the applicant obtain an onsite switching engine that meets Tier 4 standards, and that the applicant require the contracted rail provider to use Tier 4 locomotives starting in 2020. The difference between Tier 3 and Tier 4 standards, as opposed to the difference between Tier 2 and Tier 3 standards, is substantial for NOx and PM emissions, so staff believes that requiring the project to use locomotive and switching engines that meet this higher engine Tier standard is a feasible measure that would provide a significant reduction of the project's long-term transportation emissions.

As noted above, staff has included Condition of Certification **AQ-SC13** to address compliance with the federal MATS regulation. Staff expects to delete this condition assuming the District, per staff's comment on the PDOC, adds MATS compliance conditions in the FDOC.

Staff condition **AQ-SC14** is included to ensure that the two mitigation agreements the applicant has signed with the District are being complied with, specifically that the required funding has been provided in a timely manner in compliance with these two agreements.

Staff is also proposing conditions of certification (**AQ-SC11** and **AQ-SC8)** that would ensure that the license is amended as necessary to incorporate changes to the air quality permits and ensure ongoing compliance through the requirement of quarterly operations reports that demonstrate compliance, respectively.

Staff has considered the environmental justice population surrounding the site (see **Socioeconomics Figure 1**). Since the project's direct air quality impacts have been reduced to less than significant, there is no environmental justice issue for air quality.

Chemically Reactive Pollutant Impacts

The project's gaseous emissions of NOx, SO_2, VOC and ammonia can contribute to the formation of secondary pollutants: ozone and PM10/PM2.5.

Ozone Impacts

There are air dispersion models that can be used to quantify ozone impacts, but they are used for regional planning efforts where hundreds or even thousands of sources are input into the modeling to determine ozone impacts to large regions such as air basins. There are no regulatory agency models approved for assessing single source ozone precursor impacts. However, because of the known relationship of NOx and VOC emissions to ozone formation, it can be said that the emissions of NOx and VOC from HECA do have the potential (if left unmitigated) to contribute to higher ozone levels in the region. These impacts would be cumulatively significant because they would contribute to ongoing violations of the state and federal ozone ambient air quality standards as shown in **Air Quality Figure 1**, provided on page 4.1-17. Staff is recommending Condition of Certification **AQ-SC5** to reduce the NOx and VOC emissions from off-road equipment during construction. The District rules require that the NOx and VOC emissions for HECA be offset at a greater than 1:1 ratio (provided in District conditions **AQ-1**). Staff concludes that with these mitigation measures the project's ozone impacts are less than significant.

Secondary PM10/PM2.5 Impacts

Secondary PM10 formation, which is assumed to be 100 percent PM2.5, is the process of conversion from gaseous reactants to particulate products. The process of gas-to-particulate conversion, which occurs downwind from the point of emission, is complex and depends on many factors, including local humidity and the presence of air pollutants. The basic process assumes that the SOx and NOx emissions are converted into sulfuric acid and nitric acid first, and then react with ambient ammonia to form sulfate and nitrate. The sulfuric acid reacts with ammonia much faster than nitric acid and converts completely and irreversibly to particulate form. Nitric acid reacts with ammonia to form both a particulate and a gas phase of ammonium nitrate. The particulate phase will tend to fall out. However the gas phase can revert back to ammonia and nitric acid. Thus, under the right conditions, ammonium nitrate and nitric acid establish a balance of concentrations in the ambient air. There are two conditions that are of interest, described as "ammonia rich" and "ammonia poor." The term "ammonia rich" indicates that there is more than enough ammonia to react with all the sulfuric acid and to establish a balance of nitric acid-ammonium nitrate. Further ammonia emissions in this case would not necessarily lead to proportional increases in ambient PM2.5 concentrations. In the case of an "ammonia poor" environment, there is an insufficient amount of ammonia to establish a balance and thus additional ammonia would tend to increase PM2.5 concentrations.

The San Joaquin Valley has been the subject of an extensive secondary particulate formation study, the California Regional Particulate Air Quality Study, which has determined that the San Joaquin Valley is ammonia rich. Therefore, the ammonia emissions from HECA are not expected to lead to substantial further formation of ammonium nitrate or sulfate. While there would certainly be some conversion from the ammonia emitted from HECA, there is currently no regulatory model that can predict the conversion rate. Additionally, VOC emissions have the potential to convert into organic particles, where depending on the location the primary concern related to secondary PM2.5 formation from VOC is biogenic rather than anthropogenic (i.e. from natural organic releases such as turpene emissions from pine trees). However, because of the known relationship of NOx, SOx, and VOC emissions to PM2.5 formation, it can be said that the emissions of these three pollutants from HECA do have the potential (if left unmitigated) to contribute to higher PM2.5 levels in the region.

The applicant is proposing to mitigate the project's NOx, VOC, SO_2, and PM10 emissions through the use of emission offsets and limit the ammonia slip emissions to 5 ppm for the CTG/HRSG and 10 ppm for the nitric acid plant. The NOx, VOC, SO_2, and PM10 offsets are proposed by the applicant to be provided for emissions above the District offset thresholds at an offset ratio that is greater than 1 to 1, meaning offsetting with emissions reductions that are greater than the emissions increases. Additionally, the applicant has agreed to create additional emissions reductions by funding the District's Emission Reduction Incentive Program (ERIP). Staff does have questions regarding the appropriate SOx for PM interpollutant offset ratio; however, with the proposed emission offsets and additional mitigation funding, staff concludes at this time that the project would not cause significant secondary PM2.5 pollutant impacts.

DIRECT/INDIRECT IMPACTS AND MITIGATION – EOR COMPONENT

Based on the information currently available for the OEHI CO_2 EOR component, this section examines the potential air quality impacts of the OEHI CO_2 EOR component that would use HECA's separated CO_2 for tertiary oil recovery. The EOR component includes the construction of the CO_2 pipeline, the drilling of CO_2 injection wells, the construction of the CO_2 injection system and the CO_2 recovery and recycling systems. This project component is expected to be subject to the completion of a separate EIR, and if so would be required to mitigate emissions as determined to be required under CEQA by that separate environmental analysis.

The air quality impacts of this related project would include short-term construction impacts that would occur during the same timeframe as the HECA construction (see **Air Quality Table 18** for a summary of the estimated OEHI CO_2 EOR component's construction emissions); and operating impacts related to this EOR component would include stationary source emissions from the new oil recovery and CO_2 recycling systems and indirect emissions from the additional electrical energy needed for the CO_2 compressors and other electrical requirements to operate the EOR system (see **Air Quality Table 19** for a summary of the estimated OEHI CO_2 EOR component's operating emissions). However, if CO_2 were not being made available from HECA then it is possible that OEHI would use other tertiary oil recovery methods, such as water or other gas injection, to recover crude oil that could be recovered with these methods and these other tertiary oil recover methods could have operating emissions as high as or higher than the proposed CO_2 based EOR system.

Staff's initial findings regarding this project-related action are as follow:

- The construction related impacts of this EOR component would generally occur several miles from HECA, and construction emissions mitigation would be required as part of that project's CEQA/NEPA process. Staff believes that with adequate mitigation, the combined construction impacts of HECA and the EOR component would be less than significant.

- The direct operating stationary source emissions of the EOR component would require appropriate permitting from the SJVAPCD, with emission reduction mitigation as required under District Rules (such as BACT and offsets, if necessary). Therefore, staff believes that the cumulative operation impacts of HECA and the EOR component would be less than significant.

In addition, staff makes the following inter-agency request to ensure that the cumulative air quality impacts of these two projects are less than significant:

- The Energy Commission requests that the EOR component CEQA/NEPA responsible agency require construction emission mitigation measures that are as strict or stricter than the measures provided in Staff Conditions **AQ-SC3** and **AQ-SC5**.

CUMULATIVE IMPACTS

"Cumulative impacts" are defined as "two or more individual effects which, when considered together, are considerable or…compound or increase other environmental impacts." (CEQA Guidelines, § 15355.) A cumulative impact consists of an impact that is created as a result of a combination of the project evaluated in the EIR together with other projects causing related impacts." (CEQA Guidelines, § 15130(a)(1).) Such impacts may be relatively minor and incremental, yet still be significant because of the existing environmental background, particularly when one considers other closely related past, present, and reasonably foreseeable future projects.

This analysis is concerned with criteria air pollutants. Such pollutants have impacts that are usually (although not always) cumulative by nature. Rarely would a project by itself cause a violation of a federal or state criteria pollutant standard. However, a new source of pollution may contribute to violations of criteria pollutant standards because of the existing background sources or when combined with foreseeable future projects. Air districts attempt to attain the criteria pollutant standards by adopting attainment plans, which comprise a multi-faceted programmatic approach to such attainment. Depending on the air district, these plans typically include requirements for air emissions offsets and the use of Best Available Control Technology (BACT) for new sources of emissions, and restrictions of emissions from existing sources of air pollution.

Thus, much of the preceding discussion is concerned with cumulative impacts. The "Existing Ambient Air Quality" section describes the air quality background in the San Joaquin Valley Air Basin in the vicinity of the proposed project's site, including a discussion of historic ambient levels for each of the significant criteria pollutants. The "Construction Impacts and Mitigation" subsection discusses the project's contribution to the local existing background caused by project construction. The "Operation Impacts and Mitigation" section discusses the proposed project's contribution to the local existing background caused by project operation. The following subsection includes these additional analyses:

- a summary of projections for criteria pollutants by the air district and the air district's programmatic efforts to abate such pollution; and
- an analysis of the proposed project's *localized cumulative impacts*, the proposed project's direct operating emissions combined with other local major emission sources;

Summary of Projections

The SJVAPCD is the lead agency for managing air quality and coordinating planning efforts for the portion of Kern County within the SJVAB, so that the ozone and PM10 standards are attained in a timely fashion and attainment with CO standards are maintained[14]. The District is responsible for developing those portions of the State Implementation Plan (SIP) and the Air Quality Management Plan (AQMP) that deal with certain stationary and area source controls and, in cooperation with the transportation planning agencies (TPAs), the development of transportation control measures (TCMs). In this role the SJVAPCD is the agency with principal responsibility for analyzing and addressing cumulative air quality impacts, including the impacts of ambient ozone and particulate matter. The District has summarized the cumulative impacts of ozone and particulate matter on the air basin from the broad variety of its sources. Analyses of these cumulative impacts, as well as the measures the District proposes to reduce impacts to air quality and public health, are summarized in four publicly available documents that the District has adopted. These adopted air quality plans are summarized below.

2007 Ozone Plan (8-hour ozone plan)

2007 PM10 Maintenance Plan
Link: http://www.arb.ca.gov/planning/sip/sjvpm07/sjvpm07.htm

2008 PM2.5 Plan
Link:http://www.valleyair.org/Air_Quality_Plans/AQ_Final_Adopted_PM25_2008.htm

2012 PM2.5 Plan
Link: http://www.valleyair.org/Air_Quality_Plans/PM25Plans2012.htm

The Extreme Ozone Attainment Demonstration Plan for 1-hour ozone was approved by the U.S. EPA on March 8, 2010. The 2007 Ozone Plan for 8-hour ozone, attainment planning for the 1997 8-hour ozone standard, was adopted by the District on April 30,

[14] The project area is in a CO attainment area that is not a maintenance area, so the SJVAPCD CO Maintenance Plan is not applicable to the project area and CO planning will not be discussed further.

2010 and by the ARB on June 14, 2010. U.S. EPA approved the 8-hour ozone plan in December 2011. The U.S. EPA approval of the Extreme Ozone Attainment Demonstration Plan was subsequently withdrawn in November 2012, along with partially withdrawing approval of the 2007 ozone plan. The District is developing a new 1-hour ozone plan which it plans on submitting by June 2013. Additionally, the District is expecting to submit an 8-hour ozone plan by 2015 to address the current extreme non-attainment of the 2008 8-hour ozone standard.

A reasonably available control technology (RACT) demonstration for ozone is required by U.S. EPA to demonstrate that the District has satisfied all federal RACT requirements as necessary for NAAQS attainment planning purposes. The District's 2009 RACT demonstration document found that the current District rules, with two minor exceptions, meet the federal RACT requirements. One of those rules, Rule 4311 – Flares, applies to this project. The District subsequently amended Rule 4311 in 2009 to comply with the federal RACT requirement, and this project must comply with that amended rule and all of the other applicable District rules that comply with the federal RACT requirements.

The 2007 PM10 Maintenance Plan was approved and the SJVAB was redesignated as attainment for PM10 by U.S. EPA on September 2008. The 2008 PM2.5 Plan was adopted by the District on April 30, 2008 and was submitted to the U.S. EPA by ARB on June 30, 2008. U.S. EPA approved nearly all elements of the 2008 PM2.5 Plan in September, 2011. The 2012 PM2.5 Plan was adopted by the District in December 2012 and approved by ARB on January 24, 2013. Since the plan has not yet been approved by U.S. EPA, the 2008 PM2.5 Plan is the currently approved plan.

Ozone

Extreme Ozone Attainment Demonstration Plan and 2007 Ozone Plan

The 2007 Ozone Plan, like the 1-hour Extreme Ozone Plan, requested that the SJVAB be reclassified as an extreme nonattainment area, which was granted by U.S. EPA. The extreme designation will change permitting requirements and definitions; including lowering the emissions threshold for determining whether or not a proposed facility is a major source and increasing the minimum offset ratio to 1.5 to 1 assuming that the District cannot prove all major sources have implemented BACT, a requirement that has been added to Rule 2201.[15] Other requirements include the expeditious implementation of reasonably available control technology (RACT). The plan includes a number of control measures to implement the reductions needed for attainment and these include stationary source control measures, as well as incentive measures, innovative measures, and the implementation of other transportation and engine standard measures for state and federal government fleet vehicles. These plans target NOx and VOC emission reductions from a multitude of stationary source types, such as wineries, feedlots, small combustion sources, gas turbines, IC engines, and various solvent/coating sources. However, the plan would not impact the HECA emission sources because they already meet BACT requirements.

[15] However, this Rule 2201 requirement, as provided in Section 4.8.1, does not apply to HECA as the project's original permit application was deemed complete before this rule update became effective.

Compliance with Ozone Plans

The SJVAPCD rules and regulations specify performance standards, offset requirements, and emission control requirements for stationary sources. The regulations also include requirements for obtaining Authority to Construct (ATC) permits and subsequent operating permits. These regulations apply to HECA and all other projects with emission sources. In general, triennial updates of the attainment plans ensure that population, employment, and transportation trends in the region are taken into account, and compliance with SJVAPCD rules and regulations ensures consistency with the regional air quality management plans.

Energy Commission staff has evaluated a potential concern that HECA could interfere with the attainment effort of the 2007 Ozone Plan if it relies on offsets created by emission reductions prior to the plan baseline. The SJVAPCD is expecting new stationary sources like HECA to use pre-baseline credits (pre-2002 for the 2007 Ozone Plan) to allow growth from permitted stationary sources during the period of this plan, but as a safeguard, a cap would be established on the quantity of pre-baseline credits used by new sources. Additionally, the integrity of the proposed mitigation may be adversely affected by the annual equivalency demonstration required by SJVAPCD Rule 2201, Section 7, which ensures that the District's offset requirements are at least as stringent as the federal requirements. Since the project's FDOC is expected to be issued before there is any failure in the equivalency demonstration, the ERCs used for HECA need not be "surplus at time of use". The implication is that the ERCs surrendered for HECA are presently surplus and they would not be subject to discounting to demonstrate equivalency with federal offset requirements. The project could result in future failures in the annual NSR offset equivalency demonstration, which would impact how future project ERC sources are evaluated, but that would not directly impact the offset compliance status for HECA. Therefore, because the project would use BACT to control ozone precursor emissions and ERCs at a minimum offset ratio of 1.5 to 1 (for NOx and VOC) to fully offset ozone precursors as required by the effective version of New Source Review Rule 2201 at the time the project's application was deemed complete by the District, staff has determined that the project would not directly conflict with the District's 2007 Ozone Plan or regional ozone attainment goals.

Particulate Matter

2007 PM10 Maintenance Plan

The 2007 PM10 Maintenance Plan illustrates how the SJVAPCD intends to continue the efforts of the 2003 PM10 Plan and 2006 PM10 Plan that implemented aggressive PM10 controls in the region, including Reasonably Available Control Measures (RACM) for large existing sources of PM10 and fugitive dust. The 2007 PM10 Maintenance Plan includes a request for reclassification to "attainment" for the federal PM10 standard, and it provides for continued attainment for 10 years from the designation. In November 2008, the U.S. EPA redesignated the SJVAPCD to attainment for the federal PM10 standard (73 FR 66759, November 12, 2008).

2008 PM2.5 Plan

The District prepared a 2008 PM2.5 Plan which focuses primarily on the strategy to attain the 1997 annual standard set by the U.S. EPA of 65 $\mu g/m^3$ by 2015. In 2006, U.S.

EPA revised the 24-hour standard to 35 μg/m^3. Through continued implementation of the 2008 PM2.5 Plan the SJVAB is predicted to be in attainment of the 1997 annual standard by 2015.The section below discusses attainment with the revised standard.

The 2008 PM2.5 Plan contains a comprehensive list of strict regulatory and incentive-based measures to reduce directly emitted PM2.5 and precursor emissions throughout the San Joaquin Valley. The plan considers all of the following four facets of control strategy:

- Regulatory Control Measures for Stationary Sources,
- Incentive-based Strategies,
- Innovative Strategies and Programs, and
- Local, State, and Federal Sources/Partnerships

2012 PM2.5 Plan

The District prepared a 2012 PM2.5 Plan which focuses primarily on the strategy to attain the 2006 annual standard set by the U.S. EPA of 35 μg/m^3 by 2019. It is expected the majority of the Valley will be in attainment prior to the 2019 deadline. ARB approved the plan at a public hearing on January 24, 2013.

The 2012 PM2.5 Plan builds on existing strategies to reduce PM2.5 emissions. The plan incorporates local, state and federal strategies to reduce PM2.5 emissions. The strategies involve targeting both direct PM 2.5 and indirect PM 2.5 through reducing NOx emissions. NOx emissions are identified as the predominate pollutant leading to the formation of PM2.5, they are expected to be reduced by 55 percent. Focusing on NOx reductions has the added benefit of assisting with strategies aimed at reducing ozone. A critical component to the plan involves the reduction of mobile source emissions. The reduction of mobile source emissions is dependent on state and federal measures.

The 2012 plan includes the following control strategies:

- Wide-ranging regulations for both stationary sources and the public,
- Risk based approach prioritizing measures for expeditious attainment considering public health benefits,
- Incentive programs targeting mobile sources including off-road vehicles and equipment,
- Research/further studies to continue to develop policies and identify additional clean air strategies,
- Policy and legislative efforts at local state and federal levels,
- Outreach efforts to assist the public in getting involved to improve air quality,
- State and federal regulations reducing emissions from mobile sources including on-road and off-road sources,

- Incentive funding and programs to assist the District in reducing mobile source emissions, and
- Technology advancement efforts including funding and collaborative support from other agencies to develop new zero and near zero-emission technologies.

Compliance with Particulate Plans

Energy Commission staff is concerned that HECA could interfere with the attainment effort of the 2008 PM2.5 Plan if it relies on SOx emission reduction credits without an adequate interpollutant trading ratio for PM2.5 increases. The "reasonable further progress" calculations in the 2008 PM2.5 Plan shows that about ten times more tons of direct PM2.5 need to be reduced than SO_2 (Table 8-2 of 2008 PM2.5 Plan). The 2014 Receptor Modeling Documentation supporting the 2008 PM2.5 Plan indicates that reducing SOx would not be as effective as reducing direct PM2.5 as NOx. The District inventory of SOx is too small to have enough of an impact when compared to direct PM2.5 or NOx. Interpollutant trading is allowed with "the appropriate scientific demonstration of an adequate trading ratio" (Rule 2201, Section 4.13), and the SJVAPCD 2007 PM10 Maintenance Plan (see Appendix E of the Maintenance Plan) indicates that the minimum ratio would be one-to-one with higher interpollutant ratios if appropriate under Rule 2201. The PDOC indicates that the approved interpollutant offset ratio for SOx for PM10 for HECA is 1 to 1. However, staff notes that although implementation of trading under District Rule 2201 is subject to federal oversight, there is no evidence in the record indicating whether the methods used by the District in developing the interpollutant SOx for PM10 ratio has been specifically reviewed and/or approved by U.S. EPA.

Additionally, there are issues regarding the PM2.5 emission estimate for the project that have been previously commented on by Energy Commission staff (CEC 2010) and U.S EPA (U.S. EPA 2010). However, staff believes that the PM2.5 emissions, with the current operations assumptions would not exceed the Clean Air Act New Source Review trigger of 100 tons per year which would mean that the PM2.5 offsets do not have to comply with an interpollutant precursor trading ratio approved by U.S. EPA.

Although there is no formal federal endorsement of the District's interpollutant trading approach for PM10, Energy Commission staff preliminarily concludes that HECA would not conflict with regional particulate matter attainment and maintenance goals due to the following reasons and assumptions:

- The project is required to apply a distance ratio to the emission reduction credits that increases the overall offset ratio for PM10 to 1.5 to 1.
- Staff recognizes that the PM2.5 attainment plan has been previously adopted by ARB, and the SJVAPCD has determined that the interpollutant trading ratio for HECA is appropriate.
- The PDOC shows that HECA is likely to comply with the particulate matter plans by meeting its permit requirements and complying with the existing applicable rules and regulations.
- Offsets do not provide for future reductions in emissions impacts, rather they have provided past reductions and benefitted the air basin since the time of the reduction;

and a review of the SJVAB historical emissions inventories and PM2.5 ambient concentrations seems to indicate that the improvements in PM2.5 ambient concentrations may to some extent track with the reductions in SO_2 emissions that have occurred in the SJVAB over the past 15 years.

Staff may revise this preliminary conclusion if further analysis shows that the one-to-one SO_2 for PM offset ratio would significantly interfere with the attainment effort of the 2008 PM2.5 Plan.

Localized Cumulative Impacts

Since power plant direct air quality impacts can be reasonably estimated through air dispersion modeling (see the "Operation Modeling Analysis" subsection) the proposed project's contributions to localized cumulative impacts can be estimated. To represent *past* and, to an extent, *present projects* that contribute to ambient air quality conditions, the Energy Commission staff recommends the use of ambient air quality monitoring data (see the "Existing Ambient Air Quality" subsection), referred to as the *background*. The staff takes the following steps to estimate what are additional appropriate "present projects" that are not represented in the background and "reasonably foreseeable projects":

- First, the Energy Commission staff (or the applicant) works with the air district to identify all projects that have submitted, within the last year of monitoring data, new applications for an authority to construct (ATC) or permit to operate (PTO) and applications to modify an existing PTO within 6 miles of the project site. Based on staff's modeling experience, beyond 6 miles there is no statistically significant concentration overlap for non-reactive pollutant concentrations between two stationary emission sources.
- Second, the Energy Commission staff (or the applicant) works with the air district and local counties to identify any new area sources within 6 miles of the project site. As opposed to point sources, area sources include sources like agricultural fields, residential developments or other such sources that do not have a distinct point of emission. New area sources are typically identified through draft or final Environmental Impact Reports (EIRs) that are prepared for those sources. The initiation of the EIR process is a reasonable basis on which to determine what is "reasonably foreseeable" for new area sources.
- The data submitted, or generated from the applications with the air district for point sources or data from the EIR process for area sources, provides enough information to include these new emission sources in air dispersion modeling. Thus, the next step is to review the available EIR(s) and permit application(s), determine what sources must be modeled and how they must be modeled.
- Sources that are not new, but may not be represented in ambient air quality monitoring are also identified and included in the analysis. These sources include existing sources that are co-located with or adjacent to the proposed source (such as an existing power plant). In most cases, the ambient air quality measurements are not recorded close to the proposed project, thus a local major source might not be well represented by the background air monitoring data. When these sources are

included, it is typically a result of there being an existing source on the project site and the ambient air quality monitoring station being more than 2 miles away.

- The modeling results must be carefully interpreted so that they are not skewed towards a single source, in high impact areas near that source's fence line. It is not truly a cumulative impact of HECA if the high impact area is the result of high fence line concentrations from another stationary source and HECA is not providing a substantial contribution in the determined high impact area of the other source.

Once the modeling results are interpreted, they are added to the background ambient air quality monitoring data and thus the modeling portion of the cumulative assessment is complete. Due to the use of air dispersion modeling programs in staff's cumulative impacts analysis, the applicant must submit a modeling protocol, based on information requirements for an application, prior to beginning the investigation of the sources to be modeled in the cumulative analysis. The modeling protocol is typically reviewed, commented on, and eventually approved in the data adequacy phase of the Energy Commission licensing procedure. Staff typically assists the applicant in finding sources (as described above), characterizing those sources and interpreting the results of the modeling. However, the actual modeling runs are usually left to the applicant to complete. There are several reasons for this; modeling analyses take time to perform and require significant expertise, the applicant has already performed a modeling analysis of the proposed project alone (see the "Operation Modeling Analysis" subsection), and the applicant can act on its own to reduce stipulated emission rates and/or increase emission control requirements as the results warrant. Once the cumulative project emission impacts are determined, the necessity to mitigate the proposed project emissions can be evaluated, and the mitigation itself can be proposed by staff and/or the applicant (see the "Operation Mitigation" subsection).

The applicant requested a list of possible new stationary sources within six miles of the project site from the SJVAPCD in 2009 and again in 2011. The 2009 list included seven sources with minimal emissions potential (URS 2010). No significant stationary sources, with greater than 5 tons of permitted emissions of any pollutant, were identified within six miles of the project site. No additional possible new stationary sources were identified by the District in 2011 (HECA 2012e). Therefore, it has been determined that no stationary sources requiring a cumulative air dispersion modeling analysis exist within a 6-mile radius of the project site.

However, there is the potential for additional projects, such as renewable energy projects or oil and gas recovery projects, in the general area of the proposed project site. Additionally, there is the potential for significant additional development within the air basin. The corresponding potential for an increase in air basin emission sources is a major part of staff's rationale for recommending Conditions of Certification **AQ-SC6**, **AQ-SC7**, **AQ-SC9**, **AQ-SC10**, and **AQ-SC12** that are designed to mitigate the proposed project's cumulative impacts by substantially reducing mobile source and fugitive dust emissions during site operation. With these recommended mitigation measures, staff has concluded that the cumulative air quality impacts are less than significant.

While staff did not require a cumulative modeling analysis, the regional 1-hour NO_2 modeling analysis (**Air Quality Table 21**) that was completed to show compliance with the federal 1-hour NAAQS was a cumulative analysis that included a number of regional emissions sources as described by the applicant in the AFC Appendix E-7 (HECA 2012e), and the PDOC Appendix K (SJVAPCD 2013a).

Staff has considered the environmental justice population surrounding the site (see **Socioeconomics Figure 1**). Since the proposed project's cumulative air quality impacts have been mitigated to less than significant, there is no environmental justice issue for air quality cumulative impacts.

COMPLIANCE WITH LORS

The San Joaquin Valley Air Pollution Control District issued a Preliminary Determination of Compliance (PDOC) for the Hydrogen Energy California project on February 7, 2013 (SJVAPCD 2013a). The District will issue a Final Determination of Compliance (FDOC) after resolving any issues raised by the public or by agency comments. Compliance with all District rules and regulations was demonstrated to the District's satisfaction in the PDOC. The District's PDOC conditions are presented in the Conditions of Certification (**AQ-1** to **AQ-25**).

Staff submitted an official PDOC comment letter to SJVAPCD on March 28, 2013 and expects that the FDOC will contain revisions to conditions due to Energy Commission, applicant, or third party comments, and staff will provide revised FDOC findings and conditions of certification in the Final Staff Assessment (FSA).

FEDERAL

The District is responsible for issuing the federal New Source Review (NSR) permit and has delegated enforcement of the applicable New Source Performance Standards (NSPS, Subparts A, Db, GA, GG,Y, KKKK, and IIII). The U.S. Environmental Protection Agency's (EPA's) Prevention of Significant Deterioration (PSD) program has provisions for U.S. EPA to issue permits directly or to delegate administration to local agencies. Districts that are delegated and have adopted a SIP program approved by U.S. EPA are able to issue PSD permits that satisfy all of the federal Clean Air Act's PSD requirements. The SJVAPCD's PSD Rule 2410 was approved into the SIP on 6/1/2012, and U.S. EPA subsequently granted full PSD authority to the District; therefore the PSD permitting analysis has been completed by the District in the PDOC, and it will no longer be part of a separate federal action.

The PDOC issued by the SJVAPCD is undergoing a review process by the U.S. EPA concurrent with a public notice period. The U.S. EPA will provide any comments on the PDOC by the end of an extended comment period that concludes May 30, 2013. In addition the SJVAPCD held a public workshop to accept any verbal comments regarding the PDOC on April 2, 2012 and will hold a second public workshop on May 15, 2013. On March 28, 2013, staff provided the SJVAPCD a formal comment letter that identified concerns that staff has with the analysis and conditions contained in the PDOC, and expects to provide a second comment letter before the end of the comment period. Additionally, the District would have to review and address other agency and public comments, as appropriate.

Staff will evaluate any comments received from U.S. EPA on the PSA/DEIS and address them, if necessary, in the FSA.

General Conformity – DOE

Section 176(c)(1) of the Clean Air Act (CAA) requires that any entity of the federal government which engages in, supports, or in any way provides financial support for any activity demonstrate that the activity will conform to the applicable State Implementation Plans (SIPs) for achieving and maintaining National Ambient Air Quality Standards (NAAQS) for criteria pollutants before the federal entity proceeds with the activity. This requirement is referred to as the Clean Air Act's "General Conformity Rule" (GCR). As the HECA project will receive financial support from DOE, DOE must demonstrate that the project will conform to the applicable SIPs for all nonattainment and maintenance areas that would be affected by direct and indirect emissions from the project. DOE makes its conformity determination as part of their NEPA process.

A determination of conformity was performed for all the nonattainment and maintenance areas that would be affected by the HECA project – these areas are in the states of California, Arizona, and New Mexico. Emissions of criteria pollutants that would affect each of these areas from activities associated with construction and operation were estimated and compared to the *de minimis* thresholds established for the GCR to determine which emissions were subject to the rule.[16]

The estimates of emissions indicate that the total direct and indirect emissions of carbon monoxide (CO), particulate matter less than 10 microns in diameter (PM10), particulate matter less than 2.5 microns in diameter (PM2.5), and sulfur dioxide (SO_2) are below the GCR's thresholds for all years of construction and operation in all nonattainment and maintenance areas. Estimated construction and operational emissions of nitrogen oxides (NO_X) would exceed the GCR threshold during each year of construction and operation in the San Joaquin Valley Air Basin (SJVAB). Construction emissions of volatile organic compounds (VOCs) would exceed the threshold in 2014 and 2015 in the SJVAB. Accordingly, DOE must make a General Conformity Evaluation and Determination for NO_X in the SJVAB for the periods of construction and operation; and for VOC during construction. Appendix Air-1 contains the basis and supporting information used in this analysis.

The Applicant, HECA, has negotiated enforceable commitments with the San Joaquin Valley Air Pollution Control District (SJVAPCD) that call for HECA to provide funds to the District's Emission Reduction Incentive Program (ERIP), which the SJVAPCD would disburse as grants to emission reduction projects. The SJVAPCD would administer the projects and verify the emission reductions. The SJVAPCD would fund projects within the SJVAB that produce real, quantifiable, enforceable, emission reductions that would occur contemporaneously with the emissions from the project that are subject to the GCR. The District intends to fund enough projects to more than offset the HECA project's anticipated GCR emissions (that is, the SJVAPCD is requiring the applicant to provide funding for a surplus of emission reductions in the SJVAB). Through this

[16] Emissions of criteria pollutants that are regulated by a permit are exempt from the application of the GCR. Accordingly, most of the direct emissions from the operation of the HECA project are not subject to the conformity requirements.

mechanism, the District would ensure that construction and operational emissions of NO_X and VOCs from the project that exceed the GCR thresholds would be more than offset by the emission reductions achieved by the District's ERIP. On the basis of these agreements and the analysis in Appendix Air-1, DOE has determined that HECA would conform to the applicable SIPs and that its proposed financial assistance from the applicant complies with the requirements of the GCR.

General Conformity – Energy Commission Staff

The United States Department of Energy (DOE) is in the process of completing the project's General Conformity draft analysis. The draft analysis has been provided as Appendix Air-1 of this CEQA/NEPA document. Staff, along with U.S. EPA and other interested parties, will review and as necessary comment on the draft General Conformity analysis during its public review period, which will coincide with the PSA/DEIS public review period. The draft General Conformity analysis will be noticed in the Federal Register by DOE, and the final General Conformity determination will be completed by DOE separate from the Energy Commission's licensing decision.

The draft General Conformity analysis includes the determination of the annual construction period emissions and the applicable annual operating period emissions. These applicable operating period emissions include the project related traffic/rail and on-site mobile equipment emissions, but do not include the stationary source emissions that are permitted by and mitigated under the SJVAPCD rules and regulations. The analysis indicates that the project's construction emissions (NOx and VOC) and the project's operating emissions (NOx) exceed the general conformity annual thresholds for the San Joaquin Valley Air Basin. The analysis also indicates that the General Conformity thresholds for the other affected nonattainment area along the project's transportation routes are not exceeded.

HECA is not included as an emissions source within the SIP or within the growth forecasts in the SIP; therefore, the peak NOx and VOC emissions from the project will need to be mitigated. The peak annual NOx emissions are estimated to be 69.0 tons per year during the second year of construction and 43.6 tons per year during operation, and the peak VOC emissions are estimated to be 12.4 tons per year during the third year of construction. The applicant has agreed to fund the SJVAPCD's Emission Reduction Incentive Program (ERIP) to create the necessary emissions reductions to fully offset these emissions. The DOE was involved with the SJVAPCD and the applicant during the General Conformity emissions mitigation negotiations and agrees that funding the ERIP will produce real, quantifiable, enforceable and surplus emissions reductions in sufficient quantities to cover HECA's NOx and VOC General Conformity emissions obligations.

The emission reductions created through the projects funded by the ERIP could include the replacement of older equipment with newer lower emitting equipment or electrification of diesel engines, among other types of projects. Staff notes that one benefit of funding new emissions reductions in comparison with using existing ERCs is that other pollutant emissions, such as diesel particulate emissions, will also be reduced through the emissions reduction projects funded. The total funding is calculated based on the total construction period emissions (243.6 tons of NOx and 39.5 tons of VOC) and the first ten years of operations emissions (43.6 tons/year times 10 years). The mitigation fee is based on $9,350/ton with a 4 percent administration fee, so the total General Conformity based mitigation fee has been calculated to be approximately $7,000,000.

STATE

The applicant will demonstrate that the project will comply with Section 41700 of the California State Health and Safety Code, which restricts emissions that would cause nuisance or injury, through the issuance of the District's Preliminary Determination of Compliance and the Energy Commission's affirmative finding for the project.

The District's conditions and staff verifications will ensure compliance with the emission limit requirements of the ARB diesel engine air toxic control measures (ATCMs) and the applicant will also be required to comply with the idle restriction requirements of the ATCMs. District Policy APR 1905 – Risk Management Policy for Permitting New and Modified Sources, specifies that if there is an increase in emissions associated with a proposed new source, the District will perform an analysis to determine the possible impact to the nearest resident or worksite receptor. This analysis was included in the PDOC. The total facility prioritization score was greater than one. Therefore, a health risk assessment was required to determine the short-term acute and long-term chronic exposures from this project. Best available control technology for toxic emission control (T-BACT) was triggered for the CTG/HRSG, but all other facility sources were found to have prioritization scores below the trigger level for T-BACT. T-BACT for this unit would be satisfied with BACT for PM10 and VOC.

The applicant is exempt from the requirements of the Air Toxics "Hot Spots" risk assessment requirements (Section 44300 of the California Health and Safety Code) because the project will have had a risk assessment performed as part of its district permitting and the risk assessment, as provided in the District's PDOC, found that the project's emissions would result in less than significant health risks to the public.

LOCAL

As part of the Energy Commission's licensing process, in lieu of issuing a construction permit to the applicant for HECA, the District will prepare and present to the Energy Commission a DOC (both a PDOC, and after a public comment period, an FDOC). The PDOC was published on February 7, 2013 (SJVAPCD 2013a), and the FDOC will be published after the District has had time to respond to comments received on the PDOC, including comments from the applicant, the Energy Commission, and other interested parties such as U.S. EPA.

The District rules and regulations specify the emissions control and offset requirements for new sources such as HECA. Best Available Control Technology (BACT) will be implemented and emission reduction credits (ERCs) proposed by the Applicant and approved and certified by the District will fully mitigate project nonattainment pollutant emissions (including precursors) so that they would be consistent with the strategies and future emissions anticipated under the District's air quality attainment and maintenance plans. In addition, under a voluntary emissions reduction agreement with the SJVAPCD, the applicant will provide additional emissions mitigation through the funding of emission reduction projects.

The District's PDOC states that the proposed project is expected to comply with all applicable District rules and regulations. The DOC evaluates whether and under what conditions the proposed project will comply with the District's applicable rules and regulations, as described below.

Rule 1080 – Stack Monitoring

This rule grants the Air Pollution Control Officer (APCO) the authority to request the installation and use of continuous emissions monitors (CEMs), and specifies performance standards for the equipment and administrative requirements for record keeping, reporting, and notification. The facility will be equipped with CEMS for the following:

- CTG/HRSG: NOx, CO and O_2
- Nitric Acid Plant: NOx

The PDOC includes conditions to assure compliance with this rule.

Rule 1081 – Source Sampling

This rule requires adequate and safe facilities for use in sampling to determine compliance with emission limits, and specifies methods and procedures for source testing and sample collection. The PDOC includes periodic source testing requirements for the CTG, sulfur recovery unit/thermal oxidizer, CO_2 recovery and vent system, auxiliary boiler, ammonia startup heater, nitric acid unit, ammonium nitrate unit, and material handling units. Additionally, the PDOC includes fugitive emissions leak detection and repair program requirements identifying the sampling requirements for piping components and tanks in VOC or other criteria pollutant or hazardous air pollutant (HAP) service. The PDOC also includes total dissolved solids testing requirements for the cooling towers. Finally, there are other fuel and stream composition sampling requirements in the PDOC as necessary to determine composition necessary to calculate emissions or determine rule applicability and compliance. The PDOC includes conditions to assure compliance with this rule.

Rule 1100 – Equipment Breakdown

This rule defines a breakdown condition, the procedures to follow if one occurs, and the requirements for corrective action, issuance of an emergency variance, and reporting. This rule is applied to the owner of any source operation with air pollution control equipment, or related operating equipment that controls air emissions, or continuous monitoring equipment. Specific procedures for the CTG are included in the PDOC. The PDOC includes conditions to assure compliance with this rule.

Rule 2010 – Permits Required

This rule requires any person who is building, altering, replacing or operating any source that emits, may emit air contaminants, or may reduce emissions, to first obtain authorization from the District in the form of an Authority to Construct (ATC) or a Permit to Operate (PTO). For Energy Commission jurisdictional power plant projects, the District completes their analysis in the form of a DOC and the Authority to Construct and

Permit to Operate are granted by the District if they make a positive final DOC finding and the AFC is approved by the Energy Commission. The filing of the application with the District (HECA 2012e) and obtaining the ATC and PTO will fulfill the requirements of this rule.

Rule 2201 – New and Modified Stationary Source Review Rule

The main function of the District's New Source Review Rule is to allow for the issuance of Authorities to Construct, Permits to Operate, the application of Best Available Control Technology (BACT) to new or modified permit source and to require the new permit source to secure emission offsets. In addition, see Rule 2010, above.

Section 3.16 – Daily Emissions Limitation (DEL)

This requires daily emission limitations (DELs) restricting a unit's maximum daily emissions to a level at or below the emissions associated with the maximum design capacity. DELs must be contained in the applicable permits and enforceable on a daily basis. The PDOC includes conditions to assure compliance with the DELs.

Section 4.1 – Best Available Control Technology

Best Available Control Technology (BACT) is defined as the most stringent emission limitation or control technique of the following: a) achieved in practice for a category and class of source; b) contained in any State Implementation Plan and approved by the U.S. EPA for a category and class of source; c) contained in an applicable federal New Source Performance Standard; or d) any other emission limitation or control technique that the District's Air Pollution Control Officer (APCO) finds is technologically feasible and cost effective. BACT is required for any new or modified emission unit that results in an emissions increase of at least 2.0 lb/day. However, Section 4.2.1 states that BACT is not required for CO emissions from any new or modified emissions unit if those sources emit less than 200,000 lb/year of CO. In the case of HECA, BACT applies for the following equipment and pollutants:

- Gas Turbine/HRSG – NOx, CO, VOC, SOx, PM10, CO_2
- Railcar/Truck Unloading and Transfer Systems – PM10
- Feedstock Storage, Blending and Reclaim System – PM10
- Feedstock Grinding/Crushing and Drying System – PM10
- Gasification System – CO, VOC, CO_2
- Gasification Solids Handling System – PM10
- Sulfur Recovery System – SOx
- CO_2 Recovery and Vent System – VOC, CO, CO_2
- Auxiliary Boiler – NOx, CO, VOC, SOx, PM10
- Three Cooling Towers – PM10
- Gasification Flare – NOx, CO, VOC, SOx, PM10
- Sulfur Recovery Unit Flare – NOx, CO, SOx, PM10

- Rectisol® Flare – NOx, CO, VOC, SOx, PM10
- Ammonia Startup Heater – NOx, CO, VOC, SOx, PM10
- Urea Absorber and Urea Pastillation Unit – PM10
- Nitric Acid Unit – NOx
- Ammonium Nitrate Unit – PM10
- Urea Storage and Handling Operation – PM10
- Emergency Generator Engines and Firewater Pump – NOx, CO, VOC, PM10

The District has determined that the control equipment or basic equipment proposed for HECA currently meets the requirements of BACT.

The PDOC includes conditions to assure compliance with the BACT determinations, including the gas turbine/HRSG BACT demonstration requirements.

Section 4.5 through 4.13 – Emission Offset Requirements

Section 4.5 specifies that emissions offsets for new or modified sources are required when their emissions are equal to or exceed the following levels:

- Oxides of Nitrogen, NOx – 20,000 lbs/year;
- Volatile Organic Compounds, VOC – 20,000 lbs/year;
- Carbon Monoxide, CO – 200,000 lbs/year;
- PM10 – 29,200 lbs/year;
- Sulfur Oxides, SOx – 54,750 lbs/year.

If constructed, HECA would exceed the above emission levels for NOx, VOC, CO, PM10 and SOx based on the permitted equipment emission limits and the applicant's requested facility operation.

Section 4.6 specifies that emissions offsets are not required for increases of CO in attainment areas (such as in the vicinity of the proposed HECA project), if the applicant demonstrates that the emissions increase will not cause or contribute to a violation of the ambient air quality standards, and that those emissions are consistent with Reasonable Further Progress. The District completed a modeling analysis for the project's CO emissions using AERMOD. Worst case 1-hour and 8-hour CO impacts were added to the worst case ambient background concentrations and compared to the AAQS. The modeling results shown below demonstrate that the proposed increases in CO emissions will not cause a violation of the CO AAQS and therefore offsets will not be required:

	1 hr std μg/m^3	**8 hr std μg/m^3**
Worst Case Background	4,581	2,485
Facility Increment	7,244	2,856
Total	11,825	5,341
AAQS	23,000	10,000

Section 4.6 also specifies that emergency equipment used exclusively as emergency standby equipment for electrical power generation is exempt from emission offset requirements.

Section 4.8 specifies that the required emission offsets shall be adjusted according to the distance of the offset from the proposed project's site. The ratios are:

- NOx and VOC major sources - 1.5:1, regardless of distance
- PM2.5 - 1:1, regardless of distance
- Other Pollutant Distance Ratios
  - Internal or on-site source – 1 to 1;
  - Within 15 miles of the source – 1.2 to 1 (non-major source), 1.3 to 1 (major source); and
  - 15 miles or more from the source – 1.5 to 1.

Section 4.13.1 specifies that major sources (defined as those sources that emit greater than 25 tons of NOx and VOC, 100 tons CO, or 70 tons of PM10 and SOx) that are shut down and thus generate an ERC may not be used as an offset for a new major source (like HECA) unless those ERCs are included in an U.S. EPA-approved attainment plan.

Section 4.13.3 allows for the use of interpollutant offsets (including PM10 precursors for PM10) on a case-by-case basis, provided that the applicant demonstrates that the emissions increase will not cause a violation of any ambient air quality standard. The ratio for interpollutant trading shall be based on an air quality analysis and shall be equal to or greater than the minimum offsetting requirement (the distance ratios) of Section 4.8.

Section 4.13.3.2 allows for the use of interpollutant offsets between PM2.5 and PM2.5 precursors at specific ratios as established by the U.S. EPA, or as approved into the SIP by the U.S. EPA. The District has determined this restriction on the use of interpollutant offsets according to these ratios is only applicable to new major sources and major modifications of PM2.5. This requirement would not be applicable since the proposed facility's emissions of PM2.5 are low enough that it is not a new major source of PM2.5.

Section 4.13.4 requires Actual Emissions Reductions (AER) used as offsets to have occurred during the same calendar quarter as the emissions increases being offset. Exceptions to this rule (4.13.7 through 4.13.9) allow PM emission reductions that occurred from October through March to offset PM emissions occurring anytime during the year, for NOx and VOC emission reductions that occurred from April through November to offset NOx and VOC emissions occurring anytime during the year.

The District has evaluated the offset need and offsets proposed by the applicant, including evaluating the proposed interpollutant offsets. The District has found that the applicant's offset proposal will comply with these regulations (SJVAPCD 2013a).

Section 4.14 – Ambient Air Quality Standards

Section 4.14.1 requires that emissions from new stationary sources subject to public noticing requirements be modeled to determine if the emissions cause or worsen a violation of an AAQS. This District can consider mitigation of emissions through offsets in this determination. The District's modeling analysis provided in Appendix K of the PDOC determined that all pollutants would either remain below the AAQS or below relevant Significant Impact Levels (SILs) with the exception of the 24-hour and annual PM2.5 SILs. Therefore, to ensure that the project's PM2.5 emissions do not create adverse impacts, the District is requiring offsets to fully mitigate the total PM2.5 emissions from the project. Taking this mitigation into consideration, the District has determined that the project will not cause or make worse a violation of the PM2.5 AAQS. This project is not a major source of PM2.5 emissions and otherwise would not require PM2.5 emissions offsets. Compliance with this rule is expected.

Section 4.15 – Additional Requirements for new Major Sources and Federal Major Modifications

Section 4.15.2 requires that the owner of a proposed new major source or federal major modification demonstrate to the satisfaction of the District that all major stationary sources subject to emission limitations that are owned or operated by the applicant or any entity controlling or under common control with the applicant in California, are in compliance or on a schedule for compliance with all applicable emission limitations and standards. The applicant has indicated that they will provide a certification in compliance with this regulation prior to issuance of the FDOC. Compliance with this rule is expected.

Rule 2410 – Prevention of Significant Deterioration

Rule 2410 incorporates federal PSD rule requirements into the District's rules and regulations, and became effective as of June 1, 2012. PSD applies to major sources designated in attainment with NAAQS. Rule 2410 requires an air analysis demonstrating compliance with NAAQS for applicable pollutants. Therefore modeling was performed to demonstrate that regulated air pollutants would not cause or contribute to a violation of applicable NAAQS, PSD increments, Air Quality Related Values (AQRV), or result in impacts to visibility and soil and vegetation. The project is designated a PSD source for CO, NOx and PM10. The District's modeling analysis shown in Appendix K of the PDOC indicated that project specific impacts would exceed the Class II SILs for 1-hour CO and 1-hour NO_2. An additional refined cumulative screening analysis for CO determined that the cumulative CO impacts would be well below the NAAQS, so no significant CO impacts would occur. Additional cumulative impact modeling and PSD increment analysis was completed for NO_2. This refined modeling determined that the project would not cause new exceedances of the 1-hour NO_2 NAAQS. In summary, SJVAPCD determined the proposed project would not cause, or significantly contribute to, a violation of the NAAQS and demonstrated compliance with other modeling requirements of this rule. Compliance with this rule is expected.

Rule 2520 – Federally Mandated Operating Permits

Rule 2520 requires that a project owner file a Title V Operating Permit from the U.S. EPA with the District within 12 months of commencing operation. A project is subject to this requirement if any of the following apply: the project is a major stationary source (under PSD definitions), it has the potential to emit greater than 100 tons per year of a criteria pollutant, any equipment permitted is subject to New Source Performance Standards, the project is subject to Title IV Acid Rain program, or the owner is required to obtain a PSD Permit. The Title V Permit application requires that the owner submit information on the operation of the air polluting equipment, the emission controls, the quantities of emissions, the monitoring of the equipment as well as other information requirements. Title V requirements apply to HECA and the PDOC includes conditions to assure compliance with this rule.

Rule 2540 – Acid Rain Program

A project greater than 25 megawatts (MW) and installed after November 15, 1990, must submit an acid rain program permit application to the District. The acid rain requirements will become part of the Title V Operating Permit (Rule 2520). Monitoring of the NOx and SOx emissions and a relatively small quantity of SOx allowances (from a national SOx allowance bank) will be required as well as the use of a NOx CEM. An acid rain application will need to be submitted to EPA at least 24 months before the date the unit expects to generate electricity. The PDOC includes conditions to assure compliance with this rule.

Rule 2550 – Federally Mandated Preconstruction Review for Major Sources of Air Toxics

Rule 2550 applies to new facilities classified as a major toxics source. The project as proposed is not a major air toxics source because individual HAP emissions are below ten tons per year and total stationary HAP emissions are below twenty five tons per year. The PDOC includes conditions to assure the project would remain below the major air toxics source thresholds. Initial testing will be required for the CO_2 recovery and vent system and CTG. The PDOC includes conditions to assure compliance with this rule.

Rule 4001 – New Source Performance Standards

Rule 4001 specifies that a project must meet the requirements of the Federal New Source Performance Standards (NSPS), according to Title 40, Code of Federal Regulations, Part 60, Chapter 1. The specific subparts that are applicable to HECA include:

- Subpart A - General Provisions. Section 60.18 – General Control Device and Work Practice Requirements.
- Subpart Db - Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units
- Subpart Ga – Standards of Performance for Nitric Acid Plants for Which Construction, Reconstuction, or Modification Commences After October 14, 2011
- Subpart Y - Standards of Performance for Coal Preparation and Processing Plants
- Subpart GG – Standards of Performance for Stationary Gas Turbines
- Subpart IIII - Standards of Performance for Stationary Compression Ignition Internal Combustion Engines

- Subpart KKKK - Standards of Performance for Stationary Combustion Turbines

Subpart A provides general requirements that apply to control devices. For this project this subpart applies to the sulfur recovery unit (SRU) and Rectisol® flares. The specific requirements of this rule relate to visible emissions limitations and monitoring, a requirement to maintain a flame at all times (i.e. pilot flame), and compliance recordkeeping requirements. The PDOC includes conditions to assure compliance with this rule.

Subpart Db is applicable to steam generating units with a heat input capacity of greater than 100 MMBtu/hr. The proposed auxiliary boiler is applicable to this Subpart. Applicable requirements include NOx standards and testing, exhaust monitoring and recordkeeping requirements. Facilities can demonstrate compliance through the monitoring of steam generating unit operating conditions if a plan is approved by the EPA Administrator. Therefore the facility will be required to submit a plan to EPA for approval within 360 days of initial startup. The PDOC includes conditions to assure compliance with this rule.

Subpart G is applicable to each nitric acid production unit commencing construction after August 17, 1971 and on or before October 14, 2011. Any facility commencing construction after October 14, 2011 is subject to Subpart Ga.

Subpart Ga is applicable to the proposed nitric acid unit. Subpart Ga establishes performance standard of 0.20 lb-NOx per ton of nitric acid produced (expressed as 100 percent nitric acid), averaged over a 24-hour rolling hour period. The PDOC includes conditions to assure compliance with this rule. Subpart Ga also requires a CEMS for measuring NOx. In addition the subpart outlines monitoring, testing, operational specifications, recordkeeping and reporting requirements for the CEMS.

Subpart Y is applicable to coal preparation and processing plants processing more than 181 megagrams (200 tons) of coal per day. The following processes are subject to this Subpart:

- Railcar Unloading and Transfer System
- Truck Unloading and Transfer System
- Feedstock Storage, Blending, and Reclaim System
- Feedstock Grinding/Crushing and Drying System

Subpart Y exempts thermal dryers receiving all of their thermal input covered under another subpart from the requirements in Subpart Y. The proposed dryer receives all of its thermal input from the treated exhaust of the CTG/HRSG subject to Subpart KKKK. Subpart KKKK requirements (described below) include emission control performance standards such as visible emission limitations, performance testing, monitoring, and recordkeeping requirements. The PDOC includes conditions to assure compliance with this rule.

Subpart GG is applicable to all stationary gas turbines with a heat input greater than 10.7 gigajoules per hour (10.2 MMBtu/hr) commencing construction after October 3, 1977. The proposed CTG is subject to this subpart. However, it is also subject to Subpart KKKK which has provisions exempting CTGs regulated by Subpart KKKK from Subpart GG requirements.

Subpart IIII is applicable to the emergency engines and emergency fire pump. This subpart establishes emission standards, fuel requirements, hour meter requirements, limits maintenance and testing and requires proper maintenance for the engines and control devices. The facility will comply with the use of the latest EPA Tier Certification level for the applicable horsepower range, ARB-certified fuel, installation of non-resettable hour meter, maintenance and testing limitations, and proper maintenance. The PDOC includes conditions to assure compliance with this rule.

Subpart KKKK is applicable to all stationary gas turbines with a heat input greater than 10.7 gigajoules per hour (10.2 MMBtu/hr) commencing construction after February 18, 2005. Subpart KKKK requires that a project meets specific NOx and SO_2 standards, meets continuous emission monitoring system requirements, meets various emission and fuel reporting requirements, and meets specified NOx and SOx performance testing requirements. The PDOC includes conditions to assure compliance with this rule.

Rule 4002 – National Emission Standards for Hazardous Air Pollutants

Rule 4002 incorporates the National Emission Standards for Hazardous Air Pollutants (NESHAPs) from Part 61 and Part 63, Chapter I, Subchapter C, Title 40 CFR and applies to major sources of Hazardous Air Pollutants (HAPs). HECA will conduct an initial speciated HAPS compliance source test to demonstrate it is not a major source of HAPS. The PDOC includes conditions to assure compliance with this rule.

Emergency engines are subject to the following NESHAP rule if they are operated at a major or area source of HAPS.

- Subpart ZZZZ – National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Emissions (RICE)

Subpart ZZZZ requires the engines to comply with CFR 60 Subpart IIII. Additional notification is required for engines with an initial performance test. Testing is not required for emergency engines. Therefore, the notification requirement is not applicable. The PDOC includes conditions to assure compliance with CFR 60 Subpart IIII and therefore compliance with this rule.

The IGCC complex, specifically the gasification unit, CTG/HRSG, and Coal Dryer are subject to the following NESHAP rule:

- Subpart UUUUU - National Emission Standards for Hazardous Air Pollutants: Coal- and Oil-Fired Electric Utility Steam Generating Units

This rule contains various emissions limits for coal and oil fired power plants by fuel and type of plant. The project's IGCC emissions are regulated with the emissions limits presented in Table 1 of this rule. The IGCC emissions limits are as follows:

- Filterable particulate matter[17] - $7.0E^{-2}$ lbs/MWh (megawatt-hour)
- Hydrogen chloride[18] (HCl) – $2.0E^{-3}$ lbs/MWh
- Mercury (Hg) – $3.0E^{-3}$ lbs/GWh (gigawatt-hour)

Staff's review of the emissions estimates provided by the applicant indicated that they will comply with these emissions limits. The applicant is proposing mercury control systems to remove mercury evolved in the gasification system to remove it from the syngas prior to its combustion and from the coal dryer exhaust to collect any mercury volatilized from the coal in the coal dryer. However, the PDOC does not contain any conditions specific to ensure compliance with this rule. Therefore, staff has included Condition of Certification **AQ-SC13** to address compliance with this rule. Staff anticipates that based on our comments on the PDOC conditions, the District will add conditions to the FDOC to adequately address compliance with this NESHAPS regulation, and if so staff will remove condition **AQ-SC13**.

Rule 4101 – Visible Emissions

This rule prohibits visible air emissions, other than water vapor, of more than No. 1 on the Ringelmann chart (20 percent opacity) for more than three minutes in any one-hour. Considering the control equipment (SCR/CO catalyst) on the gas turbine and other stationary sources, no visible emissions greater than 20 percent opacity are expected during normal operation of the facility. The PDOC includes conditions to assure compliance with this rule.

Rule 4102 – Nuisance

This rule prohibits any emissions "which cause injury, detriment, nuisance, or annoyance to any considerable number of persons or to the public or which endanger the comfort, repose, health or safety of any such person or public or which cause or have a natural tendency to cause injury or damage to business or property." The types of emission sources at the facility, when operating normally (see Rule 1100 above for equipment breakdown requirements), are not expected to cause the potential for nuisance. The PDOC includes a condition to assure compliance with this rule.

Rule 4201 – Particulate Matter Concentration

Rule 4201 limits particulates emissions from any source that emits or may emit dust, fumes, or total suspended particulate matter to less than 0.1 grain per dry standard cubic foot (gr/dscf) of gas calculated to 12 percent of carbon dioxide. The particulate matter grain loadings expected for the proposed facility equipment are less than this standard. The PDOC includes a condition to assure compliance with this rule.

---

[17] This standard is either a filterable particulate matter emissions limit or speciated non-Hg metals emissions limits. In this case the applicant will be complying using the filterable particulate matter emissions limit.

[18] This standard is either based on hydrogen chloride or sulfur dioxide, where the sulfur dioxide emissions standard must be monitored for compliance using a continuous emissions monitoring system (CEMS). The applicant is not proposing a sulfur dioxide CEMS, and so is proposing to comply with the hydrogen chloride emissions standard.

Rule 4202 – Particulate Matter Emission Rate

This rule limits particulate matter emissions for any source operation, which emits or may emit particulate matter emissions, by establishing allowable emission rates. Calculation methods for determining the emission rate based on process weight are specified. Gaseous and liquid fuels are exempt, so the turbines and the engines are exempt from this rule.

The project's proposed cooling towers and fuel feedstock handling equipment are subject to this rule and the emissions from the cooling towers were found to comply in the PDOC's engineering analysis and the PDOC includes conditions to assure compliance with this rule.

Rule 4301 – Fuel Burning Equipment

Rule 4301 provides limits on the concentration of combustion contaminants and specifies maximum emission rates for NOx, SO_2, and combustion contaminant emissions (particulates) for any fuel burning equipment, except for air pollution control equipment which is exempt. The specified limits are 140 lbs/hour of NOx, calculated as NO_2, 200 lbs/hour of SO_2, 0.1 gr/dscf of combustion contaminants in exhaust flue gas calculated to 12 percent of carbon dioxide, and 10 lbs/hour of combustion contaminants. The combustion turbine generator and emergency engines do not meet the definition of fuel burning equipment as stated in this rule and are therefore exempt. However, the auxiliary boiler is subject to this rule, and the District has found that the maximum hourly emissions from the auxiliary boiler would be less than the emission limits set by this rule. Therefore, compliance with this rule is expected.

Rule 4304 – Equipment Tuning Procedure for Boilers, Steam Generators and Process Heaters

Rule 4304 provides equipment tuning procedures and frequencies for boilers, steam generators, and process heaters. This rule applies to the auxiliary boilers and the PDOC has a condition requiring compliance with this condition; therefore, compliance with this rule is expected.

Rule 4311 – Flares

This rule limits emissions of VOC, NOx, and SOx from the operation of flares. All three flares (gasification flare, SRU flare, and Rectisol® flare) are subject to this rule. The PDOC includes conditions to assure compliance with this rule.

Rule 4320 – Advanced Emission Reduction Options for Boilers, Steam Generators, and Process Heater Greater Than 5.0 MMBtu/hr

This rule limits emissions of NOx, CO, SO_2, and PM10 emissions from permit units burning greater than 5 MMBtu/hr of fuel. The auxiliary boiler and the ammonia synthesis unit startup heater are subject to this rule, and the PDOC includes conditions to assure compliance with this rule. Additionally, the other rules apply to these two sources:

- Rule 4305 Boilers, Steam Generators and Process Heaters – Phase 2
- Rule 4306 Boilers, Steam Generators and Process Heaters – Phase 3

However, Rule 4320 has more stringent requirements than these two rules and compliance with Rule 4320 will ensure compliance with all three of these rules.

Rule 4702 – Internal Combustion Engines – Phase 2

This rule limits emissions of NOx, CO, and VOC from internal combustion engines with a rated brake horsepower greater than 50 hp. Pursuant to Section 4.3.1.2 of this rule, the proposed emergency engines are exempted, and only need to meet the following recording requirements of Section 6.2.3 of this rule:

- 6.2.3.1 Total hours of operation,
- 6.2.3.2 The type of fuel used,
- 6.2.3.3 The purpose for operating the engine,
- 6.2.3.4 For emergency standby engines, all hours of non-emergency and emergency operation shall be reported, and
- 6.2.3.5 Other support documentation necessary to demonstrate claim to the exemption.

The PDOC includes conditions to assure compliance with this rule.

Rule 4703 – Stationary Gas Turbines

Rule 4703 limits NOx and CO emissions from stationary gas turbines. The rule establishes requirements for testing, monitoring, and record keeping for NOx and CO emissions from new or modified stationary gas turbines with a designed power of 0.3 MW or higher and/or a maximum heat input rating of more than 3,000,000 Btu per hour. Hydrogen-rich fuel does not meet the definition of gas fuel as stated in this rule. Therefore, this rule would not apply when the CTG is fired on hydrogen-rich fuel. However, the CTG is subject to this rule when fired on natural gas or co-fired with a blend of natural gas and hydrogen. The PDOC includes conditions to assure compliance with this rule.

Rule 4801 – Sulfur Compounds

Rule 4801 limits the emissions of sulfur compounds to no greater than 0.2 percent by volume calculated as SO_2 on a dry basis averaged over 15 consecutive minutes. The use of PUC-regulated natural gas and ARB-certified diesel fuel, and the District conditions providing fuel sulfur limits on the hydrogen-rich fuel will assure compliance with this rule.

Rule 7012 – Hexavalent Chromium – Cooling Towers

This rule limits emissions of hexavalent chromium from circulating water in cooling towers. Section 5.2.1 of this rule requires no hexavalent chromium containing compounds can be added to cooling tower circulating water. The PDOC includes conditions to assure compliance with this rule.

REGULATION VIII - FUGITIVE PM10 PROHIBITIONS

The District has included several conditions in the PDOC that relate mitigation and compliance requirements of these rules (**AQ-1-10** through **-19**) that would apply during project construction and operation. Staff's construction fugitive dust mitigation condition (**AQ-SC3**) generally includes the same requirements as these District rules but has been revised to note that any District rule requirement that is more stringent than those required in the staff condition shall apply. The PDOC includes conditions to assure compliance with all Regulation VIII rules, including:

Rule 8011 – General Requirements

Rule 8011 specifies the types of chemical stabilizing agents and dust suppressant materials that can (and cannot) be used to minimize fugitive dust emissions from anthropogenic (man-made) sources. The rule also specifies test methods for determining compliance with visible dust emission (VDE) standards and for stabilized surface conditions, soil moisture content, silt content for bulk materials, silt content for unpaved roads and unpaved vehicle/equipment traffic areas, and threshold friction velocity (TFV). The facility owner/operator would be required to retain records only for those days that a control measure was implemented, and the facility owner/operator must keep the records for one year following project completion to demonstrate compliance. An owner subject to Rule 2520 (Federally Mandated Operating Permits) shall keep such records for five years. A fugitive dust management plan for unpaved roads and unpaved vehicle/ equipment traffic areas is discussed as an alternative for Rule 8061 and Rule 8071 (see below). The PDOC includes conditions to assure compliance with Regulation VIII rules.

Rule 8021 – Construction, Demolition, Excavation, Extraction and Other Earthmoving Activities

Rule 8021 requires fugitive dust emissions throughout construction activities (from pre-activity to active operations and during periods of inactivity) to comply with the conditions of a stabilized surface area and to not exceed an opacity limit of 20 percent. This can be accomplished by means of water application, chemical dust suppressants, or constructing and maintaining wind barriers. A Dust Control Plan is also required and shall be submitted to the APCO prior to the start of any construction activities on any site that will include 10 acres or more of disturbed surface area for residential developments, 5 acres or more of disturbed surface area for non-residential development, or will include moving, depositing, or relocating more than 2,500 cubic yards per day of bulk materials on at least three days. HECA exceeds these limits and therefore must develop a dust control plan, but compliance with the requirements of this rule is expected.

Rule 8031 – Bulk Materials

Rule 8031 limits the fugitive dust emissions from the outdoor handling, storage and transport of bulk materials. This rule requires fugitive dust emissions to comply with the conditions of a stabilized unpaved road surface and to not exceed an opacity limit of 20 percent. It specifies that bulk materials be transported using wetting agents, allow appropriate freeboard space in the vehicles, or be covered. It also requires that stored materials be covered or stabilized. Compliance is expected.

Rule 8041 – Carryout and Trackout

Rule 8041 limits carryout and trackout during construction, demolition, excavation, extraction, and other earthmoving activities (Rule 8021, above), from bulk materials handling (Rule 8031, above), from paved and unpaved roads (Rule 8061, below), and from unpaved vehicle and equipment traffic areas (Rule 8071, below) where carryout has occurred or may occur. Carryout and trackout for this project is only related to the construction period and staff's construction fugitive dust mitigation condition **AQ-SC3** includes requirements to assure compliance with Regulation VIII rules. Compliance is expected.

Rule 8051 – Open Areas

Rule 8051 requires any open area of 0.5 acres or more within urban areas, or three acres or more within rural areas, and contains at least 1,000 square feet of disturbed surface area to comply with the conditions of a stabilized unpaved road surface and to not exceed an opacity limit of 20 percent, by means of water application, chemical dust suppressants, paving, applying and maintaining gravel, or planting vegetation. HECA exceeds these rule trigger limits, but compliance with this rule is expected.

Rule 8061 – Paved and Unpaved Roads

Rule 8061 specifies the width of paved shoulders on paved roads and guidelines for medians. It requires gravel, roadmix, paving, landscaping, watering, and/or the use of chemical dust suppressants on unpaved roadways to prevent exceeding an opacity limit of 20 percent. Exemptions to this rule include "any unpaved road segment with less than 26 annual average daily vehicle trips (AADT)." Compliance is expected.

Rule 8071 – Unpaved Vehicle/Equipment Traffic Areas

This rule limits fugitive dust from any unpaved vehicle and equipment traffic area by using gravel, roadmix, paving, landscaping, watering, and/or the use of chemical dust suppressants to prevent exceeding an opacity limit of 20 percent. Exemptions to this rule include "unpaved vehicle and equipment traffic areas with less than 50 Average Annual Daily Trips (AADT)." Compliance is expected.

DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the applicant for the HECA Project. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

RESPONSE TO AGENCY AND PUBLIC COMMENTS

The table below contains staff's responses to comments received pertinent to the criteria air pollutant topics addressed in this section that were submitted by government agencies, intervenors, and the public. Please note some of the comments received refer to multiple environmental assessment resource topics such as public health, greenhouse gases and carbon sequestration, water resources, etc. The responses provided in the table below reference only the comments or portions of the comments related to criteria pollutant air quality issues. Please see the other environmental assessment resource topic sections for responses to comments or portions of comments regarding those issue areas. This comment response includes responses to comments provided to the Energy Commission and to the DOE.

Submitted by	COMMENT and RESPONSE
AGENCY: Parks and Rec.	
Agency – Parks and Rec (TN-58852) 10/21/2010	Comment: (summarized) The Tule Elk Reserve is located less than one mile from the integrated gasification combined cycle (IGCC) main complex. The Reserve is considered a sensitive land use receptor area per the San Joaquin Valley Air Pollution Control District. According to the air quality analysis, even after very aggressive mitigation measures the construction-related pollutants of PM10 impacts are predicted to be potentially significant beyond the fence line and if constructed the proposed project would exceed air quality standards levels for NOx, VOC, CO, and SOx. As a sensitive land use receptor area and an adjacent property owner we believe that these potential offensive air pollutants could significantly impact the park visitor's experience. In addition, this project could create a potential health risk for individuals and groups that regularly visit the Reserve, including the elderly, school groups and families with young children. We are concerned that the proposed mitigation measures will not sufficiently reduce and/or eliminate these emissions of odorous substances within the Reserve. Response: The project would create a new emissions source that would likely incrementally increase existing concentrations of all criteria pollutants surrounding the site. Staff and the SJVAPCD have found that these incremental increases in non-attainment pollutant impacts (that is, for pollutants that currently exceed air quality standards) would not be substantial and that the project would not create any new exceedances of ambient air quality standards for attainment pollutants (that do meet these standards). Staff has also determined that offensive odors would not occur past the fence line under normal operating conditions. Additionally, the project would be required to provide emissions mitigation as follows: 1) BACT emissions controls and emissions offsets as required by District regulations; 2) emissions controls as recommended by staff conditions of certification to reduce emissions from the onsite and offsite emissions sources that would not be regulated by the District rules; and 3) through the completion of two emissions reduction funding agreements with the District that would fund additional

	emissions reductions in the San Joaquin Valley as necessary to fulfill General Conformity offset requirements, other District determined CEQA mitigation needs, and a voluntary agreement to address NOx emissions efficiency issues. These mitigation measures would reduce incremental impacts sufficiently such that they would not be significant.
Agency – Parks and Rec (TN-58852) 10/21/2010	<u>Comment</u>: (summarized) The proposed project will exceed the Prevention of Significant Deterioration (PSD) emission thresholds for NO_2 and CO as it pertains to the Air Quality Related Values (AQRVs). We are concerned that the proposed project will degrade and reduce the visibility within the Reserve. Public Resource Code Section 5019.65 identifies State Natural Reserves as, "... areas embracing outstanding natural or scenic characteristics or areas containing outstanding cultural resources of statewide [sic] significance.” The purpose of a State Reserve is to preserve its native ecological associations, unique faunal or floral characteristics, geologic features, and scenic qualities in a condition of undisturbed integrity. Resource manipulation shall be restricted to the minimum required to negate the deleterious influence of man. Currently, State Parks has classified only 17 State Natural Reserve units out of 279 units. As an adjacent property owner, we are concerned that these airborne pollutants will diminish the clarity and color of what the park visitors see, negatively impacting the park visitor's experience. We request that a visibility analysis be completed including photo enhancements of the project's impacts to the visibility within the Reserve. Appropriate mitigations measures should be implemented to reduce and/or eliminate these manmade effects on the visibility within the Reserve. <u>Response</u>: The project would be a new air pollutant emissions source and so would to some small degree impact visibility near the project site, either due to the effects of criteria pollutants or due to water vapor plumes from the cooling tower or other exhausts. This section includes a discussion of the required AQRV modeling analysis that is part of the PSD process. U.S. EPA requires the project to perform a significant impact level analysis for Class 1 areas (national parks, wilderness areas and national monuments). SJVAPCD performed this modeling analysis using AERMOD. Although the closest Class 1 Area is 60 km southwest, AERMOD evaluated impacts out to 50 kilometers. Results indicated maximum impacts would fall within 2-3 kilometers from the facility boundary. Predicted concentrations are below the Class I significant impact level (SIL) at 20-30 kilometers from the facility boundary. Visibility impairment associated with HECA was analyzed using procedures from EPA’s Workbook for Plume Visual Impact Screening and Analysis. A screening analysis conducted per Federal Land

	Manager's (FLM) guidance indicated that the project's emissions were below FLM screening criteria for the nearest Class I and Class II Areas, so no further visibility modeling was required. Visibility modeling addresses long range visibility impacts and does not address short-range visibility impacts, partly because the impacts of a single air pollutant emissions source, even one as large as HECA, isn't a visibility concern over a short distance. The potential for visual resource impacts, including short range impacts of the water vapor plumes from the project are discussed in the Visual Resources section of this document.
AGENCY: U.S. Environmental Protection Agency (U.S. EPA)	
Agency – U.S. EPA (TN-66381) 7/26/2012	Comment: (summarized and paraphrased) Ambient Conditions The DEIS should include a detailed discussion of ambient air conditions including the area's attainment or nonattainment status for all NAAQS. The project area is designated as nonattainment for the annual 24-hour PM2.5 standard and extreme nonattainment for the 8-hour ozone standard. Response: The PSA/DEIS includes a detailed discussion of ambient air conditions including the attainment and non-attainment status for all NAAQS and CAAQS. The attainment status information is presented in **Air Quality Table 4** and the local air quality background values for the past several years are presented in **Air Quality Table 5**.
Agency – U.S. EPA (TN-66381) 7/26/2012	Comment: (summarized) General Conformity The DEIS should address the applicability of Clean Air Act (CAA) Section 176 and EPA's general conformity regulations at 40 CFR Part 51 and 93 for those pollutants that do not exceed the NAAQS. The General Conformity rule does not require linking the conformity determination and the NEPA process, it is recommended the processes are linked for convenience and efficiency. Response: The draft General Conformity analysis is provided as Appendix Air-1 and is being linked with the NEPA process.
Agency – U.S. EPA (TN-66381) 7/26/2012	Comment: (summarized) Permitting for Attainment and Nonattainment Pollutants The DEIS should summarize all existing air quality regulation, the required demonstration and the respective air permitting agencies for federal attainment, federal non-attainment and hazardous air pollutant emission. The project will require a Significant Deterioration (PSD) permit per section 165 of the Clean Air Act for attainment pollutants. The project will require a Nonattainment New Source Review (NNSR) permit for nonattainment pollutants (40 CFR 51.160-51.165).

	For a major new source subject to PSD, the emissions must be quantified to demonstrate which attainment pollutants trigger the PSD significant emission rate thresholds; Best Available Control Technology (BACT) must be applied to those pollutants; air quality modeling analyses must be conducted for the applicable pollutants; and additional impacts analyses must be addressed. For a major new source subject to NNSR, at a minimum, emissions must be quantified to demonstrate which nonattainment pollutants trigger the New Source Review requirements, Lowest Achievable Emission Rate (LAER) must be applied to those pollutants, and emission credits must be obtained for the applicable pollutants. The following requirements should be addressed in the DEIS: BACT, LAER and air quality modeling considerations. It is important to ensure that there is not a violation of the NAAQS or applicable PSD increments, identify nearby areas designates as Class I and Class II areas, and confirm whether there are potential impacts on impairment to visibility, deposition or other air quality-related values. Response: The Air Quality section in the PSA/DEIS includes a summary and compliance demonstration for all federal, state and local laws, regulations and policies. The permitting agency is identified in the compliance with LORS section. The project requires a PSD permit which would be issued by the SJVAPCD, nonattainment pollutants are regulated under the Nonattainment New Source Review (NNSR) permitting program administered by the SJVAPCD, and the hazardous air pollutant permitting program is administered by the SJVAPCD (hazardous air pollutants are discussed in the Public Health section of the PSA/DEIS). The air quality section provides a summary of the PSD and NNSR permitting findings presented in the SJVAPCD's PDOC, including the District's criteria pollutant modeling analysis. The SJVACPD's PSD analysis, within the PDOC, includes an identification of the pollutants triggering PSD requirements. The BACT and modeled impact analyses are also provided in the PDOC. Emissions have been quantified to demonstrate the nonattainment pollutants subject to NSR requirements. LAER has been addressed and emission credits would be obtained for the applicable pollutants. Class I and Class II areas have been identified and potential impairment to visibility and required AQRV, such as deposition modeling, is included as necessary in the PDOC and discussed in this section. Therefore, the PSA/DEIS analysis includes the analysis of the specific modeling requirements identified in this comment.

Agency – U.S. EPA (TN-66381) 7/26/2012	Comment: (summarized) Mobile Sources The DEIS should identify and quantify the addition of new mobile sources associated with the project, including truck traffic and rail traffic that may result from the transport of coal and petcoke feedstocks and other materials. The expected routes of travel, frequencies, and locations of sensitive receptors should be identified and impacts assessed. See also the comment under Environmental Justice below. Response: The PSA/DEIS includes a detailed analysis of additional mobile sources associated with the project. The analyses included emissions from the transport of both coal and petcoke and the transport of product manufactured at the integrated manufacturing complex. Both transportation alternatives were analyzed. The expected routes of travel, frequency and sensitive receptors were identified. The impacts related to transportation were assessed in several sections of the PSA/DEIS including air quality, public health, and traffic and transportation.
Agency – U.S. EPA (TN-66381) 7/26/2012	Comment: (summarized) Construction Emissions Mitigation The DEIS should include a thorough analysis of impacts from the construction of the proposed project alternatives and emission estimates of all criteria pollutants and diesel particulate matter (DPM). The DEIS should include information regarding health risks associated with vehicle emissions and mobile source air toxics. Response: The PSA/DEIS includes an analysis of impacts from the proposed construction. The analysis in the air quality section includes emission estimates of criteria pollutants. The construction analysis includes an emissions estimate for all emissions sources associated with the project construction including both on-site and offsite sources for both HECA and the OEHI component. Staff reviewed these emissions estimates and required both project applicants to confirm or revise these estimates as staff considered necessary. Additionally, a modeling analysis of the HECA construction criteria pollutant emissions, prepared by the applicant and reviewed by staff, is included in the construction impacts analysis. Air toxics are discussed in the Public Health section of this document.
Agency – U.S. EPA (TN-66381) 7/26/2012	Comment: (summarized) Construction Emissions Mitigation EPA recommends including a Construction Emissions Mitigation Plan (CEMP) for fugitive dust and DPM/fine particulates in the DEIS. The plan should be adopted in the Record of Decision. Response: The PSA/DEIS includes Conditions of Certification **AQ-SC1** through **AQ-SC5** that mitigate construction emissions. **AQ-SC2**

	requires an Air Quality Construction Mitigation Plan (AQCMP) that details the steps that would be taken and the reporting conditions to comply with **AQ-SC3** through **AQ-SC5** that require mitigation of fugitive dust emission and equipment tailpipe emissions, including DPM. In addition, **AQ-SC1** requires the applicant have an onsite construction mitigation manager who would be responsible daily for the implementation and compliance of the mitigation program.
Agency – U.S. EPA (TN-66381) 7/26/2012	Comment: (summarized) Construction Emissions Mitigation EPA recommends the following to reduce diesel particulate matter, hydrocarbons and oxides of nitrogen associated with construction activities. -Minimize use and unnecessary idling -Maintain and tune engines to perform at applicable certification levels and standards. Perform periodic unscheduled visits to ensure compliance. -Prohibit tampering of engines and require adherence to manufacturer's specifications. -Lease new equipment meeting the most stringent applicable State or Federal standards. In general commit to the best available emission control technology. -Include mitigation measures to reduce greenhouse gas emissions. -Use registered particulate traps and other appropriate controls. -Use diesel fuel with a sulfur content of 15 ppm or less -Use control devices. Suitable control device determinations should be made by an independent Licensed Mechanical Engineer. Response: The PSA/DEIS includes Condition of Certification **AQ-SC5** that mitigates emissions of diesel particulate matter, hydrocarbons and oxides of nitrogen from diesel-fueled engines associated with construction activities. **AQ-SC5** requires diesel engines associated with construction to meet the highest tier rating available. Specific exceptions are built in to the requirement. **AQ-SC5** includes additional requirements to ensure the engines are properly maintained and are operated according to state regulations. Operating restrictions specifically include idling restrictions for diesel-fueled engines. Add-on tailpipe emissions control devices are only allowed if equipment with Tier 3 or 4 engines are not available, and these control devices must be verified by the California Air Resources Board or U.S. EPA. Requirements of this condition are designed to mitigate off-road equipment tailpipe emissions to the highest extent possible as long as safety requirements are met and to ensure compliance with LORS.
Agency – U.S. EPA (TN-66381) 7/26/2012	Comment: (summarized) Construction Emissions Mitigation The DEIS should identify the need for a Fugitive Dust Control Plan as required by SJVAPCD. In addition the following is recommended -Stabilize open storage piles and disturbed areas

	-Install wind fencing and phase grading operation where appropriate and use water trucks under windy conditions. -Prevent spillage and limit speeds to 15 mph for non-earthmoving equipment <u>Response</u>: The PSA/DEIS includes conditions of certification mitigating fugitive dust associated with construction emissions. **AQ-SC2** specifically requires the facility to develop an air quality construction mitigation plan (AQCMP) which includes measures to minimize fugitive dust. Condition **AQ-SC3** outlines mitigation measures imposed by the Energy Commission and states any additional mitigation measures imposed by SJVAPCD need to be included in the AQCMP. Condition **AQ-SC4** identifies additional measures to be taken when the required control measures are not adequately mitigating fugitive dust emissions. Requirements are designed to mitigate fugitive dust emissions to the highest extent possible and ensure compliance with LORS.
INTERVENOR: Association of Irritated Residents (AIR)	
Intervenor – AIR (TN-64367) 3/23/2012	<u>Comment</u>: (summarized) “NOx emissions from the CTG/HRSG will be lower…” How much lower? What are the earlier figures? Will the total NOx emissions decrease taking into account the fertilizer plant and related operation? Will using coal as 75 percent of the fuel for the life of the project instead of the first two years increase or decrease criteria air pollutants? Any changes in the fuel transportation should be included in the analysis. How much transportation is associated with the fertilizer plant including deliveries and finished product? How do project emissions change if the rail spur is not built? <u>Response</u>: A preliminary assessment was completed for the original project prior to the submittal of the amended application. According to the preliminary analysis, the annual NOx emissions for the HRSG/CTG were estimated to be 167.86 tons and total NOx stationary source operating emissions were estimated to be 194.89 tons. Total NOx emissions from the HRSG/CTG and coal dryer for the amended application are estimated to be 123.50 tons and total NOx stationary source operating emissions are estimated to be 158.93 tons, roughly 44 and 37 tons below the original project estimates, respectively. The NOx emissions limit from the use of the hydrogen-rich fuel would not be affected by the proportion of coal and petcoke. However, this higher proportion of coal use over the life of the project would be expected to increase the total transportation emissions when considering the entire length of the transportation routes for coal and petcoke. Emissions and impacts from fuel transportation are included in the

	analysis. The facility is proposing two transportation alternatives, and emissions estimates for both alternatives are included in the analysis. The first alternative includes the addition of a rail spur to the project site; the second alternative does not include the new rail spur. With a rail spur, the coal would be delivered to the project site by rail and the fertilizer products would be shipped by rail from the project site. Without a rail spur, coal would be offloaded from the coal trains at an existing transloading facility in Wasco, approximately 26.5 miles from the project site, then shipped by truck the rest of the way to the project site and the fertilizer products would be shipped by truck from the project site. The transportation emissions within the SJVAB would be somewhat lower for the rail spur alterative due to the greater efficiency of shipping by rail rather than truck. **Air Quality Tables 14** and **15** outline criteria pollutant emissions from the two transportation alternatives. Assumptions used to quantify the expected transportation emissions from the two transportation alternatives are provided in the Operational Criteria Pollutant Emissions section of the applicant's amended AFC in Appendix E-3.
Intervenor – AIR (TN-64367) 3/23/2012	<u>Comment</u>: (summarized) Please justify the use of coal as the majority fuel for the life of the project. Is there a reason why the project does not attempt carbon capture with natural gas? <u>Response</u>: The applicant responded to this question posed by the intervenor in the applicant's 4/26/2012 data response.
Intervenor – AIR (TN-66072) 6/29/2012	<u>Comment</u>: (summarized) Please justify why NO_2 data used in the analysis is from the Shafter, Walker Street station and not the Arvin, Bear Mountain station. Please include topography as well as requirements to be conservative to present worst case scenarios in the justification. Please explain how Shafter has the lowest levels of NO_2 emissions and Arvin has the highest. <u>Response</u>: First, the NO_2 concentrations from the Shafter monitoring station are higher to considerably higher than those from Arvin, not lower. A comparison of the last three years of available maximum hourly NO_2 data from Arvin (where monitoring was discontinued after 2010) is shown as follows (in ppm): <u>Arvin</u> <u>Shafter</u> 2008 0.033 0.057 2009 0.051 0.052 2010 0.032 0.074 A comparison of the annual NO_2 monitoring data and the federal 1-

	hour NO_2 concentration (three year average of the 98th percentile of maximum daily values) also clearly shows that the Arvin monitoring station has measured lower, not higher, NO_2 concentrations than the Shafter monitoring station. The NO_2 data used in the impact analysis is from the Shafter-Walker Street (Shafter) station. The Shafter station is the closest station to the proposed site. This station monitors ozone, NO_2 and VOCs which are precursors for ozone. The objective of using this station is to provide background ozone concentrations that are relevant to the nearby project site. The Arvin monitoring site, which monitors ozone and NO_2, is located further from the site than several other monitoring stations, and while it does provide conservative background concentrations for the air basin as a whole for ozone it does not provide a reasonable background for the area immediately surrounding the project site, which is used for the purpose of determining background values for the worst-case near-field impacts. The worst-case air basin conditions are reflected in the non-attainment conditions depicted in **Air Quality Table 4**. The air quality impact analysis does not include the modeling of ozone impacts, so the only pollutant modeled in the impact analysis that the Arvin site monitors is NO_2. The air dispersion modeling analysis, which is inherently conservative due to the dispersion algorithms and the input assumptions regarding NO conversion to NO_2, uses the most representative and conservative site-specific background NO_2 concentrations, which staff has determined to be Shafter, after review of the data from the closest monitoring stations surrounding the project site.
Intervenor – AIR –Tom Franz (TN-66342) 7/27/2012	Why is natural gas not considered an alternative for this project. With the large amount of NOx emitted from burning hydrogen as a fuel and because of the air quality problem in this part of the San Joaquin Valley, explain why there is no option considered to use oxygen only as the combustion air when the hydrogen fuel is burned. In other words, why is it so necessary for HECA to further pollute the air the public breathes in order to save the earth from more GHG emissions? Response: Staff's review of available technologies indicates that the use of oxygen is not technically achievable at this point. The flame temperature that would occur with a hydrogen-rich fuel and oxygen combustion mixture are beyond the current state of CTG materials technology. Other oxygen-based combustion technologies such as

	rocket engine technologies are not yet mature and are not available at the scale of this project. Additionally, the separation of the amount of oxygen necessary would create a large additional parasitic load that could reduce project efficiency significantly. The applicant indicated why natural gas isn't being used as the primary fuel in their 4/26/2012 response.
INTERVENOR: Kern County Farm Bureau	
Intervenor – Farm Bureau (TN-66242) 7/12/2012	Comment: (summarized) The Kern County Farm Bureau is concerned about the contribution of emissions negatively impacting local air quality, where farmers already face the severest regulations and costs for compliance in the world. Response: In terms of air quality, the proposed project faces some of the severest regulations and highest costs for compliance to operate in the San Joaquin Valley Air Basin (SJVAB). Additionally, the proposed project would have to comply with a number of emission reduction mitigation measures, including a Voluntary Emissions Reduction Agreement with the SJVAPCD, to reduce the project's impacts both regionally and locally.
INTERVENOR: Sierra Club	
Intervenor – Sierra Club (TN-66370) 7/27/2012	Comment: (summarized) DOE should consider an enclosed ground flare and a flare recovery system. The EIS must examine air pollution impacts from the rail and truck emissions along the entire 700 mile route. The EIS must consider the impacts to environmental justice areas. The EIS must consider mercury emissions. The EIS must consider the impacts of truck traffic. Response: The SJVAPCD is satisfied that the flare technology selected meets appropriate BACT guidelines as determined in the PDOC. Environmental Justice impacts have been evaluated in this section. The project's mercury emissions, in terms of U.S. EPA MATS rule compliance, are discussed in this section. Please also see the Public Health section of the document for a discussion of the mercury emissions impacts. This section does consider the impacts of the mobile source

	emissions (rail and truck traffic) from the project's fuel feedstock imports and product exports, and the General Conformity analysis would require emissions reductions for NOx within the SJVAB.
PUBLIC COMMENTS	
Public – Trudy Douglass (TN-65878 and TN-66096) 6/20/2012 and 7/4/2012	<u>Comment:</u> I am a teacher and I am very worried about the health of my family and students. My daughter has asthma, a friend who has never smoked has emphysema, and a young friend is one of too many in the valley who has a thy[r]oid tumor. All of these problems are related to living in this valley. <u>Response:</u> This section indicates whether the project would meet all applicable LORS, determines whether significant impacts to criteria pollutants would occur from the project, and recommends measures to reduce these impacts to the maximum extent. Based on this review, the project's criteria pollutant emissions were not determined to cause a significant impact to the health of the surrounding communities. Please see the Public Health section for the air toxics health impact discussion.
Public – Trudy Douglass (TN-65878, TN-66096, and TN-66427) 6/20/2012, 7/4/2012, and 7/27/2012	<u>Comment:</u> (summarized) The people in San Joaquin Valley are working to comply with the EPA regulations, resulting in better air quality in 10 years. A coal/coke gasification factory will erase the progress we have made by burning the dirtiest fuel 24/7. We comply with no burn days, HECA must follow the same rules we do. <u>Response:</u> This IGCC facility would not directly burn the coal and petcoke fuel feedstocks, such as in a traditional coal boiler. The coal/petcoke feedstocks would be transformed in the gasifier to a hydrogen-rich fuel that would be combusted in the gas turbine to make power. The hydrogen-rich fuel would undergo separation and cleaning processes that would remove the vast majority of the remaining sulfur and air toxics compounds before it would be combusted in the gas turbine. This technology would have criteria and air toxics emissions that are well below those from traditional coal fired power plants. Industrial facilities in the San Joaquin Valley must also comply with all local, state, and federal LORS. In addition to EPA regulations, the facility must also comply with the rules and regulations of SJVAPCD and ARB. The federal, state and local agencies together set standards, implement programs for toxics, motor vehicle emissions, locomotives, heavy-duty trucks, ships, off-road diesel equipment, stationary sources, etc. There are only a few rules that directly impact residential emission sources. As noted above, the coal and petcoke feedstock would be gasified and the resulting hydrogen-rich fuel would be cleaned prior to combustion. The

	resulting emissions from the IGCC would meet stringent BACT requirements.
Public – Trudy Douglass (TN-65878, TN-66096, TN-66389, TN-66427, TN-67235) 6/20/2012, 7/4/2012, 7/27/2012, 7/27/2012, and 9/20/2012	Comment: (summarized/combined several similar comments) The HECA site is on and surrounded by prime farm land. It sits at the closed end of the San Joaquin Valley; there is no outlet for the 520 tons of pollutants a year (not including transportation emissions) that the project will emit assuming all of HECA's gasification, storage, sequestration, and transfer processes work perfectly, and this number does not include the millions of tons of CO_2 it is supposed to sequester. This valley is world renowned for the quality, quantity, and diversity of its agricultural products. The project's pollution and particulates each year for 30 years will make our crops and orchards less able to convert the CO_2 to oxygen, will injure our whole ecosystem and may be the death of it. The project will also raise higher our levels of ozone and particles. Response: San Joaquin Valley is subject to federal, state and local air quality regulations designed to achieve healthy air quality. EPA has developed national ambient air quality standards (NAAQS) for pollutants considered harmful to public health and the environment. Primary standards are designed to provide public health protection for sensitive populations. Secondary standards are designed to provide protection against decreased visibility and damage to animals, crops, vegetation and buildings. Many of the secondary standards are the same as the primary standards and there is no secondary standard more stringent than a primary standard. Potential worst-case project emissions were modeled and compared to the NAAQS. Impacts from the project would be mitigated according to the modeling results. The rules and regulations applicable to the San Joaquin Valley were developed to reduce or maintain ambient air quality levels to meet the applicable standards taking into account the specific qualities and needs of the region. California also has adopted CAAQS to further protect these valuable resources.
Public – Trudy Douglass (TN-66096, and TN-66389) 7/4/2012, and 7/27/2012,	Comment: (summarized/combined two similar comments) SCS is using pollution monitoring numbers from Shafter, the closest station to the site. It has the lowest readings in our district, but it does not reveal a valid image of our air quality. The most appropriate baseline for our air pollution and particulate measurements in the district comes from the Arvin/Bear Mountain monitoring station at the end of the valley. Response: Please see the above response to the intervenor AIR's comment on this issue.
Public – Trudy Douglass	Comment: (summarized/combined two similar comments) We have the permanent place as the number 1 spot for the worst air quality

(TN-66245 and TN-66389) 7/12/2012, and 7/27/2012	in the US. If this project goes forth as proposed, we will have higher medical costs from pollution-based diseases: asthma, emphysema, cancer and heart disease, reduced longevity, lower productivity of the people and the land, and vehicle higher fees and fines for our failure to meet EPA particulate standards. Although HECA is responsible, they avoid censure by buying those "magical" air credits with our own tax money to offset their offense against us. This is legal but is it right? <u>Response:</u> The San Joaquin Valley is subject to federal, state and local air quality regulations designed to achieve healthy air quality. The rules and regulations applicable to the San Joaquin Valley were developed to reduce or maintain ambient air quality levels to meet the applicable standards taking into account the specific qualities and needs of the region. Federal and state laws require emission control measures for all pollutants that exceed established standards. The San Joaquin Valley is required to have a plan that outlines the measures they will take to achieve attainment with the federal ambient air quality standards. These plans are referred to as State Implementation Plans (SIPs). The SJVAPCD under the direction and review of the EPA and ARB develops rules and regulations that are designed to improve and maintain air quality so that the San Joaquin Valley is in attainment with these established standards. All projects proposed in SJVAPCD jurisdiction must comply with the rules and regulations in order to be approved. The SJVAPCD's New Source Review (NSR) Rule requires the application of Best Available Control Technology (BACT) to any new or modified emission unit with the potential to emit of 2.0 pounds per day of any criteria pollutant. BACT and other requirements must be applied regardless of offsets. In other words, the purchase and application of emission reduction credits does not equate to project approval. A project must still comply with all established laws, ordinances, regulations and standards (LORS). Additionally, this project has entered into two emissions reduction funding agreements with the District that would fund additional emissions reductions in the San Joaquin Valley as necessary to fulfill General Conformity offset requirements, other District determined CEQA mitigation needs, and a voluntary agreement to address NOx emissions efficiency issues. In comparison, most non-stationary source projects (housing, commercial development, etc.) that may cause large increases in local area emissions have no regulatory requirements to offset their emissions, although in this air basin some of these types of projects do enter into voluntary agreements with the District to fund emissions reductions.
Public – Daniel Bell (TN-66248)	<u>Comment:</u> Are there required offsets for coal transport? <u>Response:</u>

7/16/2012	The mobile source emissions associated with this project would not be directly subject to SJVAPCD permitting and so would not be subject to the SJVAPCD offset rules. However, since this project would be subject to federal approval it would have to comply with the General Conformity rule. The project's operating mobile source emissions within the SJVAB have been determined to exceed the NOx emissions threshold of this rule, so those emissions would have to be offset. The applicant has entered into an emissions reduction funding agreement with the District that would fund additional emissions reductions in the San Joaquin Valley as necessary to fulfill General Conformity offset requirements, other District determined CEQA mitigation needs, and a voluntary agreement to address NOx emissions efficiency issues.
Public – Daniel Bell (TN-66248) 7/26/2012	<u>Comment:</u> Are there required offsets for NOx, SO2, etc? <u>Response:</u> The stationary emissions source offsets, required by SJVAPCD rules and regulations, would be required to be surrendered by the applicant prior to operation of the project. SJVAPCD's NSR rule requires offsets for pollutants with permitted emissions exceeding an established threshold. The project's projected emissions exceed the thresholds for all criteria pollutants, VOC, CO, NOx, SOx, and PM10. Offsets would not be required for CO, because the NSR rule exempts offset requirements for CO if the facility demonstrates the project would not cause a violation to the ambient air quality standards for CO. So all pollutants except CO would be offset. The other emission reductions that would be required for this project would be created by funding provided by the applicant through two mitigation agreements that would fund additional emissions reductions in the San Joaquin Valley as necessary to fulfill General Conformity offset requirements, other District determined CEQA mitigation needs, and a voluntary agreement to address NOx emissions efficiency issues.
Public – Dean Clason (TN-66349) 7/26/2012	<u>Comment:</u> I am opposed to the proposed HECA plant based on the fact that we already have the worst air pollution in the country, and our air basin has no outlet in the southern valley. <u>Response:</u> Comment noted.
Public – Kathleen Parsa (TN-66385) 7/23/2012	<u>Comment:</u> The proposed HECA plant will increase air pollution. It has already been determined that Bakersfield has the worst air quality in the nation. Who wants to make it worse? <u>Response:</u> The PSA/DEIS includes an analysis of the ambient air quality in the

	project area. In addition, the impacts of the proposed project have been modeled and compared to the ambient air quality standards. The project would be required to mitigate emissions to the extent feasible and offset the remaining stationary source operating emissions from the project. The SJVAPCD and Energy Commission staff have both determined that the HECA facility could be built and operated without significantly worsening air quality.
Prior to being an intervenor Public – Chris and John Romanini, et. al. (TN-66382) 7/26/2012	Comment: Kern has the worst air in the nation. Polluted air causes health issues. Should the DOE encourage a demonstration project that will further pollute our air in the interest of global warming? Should not the DOE consider the effects on our local environment first? A small issue is the discretionary decision by local schools that restricts outdoor sports and PE for students when the air quality index (AQI) is above 201, 151, and 101. When HECA operates, will their emissions impacts have the children sitting in the gym more? Response: HECA would incrementally increase pollutants near the project site, and so would have some incremental increases in local pollutants. These impacts have been evaluated and the SJVAPCD and staff have called for mitigation measures to reduce these impacts to the extent feasible. Additionally, HECA's emissions would not be of a magnitude that would affect the AQI estimates or noticeably increase the monitored concentrations from the air monitoring network that is used to quantify the AQI.
Prior to being an intervenor Public – Chris and John Romanini, et. al. (TN-66382) 7/26/2012	Comment: HECA's figures and tables on emissions are difficult to add up. Please state the total PM2.5, PM10, NOx and SO2 emissions per year that HECA will produce. These figures should include both plant (power and chemical) and vehicle (rail and road). Response: The PSA/DEIS includes many tables totaling the calculated emissions from HECA and the OEHI CO_2 EOR component emissions sources. See **Air Quality Table 17** for a summary of annual operating emissions for HECA, including the mobile source emissions, and **Air Quality Table 19** for a summary of the EOR component's operating emissions, including the mobile source emissions. Staff's presentation of these emissions is meant to simplify the presentation and inform the public regarding the projects' emissions sources and emissions totals. Additionally, the applicant docketed revised emissions tables so that the public has the same emissions data updates/clarifications that were provided to staff, the SJVAPCD, and the Sierra Club under confidential cover.

Public – Trudy Douglass, et. al. (TN-66389) 7/27/2012	<u>Comment</u>: The HECA project will put 350 trucks and 200 employees on the road every day with a total of 1100 vehicles a day, going in and out of this factory. (The pollution from these sources is not included with the other pollution totals.) <u>Response:</u> The emissions tables in this section (**Air Quality Tables 14**, **15**, and **17**) do provide the emissions data from the mobile sources noted above. Additionally, the applicant provided mobile source pollutant emissions estimates in the AFC and then provided revised emissions estimates in the data responses to staff data requests that corrected some of the travel distance assumptions used in the mobile source emissions estimate. Finally, staff has recommended mitigation measures meant to reduce the emissions from truck transportation by requiring the use of newer/cleaner trucks (Conditions of Certification **AQ-SC6** and **AQ-SC7**) and by requiring loads to be covered or enclosed to eliminate emissions from spillage (Condition of Certification **AQ-SC10**).
Public – Trudy Douglass, et. al. (TN-66389) 7/27/2012	<u>Comment</u>: Standards for the feedstock must be established. Coke and coal are graded on a sliding scale; can we trust the HECA operators to check for quality? There are many junctures in HECA procedures where toxic waste levels of coke and coal could be added to their feedstock, adding many more heavy metals to their emissions. This kind of manipulation could save a lot of money for some, make a lot of money for others and add significantly to the pollution levels of our air, land, water, and vegetation. <u>Response</u>: HECA would have to meet air pollutant emissions limits, including hazardous air pollutant limits, regardless if they change the source of the coal or petcoke feedstocks. The hazardous metals in the coal, with the exception of very volatile metals (i.e. mercury), would end up encapsulated in the gasification solids. The eventual use or disposal of the gasification solids could be influenced by the metals content of the solids. Please see the Waste Management section for additional discussion on handling and disposal of the gasification solids.
Public – Trudy Douglass, et. al. (TN-66389) 7/27/2012	<u>Comment</u>: An off-site air-monitoring station, at HECA's expense, must be setup down-wind from the factory to monitor pollution levels especially within a 20-mile radius. These readings must be monitored daily by outside consultants, and there must be immediate pre-established consequences for violations. <u>Response</u>: The SJVAPCD operates an extensive network of air quality monitors throughout the San Joaquin Valley air basin to characterize the air quality in the basin. This data is used to determine the attainment status with both the NAAQS and CAAQS

	standards. The SJVAPCD is subject to 40 CFR Part 58 monitoring requirements and guidelines requiring SJVAPVCD to develop a monitoring network plan to ensure an effective system. The plan describes the purpose of each monitor and includes a demonstration that the location and operation of each monitor meets the requirements. The addition of a specific ambient monitor due to a new emissions source is very rarely required unless there is a significant gap in the monitoring network that would jeopardize its effectiveness. Due to mixing and varying chemical and physical properties of the pollutants, the variability of meteorological conditions (wind direction and speed), and the variability of other emissions sources it is very hard to attribute monitored pollutant levels to a specific stationary emissions source. Pollutants do not always behave the same way after they are released into the atmosphere. For example, coarse particles tend to settle more rapidly and travel shorter distances than finer particles; and other pollutants such as NO_2 and VOC chemically transform over time into secondary particulate or ozone. Therefore, it is not always possible to determine from downstream monitors the specific contribution from a source of a specific pollutant. Many times one facility will not affect the readings from downstream monitors. The HECA facility however would be required to measure the direct emissions from the plant by monitoring the emissions in the stack exhaust stream, both with continuous emissions monitoring (CEMS) on the CTG/HRSG for pollutants that can be monitored in this manner and periodic source testing for the other emissions sources. Source testing would be performed by independent contractors who are licensed in the state of California. The source testing contractors would be required to use specific standard source testing methods when testing emissions from project emissions sources. This testing would be required to demonstrate compliance with emissions limits and to check on the accuracy of the CEMS. There would be immediate consequences to the facility if they could not meet emissions limits as determined by the CEMS or if they did not pass a source test.
Public – Arthur Unger (TN-66357) 7/26/2012	<u>Comment</u>: The DEIS should quantify the plant's impacts on local air quality. How much PM10, PM2.5 and ozone from trains and trucks transporting coal from New Mexico, with and without a railroad spur to the plant? How much air pollution from employees driving to the plant, trucks carrying supplies to the plant and trucks taking urea and coal ash from the plant? How much NOx from burning hydrogen? Note that Lamont and Arvin have the worst air in this area of severe non-compliance with NAAQS. <u>Response:</u> The PSA/DEIS quantifies the impacts on local air quality from all the sources indicated in the comment. The emissions from construction, commissioning and operations are all quantified the

	PSA/DEIS. **Air Quality Table 17** summarizes HECA's permitted maximum annual emissions, including the mobile source (truck and train) emissions. **Air Quality Table 21** summarized HECA's modeled ambient air quality impacts. Additional emissions and ambient air quality impact details are presented in several other tables provided in this section.
Public – Brad Bittleston (TN-66348) 7/26/2012	<u>Comment</u>: (summarized) The poor air quality in this valley contributes to the respiratory illnesses of the citizens especially the children. Can't a more remote location somewhere else that can tolerate the changes and negative impacts be a more viable option? <u>Response:</u> Please see the previous comment responses regarding the air quality analysis provided in this section, and please also see the Public Health section for additional health impacts analysis. To some extent, based on the project's purpose, the location of this project is fixed. This project needs a nearby, willing user of CO_2, who would not only accept the CO_2 but would also sequester the CO_2. The applicant has worked out an agreement with Occidental Petroleum to use CO_2 in the Elk Hills Oil field, so any alternative location would need to be in the general proximity of this oil field. Please also see the Alternatives section for a discussion of alternative project locations.

NOTEWORTHY PUBLIC BENEFITS

No air quality related noteworthy public benefits have been identified.

CONCLUSIONS

Staff has made the following preliminary conclusions about HECA:

- Construction impacts would contribute to violations of the ozone, PM10, and PM2.5 ambient air quality standards. Staff recommends Conditions of Certification **AQ-SC1** to **AQ-SC5**, and District Condition of Certification **AQ-1-10** through **AQ-1-19**, to mitigate the project construction-phase impacts to a less than significant level.
- The project's operation would neither cause new violations of any NO_2, CO, or SO_2 ambient air quality standards nor significantly contribute to existing violations for these pollutants. Therefore, the project's direct NO_2, CO, and SO_2 impacts are less than significant.
- HECA's operation would result in a less than significant direct emissions impact under CEQA if HECA complies with staff recommended Conditions of Certification (**AQ-SC6** through **AQ-SC14**) and District required Conditions of Certification (**AQ-1** through **AQ-25**), provides the emissions mitigation funding as agreed with the District for General Conformity and CEQA compliance purposes, and provides the

emission reduction credits to offset the stationary source emissions in quantities recommended by the District (**AQ-1)**. This preliminary finding is contingent that staff's final determination regarding the appropriate interpollutant offset ratio agrees that the District's proposed SOx for PM interpollutant offset ratio, along with the other required mitigation, is adequate to provide a net air quality benefit. The final evaluation of the adequacy of this interpollutant offset ratio will in part be based on the District's response to staff's questions on this issue. Staff will determine, based on that response and the rest of the evidence provided, whether recommended adjustments need to be made to this interpollutant offset ratio for CEQA mitigation purposes. Staff will provide this final determination in the Final Staff Assessment/Final Environmental Impact Statement (FSA/FEIS).

- The proposed project's indirect (or secondary emissions) contribution to existing violations of the ozone and particulate (PM10/PM2.5) ambient air quality standards are likely significant if unmitigated. Therefore, staff recommends **AQ-SC6**, **AQ-SC7**, and **AQ-SC12** to mitigate the project's onsite and offsite transportation emissions to reduce their ozone precursor emissions; District conditions **AQ-1-10** to **AQ-1-19** and staff conditions **AQ-SC9** and **AQ-SC10** mitigate the non-stationary source operating fugitive dust emissions potential to ensure that both the potential ozone and PM10/PM2.5 impacts are mitigated to less than significant over the life of the project.
- The project will continue to operate in compliance with adoption of staff's proposed condition **AQ-SC11** that provides the administrative procedural requirements for project modifications and condition **AQ-SC8** that requires quarterly operations compliance reporting.
- Staff is recommending condition **AQ-SC13** to ensure compliance with the Federal MATS Rule. Staff expects that the District will include MATS compliance conditions in the FDOC that will allow staff to remove this recommended condition.
- Staff condition **AQ-SC14** is included to ensure that the two mitigation agreements the applicant has signed with the District are being complied with, specifically that the required funding has been provided in a timely manner in compliance with these two agreements.
- Staff has reviewed HECA's potential to create offsite odors and has determined that there is the potential for sensitive individuals to perceive odors during worst-case meteorological conditions at or near the project fence line during normal operations. However staff concludes that HECA would not create objectionable odors affecting a substantial number of people, and thus would not have significant odor impacts.
- Staff has considered the environmental justice population surrounding the site (see Socioeconomics Figure 1). Since the project's direct and cumulative air quality impacts have been reduced to less than significant, there is no environmental justice issue for air quality.

OUTSTANDING INFORMATION REQUIRED FOR COMPLETION OF THE FSA/FEIS

Staff requires the following information to complete the FSA/FEIS.

- A revised emissions estimate for HECA that matches the current project description, including but not necessarily limited to: the removal of the ammonia product shipping emissions; and the addition of the limestone fluxant. The revised emissions estimate should include the shipping, handling, and storage emissions from the fluxant and should address the shipping emissions for potential alternative shipping locations for the gasifier solids that have been provided to staff in other data responses.
- The applicant provided Energy Commission staff with updated operating data in an e-mail message for a telephone conference held May 10, 2013. During that conference, the applicant requested Energy Commission staff to prepare a set of written questions on this updated operating data so that they could respond completely to Energy Commission staff needs. These questions cover air quality, carbon sequestration and facility reliability topics. They are listed in the **Carbon Sequestration and Greenhouse Gas Emissions Section** because most of them relate to that topic.
- The District's FDOC that addresses staff's comments on the PDOC, including but not limited to: the need to provide conditions for the limestone fluxant receiving and handling; the addition of federal MATS regulation conditions; and the inconsistencies regarding the SOx for PM interpollutant offset ratio.

RECOMMENDED MITIGATION MEASURES FOR THE EOR PROJECT

Staff makes the following inter-agency request to ensure that the cumulative air quality impacts of HECA and EOR component during construction are less than significant:

The Energy Commission requests that the EOR component CEQA/NEPA responsible agency require construction emission mitigation measures that are as strict or stricter than the measures provided in Staff Conditions **AQ-SC3** through **AQ-SC5**.
The specific mitigation measure requirements requested to be implemented during the EOR component's construction are as follows:

<u>Fugitive Dust Control</u>

Apply the following fugitive dust controls, or other controls as effective:

- Pave the main access roads through the facility to the main EOR site prior to major construction activities.

- All unpaved construction roads and unpaved operation and maintenance site roads, as they are being constructed, shall be stabilized with a non-toxic soil stabilizer or soil weighting agent that can be determined to be both as efficient or more efficient for fugitive dust control as ARB precertified soil stabilizers, and shall not increase any other environmental impacts, including loss of vegetation to areas beyond where the soil stabilizers are being applied for dust control. All other disturbed areas in the project and linear construction sites shall be watered as frequently as necessary during grading; and after active construction activities are complete, the disturbed areas shall be stabilized with a non-toxic soil stabilizer or soil weighting agent, or alternative approved soil stabilizing methods. The frequency of watering can be reduced or eliminated during periods of precipitation.

- No vehicle shall exceed 10 miles per hour on unpaved areas within the construction site or along project linear facilities such as the carbon dioxide injection or well field production pipeline corridors, with the exception that vehicles may travel up to 25 miles per hour on stabilized unpaved roads as long as such speeds do not create visible dust emissions.

- Visible speed limit signs shall be posted at the construction site entrances and along traveled routes.

- All paved roads within the construction site shall be swept at least twice daily (or less during periods of precipitation) on days when construction activity occurs to prevent the accumulation of dirt and debris.

- All soil storage piles and disturbed areas that remain inactive for longer than 10 days shall be covered, or shall be treated with appropriate dust suppressant compounds.

- All vehicles used to transport solid bulk material on public roadways and that have potential to cause visible emissions shall be provided with a cover, or the materials shall be sufficiently wetted and loaded onto the trucks in a manner to provide at least one foot of freeboard.

- Wind erosion control techniques (such as windbreaks, water, chemical dust suppressants, and/or vegetation) shall be used on all construction areas that may be disturbed. Any windbreaks installed to comply with this condition shall remain in place until the soil is stabilized or permanently covered with vegetation.

- The fugitive dust control requirements of SJVAPCD Regulation VIII that are in addition to or more stringent than the requirements of parts A. through N. of this condition shall be identified and performed as necessary for compliance with SJVAPCD Rules and Regulations.

<u>Off-Road Construction Equipment</u>

Apply the following off-road construction equipment engine controls, or other controls as effective:

All off-road diesel construction equipment with a rating of 50 hp or greater used in the construction of this facility shall be powered by the cleanest engines available that also comply the California Air Resources Board's (ARB's) Regulation for In-Use Off-Road Diesel Fleets (California Code of Federal Regulations Title 13, Article 4.8, Chapter 9, Section 2449 et.seq.) and shall include the following with the lowest-emitting engine chosen in each case, as available:

A. All off-road vehicles with compression ignition engines shall comply with the California Air Resources Board's (ARB's) Regulation for In-Use Off Road Diesel Fleets.

B. To meet the highest level of emissions reduction available for the engine family of the equipment, each piece of diesel-powered equipment shall be powered by a Tier 4 engine (without add-on controls) or Tier 4i engine (without add-on controls), or a Tier 3 engine with a post-combustion retrofit device verified for use on the particular engine powering the device by the ARB or the U.S. EPA. For PM, the retrofit device shall be a particulate filter if verified, or a flow-through filter, or at least an oxidation catalyst. For NOx, the device shall meet the latest Mark level verified to be available (as of January 2012, none meet this NOx requirement).

C. For diesel powered equipment where the requirements of Part "B" cannot be met, the equipment shall be equipped with a Tier 3 engine without retrofit control devices or with a Tier 2 or lower Tier engine using retrofit controls verified by ARB or U.S. EPA as the best available control device to reduce exhaust emissions of PM and nitrogen oxides (NOx) unless certified by engine manufacturers that the use of such devices is not practical for specific engine types.

Staff believes that the District will adequately control the EOR component's operating emissions through equipment permitted BACT requirements, emissions offset requirements, and other permit emissions limitations.

PROPOSED CONDITIONS OF CERTIFICATION

Staff recommends the following conditions of certification to address the impacts associated with the construction and operation of HECA. These Conditions include Energy Commission staff's proposed conditions as well as the SJVAPCD proposed Conditions from the PDOC, with appropriate staff proposed verification language added for each condition..

STAFF CONDITIONS OF CERTIFICATION

Staff conditions **AQ-SC1** through **AQ-SC14** are all Energy Commission specific mitigation measures and associated construction and operating conditions. These conditions apply to both the HECA project site, and the associated linear facilities where applicable. The term "CPM" below refers to the Energy Commission's compliance project manager.

AQ-SC1 Air Quality Construction Mitigation Manager (AQCMM): The project owner shall designate and retain an on-site AQCMM who shall be responsible for directing and documenting compliance with Conditions of Certification **AQ-SC3**, **AQ-SC4** and **AQ-SC5** for the entire project site and linear facility construction. The on-site AQCMM may delegate responsibilities to one or more AQCMM Delegates. The AQCMM and AQCMM Delegates shall have full access to all areas of construction on the project site and linear facilities, and shall have the authority to stop any or all construction activities as warranted by applicable construction mitigation conditions. The AQCMM and AQCMM Delegates may have other responsibilities in addition to those described in this condition. The AQCMM shall not be terminated without written consent of the CPM.

Verification: At least 60 days prior to the start of ground disturbance, the project owner shall submit to the CPM for approval, the name, resume, qualifications, and contact information for the on-site AQCMM and all AQCMM Delegates.

AQ-SC2 Air Quality Construction Mitigation Plan (AQCMP): The project owner shall provide an AQCMP, for approval, which details the steps that will be taken and the reporting requirements necessary to ensure compliance with Conditions of Certification **AQ-SC3**, **AQ-SC4,** and **AQ-SC5**.

Verification: At least 60 days prior to the start of any ground disturbance, the project owner shall submit the AQCMP to the CPM for approval. The AQCMP shall include effectiveness and environmental data for the proposed soil stabilizer's use on all conditions specific to the site, including any information related to US EPA or ARB approvals or certifications for such use. The CPM will notify the project owner of any necessary modifications to the plan within 30 days from the date of receipt.

AQ-SC3 Construction Fugitive Dust Control: The AQCMM shall submit documentation to the CPM in each Monthly Compliance Report (MCR) that demonstrates compliance with the following mitigation measures for the purposes of minimizing fugitive dust emission creation from construction activities and preventing all fugitive dust plumes from leaving the project boundary. Any deviation from the AQCMP mitigation measures shall require prior CPM notification and approval.

A. The main access roads through the facility to the power block areas will be paved prior to initiating construction in the main power block area, and delivery areas for operations materials (chemicals, replacement parts, etc.) will be paved prior to taking initial deliveries.

B. All unpaved construction roads and unpaved operation and maintenance site roads, as they are being constructed, shall be stabilized with a non-toxic soil stabilizer or soil weighting agent that can be determined to be both as efficient or more efficient for fugitive dust control as ARB precertified soil stabilizers, and shall not increase any other environmental impacts, including loss of vegetation to areas beyond where the soil stabilizers are being applied for dust control. All other disturbed areas in the project and linear construction sites shall be watered as frequently as necessary during grading (consistent with Biology Conditions of Certification that address the minimization of standing water); and after active construction activities are complete, the disturbed areas shall be stabilized with a non-toxic soil stabilizer or soil weighting agent, or alternative approved soil stabilizing methods, in order to comply with the dust mitigation objectives of Condition of Certification **AQ-SC4**. The frequency of watering can be reduced or eliminated during periods of precipitation.

C. No vehicle shall exceed 10 miles per hour on unpaved areas within the construction site or along project linear facilities such as the carbon dioxide pipeline corridor, with the exception that vehicles may travel up to

25 miles per hour on stabilized unpaved roads as long as such speeds do not create visible dust emissions.

D. Visible speed limit signs shall be posted at the construction site entrances and along traveled routes.

E. All construction equipment vehicle tires shall be inspected and washed as necessary to be cleaned free of dirt prior to entering paved roadways.

F. Gravel ramps of at least 20 feet in length must be provided at the tire washing/cleaning station.

G. All unpaved exits from the construction site shall be graveled or treated to prevent track-out to public roadways.

H. All construction vehicles shall enter the construction site through the treated entrance roadways, unless an alternative route has been submitted to and approved by the CPM.

I. Construction areas adjacent to any paved roadway shall be provided with sandbags or other equivalently effective measures to prevent run-off to roadways, or other similar run-off control measures as specified in the Storm Water Pollution Prevention Plan (SWPPP), only when such SWPPP measures are necessary so that this condition does not conflict with the requirements of the SWPPP.

J. All paved roads within the construction site shall be swept, using a PM10-efficient street sweeper that would meet the requirements of SJVAPCD Rule 8061, at least twice daily (or less during periods of precipitation) on days when construction activity occurs to prevent the accumulation of dirt and debris.

K. At least the first 500 feet of any paved public roadway exiting the construction site or exiting other unpaved roads en route from the construction site or construction staging areas shall be swept at least twice daily (or less during periods of precipitation) on days when construction activity occurs or on any other day when dirt or runoff resulting from the construction site activities is visible on the public paved roadways.

L. All soil storage piles and disturbed areas that remain inactive for longer than 10 days shall be covered, or shall be treated with appropriate dust suppressant compounds.

M. All vehicles used to transport solid bulk material on public roadways and that have potential to cause visible emissions shall be provided with a cover, or the materials shall be sufficiently wetted and loaded onto the trucks in a manner to provide at least one foot of freeboard.

N. Wind erosion control techniques (such as windbreaks, water, chemical dust suppressants, and/or vegetation) shall be used on all construction areas that may be disturbed. Any windbreaks installed to comply with this condition shall remain in place until the soil is stabilized or permanently covered with vegetation.

O. The fugitive dust control requirements of SJVAPCD Regulation VIII that are in addition to or more stringent than the requirements of parts A. through N. of this condition shall be identified in the AQCMP (**AQ-SC2**), and performed as necessary for compliance with SJVAPCD Rules and Regulations and Conditions **AQ-1-10** through **AQ-1-19**.

Verification: The AQCMM shall provide to the CPM in the monthly compliance report (MCR):

A. a summary of all actions taken to maintain compliance with this condition;

B. copies of any complaints filed with the District related to project construction; and

C. any other documentation deemed necessary by the CPM or AQCMM to verify compliance with this condition. Such information may be provided via electronic format or disk at the project owner's discretion.

AQ-SC4 Dust Plume Response Requirement: The AQCMM shall monitor all construction activities for visible dust plumes. Observations of visible dust plumes that have the potential to be transported: (A) off the project site and within 400 feet upwind of any regularly occupied structures not owned by the project owner, or (B) 200 feet beyond the centerline of the construction of linear facilities indicate that existing mitigation measures are not resulting in effective mitigation. The AQCMP shall include a section detailing how the augmented mitigation measures will be accomplished within the time limits specified in Steps 1 through 3, below. The AQCMM or Delegate shall implement the following procedures for augmented mitigation measures in the event that such visible dust plumes are observed:

Step 1: The AQCMM shall direct more intensive application of the existing mitigation methods within 15 minutes of making such a determination.

Step 2: The AQCMM shall direct implementation of additional methods of dust suppression if Step 1, specified above, fails to result in adequate mitigation within 30 minutes of the original determination.

Step 3: The AQCMM shall direct a temporary shutdown of the activity causing the emissions if Step 2, specified above, fails to result in effective mitigation within one hour of the original determination. The activity shall not restart until the AQCMM is satisfied that appropriate additional mitigation or other site conditions have changed so that visual dust plumes will not result upon restarting the shutdown source. The owner/operator may appeal to the CPM any directive from the AQCMM to shut down an activity. However, the shutdown goes into effect within one hour of the original determination unless overruled by the CPM before that time

Verification: The AQCMM shall provide to the CPM in the MCR:

A. a summary of all actions taken to maintain compliance with this condition;

B. copies of any complaints filed with the District and provided to the project owner related to project construction; and

C. any other documentation deemed necessary by the CPM or AQCMM to verify compliance with this condition. Such information may be provided via electronic format or disk at the project owner's discretion.

AQ-SC5 Diesel-Fueled Engine Control: The AQCMM shall submit to the CPM, in the MCR, a table that demonstrates compliance with the AQCMP mitigation measures for purposes of controlling diesel construction-related combustion emissions. Any deviation from the AQCMP mitigation measures requires prior CPM notification and approval.

All off-road diesel construction equipment with a rating of 50 hp or greater used in the construction of this facility shall be powered by the cleanest engines available that also comply the California Air Resources Board's (ARB's) Regulation for In-Use Off-Road Diesel Fleets (California Code of Federal Regulations Title 13, Article 4.8, Chapter 9, Section 2449 et.seq.) and shall be included in the Air Quality Construction Mitigation Plan (AQCMP) required by **AQ-SC2**. The AQCMP measures shall include the following with the lowest-emitting engine chosen in each case, as available:

A. All off-road vehicles with compression ignition engines shall comply with the California Air Resources Board's (ARB's) Regulation for In-Use Off Road Diesel Fleets.

B. To meet the highest level of emissions reduction available for the engine family of the equipment, each piece of diesel-powered equipment shall be powered by a Tier 4 engine (without add-on controls) or Tier 4i engine (without add-on controls), or a Tier 3 engine with a post-combustion retrofit device verified for use on the particular engine powering the device by the ARB or the U.S. EPA. For PM, the retrofit device shall be a particulate filter if verified, or a flow-through filter, or at least an oxidation catalyst. For NOx, the device shall meet the latest Mark level verified to be available (as of January 2012, none meet this NOx requirement).

C. For diesel powered equipment where the requirements of Part "B" cannot be met, the equipment shall be equipped with a Tier 3 engine without retrofit control devices or with a Tier 2 or lower Tier engine using retrofit controls verified by ARB or U.S. EPA as the best available control device to reduce exhaust emissions of PM and nitrogen oxides (NOx) unless certified by engine manufacturers or the on-site AQCMM that the use of such devices is not practical for specific engine types. For purposes of this condition, the use of such devices is "not practical" for the following, as well as other, reasons.

1. There is no available retrofit control device that has been verified by either the California Air Resources Board or U.S. EPA to control the engine in question and the highest level of available control using retrofit or Tier 1 engines is being used for the engine in question; or

2. The use of the retrofit device would unduly restrict the vision of the operator such that the vehicle would be unsafe to operate because the device would impair the operator's vision to the front, sides, or rear of the vehicle, or

3. The construction equipment is intended to be on site for 10 work days or less

D. The CPM may grant relief from a requirement in Part "B" or "C" if the AQCMM can demonstrate a good faith effort to comply with the requirement and that compliance is not practical.

E. The use of a retrofit control device may be terminated immediately, provided that: (1) the CPM is informed within 10 working days following such termination; (2) a replacement for the construction equipment in question, which meets the level of control required, occurs within 10 work days following such termination of the use (if the equipment would be needed to continue working at this site for more than 15 work days after the use of the retrofit control device is terminated); and (3) one of the following conditions exists:

1.. The use of the retrofit control device is excessively reducing the normal availability of the construction equipment due to increased down time for maintenance, and/or reduced power output due to an excessive increase in back pressure.

2. The retrofit control device is causing or is reasonably expected to cause engine damage.

3. The retrofit control device is causing or is reasonably expected to cause a substantial risk to workers or the public.

4. Any other seriously detrimental cause which has the approval of the CPM prior to implementation of the termination.

F. All equipment with engines meeting the requirements above shall be properly maintained and the engines tuned to the engine manufacturer's specifications.

G. Construction equipment will employ electric motors when feasible.

H. If the requirements detailed above cannot be met, the AQCMM shall certify that a good faith effort was made to meet these requirements and this determination must be approved by the CPM.

I. All off-road diesel-fueled engines used in the construction of the facility shall have clearly visible tags issued by the on-site AQCMM showing that the engine meets the conditions set forth herein.

J. All diesel heavy construction equipment shall not idle for more than five minutes. Vehicles that need to idle as part of their normal operation (such as concrete trucks) are exempted from this requirement.

Verification: The AQCMM shall include in the MCR the following to demonstrate control of diesel construction-related emissions:

A. A summary of all actions taken to control diesel construction related emissions;

B. A table listing all heavy equipment used on site during that month, showing the tier level of each engine and the basis for alternative compliance with this condition for each engine not meeting Part "B" requirements. The MCR shall identify the owner of the equipment and contain a letter from each owner indicating that the equipment has been properly maintained; and

C. Any other documentation deemed necessary by the CPM and the AQCMM to verify compliance with this condition. Such information may be provided via electronic format or disk at the project owner's discretion.

AQ-SC6 The project owner, when purchasing, leasing or renting dedicated on-road or off-road vehicles for feedstock or product transport (including sulfur and gasifier solids) shall obtain vehicles that meet California on-road vehicle emission standards or appropriate U.S. EPA/California off-road engine emission standards for the latest model year available when obtained.

Verification: At least 60 days prior to the start of commercial operation, the project owner shall submit to the CPM a copy of a plan that identifies the sizes and types of on-site vehicles and equipment and the associated vehicle and equipment purchase orders and contracts and/or purchase schedule. The plan shall be updated every other year to indicate any new vehicles or equipment purchased since the previous plan submittal. The plan shall be submitted in the Annual Compliance Report.

AQ-SC7 The project owner, when contracting for haul trucks that will be hauling feedstocks or products (including sulfur and gasification solids) to and from the project site shall require that all such haul trucks are licensed in the state of California and meet or exceed 2010 model year emissions standards.

Verification: The project owner shall provide a copy of the agreement with each trucking company used for hauling feedstocks and products to and from the site to the CPM for approval that demonstrates compliance with this condition at least 30 days before any feedstock or product hauling is performed by the trucking company.

AQ-SC8 The project owner shall submit to the CPM Quarterly Operations Reports and an annual compliance report that include operational and emissions information as necessary to demonstrate compliance with this condition of certification. The Quarterly Operations Report shall specifically note or highlight any incidences of noncompliance. The Quarterly Operations Report for the fourth quarter shall also include the annual compliance report.

<u>Verification:</u> The project owner shall submit quarterly operation reports to the CPM, and District if requested, no later than 30 days following the end of each calendar quarter. This information shall be maintained on site for a minimum of five years and shall be provided to the CPM and District personnel upon request.

AQ-SC9 The project owner shall provide a site operations dust control plan, including all applicable fugitive dust control measures identified in **AQ-SC3** that would be applicable to reducing fugitive dust from ongoing operations that:

A. Describes the active operations and wind erosion control techniques such as windbreaks and chemical dust suppressants, including their ongoing maintenance procedures, that shall be used on areas that could be disturbed by vehicles or wind anywhere within the project boundaries and linear facilities; and

B. Identifies the location of signs throughout the facility that will limit traveling on unpaved surfaces. In addition, vehicle speed shall be limited to no more than 10 miles per hour on these unpaved surfaces, with the exception that vehicles may travel up to 25 miles per hour on stabilized unpaved surfaces as long as such speeds do not create visible dust emissions.

C. Identifies the street sweeping frequency and extent for the onsite and the project affected adjacent offsite paved roads, including the use of a PM10-efficient street sweeper that would meet the requirements of SJVAPCD Rule 8061.

The site operations fugitive dust control plan shall include the use of durable non-toxic soil stabilizers on all regularly used unpaved surfaces and disturbed off-road areas, or alternative methods for stabilizing disturbed off-road areas, within the project boundaries and linear facilities, and shall include the inspection and maintenance procedures that will be undertaken to ensure that the unpaved surfaces remain stabilized. The soil stabilizer used shall be a non-toxic soil stabilizer or soil weighting agent that can be determined to be as efficient as or more efficient for fugitive dust control as ARB precertified soil stabilizers, and shall not increase any other environmental impacts including loss of vegetation or adverse habitat impact.

The fugitive dust controls shall meet the performance requirements of condition **AQ-SC4**. The performance requirements of **AQ-SC4** shall also be included in the operations dust control plan.

<u>Verification:</u> At least 60 days prior to the start commercial operation, the project owner shall submit to the CPM for review and approval a copy of the plan that identifies the dust and erosion control procedures, including effectiveness and environmental data for the proposed soil stabilizer, that will be used during operation of the project and that identifies all locations of the speed limit signs. At least 60 days after the beginning of commercial operation, the project owner shall provide to the CPM a report identifying the locations of all speed limits signs, and a copy of the project employees and contractor training material that clearly identifies that project employees and contractors are aware of these procedures and that they are required to comply with all dust and erosion control procedures and on-site speed limits. The project owner shall also notify the CPM and receive prior approval before changing approved dust suppression methods.

AQ-SC10 The project owner shall use the following measures to reduce fugitive dust from railcar and truck loads serving the project site.

<u>Railcars</u>

The project owner shall ensure that a surface stabilizing compound (surfactant or water), railcars with adequate freeboard, railcars with other dust mitigation design features, or a combination of these methods are used so that: 1) coal dust is not emitted in amounts that are visible by human observation outside of the coal mine property, 2) coal and produced product of any size is not released in visible quantities alongside the rail spur from the main rail line to the project site, and 3) produced product dust is not emitted in amounts that are visible by human observation at the project site or elsewhere along the entire rail transportation route. The project owner shall inspect the length of the rail spur once a month, and shall also inspect the rail spur within a day of receiving related complaints from the public or as requested by the CPM. These inspections shall be photo documented and shall include detailed information when coal or produced product losses are discovered along the rail spur and shall detail the mitigation measures applied to remove any such material found and the measure used to control future losses along the rail spur. This measure is not required if fully enclosed railcars are used for coal or produced product transport.

<u>Trucks</u>

The project owner shall ensure that all bulk material truck loads to and from the project site are either fully enclosed or covered. The project owner shall inspect the truck access/egress route within a day of receiving any complaints of truck load spills from the public or as requested by the CPM. These inspections shall be photo documented and shall include detailed information when truck load spills are discovered along the truck route and detail the mitigation measures applied to remove the spilled material that is found and the measure used to control future truck load losses along the truck route. This measure is not required if only fully enclosed trucks are used for all bulk material transport into and out of the project site.

<u>**Verification:**</u> The project owner shall submit the monthly rail spur and any required truck route inspection reports in the Quarterly Operations Reports (**AQ-SC8**).

The applicant shall provide the method of initial railcar emissions control, including the specifications of the surface stabilizing compound if used, to the CPM for approval at least 60 days prior to shipping the first load of coal to the site. These records shall be maintained onsite for a minimum of two years and shall be provided to the CPM and District personnel upon request. For the purposes of this condition for rail transport the term “coal” means coal or petroleum coke, and “produced product” and “bulk materials” are any materials transported where such materials can be lost through wind erosion or can be spilled from loaded rail cars or trucks due to bumps or turns, as opposed to catastrophic accidents.

AQ-SC11 The project owner shall provide to the CPM copies of all District issued Authority-to-Construct (ATC) and Permit-to-Operate (PTO) documents for the facility. The project owner shall submit to the CPM for review and approval any modification proposed by the project owner to any federal air permit for the project. The project owner shall submit to the CPM any modification to any federal air permit proposed by the District or U.S. Environmental Protection Agency (U.S. EPA), and any revised federal air permit issued by the District or U.S. EPA, for the project.

Verification: The project owner shall submit any ATC, PTO, or proposed federal air permit modifications to the CPM within 5 working days of either: 1) submittal by the project owner to an agency, or 2) receipt of proposed modifications from an agency. The project owner shall submit all modified ATC/PTO documents and all federal air permits to the CPM within 15 days of receipt.

AQ-SC12 The project owner shall provide the following to mitigate locomotive engine emissions:

Line Haul Locomotives

The project owner shall complete an agreement with the rail line operator that requires the use of Tier 3 or better line haul locomotive engines for all rail transportation to and from the project site until the end of 2019, and shall require the use of Tier 4 engines thereafter. These agreements may be made in two parts with the first Tier 3 agreement due prior to the receipt of any operating coal or petroleum coke feedstock materials by rail; and the second Tier 4 agreement due by October of 2019.

Onsite Switch Locomotives

Onsite Switch Locomotives shall meet Tier 4 locomotive or Tier 4 Nonroad emissions standards, depending on which standard applies.

Verification: The project owner shall provide a copy of the agreement(s) with the rail line operator that demonstrates compliance with this condition to the CPM for approval within the specified due dates required by this condition. The project owner shall submit the engine’s specifications of the proposed project owner owned onsite switch locomotive(s) engine to the CPM for approval at least 30 days prior to purchasing or leasing the switch locomotive(s), or if the switch locomotive will be owned and operated by a third party the project owner shall provide the engine specifications to the CPM for approval at least 30 days prior to the switch locomotive being transported to the site.

AQ-SC13 The project owner shall document compliance with federal Mercury and Air Toxics Standards (MATS). The project owner shall provide source testing data or other U.S. EPA approved testing results that demonstrate compliance with the MATS (40 CFR Subpart UUUUU Table 1). The mercury emissions control system shall be in operation at all times when the gasifier and coal dryer are operating and otherwise when there is any potential for coal or petcoke derived mercury emissions. The project owner shall develop a plan to monitor the activated carbon mercury emissions control systems to identify proper carbon change out frequency to avoid saturation and emissions break through. The testing shall meet test plan preparation, notification, and test report requirements as specified in applicable provisions of Conditions of Certification **AQ-1**, **AQ-5**, **AQ-6**, **AQ-9**, and **AQ-11**.

Verification: The project owner shall submit to the CPM a summary of the results of tests required prior to commercial operation that demonstrate compliance with the appropriate 40 CFR Subpart UUUUU Table 1 emissions standards. no later than 60 days after testing is complete, and shall submit subsequent compliance demonstration data no later than 60 days after the testing is complete that meets the compliance demonstration frequency requirements of 40 CFR Subpart UUUUU. The project owner shall provide a monitoring plan for the mercury emissions control systems to the CPM for approval at least 60 days prior to operating these control systems.

AQ-SC14 The project owner shall document compliance with the two mitigation funding agreements that they have signed with the District, specifically providing proof of funding the mitigation amounts as required in the two SJVAPCD Board-approved agreements.

Verification: The project owner shall submit to the CPM a letter from the APCO acknowledging that the funding for the two mitigation agreements has been provided as required by the two SJVAPCD Board-approved mitigation agreements within 15 days of the agreement timeline requirements to receive the funding.

DISTRICT PRELIMINARY DETERMINATION OF COMPLIANCE CONDITIONS (SJVAPCD 2013a)

The SJVACPD permits each permit unit separately, which causes duplication of conditions and verifications. In total there are 1,179 conditions in the PDOC. Staff has compiled the SJVAPCD conditions by permit unit into aggregated AQ conditions, removing the general facility conditions contained in each permit unit's conditions, retaining the District condition numbers and providing less redundant verifications, as shown in the following referencing table.

Staff Condition	District Conditions
AQ-1	Contains nineteen General Facility Conditions, including all of the conditions not listed below in the specific permit unit conditions, except the two conditions that required finalization of the mitigation agreements prior to publication of the FDOC, which were removed since these two

	mitigation agreements have been finalized and approved by the SJVAPCD Governing Board.
AQ-2	Permit Unit S-7616-17-0 – Conditions 8 through 35
AQ-3	Permit Unit S-7616-18-0 – Conditions 8 through 35
AQ-4	Permit Unit S-7616-19-0 – Conditions 8 through 33
AQ-5	Permit Unit S-7616-20-0 – Conditions 8 through 32
AQ-6	Permit Unit S-7616-21-0 – Conditions 8 through 30
AQ-7	Permit Unit S-7616-22-0 – Conditions 8 through 36
AQ-8	Permit Unit S-7616-23-0 – Conditions 11 through 73
AQ-9	Permit Unit S-7616-24-0 – Conditions 8 through 19
AQ-10	Permit Unit S-7616-25-0 – Conditions 11through 45
AQ-11	Permit Unit S-7616-26-0 – Conditions 11through 91
AQ-12	Permit Unit S-7616-27-0 – Conditions 7, 9 through 20
AQ-13	Permit Unit S-7616-28-0 – Conditions 7, 9 through 20
AQ-14	Permit Unit S-7616-29-0 – Conditions 7, 9 through 20
AQ-15	Permit Unit S-7616-30-0 – Conditions 11 through 51
AQ-16	Permit Unit S-7616-31-0 – Conditions 11 through 62
AQ-17	Permit Unit S-7616-32-0 – Conditions 11 through 62
AQ-18	Permit Unit S-7616-33-0 – Conditions 11 through 63
AQ-19	Permit Unit S-7616-34-0 – Conditions 8 through 35
AQ-20	Permit Unit S-7616-35-0 – Conditions 8 through 42
AQ-21	Permit Unit S-7616-36-0 – Conditions 8 through 21
AQ-22	Permit Unit S-7616-37-0 – Conditions 8 through 34
AQ-23	Permit Unit S-7616-38-0 – Conditions 8 through 25
AQ-24	Permit Unit S-7616-39-0 – Conditions 8 through 25
AQ-25	Permit Unit S-7616-40-0 – Conditions 8 through 25

The following are the aggregated District conditions from the PDOC[19]:

AQ-1 The following conditions are general facility conditions that apply to the facility as a whole:

1. Permittee shall submit an application to comply with Rule 2520 - Federally Mandated Operating Permits within twelve months of commencing operation. [District Rule 2520]

[19] Please note that acronyms provided in the District conditions may not be defined within the conditions, but they are provided in the acronym list at the end of this section.

2. Permittee shall submit an application to comply with Rule 2540 - Acid Rain Program within twelve months of commencing operation. [District Rule 2540]

3. Prior to initial operation of S-7616-23, -25, -26, -30, -31, -32, -33, and -35, permittee shall provide NOx emission reduction credits for the following quantity of emissions: 1st quarter: 74,201 lb, 2nd quarter: 74,201 lb, 3rd quarter: 74,201 lb, and fourth quarter: 74,201 lb. Offsets shall be provided at the applicable offset ratio specified in Table 4-2 of Rule 2201 (as amended 4/21/11). [District Rule 2201]

4. Prior to initial operation of S-7616-17, -18, -19, -20, -22, -23, -25, -26, -27, -28, -29, -30, -31, -32, -33, -34, -36, -37, -38, -39, and -40, permittee shall provide PM10/PM2.5 emission reduction credits for the following quantity of emissions: 1st quarter: 39,538 lb, 2nd quarter: 39,538 lb, 3rd quarter: 39,538 lb, and 4th quarter: 39,538 lb. Offsets shall be provided at the applicable offset ratio specified in Table 4-2 of Rule 2201 (as amended 4/21/11). SOx ERCs may be used to offset PM10/PM2.5 increases at an interpollutant ratio of 1.0 lb-SOx: 1.0 lb-PM10. [District Rule 2201]

5. Prior to initial operation of S-7616-23, -25, -26, -30, -31, -32, and -33, permittee shall provide SOx emission reduction credits for the following quantity of emissions: 1st quarter: 1,170 lb, 2nd quarter: 1,170 lb, 3rd quarter: 1,170 lb, and 4th quarter: 1,170 lb. Offsets shall be provided at the applicable offset ratio specified in Table 4-2 of Rule 2201 (as amended 4/21/11). [District Rule 2201]

6. Prior to initial operation of S-7616-21, -23, -24, -25, -26, -30, -31, -32, and -33, permittee shall provide VOC emission reduction credits for the following quantity of emissions: 1st quarter: 13,792 lb, 2nd quarter: 13,792 lb, 3rd quarter: 13,792 lb, and 4th quarter: 13,792 lb. Offsets shall be provided at the applicable offset ratio specified in Table 4-2 of Rule 2201 (as amended 4/21/11). [District Rule 2201]

7. ERC certificate numbers C-1058-2, C-1058-5, S-3275-5, S-3273-2, S-3305-1, S-3557-1, and/or S-3605-1 (or a certificate split from these certificates) shall be used to supply the required offsets, unless a revised offsetting proposal is received and approved by the District, upon which this Determination of Compliance shall be reissued, administratively specifying the new offsetting proposal. Original public noticing requirements, if any, shall be duplicated prior to reissuance of this Determination of Compliance. [District Rule 2201]

8. Permittee shall provide the District at least 30 days prior notice of any performance test, except as specified under other subparts, to afford the Administrator the opportunity to have an observer present. [District Rule 4001 and 40 CFR 60.8]

9. No air contaminant shall be released into the atmosphere which causes a public nuisance. [District Rule 4102]

10. An owner/operator shall submit a Dust Control Plan to the APCO prior to the start of any construction activity on any site that will include 10 acres or more of disturbed surface area for residential developments, or 5 acres or more of disturbed surface area for non-residential development, or will include moving, depositing, or relocating more than 2,500 cubic yards per day of bulk materials on at least three days. [District Rules 8011 and 8021]

11. Disturbances of soil related to any construction, demolition, excavation, extraction, or other earthmoving activities shall comply with the requirements for fugitive dust control in District Rule 8021 unless specifically exempted under Section 4.0 of Rule 8021 or Rule 8011. [District Rules 8011 and 8021]

12. An owner/operator shall prevent or cleanup any carryout or trackout in accordance with the requirements of District Rule 8041 Section 5.0, unless specifically exempted under Section 4.0 of Rule 8041 (8/19/04) or Rule 8011(8/19/04). [District Rules 8011 and 8021]

13. Whenever open areas are disturbed, or vehicles are used in open areas, the facility shall comply with the requirements of Section 5.0 of District Rule 8051, unless specifically exempted under Section 4.0 of Rule 8051 or Rule 8011. [District Rules 8011 and 8051]

14. Any paved road or unpaved road shall comply with the requirements of District Rule 8061 unless specifically exempted under Section 4.0 of Rule 8061 or Rule 8011. [District Rules 8011 and 8061]

15. Water, gravel, roadmix, or chemical/organic dust stabilizers/suppressants, vegetative materials, or other District-approved control measure shall be applied to unpaved vehicle travel areas as required to limit Visible Dust Emissions to 20 percent opacity and comply with the requirements for a stabilized unpaved road as defined in Section 3.59 of District Rule 8011. [District Rule 8011 and 8071]

16. Where dusting materials are allowed to accumulate on paved surfaces, the accumulation shall be removed daily or water and/or chemical/organic dust stabilizers/suppressants shall be applied to the paved surface as required to maintain continuous compliance with the requirements for a stabilized unpaved road as defined in Section 3.59 of District Rule 8011 and limit Visible Dust Emissions (VDE) to 20 percent opacity. [District Rule 8011 and 8071]

17. On each day that 50 or more Vehicle Daily Trips or 25 or more Vehicle Daily Trips for vehicles with 3 axles or more will occur on an unpaved vehicle/equipment traffic area, permittee shall apply water, gravel, roadmix, or chemical/organic dust stabilizers/suppressants, vegetative materials, or other District-approved control measure as required to limit Visible Dust Emissions to 20 percent opacity and comply with the requirements for a stabilized unpaved road as defined in Section 3.59 of District Rule 8011. [District Rule 8011 and 8071]

18. Whenever any portion of the site becomes inactive, Permittee shall restrict access and periodically stabilize any disturbed surface to comply with the conditions for a stabilized surface as defined in Section 3.58 of District Rule 8011. [District Rules 8011 and 8071]

19. Records and other supporting documentation shall be maintained as required to demonstrate compliance with the requirements of the rules under Regulation VIII only for those days that a control measure was implemented. Such records shall include the type of control measure(s) used, the location and extent of coverage, and the date, amount, and frequency of application of dust suppressant, manufacturer's dust suppressant product information sheet that identifies the name of the dust suppressant and application instructions. Records shall be kept for one year following project completion that results in the termination of all dust generating activities. [District Rules 8011, 8031, and 8071]

Verification: The following verification requirements apply to applicable general facility conditions:

The project owner shall submit to both the District and CPM the Federally Mandated Operating Permit application and Acid Rain Program permit application within twelve months of commencing operation. (Conditions **AQ 1-1** and **-2**)The project owner shall submit to both the District and CPM records showing that the project's offset requirements have been met prior to initiating operation. (Conditions **AQ 1-3** through **-6**)

The project owner shall submit to the CPM a list of the ERC certificates and quantities surrendered to the District within 30 days of their surrender. The project owner shall request any changes to the ERC certificates listed in this condition at least 30 days prior to their surrender date. If the CPM, in consultation with the District, approves a substitution or modification, the CPM shall file a statement of the approval with the commission docket and mail a copy of the statement to every person on the post-certification mailing list. The CPM shall maintain an updated list of approved ERCs for the project. The initial table of the approved list of ERCs is as follows: (Condition **AQ-1-7**).

HECA Approved ERC List

ERC Certificate	Pollutant	1st Quarter lbs	2nd Quarter lbs	3rd Quarter lbs	4th Quarter lbs
S-3273-2	NOx	120,500	120,500	120,500	120,500
C-1058-2	NOx	10,100	10,100	10,100	10,100
S-3275-5	SOx	42,000	42,000	42,000	42,000
C-1058-5	SOx	24,500	24,500	24,500	24,500
S-3305-1	VOC	14,625	14,625	14,625	14,625
S-3557-1	VOC	11,437	11,438	11,438	11,437
S-3605-1	VOC	7,937	7,938	7,938	7,937

The project owner shall provide the District and the CPM at least 30 days prior notice of any performance test, except as specified under other District Conditions, and the project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing (Condition **AQ 1-8**).

The project owner shall provide the Dust Control Plan required under this condition, which will be coordinated with the plan and dust control requirements of staff conditions **AQ-SC2** and **AQ-SC3**, to the CPM and APCO at the same time, and if desired as part of plan required under staff condition **AQ-SC2**. (Condition **AQ-1-10**)

The project owner shall provide a summary of the fugitive dust mitigation measures performed as necessary to comply with this condition and staff condition AQ-SC9 during facility operation in the Annual Compliance Reports (**AQ-SC8**). During construction the facility will comply with the mitigation measures and reporting/recordkeeping requirements of conditions staff conditions **AQ-SC2** through **AQ-SC4.** (Conditions **AQ-1-10** to **-19**)

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-1** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-1-9** through **-19**)

AQ-2 The following conditions cover permit unit S-7616-17-0.
RAIL UNLOADING AND TRANSFER SYSTEM FOR THE HANDLING OF COAL, INCLUDING: ENCLOSED RAIL UNLOADING BUILDING SERVED BY BAGHOUSE DUST COLLECTOR AND DUST SUPPRESSION SPRAY SYSTEM, WITH RAILCAR UNLOADING STATION, RAIL UNLOADING BIN(S), BELT FEEDER(S), RAIL UNLOADING CONVEYOR(S) ENCLOSED IN UNLOADING TUNNEL (SERVED BY A DUST COLLECTOR) THAT TRANSFERS MATERIAL TO TOWER #1 SERVING FEEDSTOCK STORAGE (S-7616-19)

8. Unloading hopper shall be equipped with water/additive misting system, which shall be employed as needed to control dust emissions during unloading. [District Rule 2201]

9. Operation shall include the following dust collectors serving the following operation(s): rail unloading station. [District Rule 2201]

10. Railcar unloading station shall include water spray nozzles that shall be automatically activated at or prior to unloading as necessary to prevent visible emissions. [District Rule 2201]

11. All conveyors and crushers shall be fully enclosed and shall vent only to dust collectors. [District Rule 2201]

12. All feedstock processing and conveying equipment, feedstock storage systems, and feedstock transfer and loading systems shall be dust-tight (to prevent visible emissions in excess of 5 percent opacity) and shall vent only to dust collectors. [District Rules 2201, 4001, and 40 CFR 60.254]

13. Each dust collector shall be equipped with dust-tight (to prevent visible emissions in excess of 5 percent opacity) provisions to return collected material to process equipment. [District Rules 2201, 4001, and 40 CFR 60.254]

14. Each dust collector shall be equipped with operational differential pressure indicators, and during fabric collector operation read in the proper range specified by the manufacturer. [District Rule 2201]

15. The differential pressure across each compartment of the dust collectors shall be checked and the results recorded quarterly. If the differential pressure across each compartment of the dust collectors is not within the proper range specified by the manufacturer, corrective action is required prior to further operation of the equipment. Corrective action means that the cause of the improper pressure differential is corrected before operation of the equipment is resumed. [District Rule 2201]

16. Each dust collector shall automatically activate whenever process equipment served is activated. [District Rule 2201]

17. Enclosure dust suppression system water spray nozzles shall automatically operate when railcar unloading is occurring. [District Rule 2201]

18. Material shall not be conveyed or crushed unless ventilation system and dust collectors are operating and functioning properly. [District Rule 2201]

19. Permittee shall maintain daily records of the hours of operation and weight of material processed by this operation, and records shall be made available for District inspection upon request. [District Rule 2201]

20. Airflow for the following dust collector(s) shall not exceed: rail unloading station: 20,000 cfm. [District Rule 2201]

21. Particulate matter emissions from the dust collectors shall not exceed 0.001 grains/dscf in concentration. [District Rules 2201, 4001, and 40 CFR 60.254]

22. PM10 emissions shall not exceed any of the following emissions for the following operation(s): rail unloading station: 4.1 lb/day. [District Rule 2201]

23. PM10 emissions shall not exceed any of the following emissions for the following operation(s): rail unloading station: 267 lb/yr. [District Rule 2201]

24. The maximum process rates of material on a weight basis shall not exceed any of the following: rail unloading station: 6,107 ton/day. [District Rule 2201]

25. The maximum process rates of material on a weight basis shall not exceed any of the following: rail unloading station: 396,955 ton/yr. [District Rule 2201]

26. Dust collector filters shall be completely inspected annually while not in operation for tears, scuffs, abrasives or holes which might interfere with PM collection efficiency and shall be replaced as needed. [District Rule 2201]

27. Visible emissions from the operation shall be checked and the project owner shall record results quarterly. If visible emissions are observed, corrective action is required prior to further loading. Corrective action means that visible emissions are eliminated before next loading event. [District Rule 2201]

28. Records of dust control device maintenance, inspection, and repairs shall be maintained. The records shall include identification of equipment, date of inspection, corrective action taken, and identification of individual performing inspection. [District Rule 2201]

29. Testing for particulate matter concentration for each dust collector shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 12 calendar months of the date the previous performance test was required to be completed thereafter. If the results of the most recent performance test demonstrate that emissions from the affected facility are 50 percent or less of the applicable emissions standard, a new performance test must be conducted within 24 calendar months of the date that the previous performance test was required to be completed. [District Rule 4001 and 40 CFR 60.255(1), 40 CFR 60.8]

30. Testing for compliance with particulate matter concentration limit shall be conducted using EPA method 5. The sampling time and sample volume for each run shall be at least 60 minutes and 0.85 dscm (30 dscf). Sampling shall begin no less than 30 minutes after startup and shall terminate before shutdown procedures begin. A minimum of three valid test runs are needed to comprise a PM performance test. [District Rule 4001 and 40 CFR 60.255(1) and 60.257(5)(i)]

31. Testing for the opacity standards for the operations shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 90 operating days of the date the previous performance test was required to be completed thereafter. If all 6-minute average opacity readings in the most recent performance test are equal to or less than half the applicable opacity limit, a new performance test must be conducted within 12 calendar months of the date that the previous performance test was required to be completed. [District Rule 4001 and 40 CFR 60.255(2), 40 CFR 60.8]

32. Source testing to determine opacity as required by 40 CFR Part 60, Subpart Y shall be conducted using EPA method 9. [District Rule 4001 and 40 CFR 60.257(a)]

33. The permittee shall conduct monthly visual observations of all process and control equipment. If any deficiencies are observed, the necessary maintenance must be performed as expeditiously as possible. [District Rule 4001 and 40 CFR 60.257]

34. Permittee shall maintain a logbook (written or electronic) with the records specified in 40 CFR Subpart 60.258(a) on-site and make it available upon request. [District Rule 4001 and 40 CFR 60.258]

35. Permittee shall conduct testing for compliance with the particulate matter concentration limit and particulate matter emissions limit within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility. [District Rule 4001 and 40 CFR 60.258(c), 40 CFR 60.8]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-17-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-2-22** through **-25**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-2-28**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-2-21** and **-22**, to the CPM within 60 days of testing. (Condition **AQ-2-29**)
The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-2** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-2-8** through **-35**)

AQ-3 The following conditions cover permit unit S-7616-18-0.

TRUCK UNLOADING AND TRANSFER SYSTEM FOR THE HANDLING OF PETROLEUM COKE (PETCOKE) AND/OR COAL, INCLUDING: ENCLOSED TRUCK

UNLOADING BUILDING SERVED BY BAGHOUSE DUST COLLECTOR AND DUST SUPPRESSION SPRAY SYSTEM, WITH TRUCK UNLOADING STATION(S), TRUCK UNLOADING BIN(S), BELT FEEDER(S), TRUCK UNLOADING CONVEYOR(S) ENCLOSED IN AN UNLOADING TUNNEL (SERVED BY A DUST COLLECTOR) THAT TRANSFERS MATERIAL TO TOWER #1 SERVING FEEDSTOCK STORAGE (S-7616-19)

8. Unloading hopper shall be equipped with water/additive misting system, which shall be employed as needed to control dust emissions during unloading. [District Rule 2201]

9. Operation shall include the following dust collectors serving the following operation(s): truck unloading station. [District Rule 2201]

10. Truck unloading station shall include water spray nozzles that shall be automatically activated at or prior to unloading as necessary to prevent visible emissions. [District Rule 2201]

11. All conveyors and crushers shall be fully enclosed and shall vent only to dust collectors. [District Rule 2201]

12. All feedstock processing and conveying equipment, feedstock storage systems, and feedstock transfer and loading systems shall be dust-tight (to prevent visible emissions in excess of 5 percent opacity) and shall vent only to dust collectors. [District Rules 2201, 4001, and 40 CFR 60.254]

13. Each dust collector shall be equipped with dust-tight (to prevent visible emissions in excess of 5 percent opacity) provisions to return collected material to process equipment. [District Rules 2201, 4001, and 40 CFR 60.254]

14. Each dust collector shall be equipped with operational differential pressure indicators, and during fabric collector operation read in the proper range specified by the manufacturer. [District Rule 2201]

15. The differential pressure across each compartment of the dust collectors shall be checked and the results recorded quarterly. If the differential pressure across each compartment of the dust collectors is not within the proper range specified by the manufacturer, corrective action is required prior to further operation of the equipment. Corrective action means that the cause of the improper pressure differential is corrected before operation of the equipment is resumed. [District Rule 2201]

16. Each dust collector shall automatically activate whenever process equipment served is activated. [District Rule 2201]

17. Enclosure dust suppression system water spray nozzles shall automatically operate when truck unloading is occurring. [District Rule 2201]

18. Material shall not be conveyed or crushed unless ventilation system and dust collectors are operating and functioning properly. [District Rule 2201]

19. Permittee shall maintain daily records of the hours of operation and weight of material processed by this operation, and records shall be made available for District inspection upon request. [District Rule 2201]

20. Airflow for the following dust collector(s) shall not exceed: truck unloading station: 80,000 cfm. [District Rule 2201]

21. Particulate matter emissions from the dust collectors shall not exceed 0.001 grains/dscf in concentration. [District Rules 2201, 4001, and 40 CFR 60.254]

22. PM10 emissions shall not exceed any of the following emissions for the following operation(s): truck unloading station: 16.5 lb/day. [District Rule 2201]

23. PM10 emissions shall not exceed any of the following emissions for the following operation(s): truck unloading station: 535 lb/yr. [District Rule 2201]

24. The maximum process rates of material on a weight basis shall not exceed any of the following: truck unloading station: 1,368 ton/day. [District Rule 2201]

25. The maximum process rates of material on a weight basis shall not exceed any of the following: truck unloading station: 177,840 ton/yr. [District Rule 2201]

26. Dust collector filters shall be completely inspected annually while not in operation for tears, scuffs, abrasives or holes which might interfere with PM collection efficiency and shall be replaced as needed. [District Rule 2201]

27. Visible emissions from the operation shall be checked and permittee shall record results quarterly. If visible emissions are observed, corrective action is required prior to further loading. Corrective action means that visible emissions are eliminated before next loading event. [District Rule 2201]

28. Records of dust control device maintenance, inspection, and repairs shall be maintained. The records shall include identification of equipment, date of inspection, corrective action taken, and identification of individual performing inspection. [District Rule 2201]

29. Testing for particulate matter concentration for each dust collector shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 12 calendar months of the date the previous performance test was required to be completed thereafter. If the results of the most recent performance test demonstrate that emissions from the affected facility are 50 percent or less of the applicable emissions standard, a new performance test must be conducted within 24 calendar months of the date that the previous performance test was required to be completed. [District Rule 4001 and 40 CFR 60.255(1), 40 CFR 60.8]

30. Testing for compliance with particulate matter concentration limit shall be conducted using EPA method 5. The sampling time and sample volume for each run shall be at least 60 minutes and 0.85 dscm (30 dscf). Sampling shall begin no less than 30 minutes after startup and shall terminate before shutdown procedures begin. A minimum of three valid test runs are needed to comprise a PM performance test. [District Rule 4001 and 40 CFR 60.255(1) and 60.257(5)(i)]

31. Testing for the opacity standards for the operations shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 90 operating days of the date the previous performance test was required to be completed thereafter. If all 6-minute average opacity readings in the most recent performance test are equal to or less than half the applicable opacity limit, a new performance test must be conducted within 12 calendar months of the date that the previous performance test was required to be completed. [District Rule 4001 and 40 CFR 60.255(2), 40 CFR 60.8]

32. Source testing to determine opacity as required by 40 CFR Part 60, Subpart Y shall be conducted using EPA method 9. [District Rule 4001 and 40 CFR 60.257(a)]

33. The permittee shall conduct monthly visual observations of all process and control equipment. If any deficiencies are observed, the necessary maintenance must be performed as expeditiously as possible. [District Rule 4001 and 40 CFR 60.257]

34. Permittee shall maintain a logbook (written or electronic) with the records specified in 40 CFR Subpart 60.258(a) on-site and make it available upon request. [District Rule 4001 and 40 CFR 60.258]

35. Permittee shall conduct testing for compliance with the particulate matter concentration limit and particulate matter emissions limit within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility. [District Rule 4001 and 40 CFR 60.258(c), 40 CFR 60.8]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-18-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-3-22** through **-25**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-3-28**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-3-21** and **-22**, to the CPM within 60 days of testing. (Condition **AQ-3-29**)

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-3** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-3-8** through **-35**)

AQ-4 The following conditions cover permit unit S-7616-19-0.

FEEDSTOCK STORAGE, BLENDING, AND RECLAIM SYSTEM INCLUDING: TRANSFER TOWER #1 (THAT TRANSFERS FEEDSTOCK FROM RAIL AND TRUCK UNLOADING AND TRANSFER SYSTEMS, S-7616-17 AND -18) SERVED BY A DUST COLLECTOR WITH COAL CRUSHER, REJECTS CONVEYOR(S); FEEDSTOCK STORAGE BUILDING (BARN) WITH A SEPARATE COAL AND PETCOKE STORAGE AREAS, STORAGE CONVEYOR(S), DISCHARGE CHUTE(S), AND RECLAIM CONVEYOR(S); AND TRANSFER TOWER #2 (THAT TRANSFERS MATERIAL TO THE FEEDSTOCK DRYING AND GRINDING/CRUSHING OPERATION, S-7616-20) SERVED BY TWO DUST COLLECTORS (ONE OPERATING AND ONE SPARE), TWO ENCLOSED TRANSFER CONVEYORS

8. Operation shall include the following dust collectors serving the following operation(s): feedstock transfer tower 1; feedstock transfer tower 2 [District Rule 2201]

9. All conveyors and crushers shall be fully enclosed and shall vent only to dust collectors. [District Rule 2201]

10. All feedstock processing and conveying equipment, feedstock storage systems, and feedstock transfer and loading systems shall be dust-tight (to prevent visible emissions in excess of 5 percent opacity) and shall vent only to dust collectors. [District Rules 2201, 4001, and 40 CFR 60.254]

11. Each dust collector shall be equipped with dust-tight (to prevent visible emissions in excess of 5 percent opacity) provisions to return collected material to process equipment. [District Rules 2201, 4001, and 40 CFR 60.254]

12. Each dust collector shall be equipped with operational differential pressure indicators, and during fabric collector operation read in the proper range specified by the manufacturer. [District Rule 2201]

13. The differential pressure across each compartment of the dust collectors shall be checked and the results recorded quarterly. If the differential pressure across each compartment of the dust collectors is not within the proper range specified by the manufacturer, corrective action is required prior to further operation of the equipment. Corrective action means that the cause of the improper pressure differential is corrected before operation of the equipment is resumed. [District Rule 2201]

14. Each dust collector shall automatically activate whenever process equipment served is activated. [District Rule 2201]

15. Enclosure dust suppression system water spray nozzles shall automatically operate when railcar unloading is occurring. [District Rule 2201]

16. Material shall not be conveyed or crushed unless ventilation system and dust collectors are operating and functioning properly. [District Rule 2201]

17. Permittee shall maintain daily records of the hours of operation and weight of material processed by this operation, and records shall be made available for District inspection upon request. [District Rule 2201]

18. Airflow for the following dust collector(s) shall not exceed: feedstock transfer tower 1: 1,500 cfm; feedstock transfer tower 2: 1,500 cfm. [District Rule 2201]

19. Particulate matter emissions from the dust collectors shall not exceed 0.001 grains/dscf in concentration. [District Rules 2201, 4001, and 40 CFR 60.254]

20. PM10 emissions shall not exceed any of the following emissions for the following operation(s): feedstock transfer tower 1: 0.3 lb/day; feedstock transfer tower 2: 0.3 lb/day. [District Rule 2201]

21. PM10 emissions shall not exceed any of the following emissions for the following operation(s): feedstock transfer tower 1: 16.0 lb/yr; feedstock transfer tower 2: 22.5 lb/yr. [District Rule 2201]

22. The maximum process rates of material on a weight basis shall not exceed any of the following: feedstock transfer tower 1: 6,107 ton/day; feedstock transfer tower 2: 7,475 ton/day. [District Rule 2201]

23. The maximum process rates of material on a weight basis shall not exceed any of the following: feedstock transfer tower 1: 793,910 ton/yr; feedstock transfer tower 2: 1,364,188 ton/yr. [District Rule 2201]

24. Dust collector filters shall be completely inspected annually while not in operation for tears, scuffs, abrasives or holes which might interfere with PM collection efficiency and shall be replaced as needed. [District Rule 2201]

25. Visible emissions from the operation shall be checked and record results quarterly. If visible emissions are observed, corrective action is required prior to further loading. Corrective action means that visible emissions are eliminated before next loading event. [District Rule 2201]

26. Records of dust control device maintenance, inspection, and repairs shall be maintained. The records shall include identification of equipment, date of inspection, corrective action taken, and identification of individual performing inspection. [District Rule 2201]

27. Testing for particulate matter concentration for each dust collector shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 12 calendar months

of the date the previous performance test was required to be completed thereafter. If the results of the most recent performance test demonstrate that emissions from the affected facility are 50 percent or less of the applicable emissions standard, a new performance test must be conducted within 24 calendar months of the date that the previous performance test was required to be completed. [District Rule 4001 and 40 CFR 60.255(1), 40 CFR 60.8]

28. Testing for compliance with particulate matter concentration limit shall be conducted using EPA method 5. The sampling time and sample volume for each run shall be at least 60 minutes and 0.85 dscm (30 dscf). Sampling shall begin no less than 30 minutes after startup and shall terminate before shutdown procedures begin. A minimum of three valid test runs are needed to comprise a PM performance test. [District Rule 4001 and 40 CFR 60.255(1) and 60.257(5)(i)]

29. Testing for the opacity standards for the operations shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 90 operating days of the date the previous performance test was required to be completed thereafter. If all 6-minute average opacity readings in the most recent performance test are equal to or less than half the applicable opacity limit, a new performance test must be conducted within 12 calendar months of the date that the previous performance test was required to be completed. [District Rule 4001 and 40 CFR 60.255(2), 40 CFR 60.8]

30. Source testing to determine opacity as required by 40 CFR Part 60, Subpart Y shall be conducted using EPA method 9. [District Rule 4001 and 40 CFR 60.257(a)]

31. The permittee shall conduct monthly visual observations of all process and control equipment. If any deficiencies are observed, the necessary maintenance must be performed as expeditiously as possible. [District Rule 4001 and 40 CFR 60.257]

32. Permittee shall maintain a logbook (written or electronic) with the records specified in 40 CFR Subpart 60.258(a) on-site and make it available upon request. [District Rule 4001 and 40 CFR 60.258]

33. Permittee shall conduct testing for compliance with the particulate matter concentration limit and particulate matter emissions limit within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility. [District Rule 4001 and 40 CFR 60.258(c), 40 CFR 60.8]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-19-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-4-20** through **-23**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-4-26**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-4-19** and **-20**, to the CPM within 60 days of testing. (Condition **AQ-4-27**)

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-4** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-4-8** through **-33**)

AQ-5 The following conditions cover permit unit S-7616-20-0.

FEEDSTOCK DRYING AND GRINDING/CRUSHING OPERATION INCLUDING: CRUSHER BUILDING SERVED BY BAGHOUSE DUST COLLECTOR, WITH SURGE BIN(S), BELT FEEDER(S), BYPASS SCREEN(S), TWO FEEDSTOCK CRUSHERS; TWO ENCLOSED PLANT FEED CONVEYORS SERVED BY BAGHOUSE DUST COLLECTOR; MILLING AND DRYING BUILDING WITH FEEDSTOCK DRYER [WITH DRYING GAS FROM TREATED EXHAUST GAS FROM HEAT RECOVERY STEAM GENERATOR LISTED ON S-7616-26] SERVED BY BAGHOUSE DUST COLLECTOR, WITH REVERSING CONVEYOR(S), DIVERTER GATE(S), AND TWO MILLING AND DRYING SILOS

8. Operation shall include the following dust collectors serving the following operation(s): feedstock bunkers; feedstock crusher. [District Rule 2201]

9. All conveyors and crushers shall be fully enclosed and shall vent only to dust collectors. [District Rule 2201]

10. All feedstock processing and conveying equipment, feedstock storage systems, and feedstock transfer and loading systems shall be dust-tight (to prevent visible emissions in excess of 5 percent opacity) and shall vent only to dust collectors. [District Rules 2201, 4001, and 40 CFR 60.254]

11. Each dust collector shall be equipped with dust-tight (to prevent visible emissions in excess of 5 percent opacity) provisions to return collected material to process equipment. [District Rules 2201, 4001, and 40 CFR 60.254]

12. Each dust collector shall be equipped with operational differential pressure indicators, and during fabric collector operation read in the proper range specified by the manufacturer. [District Rule 2201]

13. The differential pressure across each compartment of the dust collectors shall be checked and the results recorded quarterly. If the differential pressure across each compartment of the dust collectors is not within the proper range specified by the manufacturer, corrective action is required prior to further operation of the equipment. Corrective action means that the cause of the improper pressure differential is corrected before operation of the equipment is resumed. [District Rule 2201]

14. Each dust collector shall automatically activate whenever process equipment served is activated. [District Rule 2201]

15. Material shall not be conveyed or crushed unless ventilation system and dust collectors are operating and functioning properly. [District Rule 2201]

16. Permittee shall maintain daily records of the hours of operation and weight of material processed by this operation, and records shall be made available for District inspection upon request. [District Rule 2201]

17. Airflow for the following dust collector(s) shall not exceed: feedstock bunkers: 12,600 cfm; feedstock crusher: 12,600 cfm. [District Rule 2201]

18. Particulate matter emissions from the dust collectors shall not exceed 0.001 grains/dscf in concentration. [District Rules 2201, 4001, and 40 CFR 60.254]

19. PM10 emissions shall not exceed any of the following emissions for the following operation(s): feedstock bunkers: 2.6 lb/day; feedstock crusher: 2.6 lb/day. [District Rule 2201]

20. PM10 emissions shall not exceed any of the following emissions for the following operation(s): feedstock bunkers: 473 lb/yr; feedstock crusher: 473 lb/yr. [District Rule 2201]

21. The maximum process rates of material on a weight basis shall not exceed any of the following: feedstock bunkers: 7,475 ton/day; feedstock crusher: 7,475 ton/day. [District Rule 2201]

22. The maximum process rates of material on a weight basis shall not exceed any of the following: feedstock bunkers: 1,364,188 ton/yr; feedstock crusher: 1,364,188 ton/yr. [District Rule 2201]

23. Dust collector filters shall be completely inspected annually while not in operation for tears, scuffs, abrasives or holes which might interfere with PM collection efficiency and shall be replaced as needed. [District Rule 2201]

24. Visible emissions from the operation shall be checked and record results quarterly. If visible emissions are observed, corrective action is required prior to further loading. Corrective action means that visible emissions are eliminated before next loading event. [District Rule 2201]

25. Records of dust control device maintenance, inspection, and repairs shall be maintained. The records shall include identification of equipment, date of inspection, corrective action taken, and identification of individual performing inspection. [District Rule 2201]

26. Testing for particulate matter concentration for each dust collector shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 12 calendar months

of the date the previous performance test was required to be completed thereafter. If the results of the most recent performance test demonstrate that emissions from the affected facility are 50 percent or less of the applicable emissions standard, a new performance test must be conducted within 24 calendar months of the date that the previous performance test was required to be completed. [District Rule 4001 and 40 CFR 60.255(1), 40 CFR 60.8]

27. Testing for compliance with particulate matter concentration limit shall be conducted using EPA method 5. The sampling time and sample volume for each run shall be at least 60 minutes and 0.85 dscm (30 dscf). Sampling shall begin no less than 30 minutes after startup and shall terminate before shutdown procedures begin. A minimum of three valid test runs are needed to comprise a PM performance test. [District Rule 4001 and 40 CFR 60.255(1) and 60.257(5)(i)]

28. Testing for the opacity standards for the operations shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 90 operating days of the date the previous performance test was required to be completed thereafter. If all 6-minute average opacity readings in the most recent performance test are equal to or less than half the applicable opacity limit, a new performance test must be conducted within 12 calendar months of the date that the previous performance test was required to be completed. [District Rule 4001 and 40 CFR 60.255(2), 40 CFR 60.8]

29. Source testing to determine opacity as required by 40 CFR Part 60, Subpart Y shall be conducted using EPA method 9. [District Rule 4001 and 40 CFR 60.257(a)]

30. The permittee shall conduct monthly visual observations of all process and control equipment. If any deficiencies are observed, the necessary maintenance must be performed as expeditiously as possible. [District Rule 4001 and 40 CFR 60.257]

31. Permittee shall maintain a logbook (written or electronic) with the records specified in 40 CFR Subpart 60.258(a) on-site and make it available upon request. [District Rule 4001 and 40 CFR 60.258]

32. Permittee shall conduct testing for compliance with the particulate matter concentration limit and particulate matter emissions limit within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility. [District Rule 4001 and 40 CFR 60.258(c), 40 CFR 60.8]

<u>Verification:</u> The following verification requirements apply to applicable conditions for permit unit S-7616-20-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-5-19** through **-22**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-5-25**) in the Annual Compliance Reports (**AQ-SC8)**.

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-5-18** and **-19**, to the CPM within 60 days of testing. (Condition **AQ-5-27**)

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-5** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-5-8** through **-32**)

AQ-6 The following conditions cover permit unit S-7616-21-0.

GASIFICATION SYSTEM INCLUDING: ONE MHI OXYGEN-BLOWN GASIFIER; SYNGAS SCRUBBING SYSTEM; SOUR SHIFT/LOW TEMPERATURE GAS COOLING (LTGC) SYSTEM; SOUR WATER TREATMENT SYSTEM, MERCURY REMOVAL SYSTEM, AND RECTISOL ACID GAS REMOVAL (AGR) UNIT

8. Components attributed to this unit shall include those components serving the following process streams: methanol, syngas, shifted syngas, propylene, sour water, H2S-laden methanol, CO_2-laden methanol, acid gas, and ammonia-laden gas. [District Rule 2201]

9. Fugitive VOC emission rate from the unit shall not exceed 86.6 lb/day based on the component count and emission factors from EPA document Protocol for Equipment Leak Emission Estimates (EPA-453/R-95-017), Table 2-1, SOCMI Average Emissions Factors and the applicable control efficiency for those components subject to a leak detection and repair (LDAR) program. Components serving the following streams associated with this unit shall be subject to a leak detection and repair (LDAR) program: methanol, propylene, H2S-laden methanol, CO_2-laden methanol, acid gas, and ammonia laden gas. The following control efficiencies in Table 5-2 of the EPA document shall apply to those components under an LDAR program: gas valves: 92 percent; light liquid valves: 88 percent; light liquid pump seals: 75 percent; and connectors: 93 percent. [District Rules 2201 and 2410]

10. Fugitive CO emission rate from the unit shall not exceed 30.3 lb/day based on the component count, CO percentage in the fluid stream, emission factors from Protocol for Equipment Leak Emission Estimates (EPA-453/R-95-017), Table 2-1, SOCMI Average Emissions Factors and the applicable control efficiency for those components subject to a leak detection and repair (LDAR) program. [District Rule 2201]

11. Permittee shall maintain with the DOC an accurate fugitive component count and the resulting emissions calculated using above specified leak rates and control efficiencies. [District Rule 2201]

12. The VOC content of the gas in the following streams shall not exceed 10 percent by weight: syngas, shifted syngas, sour water, acid gas, ammonia-laden gas. [District Rule 2201]

13. Operator shall conduct quarterly gas sampling to qualify for exemption from fugitive component counts for those components handling fluids with VOC content equal to or less than 10 percent by weight. If gas samples are equal to or less than 10 percent VOC by weight for 8 consecutive quarterly samplings, sampling frequency shall only be required annually. [District Rule 2201]

14. VOC content of gas streams shall be determined by ASTM D1945, EPA Method 18 referenced as methane, or equivalent test method with prior District approval. [District Rule 2201]

15. All sampling connections, open-ended valves, and lines shall be equipped with two closed valves or be sealed with blind flanges, caps, or threaded plugs except during actual use. [District Rule 2201]

16. Permittee shall maintain records of the VOC content test results for a period of five years and make such records available for inspection upon request. [District Rule 1070]

17. For valves and connectors attributed to this unit, a leak shall be defined as a reading of methane in excess of 100 ppmv above background when measured per EPA Method 21. For pump and compressor seals attributed to this unit, a leak shall be defined as a reading of methane in excess of 500 ppmv above background when measure per EPA Method 21. [District Rule 2201]

18. The operator shall audio-visually inspect for leaks all accessible operating pumps, compressors and Pressure Relief Devices (PRDs) in service at least once every 24 hours, except when operators do not report to the facility for that given 24 hours. Any identified leak that cannot be immediately repaired shall be reinspected within 24 hours using a portable analyzer. If a leak is found, it shall be repaired as soon as practical but not later than the time frame specified in Rule 4455 Table 3. [District Rule 2201]

19. The operator shall inspect all components at least once every calendar quarter, except for inaccessible components, unsafe-to-monitor components and pipes. Inaccessible components, unsafe-to-monitor components and pipes shall be inspected in accordance with the requirements set forth in Rule 4455 Sections 5.2.5, 5.2.6, and 5.2.7. New, replaced, or repaired fittings, flanges and threaded connections shall be inspected immediately after being placed into service. Components shall be inspected using EPA Method 21. [District Rule 2201]

20. The operator may apply for a written approval from the APCO to change the inspection frequency from quarterly to annually for a component type, provided the operator meets all the criteria specified in Rule 4455 Sections 5.2.8.1 through 5.2.8.3. This approval shall apply to accessible component types, specifically

designated by the APCO, except pumps, compressors, and PRDs which shall continue to be inspected on a quarterly basis. [District Rule 2201]

21. An annual inspection frequency approved by the APCO shall revert to quarterly inspection frequency for a component type if either the operator inspection or District inspection demonstrates that a violation of the provisions of Rule 4455 Sections 5.1, 5.2 and 5.3 of the rule exists for that component type, or the APCO issued a Notice of Violation for violating any of the provisions of Rule 4455 during the annual inspection period for that component type. When the inspection frequency changes from annual to quarterly inspections, the operator shall notify the APCO in writing within five (5) calendar days after changing the inspection frequency, giving the reason(s) and date of change to quarterly inspection frequency. [District Rule 2201]

22. The operator shall initially inspect a process PRD that releases to the atmosphere as soon as practicable but not later than 24 hours after the time of the release. To insure that the process PRD is operating properly, and is leak-free, the operator shall re-inspect the process PRD not earlier than 24 hours after the initial inspection but not later than 15 calendar days after the date of the release using EPA Method 21. If the process PRD is found to be leaking at either inspection, the PRD leak shall be treated as if the leak was found during quarterly operator inspections. [District Rule 2201]

23. Except for process PRD, a component shall be inspected within 15 calendar days after repairing the leak or replacing the component using EPA Method 21. [District Rule 2201]

24. Upon detection of a leaking component, the operator shall affix to that component a weatherproof readily visible tag that contains the information specified in Rule 4455 Section 5.3.3. The tag shall remain affixed to the component until the leaking component has been repaired or replaced; has been re-inspected using EPA Method 21; and is found to be in compliance with leak, inspection, and maintenance requirements. [District Rule 2201]

25. An operator shall minimize all component leaks immediately to the extent possible, but not later than one (1) hour after detection of leaks in order to stop or reduce leakage to the atmosphere. [District Rule 2201]

26. If the leak has been minimized but the leak still exceeds the applicable leak standards of this DOC, an operator shall repair or replace the leaking component, vent the leaking component to a closed vent system, or remove the leaking component from operation as soon as practicable but not later than the time period specified in Rule 4455 Table 3. For each calendar quarter, the operator may be allowed to extend the repair period as specified in Rule 4455 Table 3, for a total number of leaking components, not to exceed 0.05 percent of the number of components inspected, by type, rounded upward to the nearest integer where required. [District Rule 2201]

27. If the leaking component is an essential component or a critical component which cannot be immediately shut down for repairs, the operator shall minimize the leak

within one hour after detection of the leak. If the leak has been minimized, but the leak still exceeds any of the applicable leak standards of the DOC, the essential component or critical component shall be repaired or replaced to eliminate the leak during the next process unit turnaround, but in no case later than one year from the date of the original leak detection, whichever comes earlier. [District Rule 2201]

28. For any component that has incurred five repair actions for major gas leaks or major liquid leaks, or any combination of major gas leaks and major liquid leaks within a continuous 12-month period, the operator shall comply with at least one of the requirements specified in Rule 4455 Sections 5.3.7.1, 5.3.7.2, 5.3.7.3, or 5.3.7.4 by the applicable deadlines specified in Sections 5.3.7.5 and 5.3.7.6. If the original leaking component is replaced with a new like-in-kind component before incurring five repair actions for major leaks within 12-consecutive months, the repair count shall start over for the new component. An entire compressor or pump need not be replaced provided the compressor part(s) or pump part(s) that have incurred five repair actions as described in Section 5.3.7 are brought into compliance with at least one of the requirements of Sections 5.3.7.1 through 5.3.7.6. [District Rule 2201]

29. All records required by this DOC shall be retained for a period of at least 5 years and shall be made available to the District upon request. [District Rules 1070 and 2201]

30. Sampling ports adequate for extraction of grab samples and measurement of gas flow rate shall be provided for both the influent and the effluent gas streams of the acid gas removal unit. [District Rules 1081 and 2410]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-21-0:

The project owner shall provide a summary of non-compliance events and associated corrective maintenance (Condition **AQ-6-29**) in the Annual Compliance Reports (**AQ-SC8**).
The project owner shall provide a summary of the fugitive emissions LDAR program, per Conditions **AQ-6-8** through **-28**, in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all AQ-6 Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-6-8** through **-30**)

AQ-7 The following conditions cover permit unit S-7616-22-0.

GASIFICATION SOLIDS MATERIAL HANDLING AND STORAGE SYSTEM INCLUDING: GASIFICATION SOLIDS UNLOADING BUNKER (STORAGE COVER WITH ROOFING AND PARTIAL SIDING) WITH DEWATERING TANK(S), STORAGE PILE(S), RECLAIM HOPPER AND GRIZZLY, BUCKET ELEVATOR FEED CONVEYOR SERVED BY DUST COLLECTOR, ENCLOSED TRANSFER CONVEYOR (TO GASIFICATION SOLIDS TRANSFER TOWER), GASIFICATION SOLIDS TRANSFER TOWER SERVED BY DUST COLLECTOR, WITH ENCLOSED LOAD-

OUT FEED CONVEYOR (TO GASIFICATION SOLIDS LOAD-OUT BUILDING); AND ENCLOSED GASIFICATION SOLIDS LOAD-OUT BUILDING SERVED BY BAGHOUSE DUST COLLECTOR, WITH GASIFICATION SOLIDS LOAD-OUT SYSTEM WITH ONE TRUCK AND ONE RAIL LOAD-OUT STATION

8. Operation shall include the following dust collectors serving the following operation(s): gasification solids bucket elevator; gasification solids transfer tower; gasification solids load-out system. [District Rule 2201]

9. All conveyors and crushers shall be fully enclosed and shall vent only to dust collectors. [District Rule 2201]

10. All material processing and conveying equipment, material storage systems, and material transfer and loading systems shall be dust-tight (to prevent visible emissions in excess of 5 percent opacity) and shall vent only to dust collectors. [District Rules 2201, 4001, and 40 CFR 60.254]

11. Each dust collector shall be equipped with dust-tight (to prevent visible emissions in excess of 5 percent opacity) provisions to return collected material to process equipment. [District Rules 2201, 4001, and 40 CFR 60.254]

12. Each dust collector shall be equipped with operational differential pressure indicators, and during fabric collector operation read in the proper range specified by the manufacturer. [District Rule 2201]

13. The differential pressure across each compartment of the dust collectors shall be checked and the results recorded quarterly. If the differential pressure across each compartment of the dust collectors is not within the proper range specified by the manufacturer, corrective action is required prior to further operation of the equipment. Corrective action means that the cause of the improper pressure differential is corrected before operation of the equipment is resumed. [District Rule 2201]

14. Each dust collector shall automatically activate whenever process equipment served is activated. [District Rule 2201]

15. Material shall not be conveyed or crushed unless ventilation system and dust collectors are operating and functioning properly. [District Rule 2201]

16. Permittee shall maintain daily records of the hours of operation and weight of material processed by this operation, and records shall be made available for District inspection upon request. [District Rule 2201]

17. Airflow for the following dust collector(s) shall not exceed: gasification solids bucket elevator: 3,000 cfm; gasification solids transfer tower: 3,000 cfm; gasification solids load-out system: 10,000 cfm. [District Rule 2201]

18. Particulate matter emissions from the dust collectors shall not exceed 0.001 grains/dscf in concentration. [District Rules 2201, 4001, and 40 CFR 60.254]

19. PM10 emissions shall not exceed any of the following emissions for the following operation(s): gasification solids bucket elevator: 0.6 lb/day; gasification solids transfer tower: 0.6 lb/day; gasification solids load-out system: 2.1 lb/day; gasification solids pad stacking: 0.1 lb/day; gasification solids pad reclaim: 0.2 lb/day. [District Rule 2201]

20. PM10 emissions shall not exceed any of the following emissions for the following operation(s): gasification solids bucket elevator: 225 lb/yr; gasification solids transfer tower: 32 lb/yr; gasification solids load-out system: 107 lb/yr; gasification solids pad stacking: 48 lb/yr; gasification solids pad reclaim: 85 lb/yr. [District Rule 2201]

21. The maximum process rates of material on a weight basis shall not exceed any of the following: gasification solids bucket elevator: 1,678 ton/day; gasification solids transfer tower: 1,678 ton/day; gasification solids load-out system: 1,678 ton/day. [District Rule 2201]

22. The maximum process rates of material on a weight basis shall not exceed any of the following: gasification solids bucket elevator: 612,470 ton/yr; gasification solids transfer tower: 87,256 ton/yr; gasification solids load-out system: 87,256 ton/yr. [District Rule 2201]

23. Moisture content of the solids stacking material shall be maintained at 12 percent or greater, by weight, and moisture content of solids reclaim material shall be maintained at 8 percent or greater, by weight. [District Rule 2201]

24. The percent moisture of the solids stacking material and the solids reclaim material shall be determined by weighing an approximately 2-lb sample of each material from in the material handling area, bringing the sample to dryness in a drying oven, then weighing the dried sample; the weight difference divided by the initial weigh of the sample; all multiply by 100 percent is the moisture content (percent moisture = ((initial weight - dry weight)/initial weight) x 100 percent). [District Rule 2201]

25. Moisture content of the solids stacking material and the solids reclaim material shall be measured on monthly basis and when requested by the District. [District Rule 2201]

26. Records of monthly moisture content of the solids stacking material and the solids reclaim material shall be maintained, retained on-site for a period of at least five (5) years and made available for District inspection upon request. [District Rule 2201]

27. Dust collector filters shall be completely inspected annually while not in operation for tears, scuffs, abrasives or holes which might interfere with PM collection efficiency and shall be replaced as needed. [District Rule 2201]

28. Visible emissions from the operation shall be checked and record results quarterly. If visible emissions are observed, corrective action is required prior to

further loading. Corrective action means that visible emissions are eliminated before next loading event. [District Rule 2201]

29. Records of dust control device maintenance, inspection, and repairs shall be maintained. The records shall include identification of equipment, date of inspection, corrective action taken, and identification of individual performing inspection. [District Rule 2201]

30. Testing for particulate matter concentration for each dust collector shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 12 calendar months of the date the previous performance test was required to be completed thereafter. If the results of the most recent performance test demonstrate that emissions from the affected facility are 50 percent or less of the applicable emissions standard, a new performance test must be conducted within 24 calendar months of the date that the previous performance test was required to be completed. [District Rule 4001 and 40 CFR 60.255(1), 40 CFR 60.8]

31. Testing for compliance with particulate matter concentration limit shall be conducted using EPA method 5. The sampling time and sample volume for each run shall be at least 60 minutes and 0.85 dscm (30 dscf). Sampling shall begin no less than 30 minutes after startup and shall terminate before shutdown procedures begin. A minimum of three valid test runs are needed to comprise a PM performance test. [District Rule 4001 and 40 CFR 60.255(1) and 60.257(5)(i)]

32. Testing for the opacity standards for the operations shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 90 operating days of the date the previous performance test was required to be completed thereafter. If all 6-minute average opacity readings in the most recent performance test are equal to or less than half the applicable opacity limit, a new performance test must be conducted within 12 calendar months of the date that the previous performance test was required to be completed. [District Rule 4001 and 40 CFR 60.255(2), 40 CFR 60.8]

33. Source testing to determine opacity as required by 40 CFR Part 60, Subpart Y shall be conducted using EPA method 9. [District Rule 4001 and 40 CFR 60.257(a)]

34. The permittee shall conduct monthly visual observations of all process and control equipment. If any deficiencies are observed, the necessary maintenance must be performed as expeditiously as possible. [District Rule 4001 and 40 CFR 60.257]

35. Permittee shall maintain a logbook (written or electronic) with the records specified in 40 CFR Subpart 60.258(a) on-site and make it available upon request. [District Rule 4001 and 40 CFR 60.258]

36. Permittee shall conduct testing for compliance with the particulate matter concentration limit and particulate matter emissions limit within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility. [District Rule 4001 and 40 CFR 60.258(c), 40 CFR 60.8]

<u>Verification:</u> The following verification requirements apply to applicable conditions for permit unit S-7616-20-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-7-19** through **-22**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-7-29**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-7-18** and **-19**, to the CPM within 60 days of testing. (Condition **AQ-7-30**)

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-7** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-7-8** through **-36**)

AQ-8 The following conditions cover permit unit S-7616-23-0.

SULFUR RECOVERY AND TAIL GAS COMPRESSION SYSTEM CONSISTING OF SULFUR RECOVERY UNIT (SRU), A TAIL GAS UNIT (TGU) WITH A NATURAL GAS-FIRED TAIL GAS THERMAL OXIDIZER RATED UP TO 96 MMBTU/HR, AND MISCELLANEOUS TANKS, COMPRESSORS, PUMPS, CONDENSERS, HEAT EXCHANGERS, PIPING

11. The sulfur recovery unit shall consist of a single train designed to include two Claus converters, two reheaters, three sulfur condensers, waste gas boiler, reaction furnace, oxygen preheater (optional), main burner, acid gas preheater, acid gas wash drum, acid gas wash drum pumps, sour water stripper (SWS) acid gas knockout drum, SWS acid gas preheater, SWS acid gas drum pumps, combustion air blower(s), and piping. [District Rule 2201]

12. Tail gas unit (TGU) shall be designed to include a tail gas heater, tail gas trim heater (optional), hydrogenation reactor, reactor effluent cooler, contact condenser/desuperheater, desuperheater pumps, contact condenser cooler, tailgas compressor, and thermal oxidizer. [District Rule 2201]

13. The operation shall include continuously recording H2S monitor for incinerator inlet (on the TGU absorber overhead) and incinerator with continuously recording SO2 and O2 monitors. [District Rule 2201]

14. Exhaust stack shall be equipped with adequate provisions facilitating the collection of samples consistent with EPA test methods. [District Rule 1080]

15. Incinerator firebox temperature shall be maintained above 1,200 degrees F. [District Rule 2201]

16. Permittee shall maintain accurate records of the incinerator firebox temperature, and such records shall be maintained on site readily available for District inspection. [District Rule 2201]

17. Sulfur production shall not exceed 100 short tons/day. [District Rule 2201]

18. Permittee shall maintain accurate records of daily sulfur production, and such records shall be maintained on site readily available for District inspection. [District Rule 2201]

19. Shutdown is defined as the period beginning with the termination of acid gas feed and the initiation of fuel feed gas or nitrogen purge operation feed (for the purpose of heat stripping sulfur from the internal surfaces of the SRU). [District Rule 2201]

20. Warm standby is defined as the period between shutdown and startup when the SRU feed is solely natural gas. [District Rule 2201]

21. Startup is defined as the period beginning with the introduction (or increased utilization) of natural gas to the SRU to raise the temperature of the catalytic reactors to operating temperature (approximately 350 degrees F). Startup ends when the concentration of H2S in the TGU absorber offgas does not exceed 10 ppmv (moving 3-hour average). [District Rule 2201]

22. Except during shutdown, warm standby, startup, and breakdown (as defined in Rule 1100) conditions, concentration of H2S in the TGU absorber offgas when feeding the TGU incinerator shall not exceed 10 ppmv H2S (moving 3-hour average). [District Rule 2201]

23. The permittee shall, at all times including periods of startup, shutdown, and malfunction, maintain and operate the SRU and associated control equipment in a manner consistent with good air pollution control practice for minimizing emissions. [District Rule 2201]

24. In case of any exceedance of any H2S or SOx (as SO2) emission limit or any malfunction, permittee shall begin actions to minimize emissions exceedance or amount of sour gas flared, by removing high sulfur feed stocks and reducing unit rates, or by other means approved by the District. [District Rule 2201]

25. Emission rates from the tail gas thermal oxidizer shall not exceed the following: NOx: 0.24 lb/MMBtu; CO: 0.20 lb/MMBtu; VOC: 0.0055 lb/MMBtu; PM10: 0.0076 lb/MMBtu. [District Rule 2201]

26. SOx (as SO2) emissions from the tail gas thermal oxidizer shall not exceed 0.0204 lb/MMBtu for the disposal of SRU startup gas nor 2.00 lb/hr for the disposal of the process vent gas. [District Rule 2201]

27. The thermal oxidizer shall be fired solely on PUC-quality natural gas. [District Rules 2201 and 2410]

28. The thermal oxidizer firing rate shall not exceed 13.0 MMBtu/hr of natural gas from normal operation (for the disposal of process vent gas). The thermal oxidizer firing rate shall not exceed 80.0 MMBtu/hr of natural gas from SRU startup operation (for the disposal of SRU startup gas). [District Rule 2201]

29. The thermal oxidizer shall not exceed 8,314 hours per calendar year of normal operation (for the disposal of process vent gas) nor 48 hours per calendar year of SRU startup operation (for the disposal of SRU startup gas). [District Rules 2201 and 2410]

30. The annual heat input of the unit shall not exceed 111.9 billion Btu/yr. [District Rule 2201]

31. A non-resettable, totalizing, continuously recording, mass or volumetric fuel flow meter to measure the amount of natural gas combusted in the unit shall be installed, utilized and maintained. [District Rules 2201 and 2410]

32. Permittee shall maintain records of the annual heat input of the unit. [District Rules 1070 and 2201]

33. During SRU shutdown, SRU tail gas shall be directed to the TGU provided the O2 content of the SRU tail gas is less than or equal to 0.5 percent by weight as measured with portable O2 analyzer or equivalent CO value as measured by the CO/CO_2 analyzer. During such periods, SRU tail gas shall be directed to the TGU. During the final 12 hours of SRU shutdown, the SRU tail gas may bypass the TGU and be introduced directly to the incinerator. [District Rule 2201]

34. During SRU warm standby, SRU tail gas may bypass the TGU and be introduced directly to the incinerator. [District Rule 2201]

35. During SRU startup (after being completely down), SRU tail gas may bypass the TGU and be introduced directly to the incinerator provided the O2 content of the SRU tail is greater than zero percent by volume as measured with portable O2 analyzer or equivalent CO value as measured by the CO/CO_2 analyzer. The duration in which the TGU is bypassed shall not exceed 72 hours. [District Rule 2201]

36. During SRU startup (after being in warm standby), SRU tail gas shall be directed to the TGU. Within 24 hours of directing the SRU tail gas to the TGU, the TGU absorber offgas H2S content shall not exceed 10 ppmv (moving 3-hour average). [District Rule 2201]

37. All required source testing shall conform to the compliance testing procedures described in District Rule 1081. [District Rule 1081]

38. Within 90 days of startup and annually thereafter, operator shall conduct source testing of the thermal oxidizer to demonstrate compliance with SOx, NOx, CO and VOC emission limits. [District Rules 2201]

39. The results of each source test shall be submitted to the District within 60 days thereafter. [District Rule 1081]

40. Source test results for NOx emissions shall be submitted to the District as NOx, NO, and NO2 when available. [District Rule 2410]

41. Source testing shall be conducted using the methods and procedures approved by the District. The District must be notified at least 30 days prior to any compliance source test, and a source test plan must be submitted for approval at least 15 days prior to testing. [District Rule 1081]

42. Copies of all fuel invoices, gas purchase contracts, supplier certifications, and test results to determine compliance with the conditions of this FDOC shall be maintained. The operator shall record daily amount and type(s) of fuel(s) combusted and all dates on which unit is fired on any noncertified fuel. [District Rule 2201]

43. Particulate matter emissions shall not exceed 0.1 grain/dscf calculated to 12 percent CO_2, nor 10 lb/hr. [District Rules 4201 and 4301, 5.1 and 5.2.3]

44. For the sulfur recovery unit, operator shall not discharge or cause the discharge of any gases into the atmosphere in excess of 10 ppm by volume (dry basis) of H2S at zero percent excess air (moving 3-hour average). [District Rule 2201]

45. For the sulfur recovery unit, a continuous emissions monitoring system shall be installed, calibrated, operated, and reported. Operator shall report all 3-hour periods during which the average concentration of H2S as measured by the H2S continuous monitoring system exceeds 10 ppm (dry basis, zero percent excess air). [District Rule 2201]

46. Operator shall determine compliance with the SO2 and H2S standard using EPA Method 3, EPA Method 6, and EPA Method 15. [District Rule 2201]

47. Components attributed to this unit shall include those components serving the following process streams: sulfur and tail gas unit (TGU) process gas. [District Rule 2201]

48. Fugitive VOC emission rate from the unit shall not exceed 0.0 lb/day based on the component count and emission factors from EPA document Protocol for Equipment Leak Emission Estimates (EPA-453/R-95-017), Table 2-1, SOCMI Average Emissions Factors. [District Rule 2201]

49. Fugitive CO emission rate from the unit shall not exceed 2.7 lb/day based on the component count, CO percentage in the fluid stream, emission factors from

Protocol for Equipment Leak Emission Estimates (EPA-453/R-95-017), Table 2-1, SOCMI Average Emissions Factors. [District Rule 2201]

50. Permittee shall maintain with the DOC an accurate fugitive component count and the resulting emissions calculated using above specified leak rates and control efficiencies. [District Rule 2201]

51. The VOC content of the gas in the following streams shall not exceed 10 percent by weight: sulfur, tail gas unit process gas. [District Rule 2201]

52. Operator shall conduct quarterly gas sampling to qualify for exemption from fugitive component counts for those components handling fluids with VOC content equal to or less than 10 percent by weight. If gas samples are equal to or less than 10 percent VOC by weight for 8 consecutive quarterly samplings, sampling frequency shall only be required annually. [District Rule 2201]

53. VOC content of gas streams shall be determined by ASTM D1945, EPA Method 18 referenced as methane, or equivalent test method with prior District approval. [District Rule 2201]

54. All sampling connections, open-ended valves, and lines shall be equipped with two closed valves or be sealed with blind flanges, caps, or threaded plugs except during actual use. [District Rule 2201]

55. Permittee shall maintain records of the VOC content test results for a period of five years and make such records available for inspection upon request. [District Rule 1070]

56. For valves and connectors attributed to this unit, a leak shall be defined as a reading of methane in excess of 100 ppmv above background when measured per EPA Method 21. For pump and compressor seals attributed to this unit, a leak shall be defined as a reading of methane in excess of 500 ppmv above background when measure per EPA Method 21. [District Rule 2201]

57. The operator shall audio-visually inspect for leaks all accessible operating pumps, compressors and Pressure Relief Devices (PRDs) in service at least once every 24 hours, except when operators do not report to the facility for that given 24 hours. Any identified leak that cannot be immediately repaired shall be reinspected within 24 hours using a portable analyzer. If a leak is found, it shall be repaired as soon as practical but not later than the time frame specified in Rule 4455 Table 3. [District Rule 2201]

58. The operator shall inspect all components at least once every calendar quarter, except for inaccessible components, unsafe-to-monitor components and pipes. Inaccessible components, unsafe-to-monitor components and pipes shall be inspected in accordance with the requirements set forth in Rule 4455 Sections 5.2.5, 5.2.6, and 5.2.7. New, replaced, or repaired fittings, flanges and threaded connections shall be inspected immediately after being placed into service. Components shall be inspected using EPA Method 21. [District Rule 2201]

59. The operator may apply for a written approval from the APCO to change the inspection frequency from quarterly to annually for a component type, provided the operator meets all the criteria specified in Rule 4455 Sections 5.2.8.1 through 5.2.8.3. This approval shall apply to accessible component types, specifically designated by the APCO, except pumps, compressors, and PRDs which shall continue to be inspected on a quarterly basis. [District Rule 2201]

60. An annual inspection frequency approved by the APCO shall revert to quarterly inspection frequency for a component type if either the operator inspection or District inspection demonstrates that a violation of the provisions of Rule 4455 Sections 5.1, 5.2 and 5.3 of the rule exists for that component type, or the APCO issued a Notice of Violation for violating any of the provisions of Rule 4455 during the annual inspection period for that component type. When the inspection frequency changes from annual to quarterly inspections, the operator shall notify the APCO in writing within five (5) calendar days after changing the inspection frequency, giving the reason(s) and date of change to quarterly inspection frequency. [District Rule 2201]

61. The operator shall initially inspect a process PRD that releases to the atmosphere as soon as practicable but not later than 24 hours after the time of the release. To insure that the process PRD is operating properly, and is leak-free, the operator shall re-inspect the process PRD not earlier than 24 hours after the initial inspection but not later than 15 calendar days after the date of the release using EPA Method 21. If the process PRD is found to be leaking at either inspection, the PRD leak shall be treated as if the leak was found during quarterly operator inspections. [District Rule 2201]

62. Except for process PRD, a component shall be inspected within 15 calendar days after repairing the leak or replacing the component using EPA Method 21. [District Rule 2201]

63. Upon detection of a leaking component, the operator shall affix to that component a weatherproof readily visible tag that contains the information specified in Rule 4455 Section 5.3.3. The tag shall remain affixed to the component until the leaking component has been repaired or replaced; has been re-inspected using EPA Method 21; and is found to be in compliance with leak, inspection, and maintenance requirements. [District Rule 2201]

64. An operator shall minimize all component leaks immediately to the extent possible, but not later than one (1) hour after detection of leaks in order to stop or reduce leakage to the atmosphere. [District Rule 2201]

65. If the leak has been minimized but the leak still exceeds the applicable leak standards of this PDOC, an operator shall repair or replace the leaking component, vent the leaking component to a closed vent system, or remove the leaking component from operation as soon as practicable but not later than the time period specified in Rule 4455 Table 3. For each calendar quarter, the operator may be allowed to extend the repair period as specified in Rule 4455 Table 3, for a total number of leaking components, not to exceed 0.05 percent of

the number of components inspected, by type, rounded upward to the nearest integer where required. [District Rule 2201]

66. If the leaking component is an essential component or a critical component and which cannot be immediately shut down for repairs, the operator shall minimize the leak within one hour after detection of the leak. If the leak has been minimized, but the leak still exceeds any of the applicable leak standards of the PDOC, the essential component or critical component shall be repaired or replaced to eliminate the leak during the next process unit turnaround, but in no case later than one year from the date of the original leak detection, whichever comes earlier. [District Rule 2201]

67. For any component that has incurred five repair actions for major gas leaks or major liquid leaks, or any combination of major gas leaks and major liquid leaks within a continuous 12-month period, the operator shall comply with at least one of the requirements specified in Rule 4455 Sections 5.3.7.1, 5.3.7.2, 5.3.7.3, or 5.3.7.4 by the applicable deadlines specified in Sections 5.3.7.5 and 5.3.7.6. If the original leaking component is replaced with a new like-in-kind component before incurring five repair actions for major leaks within 12-consecutive months, the repair count shall start over for the new component. An entire compressor or pump need not be replaced provided the compressor part(s) or pump part(s) that have incurred five repair actions as described in Section 5.3.7 are brought into compliance with at least one of the requirements of Sections 5.3.7.1 through 5.3.7.6. [District Rule 2201]

68. All records required by this DOC shall be retained for a period of at least 5 years and shall be made available to the District upon request. [District Rules 1070 and 2201]

69. The permittee shall obtain written District approval for the use of any equivalent equipment not specifically approved by this Determination of Compliance. Approval of the equivalent equipment shall be made only after the District's determination that the submitted design and performance of the proposed alternate equipment is equivalent to the specifically authorized equipment. [District Rule 2201]

70. The permittee's request for approval of equivalent equipment shall include the make, model, manufacturer's maximum rating, manufacturer's guaranteed emission rates, equipment drawing(s), and operational characteristics/parameters. [District Rule 2201]

71. Alternate equipment shall be of the same class and category of source as the equipment authorized by the Determination of Compliance. [District Rule 2201]

72. No emission factor and no emission shall be greater for the alternate equipment than for the proposed equipment. No changes in the hours of operation, operating rate, throughput, or firing rate may be authorized for any alternate equipment. [District Rule 2201]

73. The air quality modeled impacts of the proposed alternative equivalent equipment shall not result in any more adverse impacts than the equipment it replaces. [District Rule 2201]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-23-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-8-17**, **-22**, **-25**, **-26**, and **-28** through **-30**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-8-68**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans in compliance with Condition **AQ-8-41** to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-8-22**, **-25**, and **-26**, to the CPM within 60 days of testing. (Conditions **AQ-8-38** and **-39**)

The project owner shall provide a summary of the fugitive emissions LDAR program, per Conditions **AQ-8-47** through **AQ-8-67**, in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit the written request for the use of alternate equipment, if necessary, to both the District and CPM for approval in accordance with, and that meets, the standards of, Conditions **AQ-8-69** through **-73**.

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-8** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-8-11** through **-73**)

AQ-9 The following conditions cover permit unit S-7616-24-0.

CO_2 RECOVERY (CAPTURE, COMPRESSION, AND TRANSPORTATION) AND VENT SYSTEM FOR EMERGENCY RELEASES OF A STREAM OF PRIMARILY CO_2 FROM THE ACID GAS REMOVAL UNIT

8. Emission rates from the vent stream shall not exceed 492.4 lb-CO/hour, 11.3 lb-VOC/hour, 58.0 lb-COS/hour, nor 6.0 lb-H2S/hour. Compliance with these rates shall be demonstrated by measuring the vent stream flowrate and the concentration of these constituents in the vent stream. [District Rule 2201]

9. Venting shall only be allowed when compression and transportation system is unavailable or CO_2 delivery system is unavailable due to cold gasification block startup, CO_2 compressor unplanned outage, CO_2 pipeline unplanned outage, or CO_2 off-taker unable to accept, and emissions from such venting shall not exceed 124.07 tons-CO/yr, 2.34 tons-VOC/yr, nor 14.62 tons-COS/yr, per rolling 12-month period. Compliance with these rates shall be demonstrated by

measuring the vent stream flowrate and the concentration of these constituents in the vent stream. [District Rules 2201 and 2410]

10. Venting shall not exceed 504 hours per rolling 12-month period. [District Rules 2201and 2410]

11. Vent stream concentration shall not exceed 1,000 ppm-CO, 40 ppm-VOC, 55 ppm-COS, nor 10 ppm-H2S. [District Rules 2201 and 2410]

12. Emission rates from the vent stream shall not exceed 11,816.5 lb-CO/day nor 270.1 lb-VOC/day. [District Rules 2201 and 2410]

13. A non-resettable, totalizing mass or volumetric flow meter to measure the amount of gas vented shall be installed, utilized and maintained. [District Rules 2201 and 2410]

14. Each period of venting shall be reported to the District by the following working day, including the duration of the venting event and the vent gas composition observed. [District Rule 2201]

15. Hazardous Air Pollutant (HAP) emissions for the stationary source shall not exceed 25 ton/year for all HAPs nor 10 ton/year for any single HAP. [District Rule 4002]

16. Permittee shall conduct an initial speciated HAPs and total VOC source test for the CO_2 recovery and vent system by District witnessed in situ sampling of vented stream by a qualified independent source test firm. The permittee shall determine the total HAPs emissions rate, the single highest HAP emission rate, and the VOC mass emission during the source test. Initial compliance with the HAPs emissions limit (25 tpy all HAPs or 10 tpy any single HAP) shall be demonstrated by the combined VOC emissions rates determined during initial compliance source testing and the correlation between VOC emissions and HAP(s). Ongoing compliance shall be determined using mass flow and VOC sampling during venting occurrences as described in the condition below. [District Rule 4002]

17. The vent stream composition of CO, VOC, H2S, COS, and the HAPs identified in the initial speciated HAPs and total VOC source test, shall be measured during each venting occurrence exceeding 500,000 scf/day using EPA-approved test methods with a gas chromatograph or equivalent equipment as determined by the District in writing. [District Rule 2201]

18. Permittee shall monitor the CO_2 concentration in the CO_2 stream prior to the custody transfer. The permittee shall calculate the CO_2e emissions for each calendar month and shall maintain such records of onsite for District review. [District Rule 2410]

19. Permittee shall maintain records of the CO_2 concentration of the CO_2 stream prior to custody transfer and records of venting events, including the flowrate of the vent stream and reasons for venting event, and such records shall be

retained on site readily available for District inspection. [District Rules 2201 and 2410]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-24-0:

The project owner shall provide a written summary of each CO_2 venting event, including the duration of the event, an estimate of the pollutant concentrations, an estimate of the pollutant mass emission rates, and the reason for venting, to the District by the following working day as required in this condition, and shall provide a summary of these reports and a summary of the venting emissions in the Annual Compliance Reports (**AQ-SC8**). (Conditions **AQ-9-14** and **-18**)

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-9-8**, **-11**, and **-12**, to the CPM within 60 days of testing. (Condition **AQ-9-16**)

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-9** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-9-8** through **-19**)

AQ-10 The following conditions cover permit unit S-7616-25-0.

230 MMBTU/HR NATURAL GAS-FIRED AUXILIARY BOILER EQUIPPED WITH LOW-NOX BURNER WITH FLUE GAS RECIRCULATION AND SELECTIVE CATALYTIC REDUCTION (SCR) SYSTEM (OR EQUIVALENT)

11. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, Ringelmann 1 or 20 percent opacity. [District Rule 4101]

12. Particulate matter emissions shall not exceed 0.1 grains/dscf in concentration. [District Rule 4201]

13. The unit shall be fired solely on PUC-quality natural gas. [District Rules 2201, 2410, 4320, 2410]

14. The boiler shall be equipped with an economizer and condensate recovery system. [District Rules 2201 and 2410]

15. Duration of startup and shutdown of heater shall not exceed 2 hours each per occurrence. The emission control system shall be in operation and emissions shall be minimized insofar as technologically feasible during startup and shutdown. The operator shall maintain records of the duration of startup and shutdown. [District Rules 4305, 4306, and 4320]

16. Emissions from this unit, except during startup or shutdown, shall not exceed any of the following limits: NOx (as NO_2): 5.0 ppmvd @ 3 percent O_2 or 0.006 lb/MMBtu, SOx (as SO_2): 0.00285 lb/MMBtu, PM10: 0.005 lb/MMBtu, CO: 50.8 ppmvd @ 3 percent O_2 or 0.037 lb/MMBtu, or VOC: 0.0040 lb/MMBtu. [District Rules 2201, 4305, 4306 and 4320]

17. The maximum allowable heat input of the boiler shall not exceed 213 MMBtu/hr. [District Rule 2201]

18. The annual heat input of the unit shall not exceed 466.0 billion Btu per calendar year. [District Rules 2201 and 2410]

19. A non-resettable, totalizing, continuously recording, mass or volumetric fuel flow meter to measure the amount of natural gas combusted in the unit shall be installed, utilized and maintained. [District Rules 2201 and 2410]

20. Permittee shall maintain records of the annual heat input of the unit. [District Rules 1070 and 2201]

21. The operator shall tune the unit at least twice per calendar year, (from four to eight months apart) by a qualified technician, in accordance with the procedure described in Rule 4304 (Equipment Tuning Procedure for Boilers, Steam Generators, and Process Heaters). If the unit does not operate throughout a continuous six-month period within a calendar year, only one tune-up is required for that calendar year. No tune-up is required for any unit that is not operated during that calendar year; this unit may be test fired to verify availability of the unit for its intended use, but once the test firing is completed the unit shall be shutdown. [District Rule 2410]

22. The permittee shall monitor and record the stack concentration of NO_X, CO, and O_2 at least once every month (in which a source test is not performed) using a portable analyzer that meets District specifications. Monitoring shall not be required if the unit is not in operation, i.e. the unit need not be started solely to perform monitoring. Monitoring shall be performed within 5 days of restarting the unit unless monitoring has been performed within the last month. [District Rules 4305 and 4306]

23. If either the NO_X or CO concentrations corrected to 3 percent O_2, as measured by the portable analyzer, exceed the allowable emissions concentration, the permittee shall return the emissions to within the acceptable range as soon as possible, but no longer than 1 hour of operation after detection. If the portable analyzer readings continue to exceed the allowable emissions concentration after 1 hour of operation after detection, the permittee shall notify the District within the following 1 hour and conduct a certified source test within 60 days of the first exceedance. In lieu of conducting a source test, the permittee may stipulate a violation has occurred, subject to enforcement action. The permittee must then correct the violation, show compliance has been re-established, and resume monitoring procedures. If the deviations are the result of a qualifying breakdown condition pursuant to Rule 1100, the permittee may fully comply with Rule 1100

in lieu of performing the notification and testing required by this condition. [District Rules 4305 and 4306]

24. All alternate monitoring parameter emission readings shall be taken with the unit operating either at conditions representative of normal operations or conditions specified in the permit-to-operate. The analyzer shall be calibrated, maintained, and operated in accordance with the manufacturer's specifications and recommendations or a protocol approved by the APCO. Emission readings taken shall be averaged over a 15 consecutive-minute period by either taking a cumulative 15 consecutive-minute sample reading or by taking at least five (5) readings, evenly spaced out over the 15 consecutive-minute period. [District Rules 4305 and 4306]

25. The permittee shall maintain records of: (1) the date and time of NO_X, CO, and O_2 measurements, (2) the O_2 concentration in percent by volume and the measured NO_X and CO concentrations corrected to 3 percent O2, (3) make and model of exhaust gas analyzer, (4) exhaust gas analyzer calibration records, and (5) a description of any corrective action taken to maintain the emissions within the acceptable range. [District Rules 4305 and 4306]

26. This unit shall be tested for compliance with the NOx and CO emissions limits within 60 days of initial startup and at least once every twelve (12) months. After demonstrating compliance on two (2) consecutive annual source tests, the unit shall be tested not less than once every thirty-six (36) months. If the result of the 36-month source test demonstrates that the unit does not meet the applicable emission limits, the source testing frequency shall revert to at least once every twelve (12) months. [District Rules 4305, 4306, and 4320]

27. The results of each source test shall be submitted to the District within 60 days thereafter. [District Rule 1081]

28. Source test results for NOx emissions shall be submitted to the District as NOx, NO, and NO2 when available. [District Rule 2410]

29. Source testing shall be conducted using the methods and procedures approved by the District. The District must be notified at least 30 days prior to any compliance source test, and a source test plan must be submitted for approval at least 15 days prior to testing. [District Rule 1081]

30. The source test plan shall identify which basis (ppmv or lb/MMBtu) will be used to demonstrate compliance. [District Rules 4305, 4306, and 4320]

31. All emissions measurements shall be made with the unit operating either at conditions representative of normal operations or conditions specified in the DOC. No determination of compliance shall be established within two hours after a continuous period in which fuel flow to the unit is shut off for 30 minutes or longer, or within 30 minutes after a re-ignition as defined in Section 3.0 of District Rule 4306. [District Rules 4305 and 4306]

32. The following test methods shall be used: NOx (ppmv) - EPA Method 7E or ARB Method 100, NOx (lb/MMBtu) - EPA Method 19, CO (ppmv) - EPA Method 10 or 10B or ARB Method 100, stack gas oxygen - EPA Method 3 or 3A or ARB Method 100, SOx (lb/MMBtu) - ARB Method 100 or EPA Method 6, 6C or fuel gas sulfur content analysis and EPA Method 19, fuel gas sulfur content - EPA Method 11 or 15, ASTM D3246 or double GC for H2S and mercaptans performed in a laboratory, fuel gas hhv - ASTM D1826 or D1945 in conjunction with ASTM D3588. [District Rules 4305, 4306 and 4320]

33. The permittee shall monitor and record the stack concentration of NOx, CO, and O2 at least once every month (in which a source test is not performed) using a portable analyzer that meets District specifications. Monitoring shall not be required if the unit is not in operation, i.e. the unit need not be started solely to perform monitoring. Monitoring shall be performed within 5 days of restarting the unit unless monitoring has been performed within the last month. [District Rules 4305, 4306, and 4320]

34. If either the NOx or CO concentrations corrected to 3 percent O2, as measured by the portable analyzer, exceed the allowable emissions concentration, the permittee shall return the emissions to within the acceptable range as soon as possible, but no longer than 1 hour of operation after detection. If the portable analyzer readings continue to exceed the allowable emissions concentration after 1 hour of operation after detection, the permittee shall notify the District within the following 1 hour and conduct a certified source test within 60 days of the first exceedance. In lieu of conducting a source test, the permittee may stipulate a violation has occurred, subject to enforcement action. The permittee must then correct the violation, show compliance has been re-established, and resume monitoring procedures. If the deviations are the result of a qualifying breakdown condition pursuant to Rule 1100, the permittee may fully comply with Rule 1100 in lieu of performing the notification and testing required by this condition. [District Rules 4305, 4306, and 4320]

35. All alternate monitoring parameter emission readings shall be taken with the unit operating either at conditions representative of normal operations or conditions specified in the DOC. The analyzer shall be calibrated, maintained, and operated in accordance with the manufacturer's specifications and recommendations or a protocol approved by the APCO. Emission readings taken shall be averaged over a 15 consecutive-minute period by either taking a cumulative 15 consecutive-minute sample reading or by taking at least five (5) readings, evenly spaced out over the 15 consecutive-minute period. [District Rules 4305, 4306, and 4320]

36. The permittee shall maintain records of: (1) the date and time of NOx, CO, and O2 measurements, (2) the O2 concentration in percent by volume and the measured NOX and CO concentrations corrected to 3 percent O2, (3) make and model of exhaust gas analyzer, (4) exhaust gas analyzer calibration records, and (5) a description of any corrective action taken to maintain the emissions within the acceptable range. [District Rules 4305, 4306, and 4320]

37. For emissions source testing, the arithmetic average of three 30-consecutive-minute test runs shall apply. If two of three runs are above an applicable limit the test cannot be used to demonstrate compliance with an applicable limit. [District Rules 4305, 4306, and 4320]

38. All records shall be maintained and retained on-site for a minimum of five (5) years, and shall be made available for District inspection upon request. [District Rules 1070, 2201, 4305, 4306, and 4320]

39. Permittee shall comply with all applicable NSPS requirements, including monitoring, notification and reporting requirements as described in 40 CFR 60 Subparts A and Db. [District Rule 4001]

40. Permittee shall submit to the EPA Regional Administrator for approval a plan that identifies the operating conditions to be monitored under 40 CFR 60.48b (g)(2) and the records to be maintained under 60.49b (j). This plan shall be submitted to the EPA Regional Administrator for approval within 360 days of the initial startup of the affected facility. [District Rule 4001]

41. The permittee shall obtain written District approval for the use of any equivalent equipment not specifically approved by this Determination of Compliance. Approval of the equivalent equipment shall be made only after the District's determination that the submitted design and performance of the proposed alternate equipment is equivalent to the specifically authorized equipment. [District Rule 2201]

42. The permittee's request for approval of equivalent equipment shall include the make, model, manufacturer's maximum rating, manufacturer's guaranteed emission rates, equipment drawing(s), and operational characteristics/parameters. [District Rule 2201]

43. Alternate equipment shall be of the same class and category of source as the equipment authorized by the Determination of Compliance. [District Rule 2201]

44. No emission factor and no emission shall be greater for the alternate equipment than for the proposed equipment. No changes in the hours of operation, operating rate, throughput, or firing rate may be authorized for any alternate equipment. [District Rule 2201]

45. The air quality modeled impacts of the proposed alternative equivalent equipment shall not result in any more adverse impacts than the equipment it replaces. [District Rule 2201]

__**Verification:**__ The following verification requirements apply to applicable conditions for permit unit S-7616-25-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-10-15**, **-17**, **-18**, **-38**, and **-39**); 2) portable analyzer test results (Conditions **AQ-10-20** through **-23**); and 3) non-compliance events and associated corrective maintenance (Conditions **AQ-10-21** and **-38**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Condition **AQ-10-16**, to the CPM within 60 days of testing. (Condition **AQ-10-26**)

The project owner shall provide a copy of the NSPS operating plan, which shall be submitted to U.S.EPA within 360 days of initial facility startup, to the District and the CPM within a week of its submittal to U.S.EPA.

The project owner shall submit the written request for the use of alternate equipment, if necessary, to both the District and CPM for approval in accordance with, and that meets the standards of, Conditions **AQ-10-41** through **-45**.

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-10** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-10-11** through **-45**)

AQ-11 The following conditions cover permit unit S-7616-26-0.

431 MW NOMINAL (GROSS) COMBINED-CYCLE POWER GENERATING SYSTEM CONSISTING OF HYDROGEN-RICH SYNGAS FUEL AND/OR BACK UP NATURAL GAS-FIRED MHI 501GAC® G-CLASS, AIR-COOLED ADVANCED COMBUSTION TURBINE GENERATOR (CTG), WITH A HEAT RECOVERY STEAM GENERATOR (HRSG), AND A CONDENSING STEAM TURBINE-GENERATOR (STG) OPERATING IN COMBINED CYCLE MODE

11. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, Ringelmann 1 or 20 percent opacity. [District Rule 4101]

12. Particulate matter emissions shall not exceed 0.1 grains/dscf in concentration. [District Rule 4201]

13. The owner/operator of the facility shall minimize the emissions from the gas turbine to the maximum extent possible during the commissioning period. [District Rule 2201]

14. Commissioning activities are defined as, but not limited to, all testing, adjustment, tuning, and calibration activities recommended by the equipment manufacturers and the construction contractor to insure safe and reliable steady state operation of the gas turbines and associated electrical delivery systems. [District Rule 2201]

15. Commissioning period shall commence when all mechanical, electrical, and control systems are installed and individual system startup has been completed, or when a gas turbine is first fired, whichever occurs first. The commissioning period shall terminate when the plant has completed initial performance testing, completed final plant tuning, and is available for commercial operation. Two commissioning periods will occur: when firing on natural gas and when firing on hydrogen-rich fuel. [District Rule 2201]

16. At the earliest feasible opportunity, in accordance with the recommendations of the equipment manufacturer and the construction contractor, the combustors of this unit shall be tuned to minimize emissions. [District Rule 2201]

17. At the earliest feasible opportunity, in accordance with the recommendations of the equipment manufacturer and the construction contractor, the Selective Catalytic Reduction (SCR) system and the oxidation catalyst shall be installed, adjusted, and operated to minimize emissions from this unit. [District Rule 2201]

18. The permittee shall submit a plan to the District at least four weeks prior to the first firing of this unit, describing the procedures to be followed during the commissioning period. The plan shall include a description of each commissioning activity, the anticipated duration of each activity in hours, and the purpose of the activity. The activities described shall include, but not limited to, the tuning of the combustors, the installation and operation of the SCR system and the oxidation catalyst, the installation, calibration, and testing of the NOx and CO continuous emissions monitors, and any activities requiring the firing of this unit without abatement by the SCR system or oxidation catalyst. [District Rule 2201]

19. During the commissioning period when firing on natural gas, emission rates from the CTG/HRSG stack shall not exceed any of the following limits: NOx (as NO2) - 391.20 lb/hr; SOx - 4.80 lb/hr; PM10 - 15.00 lb/hr; CO - 2,270.00 lb/hr; or VOC (as methane) - 65.00 lb/hr. During the commissioning period when firing on hydrogen-rich fuel, emission rates from the CTG shall not exceed any of the following limits: NOx (as NO2) - 99.04 lb/hr; SOx - 5.00 lb/hr; PM10 - 15.00 lb/hr; CO - 1622.60 lb/hr; or VOC (as methane) - 35.12 lb/hr. [District Rule 2201]

20. During the commissioning period, the permittee shall demonstrate NOx and CO compliance with the condition above through the use of properly operated and maintained continuous emissions monitors and recorders as specified in this document. The monitored parameters for this unit shall be recorded at least once every 15 minutes (excluding normal calibration periods or when the monitored source is not in operation). [District Rule 2201]

21. The continuous emissions monitors specified in these conditions shall be installed, calibrated and operational prior to the first firing of the unit. After first firing, the detection range of the CEMS shall be adjusted as necessary to accurately measure the resulting range of NOx and CO emissions concentrations. [District Rule 2201]

22. During the commissioning period on natural gas, this unit shall not fire more than 456 total hours without abatement of emissions by the SCR system and/or the oxidation catalyst. During the commissioning period on hydrogen-rich fuel, this unit shall not fire more than 50 total hours without abatement of emissions by the SCR system and/or the oxidation catalyst and shall not fire more than 200 total hours without the partial operation of the SCR system and/or the oxidation catalyst. Such operation of this unit without abatement shall be limited to discrete commissioning activities that can only be properly executed without the SCR system and the oxidation catalyst in place. Upon completion of these activities, the permittee shall provide written notice to the District and the unused balance of the firing hours without abatement shall expire. Records of the commissioning hours of operation for the unit shall be maintained. [District Rule 2201]

23. The total mass emissions of NOx, SOx, PM10, CO, and VOC that are emitted during the commissioning period shall accrue towards the consecutive twelve month emission limits specified in this document. NOx and CO total mass emissions will be determined from CEMs data and SOx, PM10, and VOC total mass emissions will be calculated. [District Rule 2201]

24. A selective catalytic reduction (SCR) system and an oxidation catalyst shall serve the gas turbine engine. Exhaust ducting may be equipped (if required) with a fresh air inlet blower to be used to lower the exhaust temperature prior to inlet of the SCR system catalyst. The permittee shall submit SCR and oxidation catalyst design details to the District at least 30 days prior to commencement of construction. [District Rule 2201]

25. Permittee shall submit continuous emission monitor design, installation, and operational details to the District at least 30 days prior to commencement of construction. [District Rule 2201]

26. The permittee shall submit to the District information correlating the NOx control system operating parameters to the associated measured NOx output. The information must be sufficient to allow the District to determine compliance with the NOx emission limits of this DOC when no continuous emission monitoring data for NOx is available or when the continuous emission monitoring system is not operating properly. [District Rule 4703]

27. All equipment shall be maintained in good operating condition and shall be operated in a manner to minimize emissions of air contaminants into the atmosphere. [District Rule 2201]

28. Combustion turbine generator (CTG) and electrical generator lube oil vents shall be equipped with mist eliminators. Visible emissions from lube oil vents shall not exhibit opacity of 5 percent or greater, except for a period or periods not exceeding three minutes in any one hour. [District Rules 2201 and 4101]

29. This unit shall be fired on hydrogen-rich fuel or on PUC-regulated natural gas backup fuel. Firing on backup PUC-quality natural gas shall only occur during CTG startups (with firing on natural gas not to exceed 5 total hours per calendar

year), CTG shutdowns (with firing on natural gas not to exceed 10 hours per calendar year), or during periods of unplanned equipment outages (with firing on natural gas not to exceed 336 hours per calendar year). [District Rule 2201 and 2410]

30. This unit shall be fired on hydrogen-rich fuel with a sulfur content no greater than 10 ppmv, or on PUC-regulated natural gas with a sulfur content of no greater than 0.75 grain of sulfur compounds (as S) per 100 dry scf of natural gas. [District Rules 2201 and 2410, and 40 CFR 60.4330(a)(2)]

31. During normal operation (excluding startup and shutdown), emission rate from the CTG/HRSG stack when firing on hydrogen-rich fuel shall not exceed any of the following: NOx (as NO2) - 25.0 lb/hr and 2.5 ppmvd-NOx @ 15 percent O2 (1-hour average); VOC (as methane) - 3.5 lb/hr and 1.0 ppmvd-VOC @ 15 percent O2; CO - 18.3 lb/hr and 3.0 ppmvd-CO @ 15 percent O2; PM10 - 12.9 lb/hr; or SOx (as SO2) - 4.1 lb/hr. The NOx (as NO2) emission limit indicated above is a one-hour rolling average. All other pollutant emission limits are three-hour rolling averages. [District Rules 2201 and 4703 and 40 CFR 60.4320(a) & (b)]

32. During normal operation (excluding startup and shutdown), emission rate from the feedstock dryer stack when firing on hydrogen-rich fuel shall not exceed any of the following: NOx (as NO2) - 4.4 lb/hr and 2.5 ppmvd-NOx @ 15 percent O2 (1-hour average); VOC (as methane) - 0.6 lb/hr and 1.0 ppmvd-VOC @ 15 percent O2; CO - 3.2 lb/hr and 3.0 ppmvd-CO @ 15 percent O2; PM10 - 1.4 lb/hr; or SOx (as SO2) - 0.9 lb/hr. The NOx (as NO2) emission limit indicated above is a one-hour rolling average. All other pollutant emission limits are three-hour rolling averages. [District Rules 2201 and 4703 and 40 CFR 60.4320(a) & (b)]

33. During normal operation (excluding startup and shutdown), emission rate from the CTG/HRSG stack when firing on natural gas shall not exceed any of the following: NOx (as NO2) - 34.1 lb/hr and 4.0 ppmvd-NOx @ 15 percent O2; VOC (as methane) - 5.9 lb/hr and 2.0 ppmvd-VOC @ 15 percent O2; CO - 26.0 lb/hr and 5.0 ppmvd-CO @ 15 percent O2; PM10 - 15.0 lb/hr; or SOx (as SO2) - 4.7 lb/hr. All pollutant emission limits are three-hour rolling averages. [District Rules 2201 and 4703 and 40 CFR 60.4320(a) & (b)]

34. Ammonia (NH3) emissions shall not exceed either of the following limits: 18.50 lb/hr or 5.0 ppmvd @ 15 percent O2 (based on a 24 hour rolling average). [District Rule 2201]

35. During startup, emission rates from the CTG/HRSG stack shall not exceed any of the following: NOx (as NO2) - 107.20 lb/hr, SOx - 2.40 lb/hr, PM10 - 15.00 lb/hr, CO - 2,270.00 lb/hr, or VOC - 65.00 lb/hr, based on one-hour averages. During startup, emission rates from the CTG/HRSG stack shall not exceed any of the following: NOx (as NO2) - 381.2 lb/day, SOx - 10.7 lb/day, PM10 - 59.7 lb/day, CO - 3,385.0 lb/day, or VOC - 67.7 lb/day. [District Rule 2201]

36. During startup, emission rates from the feedstock dryer stack shall not exceed any of the following: NOx (as NO2) - 15.10 lb/hr, SOx - 0.30 lb/hr, PM10 - 0.90 lb/hr, CO - 147.40 lb/hr, or VOC - 1.90 lb/hr, based on one-hour averages. During startup, emission rates from the feedstock dryer stack shall not exceed any of the following: NOx (as NO2) - 49.0 lb/day, SOx - 1.2 lb/day, PM10 - 3.6 lb/day, CO - 317.8 lb/day, or VOC - 5.2 lb/day. [District Rule 2201]

37. During shutdown, emission rates from the CTG/HRSG stack shall not exceed any of the following: NOx (as NO2) - 122.0 lb/hr, SOx - 2.7 lb/hr, PM10 - 15.0 lb/hr, CO - 2,270.0 lb/hr, or VOC - 64.8 lb/hr, based on one-hour averages. During shutdown, emission rates from the CTG/HRSG stack shall not exceed any of the following: NOx (as NO2) - 766.6 lb/day, SOx - 21.9 lb/day, PM10 - 127.0 lb/day, CO - 8,437.0 lb/day, or VOC - 193.9 lb/day. [District Rule 2201]

38. During shutdown, emission rates from the feedstock dryer stack shall not exceed any of the following: NOx (as NO2) - 9.4 lb/hr, SOx - 0.3 lb/hr, PM10 - 0.9 lb/hr, CO - 11.5 lb/hr, or VOC - 0.7 lb/hr, based on one-hour averages. During shutdown, emission rates from the feedstock dryer stack shall not exceed any of the following: NOx (as NO2) - 37.6 lb/day, SOx - 1.2 lb/day, PM10 - 3.6 lb/day, CO - 46.0 lb/day, or VOC - 2.8 lb/day. [District Rule 2201]

39. Startup shall be defined as the period of time during which a unit is brought from a shutdown status to its operating temperature and pressure, including the time required by the unit's emission control system to reach full operation. Shutdown shall be defined as the period of time during which a unit is taken from an operational to a non-operational status by allowing it to cool down from its operating temperature to ambient temperature as the fuel supply to the unit is completely turned off. [District Rules 2201 and 4703]

40. For CTG/HRSG, the duration of each startup event shall not exceed 4.5 hours, and the duration of each shutdown event shall not exceed 9.0 hours. For feedstock dryer, the duration of each startup event shall not exceed 4.0 hours, and the duration of each shutdown event shall not exceed 4.0 hours. Startup and shutdown emissions shall be counted toward all applicable emission limits. [District Rules 2201 and 4703]

41. CTG/HRSG and feedstock dryer shall each be limited to two startups and two shutdowns per calendar year. [District Rule 2201]

42. The emission control systems shall be in operation and emissions shall be minimized insofar as technologically feasible during startup and shutdown. [District Rule 4703]

43. Daily emissions from the CTG/HRSG stack when firing on hydrogen-rich fuel on days without a startup or shutdown shall not exceed any of the following: NOx (as NO2) - 600.0 lb/day; CO - 439.2 lb/day; VOC - 84.0 lb/day; PM10 - 309.6 lb/day; SOx (as SO2) - 98.4 lb/day, or NH3 - 444.0 lb/day. [District Rule 2201]

44. Daily emissions from the CTG/HRSG stack when firing on natural gas on days without a startup or shutdown shall not exceed any of the following: NOx (as NO2) - 818.4 lb/day; CO - 624.0 lb/day; VOC - 141.6 lb/day; PM10 - 360.0 lb/day; SOx (as SO2) - 112.8 lb/day, or NH3 - 379.2 lb/day. [District Rule 2201]

45. Daily emissions from the feedstock dryer stack when firing on hydrogen-rich fuel on days without a startup or shutdown shall not exceed any of the following: NOx (as NO2) - 105.6 lb/day; CO - 76.8 lb/day; VOC - 14.4 lb/day; PM10 - 33.6 lb/day; SOx (as SO2) - 21.6 lb/day, or NH3 - 76.8 lb/day. [District Rule 2201]

46. Annual emissions from the CTG/HRSG stack, calculated on a twelve-consecutive month rolling basis, shall not exceed any of the following: NOx (as NO2) - 212,953 lb/year; SOx (as SO2) - 34,445 lb/year; PM10 - 107,813 lb/year; CO - 177,980 lb/year; or VOC - 30,506 lb/year. [District Rule 2201]

47. Annual emissions from the feedstock dryer stack, calculated on a twelve-consecutive month rolling basis, shall not exceed any of the following: NOx (as NO2) - 33,773 lb/year; SOx (as SO2) - 5,605 lb/year; PM10 - 11,257 lb/year; CO - 25,528 lb/year; or VOC - 4,816 lb/year. [District Rule 2201]

48. Each one-hour period shall commence on the hour. Each one-hour period in a three-hour rolling average will commence on the hour. The three-hour average will be compiled from the three most recent one-hour periods. Each one-hour period in a twenty-four hour average for ammonia slip will commence on the hour. [District Rule 2201]

49. Daily emissions will be compiled for a twenty-four hour period starting and ending at twelve-midnight. Each month in the twelve consecutive month rolling average emissions shall commence at the beginning of the first day of the month. The twelve consecutive month rolling average emissions to determine compliance with annual emissions limitations shall be compiled from the twelve most recent calendar months. [District Rule 2201]

50. Compliance with the ammonia emission limits shall be demonstrated utilizing one of the following procedures: 1.) calculate the daily ammonia emissions using the following equation: (ppmvd @ 15 percent O2) = ((a - (b x c/1,000,000)) x (1,000,000 / b)) x d, where a = average ammonia injection rate (lb/hr) / (17 lb/lb mol), b = dry exhaust flow rate (lb/hr) / (29 lb/lb mol), c = change in measured NOx concentration ppmvd @ 15 percent O2 across the catalyst, and d = correction factor. The correction factor shall be derived annually during compliance testing by comparing the measured and calculated ammonia slip; 2.) Utilize another District-approved calculation method using measured surrogate parameters to determine the daily ammonia emissions in ppmvd @ 15 percent O2. If this option is chosen, the permittee shall submit a detailed calculation protocol for District approval at least 60 days prior to commencement of operation; 3.) Alternatively, the permittee may utilize a continuous in-stack ammonia monitor to verify compliance with the ammonia emissions limit. If this option is chosen, the permittee shall submit a monitoring plan for District

approval at least 60 days prior to commencement of operation. [District Rule 2201]

51. Source testing to measure startup and shutdown NOx, CO, and VOC mass emission rates shall be conducted prior to the end of the commissioning period and at least once every seven years thereafter. CEM relative accuracy shall be determined during startup source testing in accordance with 40 CFR 60, Appendix B. If CEM data is not certifiable to determine compliance with NOx and CO startup emission limits, then source testing to measure startup NOx and CO mass emission rates shall be conducted at least once every 12 months. [District Rule 1081]

52. Hazardous Air Pollutant (HAP) emissions for the stationary source shall not exceed 25 ton/year for all HAPS nor 10 ton/year for any single HAP. [District Rule 4002]

53. Permittee shall conduct an initial speciated HAPs and total VOC source test for the combustion turbine generator, by District witnessed in situ sampling of exhaust gases by a qualified independent source test firm. The permittee shall correlate the total HAPs emissions rate and the single highest HAP emission rate to the VOC mass emission determined during the speciated HAPs source test. Initial and annual compliance with the HAPs emissions limit (25 tpy all HAPs or 10 tpy any single HAP) shall be demonstrated by the combined VOC emissions rates for the combustion gas turbine determined during initial and annual compliance source testing and the correlation between VOC emissions and HAP(s). [District Rule 4002]

54. Source testing to measure the NOx, CO, VOC, and NH3 emission rates (lb/hr and ppmvd @ 15 percent O2) and PM10 emission rate (lb/hr) shall be conducted within 60 days after the conclusion of the commissioning period and at least once every twelve months thereafter. [District Rules 1081 and 4703 and 40 CFR 60.4400(a)]

55. The results of each source test shall be submitted to the District within 60 days thereafter. [District Rule 1081]

56. Source test results for NOx emissions shall be submitted to the District as NOx, NO, and NO2 when available. [District Rule 2410]

57. The sulfur content of the natural gas fuel source shall be: (i) documented in a valid purchase contract, a supplier certification, a tariff sheet or transportation contract or (ii) shall be demonstrated within 60 days after the end of the commissioning period and monitored weekly thereafter. If the sulfur content is demonstrated to be less than 0.75 gr/100 scf for eight consecutive weeks, then the monitoring frequency shall be every six months. If the result of any six month monitoring demonstrates that the fuel does not meet the fuel sulfur content limit, weekly monitoring shall resume. [40 CFR 60.4360, 60.4365(a) and 60.4370(c)]

58. The following test methods shall be used: NOx - EPA Method 7E or 20, PM10 - EPA Method 5/202 (front half and back half), CO - EPA Method 10 or 10B, O2 - EPA Method 3, 3A, or 20, VOC - EPA Method 18 or 25, and ammonia - EPA Method 206. EPA approved alternative test methods as approved by the District may also be used to address the source testing requirements of this DOC. The request to utilize EPA approved alternative source testing methods must be submitted in writing and written approval received from the District prior to the submission of the source test plan. [District Rules 1081 and 4703 and 40 CFR 60.4400(1)(i)]

59. HHV and LHV of the fuel shall be determined using ASTM D3588, ASTM 1826, or ASTM 1945. [40 CFR 60.332(a),(b) and District Rule 4703, 6.4.5]

60. Fuel sulfur content shall be monitored using one of the following methods: ASTM Methods D1072, D3246, D4084, D4468, D4810, D6228, D6667 or Gas Processors Association Standard 2377. [40 CFR 60.4415(a)(1)(i)]

61. The exhaust stack shall be equipped with permanent provisions to allow collection of stack gas samples consistent with EPA test methods and shall be equipped with safe permanent provisions to sample stack gases with a portable NOx, CO, and O2 analyzer during District inspections. The sampling ports shall be located in accordance with the CARB regulation titled California Air Resources Board Air Monitoring Quality Assurance Volume VI, Standard Operating Procedures for Stationary Source Emission Monitoring and Testing. [District Rule 1080]

62. Compliance demonstration (source testing) shall be District witnessed or authorized and samples shall be collected by a certified testing laboratory. Source testing shall be conducted using the methods and procedures approved by the District. The District must be notified 30 days prior to any compliance source test, and a source test plan must be submitted for approval 15 days prior to testing. The results of each source test shall be submitted to the District within 60 days thereafter. [District Rule 1081]

63. The turbine shall be equipped with a continuous monitoring system to measure and record fuel consumption. [District Rules 2201 and 4703 and 40 CFR 60.4335(b)(1)]

64. The owner or operator shall install, certify, maintain, operate and quality-assure a Continuous Emission Monitoring System (CEMS) which continuously measures and records the exhaust gas NOx, CO and O2 concentrations. Continuous emissions monitor(s) shall be capable of monitoring emissions during normal operating conditions, and during startups and shutdowns provided the CEMS pass the relative accuracy requirement for startups and shutdowns specified herein. If relative accuracy of CEMS cannot be demonstrated during startup conditions, CEMS results during startup and shutdown events shall be replaced with startup emission rates obtained from source testing to determine compliance with emission limits contained in this document. [District Rules 1080, 2201, and 4703 and 40 CFR 60.4335(b)(1)]

65. CEMS shall continuously measure and record the parameters required in the condition above for both the CTG/HRSG exhaust and the feedstock dryer exhaust. [District Rules 1080, 2201, and 4703 and 40 CFR 60.4335(b)(1)]

66. The CEMS shall complete a minimum of one cycle of operation (sampling, analyzing, and data recording) for each successive 15-minute period or shall meet equivalent specifications established by mutual agreement of the District, the ARB and the EPA. [District Rule 1080 and 40 CFR 60.4345(b)]

67. The NOx, CO and O2 CEMS shall meet the requirements in 40 CFR 60, Appendix F Procedure 1 and Part 60, Appendix B Performance Specification 2 (PS 2), or shall meet equivalent specifications established by mutual agreement of the District, the ARB, and the EPA. [District Rule 1080 and 40 CFR 60.4345(a)]

68. Audits of continuous emission monitors shall be conducted quarterly, except during quarters in which relative accuracy and total accuracy testing is performed, in accordance with EPA guidelines. The District shall be notified prior to completion of the audits. Audit reports shall be submitted along with quarterly compliance reports to the District. [District Rule 1080]

69. The owner/operator shall perform a relative accuracy test audit (RATA) for the NOx, CO, and O2 CEMs as specified by 40 CFR Part 60, Appendix F, 5.11, at least once every four calendar quarters. The permittee shall comply with the applicable requirements for quality assurance testing and maintenance of the continuous emission monitor equipment in accordance with the procedures and guidance specified in 40 CFR Part 60, Appendix F. [District Rule 1080]

70. Results of the CEM system shall be averaged over a one hour period for NOx emissions and a three hour period for CO emissions using consecutive 15-minute sampling periods in accordance with all applicable requirements of CFR 60.13. [District Rule 4703 and 40 CFR 60.13]

71. Excess emissions shall be defined as any operating hour in which the 4-hour or 30-day rolling average NOx concentration exceeds applicable emissions limit and a period of monitor downtime shall be any unit operating hour in which sufficient data are not obtained to validate the hour for either NOx or O2 (or both). [40 CFR 60.4380(b)(1)]

72. Results of continuous emissions monitoring shall be reduced according to the procedure established in 40 CFR, Part 51, Appendix P, paragraphs 5.0 through 5.3.3, or by other methods deemed equivalent by mutual agreement with the District, the ARB, and the EPA. [District Rule 1080]

73. The permittee shall install and maintain equipment, facilities, and systems compatible with the District's CEM data polling software system and shall make CEM data available to the District's automated polling system on a daily basis. [District Rule 1080]

74. Upon notice by the District that the facility's CEM system is not providing polling data, the facility may continue to operate without providing automated data for a maximum of 30 days per calendar year provided the CEM data is sent to the District by a District-approved alternative method. [District Rule 1080]

75. The owner or operator shall, upon written notice from the APCO, provide a summary of the data obtained from the CEM systems. This summary shall be in the form and the manner prescribed by the APCO. [District Rule 1080]

76. The owner or operator shall submit a written report of CEM operations for each calendar quarter to the APCO. The report is due on the 30th day following the end of the calendar quarter and shall include the following: Time intervals, data and magnitude of excess NOx emissions, nature and the cause of excess (if known), corrective actions taken and preventative measures adopted; Averaging period used for data reporting corresponding to the averaging period specified in the emission test period and used to determine compliance with an emissions standard; Applicable time and date of each period during which the CEM was inoperative (monitor downtime), except for zero and span checks, and the nature of system repairs and adjustments; A negative declaration when no excess emissions occurred. [District Rule 1080 and 40 CFR 60.4375(a) and 60.4395]

77. APCO or an authorized representative shall be allowed to inspect, as determined to be necessary, the required monitoring devices to ensure that such devices are functioning properly. [District Rule 1080]

78. Permittee shall notify the District of any breakdown condition as soon as reasonably possible, but no later than one hour after its detection, unless the owner or operator demonstrates to the District's satisfaction that the longer reporting period was necessary. [District Rule 1100, 6.1]

79. The District shall be notified in writing within ten days following the correction of any breakdown condition. The breakdown notification shall include a description of the equipment malfunction or failure, the date and cause of the initial failure, the estimated emissions in excess of those allowed, and the methods utilized to restore normal operations. [District Rule 1100, 7.0]

80. When operating the turbine on hydrogen-rich fuel, no less than 90 percent (by weight) of the pre-combustion carbon in the gasified fuel stream shall be removed. [District Rule 2410]

81. Sampling ports adequate for extraction of grab samples and measurement of gas flow rate shall be provided for both the influent and the effluent gas streams of the acid gas removal unit. [District Rules 1081 and 2410]

82. Operator shall monitor the syngas flow rate and the CO, CO_2, and CH4 concentration in the gas upstream and downstream of the acid gas removal (AGR) unit using laboratory sample analysis at least once every month. [District Rules 1081 and 2410]

83. Compliance with the 90 percent (by weight) reduction in the pre-combustion carbon content in the gasified fuel stream shall be demonstrated by the results of the laboratory sample analysis and flow rates once every month. [District Rules 1081 and 2410]

84. The permittee shall maintain records of the CO, CO_2, and CH4 concentration upstream and downstream of the AGR unit, the syngas flow rate, and the carbon capture percentage captured. [District Rule 2410]

85. Except as noted below, removed pre-combustion CO_2 stream shall be transported and sequestered to Occidental of Elk Hills (OEHI) in compliance with the latest OEHI CO_2 project Monitoring, Reporting and Verification (MRV) Plan that has been approved by California Department of Oil, Gas and Geothermal Resource. Venting of the CO_2 stream shall only be allowed when compression and transportation system is unavailable or CO_2 delivery system is unavailable due to cold gasification block startup, CO_2 compressor unplanned outage, CO_2 pipeline unplanned outage, or CO_2 off-taker unable to accept. Such venting shall not exceed 504 hours per rolling 12-month period. [District Rule 2410]

86. The permittee shall demonstrate compliance with the emission performance standard of 400 lb/MWh using the calculation methodology established by SB 1368 (Greenhouse Gases Emission Performance Standard) for each calendar month. The permittee shall calculate the facility's emission performance value and maintain records of this value. [District Rule 2410]

87. CO_2e emissions from entire stationary source (S-7616) shall not exceed 595,917 tons per calendar year. The permittee shall calculate the CO_2e emissions for each calendar month and shall maintain such records onsite for District review. [District Rule 2410]

88. The circuit breakers at the facility shall be enclosed-pressure SF6 circuit breakers with a leak detection system that consists of a density alarm that provides a warning prior to a total of 10 percent of the SF6 (by weight) of the circuit breakers has escaped. Within 30 days of the alarm, circuit breakers shall be replaced or the leak shall be repaired to prevent further release of the gas. [District Rule 2410]

89. The permittee shall maintain the following records: date and time, duration, and type of any startup, shutdown, or malfunction; performance testing, evaluations, calibrations, checks, adjustments, any period during which a continuous monitoring system or monitoring device was inoperative, and maintenance of any continuous emission monitor. [District Rules 2201 and 4703]

90. The permittee shall maintain the following records: quarterly hours of operation, fuel consumption (scf/hr and scf/rolling twelve month period), continuous emission monitor measurements, calculated ammonia slip, and calculated NOx mass emission rates (lb/hr and lb/twelve month rolling period). [District Rules 2201 and 4703]

91. All records shall be maintained and retained on-site for a period of at least 5 years and shall be made available for District inspection upon request. [District Rules 1070, 2201, and 4703]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-26-0:

The project owner shall submit, at least four weeks prior to first fire of the gas turbine, to the APCO for approval and the CPM for review, the commissioning plan for the gas turbine (Condition **AQ-11-18**). The project owner shall submit to the CPM in the Monthly Compliance Reports information demonstrating compliance with the initial commissioning continuous emissions monitoring requirements (Conditions **AQ-11-20** and **-21**). The project owner shall provide a summary of the gas turbine operations during initial commissioning to the CPM in the final Monthly Compliance Report demonstrating compliance with the requirements of Conditions **AQ-11-13**, **-16**, **-17**, **-19**, and **-22**.

The project owner shall provide the SCR system and oxidation catalyst system design plans and a Continuous Emission Monitoring System (CEM) design plan to the APCO for approval and the CPM for review at least 30 days prior to commencement of construction (Conditions **AQ-11-24** and **-25**). The CEMS shall be designed to comply with Conditions **AQ-11-63** through **-77**.

The project owner shall provide the APCO for approval and the CPM for review NOx control system operations versus measured NOx emissions correlations after each NOx source test performed for this unit within the source test report or separately within 30 days of submittal of the source test report. (Condition **AQ-11-26**)

The project owner shall provide a summary of: 1) operations throughput and emissions estimates based on CEMS and source test data (Conditions **AQ-11-29**, **-30** through **-47**, and **-52**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-11-89**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-11-31** through **-38**, as appropriate to the test, to the CPM within 60 days of testing (Conditions **AQ-11-55** and **-62**). The source test timing and methods shall follow the specification of Conditions **AQ-11-51**, **-53**, **-54**, **-56**, **-58**, and **-61**.

The project owner shall submit the CEMS audit reports to the District in the District's quarterly operation reports and to the CPM in the Quarterly Operation Reports (**AQ-SC8**).

The project owner shall submit a summary of the results of the fuel HHV/LHV and sulfur content tests, performed as required in Conditions **AQ-11-57**, **-59**, and **-60**, in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-11** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-11-11** through **-91**)

The project owner shall submit CO_2 and CO_2E emissions estimates to the CPM as required in staff Conditions of Certification **GHG-1** through **GHG-5** that demonstrate compliance with Conditions **AQ-11-80** through **-88**.

AQ-12 The following conditions cover permit unit S-7616-27-0.

MULTI-CELL MECHANICAL-DRAFT COOLING TOWER WITH HIGH-EFFICIENCY DRIFT ELIMINATORS, SERVING GASIFICATION BLOCK AND PROCESS UNITS

7. Permittee shall submit cooling tower design details including the cooling tower type, drift eliminator design details, and materials of construction to the District at least 90 days before the tower is operated. [District Rule 7012]

9. All equipment shall be maintained in good operating condition and shall be operated in a manner to minimize emissions of air contaminants into the atmosphere. [District Rule 2201]

10. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, Ringelmann 1 or 20 percent opacity. [District Rule 4101]

11. Particulate matter emissions shall not exceed 0.1 grains/dscf in concentration. [District Rule 4201]

12. No hexavalent chromium containing compounds shall be added to cooling tower circulating water. [District Rule 7012]

13. Drift eliminator drift rate shall not exceed 0.0005 percent. [District Rule 2201]

14. Total dissolved solids (TDS) in circulating water shall not exceed 9,000 mg/liter. [District Rule 2201]

15. Compliance with TDS limit shall be determined by cooling water sample analysis by independent laboratory within 60 days of initial operation and quarterly thereafter. [District Rule 1081]

16. Cooling tower circulation water flow rate shall not exceed 162,582 gallons per minute nor 81.1 billion gallons per calendar year. [District Rule 2201]

17. A non-resettable, totalizing mass or volumetric flow meter to measure circulation water flow rate shall be installed, utilized and maintained. [District Rule 2201]

18. PM10 emission rate from the cooling tower shall not exceed 87.9 lb/day. [District Rule 2201]

19. Compliance with the PM10 daily emission limit shall be demonstrated as follows: PM10 lb/day = circulating water recirculation rate x total dissolved solids concentration in the circulating water x manufacturer's design drift rate. [District Rule 2201]

20. Records of the cooling tower circulating water flow rate and cooling tower water TDS shall be kept at the facility and made readily available for District inspection upon request for 5 years. [District Rule 1070]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-27-0:

The project owner shall provide the manufacturer data for cooling tower, including the guarantee data for the drift eliminator, showing compliance with Condition **AQ-12-13** shall be provided to the CPM and the District at least 90 days prior to cooling tower operation. (Condition **AQ-12-7**)

The project owner shall provide a summary of the water sample analyses showing compliance with the TDS limits in Condition **AQ-12-14**, and daily and annual emissions summaries showing compliance with Condition **AQ-12-18** shall be provided as part of the Annual Compliance Reports (**AQ-SC8**).

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-12** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-12-7** through **-20**)

AQ-13 The following conditions cover permit unit S-7616-28-0.

MULTI-CELL MECHANICAL-DRAFT COOLING TOWER WITH HIGH-EFFICIENCY DRIFT ELIMINATORS, SERVING AIR SEPARATION UNIT

7. Permittee shall submit cooling tower design details including the cooling tower type, drift eliminator design details, and materials of construction to the District at least 90 days before the tower is operated. [District Rule 7012]

9. All equipment shall be maintained in good operating condition and shall be operated in a manner to minimize emissions of air contaminants into the atmosphere. [District Rule 2201]

10. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, Ringelmann 1 or 20 percent opacity. [District Rule 4101]

11. Particulate matter emissions shall not exceed 0.1 grains/dscf in concentration. [District Rule 4201]

12. No hexavalent chromium containing compounds shall be added to cooling tower circulating water. [District Rule 7012]

13. Drift eliminator drift rate shall not exceed 0.0005 percent. [District Rule 2201]

14. Total dissolved solids (TDS) in circulating water shall not exceed 2,000 mg/liter. [District Rule 2201]

15. Compliance with TDS limit shall be determined by cooling water sample analysis by independent laboratory within 60 days of initial operation and quarterly thereafter. [District Rule 1081]

16. Cooling tower circulation water flow rate shall not exceed 44,876 gallons per minute nor 22.40 billion gallons per calendar year. [District Rule 2201]

17. A non-resettable, totalizing mass or volumetric flow meter to measure circulation water flow rate shall be installed, utilized and maintained. [District Rule 2201]

18. PM10 emission rate from the cooling tower shall not exceed 8.1 lb/day. [District Rule 2201]

19. Compliance with the PM10 daily emission limit shall be demonstrated as follows: PM10 lb/day = circulating water recirculation rate x total dissolved solids concentration in the circulating water x manufacturer's design drift rate. [District Rule 2201]

20. Records of the cooling tower circulating water flow rate and cooling tower water TDS shall be kept at the facility and made readily available for District inspection upon request for 5 years. [District Rule 1070]

<u>Verification:</u> The following verification requirements apply to applicable conditions for permit unit S-7616-28-0:

The project owner shall provide the manufacturer data for cooling tower, including the guarantee data for the drift eliminator, showing compliance with Condition **AQ-13-13** to the CPM and the District at least 90 days prior to cooling tower operation. (District Condition 7)

The project owner shall provide a summary of the water sample analyses showing compliance with the TDS limits in Condition **AQ-13-14**, and daily and annual emissions summaries showing compliance with Condition **AQ-13-18** shall be provided as part of the Annual Compliance Reports (**AQ-SC8**).

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-13** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-13-7** through **-20**)

AQ-14 The following conditions cover permit unit S-7616-29-0.

MULTI-CELL MECHANICAL-DRAFT COOLING TOWER WITH HIGH-EFFICIENCY DRIFT ELIMINATORS, SERVING POWER BLOCK

7. Permittee shall submit cooling tower design details including the cooling tower type, drift eliminator design details, and materials of construction to the District at least 90 days before the tower is operated. [District Rule 7012]

9. All equipment shall be maintained in good operating condition and shall be operated in a manner to minimize emissions of air contaminants into the atmosphere. [District Rule 2201]

10. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, Ringelmann 1 or 20 percent opacity. [District Rule 4101]

11. Particulate matter emissions shall not exceed 0.1 grains/dscf in concentration. [District Rule 4201]

12. No hexavalent chromium containing compounds shall be added to cooling tower circulating water. [District Rule 7012]

13. Drift eliminator drift rate shall not exceed 0.0005 percent. [District Rule 2201]

14. Total dissolved solids (TDS) in circulating water shall not exceed 9,000 mg/liter. [District Rule 2201]

15. Compliance with TDS limit shall be determined by cooling water sample analysis by independent laboratory within 60 days of initial operation and quarterly thereafter. [District Rule 1081]

16. Cooling tower circulation water flow rate shall not exceed 95,000 gallons per minute nor 49.41 billion gallons per calendar year. [District Rule 2201]

17. A non-resettable, totalizing mass or volumetric flow meter to measure circulation water flow rate shall be installed, utilized and maintained. [District Rule 2201]

18. PM10 emission rate from the cooling tower shall not exceed 51.6 lb/day. [District Rule 2201]

19. Compliance with the PM10 daily emission limit shall be demonstrated as follows: PM10 lb/day = circulating water recirculation rate x total dissolved solids

concentration in the circulating water x manufacturer's design drift rate. [District Rule 2201]

20. Records of the cooling tower circulating water flow rate and cooling tower water TDS shall be kept at the facility and made readily available for District inspection upon request for 5 years. [District Rule 1070]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-29-0:

The project owner shall provide the manufacturer data for cooling tower, including the guarantee data for the drift eliminator, showing compliance with Condition **AQ-14-13** to the CPM and the District at least 90 days prior to cooling tower operation. (Condition **AQ-14-7**)

The project owner shall provide a summary of the water sample analyses showing compliance with the TDS limits in Condition **AQ-14-14**, and daily and annual emissions summaries showing compliance with Condition **AQ-14-18** shall be provided as part of the Annual Compliance Reports (**AQ-SC8**).

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-14** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-14-7** through **-20**)

AQ-15 The following conditions cover permit unit S-7616-30-0.

4,000 MMBTU/HR ELEVATED FLARE WITH 0.5 MMBTU/HR NATURAL GAS-FIRED PILOT, PRIMARILY SERVING GASIFICATION BLOCK (OR EQUIVALENT)

11. Flare pilot shall be fired solely on PUC-quality natural gas. [District Rules 2201 and 2410]

12. Flare shall be equipped with a non-resettable, totalizing flare gas volume flow meter. [District Rules 2201 and 4311]

13. Flare shall be equipped with control valves and relief valves that will maintain a tight shutoff arrangement where no unintended flow is expected, except during actual flaring events. [District Rule 2201]

14. The outlet shall be equipped with an automatic ignition system or shall operate with a pilot flame present at all times when combustible gases are vented through the flare, except during purge periods for automatic-ignition equipped flares. [District Rule 4311, 5.3]

15. Except for flares equipped with a flow-sensing ignition system, a heat sensing device such as a thermocouple, ultraviolet beam sensor, infrared sensor, or an equivalent device, capable of continuously detecting at least one pilot flame or

the flare flame is present shall be installed and operated. Request for determination of an alternate equivalent flame sensing or heat sensing device shall be submitted to the District in writing 30 days prior to installation for District approval. [District Rule 4311, 5.4]

16. Flares using a flow-sensing automatic ignition systems and which do not use a continuous flame pilot shall use purge gas for purging. [District Rule 4311, 5.5]

17. A flame shall be present at all times when combustible gases are vented through the flare. [District Rules 2201, 4311, 5.2]

18. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than five minutes in any two hours which is as dark as, or darker than, Ringelmann 1/4 or 5 percent opacity. [District Rule 4101]

19. Maximum amount of gas combusted in the flare during planned flaring shall not exceed any of the following: 21,936 MMBtu/yr of natural gas (including pilot gas); 9,544 MMBtu/yr of unshifted syngas; 43,434 MMBtu/yr of shifted gas. [District Rules 2201 and 2410]

20. Emissions from the flare, during the non-emergency combustion of natural gas, shall not exceed any of the following (based on total gas combusted): PM10: 0.003 lb/MMBtu; NOx (as NO2): 0.068 lb/MMBtu; VOC: 0.0004 lb/MMBtu; CO: 0.08 lb/MMBtu; or SOx: 0.00214 lb/MMBtu. [District Rule 2201]

21. Emissions from the flare, during the non-emergency combustion of syngas and waste gas, shall not exceed any of the following (based on total gas combusted): PM10: 0.000 lb/MMBtu; NOx (as NO2): 0.068 lb/MMBtu; VOC: 0.000 lb/MMBtu; CO: 2.0 lb/MMBtu on unshifted syngas and 0.37 lb/MMBtu on shifted syngas; or SOx: 0.000 lb/MMBtu. [District Rule 2201]

22. Total sulfur content of natural gas combusted shall not exceed 0.75 grain/100 scf. [District Rule 2201]

23. Emissions from the flare shall not exceed any of the following: NOx: 2,399.0 lb/day; SOx: 18.8 lb/day; PM10: 26.4 lb/day; CO: 20,335.2 lb/day; or VOC: 11.4 lb/day. [District Rule 2201]

24. Other than the planned flaring limited in the condition above, this flare shall be operated solely for emergency situations, which are any situations or conditions arising from a sudden and reasonably unforeseen and unpreventable event beyond the control of the operator. Examples include, but are not limited to, not preventable equipment failure, natural disaster, act of war or terrorism, or external power curtailment, excluding a power curtailment due to an interruptible power service agreement from a utility. A flaring event due to improperly designed equipment, lack of preventative maintenance, careless or improper operation, operator error or willful misconduct does not quality as an emergency. An emergency situation requires immediate corrective action to restore safe

operation. A planned flaring event shall not be considered as an emergency. [District Rules 2201 and 4311]

25. A trained observer, as defined in EPA Method 22, shall check visible emissions at least once annually for a period of 15 minutes. If visible emissions are detected at any time during this period, the observation period shall be extended to two hours. A record containing the results of these observations shall be maintained, which also includes company name, process unit, observer's name and affiliation, date, estimated wind speed and direction, sky condition, and the observer's location relative to the source and sun. [District Rule 4311]

26. No less than 90 days prior to installation of the flare, permittee shall submit a flare minimization plan (FMP) that complies with the requirements of Rule 4311 Section 6.5 to the APCO for approval. [District Rules 4311, 6.5 and 2410]

27. Records of the duration of flare operation, amount of gas burned, and the nature of the emergency situation for flare used during an emergency situation shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1]

28. Copies of approved flare minimization plan pursuant to Rule 4311 Section 6.5 shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1]

29. Flare gas pressure shall not be less than 5 psig when incinerating combustible gasses. [District Rule 4311, 5.6]

30. Copies of monitoring data collected pursuant to Rule 4311 Section 5.10 shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1]

31. The operator shall notify the APCO of an unplanned flaring event within 24 hours after the start of the next business day or within 24 hours of their discovery, whichever occurs first. The notification shall include the flare source identification, the start date and time, and the end date and time. [District Rule 4311, 6.2]

32. The operator of a flare subject to flare minimization plans pursuant to Section 5.8 shall submit an annual report to the APCO that summarizes all Reportable Flaring Events as defined in Rule 4311 Section 3.0 that occurred during the previous 12 month period. The report shall be submitted within 30 days following the end of the twelve month period of the previous year. [District Rule 4311, 6.2]

33. The operator of a flare subject to flare monitoring requirements pursuant to Sections 5.10, 6.6, 6.7, 6.8, 6.9, and 6.10, as appropriate, shall submit an annual report to the APCO as specified in Rule 4311 Section 6.2.3 within 30 days following the end of each 12 month period. [District Rule 4311, 6.2]

34. Pursuant to Rule 4311 Section 6.6, the operator shall monitor vent gas composition using one the methods pursuant to Section 6.6.1 through Section 6.6.5 as appropriate. [District Rule 4311, 6.6]

35. The operator shall monitor the volumetric flows of purge and pilot gases with flow measuring devices. [District Rule 4311, 6.7]

36. If the flare is equipped with a water seal, the operator shall monitor and record the water level and pressure of the water seal that services each flare daily. [District Rule 4311, 6.8]

37. Periods of flare monitoring system in operation greater than 24 continuous hours shall be reported by the following working day, followed by notification of resumption of monitoring. Periods of inoperation of monitoring equipment shall not exceed 14 days per any 18-consecutive-month period. Periods of flare monitoring system inoperation do not include the periods when the system feeding the flare is not operating. [District Rule 4311, 6.9]

38. During periods of inoperation of continuous analyzers or auto-samplers installed pursuant to Section 6.6, operators responsible for monitoring shall take one sample within 30 minutes of the commencement of flaring, from the flare header or from an alternate location at which samples are representative of vent gas composition and have samples analyzed pursuant to Section 6.3.4. During periods of inoperation of flow monitors required by Section 5.10, flow shall be calculated using good engineering practices. [District Rule 4311, 6.9]

39. Operator shall maintain and calibrate all required monitors and recording devices in accordance with the applicable manufacturer's specifications. In order to claim that a manufacturer's specification is not applicable, the person responsible for emissions must have, and follow, a written maintenance policy that was developed for the device in question. The written policy must explain and justify the difference between the written procedure and the manufacturer's procedure. [District Rule 4311, 6.9]

40. All in-line continuous analyzer and flow monitoring data must be continuously recorded by an electronic data acquisition system capable of one-minute averages. Flow monitoring data shall be recorded as one-minute averages. [District Rule 4311, 6.9]

41. The owner or operator shall notify the District of any emergency use of the flare within one hour after confirmation that an actual flaring event has occurred, unless the owner or operator demonstrates to the District's satisfaction that a longer notification period was necessary. However, in the event that confirmation of an actual flaring event cannot be made, then the owner or operator shall notify the District no more than 3 hours after an alarm indicates that a flaring event may have occurred, unless the owner or operator demonstrates to the District's satisfaction that a longer notification period was necessary. [District Rule 1070]

42. The permittee shall report to the District in writing within ten days following the emergency use of the flare. The report shall include 1) a statement that the failure or malfunction has been corrected, the date corrected, and proof of correction; 2) a specific statement of the reason or cause for the occurrence; 3) a description of the corrective measures undertaken and/or to be undertaken to avoid such an occurrence in the future; and 4) an estimate of the emissions caused by the emergency use, specifically including duration of flare operation and amount of gas burned. [District Rules 1070 and 4311]

43. The flare shall be inspected during operation for visible emissions, using EPA Method 22. If visible emissions are observed, corrective action shall be taken. If visible emissions cannot be eliminated, an EPA Method 9 test shall be conducted within 72 hours. [District Rule 2201]

44. The permittee shall keep accurate daily records of the amount of gas combusted in the flare, gas type, reason for flaring, hours of operation, the sulfur content and heat content of the gas combusted. The permittee shall keep these records for a period of at least five years and shall make such records available for District inspection upon request. [District Rules 2201 and 4311]

45. Permittee shall record the sulfur content and the quantity of gas flared and shall demonstrate compliance with the SOx emission limit. [District Rule 2201]

46. The permittee shall obtain written District approval for the use of any equivalent equipment not specifically approved by this Determination of Compliance. Approval of the equivalent equipment shall be made only after the District's determination that the submitted design and performance of the proposed alternate equipment is equivalent to the specifically authorized equipment. [District Rule 2201]

47. The permittee's request for approval of equivalent equipment shall include the make, model, manufacturer's maximum rating, manufacturer's guaranteed emission rates, equipment drawing(s), and operational characteristics/parameters. [District Rule 2201]

48. Alternate equipment shall be of the same class and category of source as the equipment authorized by the Determination of Compliance. [District Rule 2201]

49. No emission factor and no emission shall be greater for the alternate equipment than for the proposed equipment. No changes in the hours of operation, operating rate, throughput, or firing rate may be authorized for any alternate equipment. [District Rule 2201]

50. The air quality modeled impacts of the proposed alternative equivalent equipment shall not result in any more adverse impacts than the equipment it replaces. [District Rule 2201]

51. All records shall be maintained and retained on-site for a period of at least 5 years and shall be made available for District inspection upon request. [District Rule 1070]

__**Verification:**__ The following verification requirements apply to applicable conditions for permit unit S-7616-30-0:

The project owner shall provide a summary of: 1) planned and unplanned flaring events with their duration and estimated heat content throughput and annual emissions estimates (Conditions **AQ-15-19**, **-20**, **-21**, **-23**); 2) visible emissions monitoring (Condition **AQ-15-43**); and 3) non-compliance events and associated corrective maintenance (Condition **AQ-15-51**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall provide a flare minimization plan to the District for approval and CPM for review at least 90 days before installation of the flare (Condition **AQ-15-26**).

The project owner shall provide notification of emergency flaring events to the CPM and District as required in Condition AQ-15-41.

The project owner shall submit the written request for the use of alternate equipment, if necessary, to both the District and CPM for approval in accordance with, and that meets the standards of, Conditions **AQ-15-46** through **-50**.

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-15** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-15-11** through **-51**)

AQ-16 The following conditions cover permit unit S-7616-31-0.

800 MMBTU/HR ELEVATED FLARE WITH 0.3 MMBTU/HR NATURAL GAS FIRED PILOT, PRIMARILY SERVING SULFUR RECOVERY UNIT (OR EQUIVALENT)

11. Flare pilot shall be fired solely on PUC-quality natural gas. [District Rules 2201 and 2410]

12. Flare shall be equipped with a non-resettable, totalizing flare gas volume flow meter. [District Rules 2201 and 4311]

13. Flare shall be equipped with control valves and relief valves that will maintain a tight shutoff arrangement where no unintended flow is expected, except during actual flaring events. [District Rule 2201]

14. The outlet shall be equipped with an automatic ignition system or shall operate with a pilot flame present at all times when combustible gases are vented through the flare, except during purge periods for automatic-ignition equipped flares. [District Rule 4311, 5.3 and 40 CFR 60.18]

15. Except for flares equipped with a flow-sensing ignition system, a heat sensing device such as a thermocouple, ultraviolet beam sensor, infrared sensor, or an equivalent device, capable of continuously detecting at least one pilot flame or the flare flame, is present, shall be installed and operated. Request for determination of an alternate equivalent flame sensing or heat sensing device shall be submitted to the District in writing 30 days prior to installation for District approval. [District Rule 4311, 5.4 and 40 CFR 60.18]

16. Flares using a flow-sensing automatic ignition systems and which do not use a continuous flame pilot shall use purge gas for purging. [District Rule 4311, 5.5]

17. A flame shall be present at all times when combustible gases are vented through the flare. [District Rules 2201, 4311, 5.2 and 40 CFR 60.18(c)(2)]

18. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than five minutes in any two hours which is as dark as, or darker than, Ringelmann 1/4 or 5 percent opacity. [District Rule 4101 and 40 CFR 60.18]

19. Total time of planned flaring shall not exceed 40 hours per calendar year. [District Rule 2201 and 2410]

20. During planned flaring events, no more than 36 MMBtu/hr shall be combusted. [District Rules 2201 and 2410]

21. Emissions from the flare shall not exceed any of the following (based on total gas combusted): PM10: 0.003 lb/MMBtu; NOx (as NO2): 0.068 lb/MMBtu; VOC: 0.0013 lb/MMBtu; or CO: 0.08 lb/MMBtu. [District Rule 2201]

22. SOx emissions from the flare shall not exceed 0.00214 lb/MMBtu during pilot gas combustion nor 18.4 lb/hr during other non-emergency combustion. [District Rule 2201]

23. Total sulfur content of natural gas combusted shall not exceed 0.75 grain/100 scf. [District Rule 2201]

24. Other than the planned flaring limited in the condition above, this flare shall be operated solely for emergency situations, which are any situations or conditions arising from a sudden and reasonably unforeseen and unpreventable event beyond the control of the operator. Examples include, but are not limited to, not preventable equipment failure, natural disaster, act of war or terrorism, or external power curtailment, excluding a power curtailment due to an interruptible power service agreement from a utility. A flaring event due to improperly designed equipment, lack of preventative maintenance, careless or improper operation, operator error or willful misconduct does not quality as an emergency. An emergency situation requires immediate corrective action to restore safe operation. A planned flaring event shall not be considered as an emergency. [District Rules 2201 and 4311]

25. A trained observer, as defined in EPA Method 22, shall check visible emissions at least once annually for a period of 15 minutes. If visible emissions are detected at any time during this period, the observation period shall be extended to two hours. A record containing the results of these observations shall be maintained, which also includes company name, process unit, observer's name and affiliation, date, estimated wind speed and direction, sky condition, and the observer's location relative to the source and sun. [District Rule 4311]

26. No less than 90 days prior to installation of the flare, permittee shall submit a flare minimization plan (FMP) that complies with the requirements of Rule 4311 Section 6.5 to the APCO for approval. [District Rules 4311, 6.5 and 2410]

27. Records of the duration of flare operation, amount of gas burned, and the nature of the emergency situation for flare used during an emergency, situation shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1]

28. Copies of approved flare minimization plan pursuant to Rule 4311 Section 6.5 shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1]

29. Copies of compliance determination pursuant to 40 CFR 60.18 shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1 and 40 CFR 60.18]

30. Copies of monitoring data collected pursuant to Rule 4311 Section 5.10 shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1]

31. The operator shall notify the APCO of an unplanned flaring event within 24 hours after the start of the next business day or within 24 hours of their discovery, whichever occurs first. The notification shall include the flare source identification, the start date and time, and the end date and time. [District Rule 4311, 6.2]

32. The operator of a flare subject to flare minimization plans pursuant to Section 5.8 shall submit an annual report to the APCO that summarizes all Reportable Flaring Events as defined in Rule 4311 Section 3.0 that occurred during the previous 12 month period. The report shall be submitted within 30 days following the end of the twelve month period of the previous year. [District Rule 4311, 6.2]

33. The operator of a flare subject to flare monitoring requirements pursuant to Sections 5.10, 6.6, 6.7, 6.8, 6.9, and 6.10, as appropriate, shall submit an annual report to the APCO as specified in Rule 4311 Section 6.2.3 within 30 days following the end of each 12 month period. [District Rule 4311, 6.2]

34. Pursuant to Rule 4311 Section 6.6, the operator shall monitor vent gas composition using one the methods pursuant to Section 6.6.1 through Section 6.6.5 as appropriate. [District Rule 4311, 6.6]

35. The operator shall monitor the volumetric flows of purge and pilot gases with flow measuring devices. [District Rule 4311, 6.7]

36. If the flare is equipped with a water seal, the operator shall monitor and record the water level and pressure of the water seal that services each flare daily. [District Rule 4311, 6.8]

37. Periods of flare monitoring system in operation greater than 24 continuous hours shall be reported by the following working day, followed by notification of resumption of monitoring. Periods of inoperation of monitoring equipment shall not exceed 14 days per any 18-consecutive-month period. Periods of flare monitoring system inoperation do not include the periods when the system feeding the flare is not operating. [District Rule 4311, 6.9]

38. During periods of inoperation of continuous analyzers or auto-samplers installed pursuant to Section 6.6, operators responsible for monitoring shall take one sample within 30 minutes of the commencement of flaring, from the flare header or from an alternate location at which samples are representative of vent gas composition, and have samples analyzed pursuant to Section 6.3.4. During periods of inoperation of flow monitors required by Section 5.10, flow shall be calculated using good engineering practices. [District Rule 4311, 6.9]

39. Operator shall maintain and calibrate all required monitors and recording devices in accordance with the applicable manufacturer's specifications. In order to claim that a manufacturer's specification is not applicable, the person responsible for emissions must have, and follow, a written maintenance policy that was developed for the device in question. The written policy must explain and justify the difference between the written procedure and the manufacturer's procedure. [District Rule 4311, 6.9]

40. All in-line continuous analyzer and flow monitoring data must be continuously recorded by an electronic data acquisition system capable of one-minute averages. Flow monitoring data shall be recorded as one-minute averages. [District Rule 4311, 6.9]

41. The owner or operator shall notify the District of any emergency use of the flare within one hour after confirmation that an actual flaring event has occurred, unless the owner or operator demonstrates to the District's satisfaction that a longer notification period was necessary. However, in the event that confirmation of an actual flaring event cannot be made, then the owner or operator shall notify the District no more than 3 hours after an alarm indicates that a flaring event may have occurred, unless the owner or operator demonstrates to the District's satisfaction that a longer notification period was necessary. [District Rule 1070]

42. The permittee shall report to the District in writing within ten days following the emergency use of the flare. The report shall include 1) a statement that the failure or malfunction has been corrected, the date corrected, and proof of correction; 2) a specific statement of the reason or cause for the occurrence; 3) a description of the corrective measures undertaken and/or to be undertaken to avoid such an occurrence in the future; and 4) an estimate of the emissions caused by the emergency use, specifically including duration of flare operation and amount of gas burned. [District Rules 1070 and 4311]

43. Open flares (air-assisted, steam-assisted, or non-assisted) in which the flare gas pressure is less than 5 psig shall be operated in such a manner that meets the

provisions of 40 CFR 60.18. The requirements of this section shall not apply to Coanda effect flares. [District Rule 4311, 5.6]

44. No less than 90 days prior to installation, the applicant shall demonstrate to the District how compliance with 40 CFR 60.18 (c)(3) shall be satisfied. Compliance with either subparts (c)(3)(i), or (c)(3)(ii) and (c)(4) shall be demonstrated to the District. [40 CFR 60.18 (c)(3)]

45. If the permittee opts to comply with 40 CFR 60.18 (c)(3)(i), a non-assisted flare shall have a diameter of 3 inches or greater, have a minimum hydrogen content of 8.0 percent by volume, and be designed for and operated with an exit velocity less than 122 ft/sec and less than the velocity Vmax, as determined by the equation specified in paragraph 40 CFR 60.18 (c)(3)(i)(A). [40 CFR 60.18]

46. If the permittee opts to comply with 40 CFR 60.18 (c)(3)(ii) and (c)(4), the heating value of the gas combusted in the flare shall be at least 200 Btu/scf. [District Rule 4311 and 40 CFR 60.18]

47. If the permittee opts to comply with 40 CFR 60.18 (c)(3)(ii) and (c)(4), non-assisted flares may be operated with an exit velocity equal to or greater than 60 ft/sec, but less than 400 ft/sec, if the net heating value of the gas being combusted is greater than 1,000 Btu/scf. [40 CFR 60.18]

48. If the permittee opts to comply with 40 CFR 60.18 (c)(3)(ii) and (c)(4), non-assisted flares shall be operated with an exit velocity less than 60 ft/sec, except as provided in 40 CFR 60.18 (c)(4)(ii) and (iii). [40 CFR 60.18]

49. If the permittee opts to comply with 40 CFR 60.18 (c)(3)(ii) and (c)(4), non-assisted flares may be operated with an exit velocity less than the maximum velocity Vmax, as determined by the methods specified in 40 CFR 60.18 (f)(5), and less than 400 ft/sec. [40 CFR 60.18]

50. The net heating value of the gas being combusted the flare shall be calculated pursuant to 40 CFR 60.18(f)(3) or by using EPA Method 18, ASTM D1946, and ASTM D2382 if published values are not available or cannot be calculated. [40 CFR 60.18]

51. The flare shall be inspected during operation for visible emissions, using EPA Method 22. If visible emissions are observed, corrective action shall be taken. If visible emissions cannot be eliminated, an EPA Method 9 test shall be conducted within 72 hours. [District Rule 2201 and 40 CFR 60.18]

52. The actual exit velocity of a flare shall be determined by dividing the volumetric flowrate (in units of standard temperature and pressure), as determined by Reference Methods 2, 2A, 2C, or 2D as appropriate; by the unobstructed (free) cross sectional area of the flare tip. [40 CFR 60.18]

53. Upon request, operator shall make available to the APCO the compliance determination records that demonstrate compliance with the provisions of 40 CFR 60.18. [District Rule 4311, 6.1]

54. Semi-annual reports of all periods without the presence of a flare pilot flame shall be furnished to the District Compliance Division and EPA. [District Rule 4001 and 40 CFR 60.115b(d)(3)]

55. The permittee shall keep accurate daily records of the amount of gas combusted in the flare, gas type, reason for flaring, hours of operation, the sulfur content and heat content of the gas combusted, and records demonstrating compliance with the provisions of 40 CFR 60.18, (c)(3) through (c)(5). The permittee shall keep these records for a period of at least five years and shall make such records available for District inspection upon request. [District Rules 2201, 4311, 40 CFR 60.18]

56. Permittee shall record the sulfur content and the quantity of gas flared and shall demonstrate compliance with the SOx emission limit. [District Rule 2201]

57. The permittee shall obtain written District approval for the use of any equivalent equipment not specifically approved by this Determination of Compliance. Approval of the equivalent equipment shall be made only after the District's determination that the submitted design and performance of the proposed alternate equipment is equivalent to the specifically authorized equipment. [District Rule 2201]

58. The permittee's request for approval of equivalent equipment shall include the make, model, manufacturer's maximum rating, manufacturer's guaranteed emission rates, equipment drawing(s), and operational characteristics/parameters. [District Rule 2201]

59. Alternate equipment shall be of the same class and category of source as the equipment authorized by the Determination of Compliance. [District Rule 2201]

60. No emission factor and no emission shall be greater for the alternate equipment than for the proposed equipment. No changes in the hours of operation, operating rate, throughput, or firing rate may be authorized for any alternate equipment. [District Rule 2201]

61. The air quality modeled impacts of the proposed alternative equivalent equipment shall not result in any more adverse impacts than the equipment it replaces. [District Rule 2201]

62. All records shall be maintained and retained on-site for a period of at least 5 years and shall be made available for District inspection upon request. [District Rule 1070]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-31-0:

The project owner shall provide a summary of: 1) planned and unplanned flaring events with their duration and estimated heat content throughput and annual emissions estimates (Conditions **AQ-16-19** through **-22**); 2) visible emissions monitoring (Condition **AQ-16-51**); and 3) non-compliance events and associated corrective maintenance (Condition **AQ-16-62**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall provide a flare minimization plan to the District for approval and CPM for review at least 90 days before installation of the flare (Condition **AQ-16-26**).

The project owner shall submit the written request for the use of alternate equipment, if necessary, to both the District and CPM for approval in accordance with, and that meets the standards of, Conditions **AQ-16-57** through **-61**.

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-16** conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-16-11** through **-62**)

AQ-17 The following conditions cover permit unit S-7616-32-0.

5,500 MMBTU/HR ELEVATED FLARE WITH 0.3 MMBTU/HR NATURAL GAS-FIRED PILOT, PRIMARILY SERVING RECTISOL UNIT (OR EQUIVALENT)

11. Flare pilot shall be fired solely on PUC-quality natural gas. [District Rules 2201, 2410]
12. Flare shall be equipped with a non-resettable, totalizing flare gas volume flow meter. [District Rules 2201 and 4311]
13. Flare shall be equipped with control valves and relief valves that will maintain a tight shutoff arrangement where no unintended flow is expected, except during actual flaring events. [District Rule 2201]
14. The outlet shall be equipped with an automatic ignition system or shall operate with a pilot flame present at all times when combustible gases are vented through the flare, except during purge periods for automatic-ignition equipped flares. [District Rule 4311, 5.3 and 40 CFR 60.18]
15. Except for flares equipped with a flow-sensing ignition system, a heat sensing device such as a thermocouple, ultraviolet beam sensor, infrared sensor, or an equivalent device, capable of continuously detecting at least one pilot flame or the flare flame is present shall be installed and operated. Request for determination of an alternate equivalent flame sensing or heat sensing device shall be submitted to the District in writing 30 days prior to installation for District approval. [District Rule 4311, 5.4 and 40 CFR 60.18]
16. Flares using a flow-sensing automatic ignition systems and which do not use a continuous flame pilot shall use purge gas for purging. [District Rule 4311, 5.5]

17. A flame shall be present at all times when combustible gases are vented through the flare. [District Rules 2201, 4311, 5.2 and 40 CFR 60.18(c)(2)]

18. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than five minutes in any two hours which is as dark as, or darker than, Ringelmann 1/4 or 5 percent opacity. [District Rule 4101 and 40 CFR 60.18]

19. Total time of planned flaring shall not exceed 8 hours per day nor 40 hours per calendar year. [District Rules 2201 and 2410]

20. During planned flaring events, no more than 430 MMBtu/hr shall be combusted. [District Rule 2201 and 2410]

21. Emissions from the flare during pilot and other non-emergency operation shall not exceed any of the following: PM10: 0.003 lb/MMBtu; NOx (as NO2): 0.068 lb/MMBtu; VOC: 0.0013 lb/MMBtu; or CO: 0.08 lb/MMBtu. [District Rule 2201]

22. SOx emissions from the flare shall not exceed 0.00214 lb/MMBtu during pilot gas combustion nor 15.0 lb/hr during other non-emergency combustion. [District Rule 2201]

23. Total sulfur content of natural gas combusted shall not exceed 0.75 grain/100 scf. [District Rule 2201]

24. Other than the planned flaring limited in the condition above, this flare shall be operated solely for emergency situations, which are any situations or conditions arising from a sudden and reasonably unforeseen and unpreventable event beyond the control of the operator. Examples include, but are not limited to, not preventable equipment failure, natural disaster, act of war or terrorism, or external power curtailment, excluding a power curtailment due to an interruptible power service agreement from a utility. A flaring event due to improperly designed equipment, lack of preventative maintenance, careless or improper operation, operator error or willful misconduct does not quality as an emergency. An emergency situation requires immediate corrective action to restore safe operation. A planned flaring event shall not be considered as an emergency. [District Rules 2201 and 4311]

25. A trained observer, as defined in EPA Method 22, shall check visible emissions at least once annually for a period of 15 minutes. If visible emissions are detected at any time during this period, the observation period shall be extended to two hours. A record containing the results of these observations shall be maintained, which also includes company name, process unit, observer's name and affiliation, date, estimated wind speed and direction, sky condition, and the observer's location relative to the source and sun. [District Rule 4311]

26. No less than 90 days prior to installation of the flare, permittee shall submit a flare minimization plan (FMP) that complies with the requirements of Rule 4311 Section 6.5 to the APCO for approval. [District Rules 4311, 6.5 and 2410]

27. Records of the duration of flare operation, amount of gas burned, and the nature of the emergency situation for flare used during an emergency situation shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1]

28. Copies of approved flare minimization plan pursuant to Rule 4311 Section 6.5 shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1]

29. Copies of compliance determination pursuant to 40 CFR 60.18 shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1 and 40 CFR 60.18]

30. Copies of monitoring data collected pursuant to Rule 4311 Section 5.10 shall be made readily available to the APCO, ARB, and EPA upon request for a minimum of 5 years. [District Rule 4311, 6.1]

31. The operator shall notify the APCO of an unplanned flaring event within 24 hours after the start of the next business day or within 24 hours of their discovery, whichever occurs first. The notification shall include the flare source identification, the start date and time, and the end date and time. [District Rule 4311, 6.2]

32. The operator of a flare subject to flare minimization plans pursuant to Section 5.8 shall submit an annual report to the APCO that summarizes all Reportable Flaring Events as defined in Rule 4311 Section 3.0 that occurred during the previous 12 month period. The report shall be submitted within 30 days following the end of the twelve month period of the previous year. [District Rule 4311, 6.2]

33. The operator of a flare subject to flare monitoring requirements pursuant to Sections 5.10, 6.6, 6.7, 6.8, 6.9, and 6.10, as appropriate, shall submit an annual report to the APCO as specified in Rule 4311 Section 6.2.3 within 30 days following the end of each 12 month period. [District Rule 4311, 6.2]

34. Pursuant to Rule 4311 Section 6.6, the operator shall monitor vent gas composition using one the methods pursuant to Section 6.6.1 through Section 6.6.5 as appropriate. [District Rule 4311, 6.6]

35. The operator shall monitor the volumetric flows of purge and pilot gases with flow measuring devices. [District Rule 4311, 6.7]

36. If the flare is equipped with a water seal, the operator shall monitor and record the water level and pressure of the water seal that services each flare daily. [District Rule 4311, 6.8]

37. Periods of flare monitoring system in operation greater than 24 continuous hours shall be reported by the following working day, followed by notification of resumption of monitoring. Periods of inoperation of monitoring equipment shall not exceed 14 days per any 18-consecutive-month period. Periods of flare

monitoring system inoperation do not include the periods when the system feeding the flare is not operating. [District Rule 4311, 6.9]

38. During periods of inoperation of continuous analyzers or auto-samplers installed pursuant to Section 6.6, operators responsible for monitoring shall take one sample within 30 minutes of the commencement of flaring, from the flare header or from an alternate location at which samples are representative of vent gas composition and have samples analyzed pursuant to Section 6.3.4. During periods of inoperation of flow monitors required by Section 5.10, flow shall be calculated using good engineering practices. [District Rule 4311, 6.9]

39. Operator shall maintain and calibrate all required monitors and recording devices in accordance with the applicable manufacturer's specifications. In order to claim that a manufacturer's specification is not applicable, the person responsible for emissions must have, and follow, a written maintenance policy that was developed for the device in question. The written policy must explain and justify the difference between the written procedure and the manufacturer's procedure. [District Rule 4311, 6.9]

40. All in-line continuous analyzer and flow monitoring data must be continuously recorded by an electronic data acquisition system capable of one-minute averages. Flow monitoring data shall be recorded as one-minute averages. [District Rule 4311, 6.9]

41. The owner or operator shall notify the District of any emergency use of the flare within one hour after confirmation that an actual flaring event has occurred, unless the owner or operator demonstrates to the District's satisfaction that a longer notification period was necessary. However, in the event that confirmation of an actual flaring event cannot be made, then the owner or operator shall notify the District no more than 3 hours after an alarm indicates that a flaring event may have occurred, unless the owner or operator demonstrates to the District's satisfaction that a longer notification period was necessary. [District Rule 1070]

42. The permittee shall report to the District in writing within ten days following the emergency use of the flare. The report shall include 1) a statement that the failure or malfunction has been corrected, the date corrected, and proof of correction; 2) a specific statement of the reason or cause for the occurrence; 3) a description of the corrective measures undertaken and/or to be undertaken to avoid such an occurrence in the future; and 4) an estimate of the emissions caused by the emergency use, specifically including duration of flare operation and amount of gas burned. [District Rules 1070 and 4311]

43. Open flares (air-assisted, steam-assisted, or non-assisted) in which the flare gas pressure is less than 5 psig shall be operated in such a manner that meets the provisions of 40 CFR 60.18. The requirements of this section shall not apply to Coanda effect flares. [District Rule 4311, 5.6]

44. No less than 90 days prior to installation, the applicant shall demonstrate to the District how compliance with 40 CFR 60.18 (c)(3) shall be satisfied. Compliance

with either subparts (c)(3)(i), or (c)(3)(ii) and (c)(4) shall be demonstrated to the District. [40 CFR 60.18 (c)(3)]

45. If the permittee opts to comply with 40 CFR 60.18 (c)(3)(i), a non-assisted flare shall have a diameter of 3 inches or greater, have a minimum hydrogen content of 8.0 percent by volume, and be designed for and operated with an exit velocity less than 122 ft/sec and less than the velocity Vmax, as determined by the equation specified in paragraph 40 CFR 60.18 (c)(3)(i)(A). [40 CFR 60.18]

46. If the permittee opts to comply with 40 CFR 60.18 (c)(3)(ii) and (c)(4), the heating value of the gas combusted in the flare shall be at least 200 Btu/scf. [District Rule 4311 and 40 CFR 60.18]

47. If the permittee opts to comply with 40 CFR 60.18 (c)(3)(ii) and (c)(4), non-assisted flares may be operated with an exit velocity equal to or greater than 60 ft/sec, but less than 400 ft/sec, if the net heating value of the gas being combusted is greater than 1,000 Btu/scf. [40 CFR 60.18]

48. If the permittee opts to comply with 40 CFR 60.18 (c)(3)(ii) and (c)(4), non-assisted flares shall be operated with an exit velocity less than 60 ft/sec, except as provided in 40 CFR 60.18 (c)(4)(ii) and (iii). [40 CFR 60.18]

49. If the permittee opts to comply with 40 CFR 60.18 (c)(3)(ii) and (c)(4), non-assisted flares may be operated with an exit velocity less than the velocity Vmax, as determined by the methods specified in 40 CFR 60.18 (f)(5), and less than 400 ft/sec. [40 CFR 60.18]

50. The net heating value of the gas being combusted the flare shall be calculated pursuant to 40 CFR 60.18(f)(3) or by using EPA Method 18, ASTM D1946, and ASTM D2382 if published values are not available or cannot be calculated. [40 CFR 60.18]

51. The flare shall be inspected during operation for visible emissions, using EPA Method 22. If visible emissions are observed, corrective action shall be taken. If visible emissions cannot be eliminated, an EPA Method 9 test shall be conducted within 72 hours. [District Rule 2201 and 40 CFR 60.18]

52. The actual exit velocity of a flare shall be determined by dividing the volumetric flowrate (in units of standard temperature and pressure), as determined by Reference Methods 2, 2A, 2C, or 2D as appropriate; by the unobstructed (free) cross sectional area of the flare tip. [40 CFR 60.18]

53. Upon request, operator shall make available to the APCO the compliance determination records that demonstrate compliance with the provisions of 40 CFR 60.18. [District Rule 4311, 6.1]

54. Semi-annual reports of all periods without the presence of a flare pilot flame shall be furnished to the District Compliance Division and EPA. [District Rule 4001 and 40 CFR 60.115b(d)(3)]

55. The permittee shall keep accurate daily records of the amount of gas combusted in the flare, gas type, reason for flaring, hours of operation, the sulfur content and heat content of the gas combusted, and records demonstrating compliance with the provisions of 40 CFR 60.18, (c)(3) through (c)(5). The permittee shall keep these records for a period of at least five years and shall make such records available for District inspection upon request. [District Rules 2201, 4311, 40 CFR 60.18]

56. Permittee shall record the sulfur content and the quantity of gas flared and shall demonstrate compliance with the SOx emission limit. [District Rule 2201]

57. The permittee shall obtain written District approval for the use of any equivalent equipment not specifically approved by this Determination of Compliance. Approval of the equivalent equipment shall be made only after the District's determination that the submitted design and performance of the proposed alternate equipment is equivalent to the specifically authorized equipment. [District Rule 2201]

58. The permittee's request for approval of equivalent equipment shall include the make, model, manufacturer's maximum rating, manufacturer's guaranteed emission rates, equipment drawing(s), and operational characteristics/parameters. [District Rule 2201]

59. Alternate equipment shall be of the same class and category of source as the equipment authorized by the Determination of Compliance. [District Rule 2201]

60. No emission factor and no emission shall be greater for the alternate equipment than for the proposed equipment. No changes in the hours of operation, operating rate, throughput, or firing rate may be authorized for any alternate equipment. [District Rule 2201]

61. The air quality modeled impacts of the proposed alternative equivalent equipment shall not result in any more adverse impacts than the equipment it replaces. [District Rule 2201]

62. {3246} All records shall be maintained and retained on-site for a period of at least 5 years and shall be made available for District inspection upon request. [District Rule 1070]

<u>Verification:</u> The following verification requirements apply to applicable conditions for permit unit S-7616-32-0:

The project owner shall provide a summary of: 1) planned and unplanned flaring events with their duration and estimated heat content throughput and annual emissions estimates (Conditions **AQ-17-19** through **-22**); 2) visible emissions monitoring (Condition **AQ-17-51**); and 3) non-compliance events and associated corrective maintenance (Condition **AQ-17-62**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall provide a flare minimization plan to the District for approval and CPM for review at least 90 days before installation of the flare (Condition **AQ-17-26**).

The project owner shall submit the written request for the use of alternate equipment, if necessary, to both the District and CPM for approval in accordance with, and that meets the standards of, Conditions **AQ-17-57** through **-61**.

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-17** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-17-11** through **-62**)

AQ-18 The following conditions cover permit unit S-7616-33-0.

AMMONIA SYNTHESIS UNIT CONSISTING OF: ONE 56.0 MMBTU/HR NATURAL GAS-FIRED AMMONIA STARTUP HEATER EQUIPPED WITH FOUR LOW-NOX BURNERS, EACH RATED AT 14.0 MMBTU/HR (OR EQUIVALENT); AMMONIA SYNTHESIS CONVERTER; SEPARATORS; ELECTRIC SYNGAS COMPRESSOR; ELECTRIC AMMONIA REFRIGERATION COMPRESSOR; AMMONIA ACCUMULATOR; AMMONIA REFRIGERATION SYSTEM; COLD LIQUID AMMONIA STORAGE SYSTEM; AMMONIA RECOVERY UNIT

11. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, Ringelmann 1 or 20 percent opacity. [District Rule 4101]

12. Particulate matter emissions shall not exceed 0.1 grains/dscf in concentration. [District Rule 4201]

13. Heater shall be fired solely on PUC-quality natural gas. [District Rules 2201, 2410, and 4320]

14. Duration of startup and shutdown of heater shall not exceed 2 hours each per occurrence. The emission control system shall be in operation and emissions shall be minimized insofar as technologically feasible during startup and shutdown. The operator shall maintain records of the duration of startup and shutdown. [District Rules 4305, 4306, and 4320]

15. Emissions from heater, except during startup or shutdown, shall not exceed any of the following limits: NOx (as NO2): 9.0 ppmvd @ 3 percent O2 or 0.011 lb/MMBtu, SOx (as SO2): 0.00285 lb/MMBtu, PM10: 0.005 lb/MMBtu, CO: 50 ppmvd @ 3 percent O2 or 0.037 lb/MMBtu, or VOC: 0.0040 lb/MMBtu. [District Rules 2201, 4305, 4306 and 4320]

16. The annual heat input of the heater shall not exceed 7.84 billion Btu per calendar year. [District Rules 2201 and 2410]

17. Pursuant to Rule 4320, the operator shall pay an annual emission fee to the District for NOx emissions from this heater for the previous calendar year.

Payments are due by July 1 of each year. Payments shall continue annually until either the unit is permanently removed from service in the District or the operator demonstrates compliance with the applicable NOx emission limit listed in Rule 4320. [District Rule 4320]

18. A non-resettable, totalizing mass or volumetric fuel flow meter to measure the amount of natural gas combusted in the unit shall be installed, utilized and maintained. [District Rule 2201]

19. Permittee shall maintain records of the annual heat input of the unit. [District Rules 1070, 2201]

20. The permittee shall monitor and record the stack concentration of NOX, CO, and O2 at least once every month (in which a source test is not performed) using a portable analyzer that meets District specifications. Monitoring shall not be required if the unit is not in operation, i.e. the unit need not be started solely to perform monitoring. Monitoring shall be performed within 5 days of restarting the unit unless monitoring has been performed within the last month. [District Rules 4305, 4306, and 4320]

21. If either the NOX or CO concentrations corrected to 3 percent O2, as measured by the portable analyzer, exceed the allowable emissions concentration, the permittee shall return the emissions to within the acceptable range as soon as possible, but no longer than 1 hour of operation after detection. If the portable analyzer readings continue to exceed the allowable emissions concentration after 1 hour of operation after detection, the permittee shall notify the District within the following 1 hour and conduct a certified source test within 60 days of the first exceedance. In lieu of conducting a source test, the permittee may stipulate a violation has occurred, subject to enforcement action. The permittee must then correct the violation, show compliance has been re-established, and resume monitoring procedures. If the deviations are the result of a qualifying breakdown condition pursuant to Rule 1100, the permittee may fully comply with Rule 1100 in lieu of performing the notification and testing required by this condition. [District Rules 4305, 4306, and 4320]

22. All alternate monitoring parameter emission readings shall be taken with the unit operating either at conditions representative of normal operations or conditions specified in the permit-to-operate. The analyzer shall be calibrated, maintained, and operated in accordance with the manufacturer's specifications and recommendations or a protocol approved by the APCO. Emission readings taken shall be averaged over a 15 consecutive-minute period by either taking a cumulative 15 consecutive-minute sample reading or by taking at least five (5) readings, evenly spaced out over the 15 consecutive-minute period. [District Rules 4305, 4306, and 4320]

23. The permittee shall maintain records of: (1) the date and time of NOX, CO, and O2 measurements, (2) the O2 concentration in percent by volume and the measured NOX and CO concentrations corrected to 3 percent O2, (3) make and model of exhaust gas analyzer, (4) exhaust gas analyzer calibration records, and

(5) a description of any corrective action taken to maintain the emissions within the acceptable range. [District Rules 4305, 4306, and 4320]

24. This unit shall be tested for compliance with the NOx and CO emissions limits at least once every twelve (12) months. After demonstrating compliance on two (2) consecutive annual source tests, the unit shall be tested not less than once every thirty-six (36) months. If the result of the 36-month source test demonstrates that the unit does not meet the applicable emission limits, the source testing frequency shall revert to at least once every twelve (12) months. [District Rules 4305, 4306, and 4320]

25. The results of each source test shall be submitted to the District within 60 days thereafter. [District Rule 1081]

26. Source test results for NOx emissions shall be submitted to the District as NOx, NO, and NO2 when available. [District Rule 2410]

27. Source testing shall be conducted using the methods and procedures approved by the District. The District must be notified at least 30 days prior to any compliance source test, and a source test plan must be submitted for approval at least 15 days prior to testing. [District Rule 1081]

28. The source test plan shall identify which basis (ppmv or lb/MMBtu) will be used to demonstrate compliance. [District Rules 4305, 4306, and 4320]

29. All emissions measurements shall be made with the unit operating either at conditions representative of normal operations or conditions specified in the DOC. No determination of compliance shall be established within two hours after a continuous period in which fuel flow to the unit is shut off for 30 minutes or longer, or within 30 minutes after a re-ignition as defined in Section 3.0 of District Rule 4306. [District Rules 4305 and 4306]

30. The following test methods shall be used: NOx (ppmv) - EPA Method 7E or ARB Method 100, NOx (lb/MMBtu) - EPA Method 19, CO (ppmv) - EPA Method 10 or 10B or ARB Method 100, stack gas oxygen - EPA Method 3 or 3A or ARB Method 100, SOx (lb/MMBtu) - ARB Method 100 or EPA Method 6, 6C or fuel gas sulfur content analysis and EPA Method 19, fuel gas sulfur content - EPA Method 11 or 15, ASTM D3246 or double GC for H2S and mercaptans performed in a laboratory, fuel gas hhv - ASTM D1826 or D1945 in conjunction with ASTM D3588. [District Rules 4305, 4306 and 4320]

31. The permittee shall monitor and record the stack concentration of NOx, CO, and O2 at least once every month (in which a source test is not performed) using a portable analyzer that meets District specifications. Monitoring shall not be required if the unit is not in operation, i.e. the unit need not be started solely to perform monitoring. Monitoring shall be performed within 5 days of restarting the unit unless monitoring has been performed within the last month. [District Rules 4305, 4306, and 4320]

32. If either the NOx or CO concentrations corrected to 3 percent O2, as measured by the portable analyzer, exceed the allowable emissions concentration, the permittee shall return the emissions to within the acceptable range as soon as possible, but no longer than 1 hour of operation after detection. If the portable analyzer readings continue to exceed the allowable emissions concentration after 1 hour of operation after detection, the permittee shall notify the District within the following 1 hour and conduct a certified source test within 60 days of the first exceedance. In lieu of conducting a source test, the permittee may stipulate a violation has occurred, subject to enforcement action. The permittee must then correct the violation, show compliance has been re-established, and resume monitoring procedures. If the deviations are the result of a qualifying breakdown condition pursuant to Rule 1100, the permittee may fully comply with Rule 1100 in lieu of performing the notification and testing required by this condition. [District Rules 4305, 4306, and 4320]

33. All alternate monitoring parameter emission readings shall be taken with the unit operating either at conditions representative of normal operations or conditions specified in the DOC. The analyzer shall be calibrated, maintained, and operated in accordance with the manufacturer's specifications and recommendations or a protocol approved by the APCO. Emission readings taken shall be averaged over a 15 consecutive-minute period by either taking a cumulative 15 consecutive-minute sample reading or by taking at least five (5) readings, evenly spaced out over the 15 consecutive-minute period. [District Rules 4305, 4306, and 4320]

34. The permittee shall maintain records of: (1) the date and time of NOx, CO, and O2 measurements, (2) the O2 concentration in percent by volume and the measured NOx and CO concentrations corrected to 3 percent O2, (3) make and model of exhaust gas analyzer, (4) exhaust gas analyzer calibration records, and (5) a description of any corrective action taken to maintain the emissions within the acceptable range. [District Rules 4305, 4306, and 4320]

35. For emissions source testing, the arithmetic average of three 30-consecutive-minute test runs shall apply. If two of three runs are above an applicable limit the test cannot be used to demonstrate compliance with an applicable limit. [District Rules 4305, 4306, and 4320]

36. All records shall be maintained and retained on-site for a minimum of five (5) years, and shall be made available for District inspection upon request. [District Rules 1070, 2201, 4305, 4306, and 4320]

37. Components attributed to this unit shall include those components serving the following process streams: low NH3 concentration, moderate NH3 concentration, high NH3 concentration, low CO_2 concentration, moderate CO_2 concentration, high CO_2 concentration, NO_2, nitric acid (HNO3), and PSA off gas. [District Rule 2201]

38. Fugitive VOC emission rate from the unit shall not exceed 0.0 lb/day based on the component count and emission factors from EPA document Protocol for Equipment Leak Emission Estimates (EPA-453/R-95-017), Table 2-1, SOCMI

Average Emissions Factors and the applicable control efficiency for those components subject to a leak detection and repair (LDAR) program. Components serving the following streams associated with this unit shall be subject to a leak detection and repair (LDAR) program: low NH3 concentration, moderate NH3 concentration, high NH3 concentration, low CO_2 concentration, moderate CO_2 concentration, high CO_2 concentration, NO_2, nitric acid (HNO3), and PSA off gas. The following control efficiencies in Table 5-2 of the EPA document shall apply to those components under an LDAR program: gas valves: 92 percent; light liquid valves: 88 percent; light liquid pump seals: 75 percent; and connectors: 93 percent. [District Rules 2201 and 2410]

39. Fugitive CO emission rate from the unit shall not exceed 5.9 lb/day based on the component count, CO percentage in the fluid stream, emission factors from Protocol for Equipment Leak Emission Estimates (EPA-453/R-95-017), Table 2-1, SOCMI Average Emissions Factors and the applicable control efficiency for those components subject to a leak detection and repair (LDAR) program. [District Rule 2201]

40. Permittee shall maintain with the DOC an accurate fugitive component count and the resulting emissions calculated using above specified leak rates and control efficiencies. [District Rule 2201]

41. The VOC content of the gas in the following streams shall not exceed 10 percent by weight: low NH3 concentration, moderate NH3 concentration, high NH3 concentration, low CO_2 concentration, moderate CO_2 concentration, high CO_2 concentration, NO_2, nitric acid (HNO3), and PSA off gas. [District Rule 2201]

42. Operator shall conduct quarterly gas sampling to qualify for exemption from fugitive component counts for those components handling fluids with VOC content equal to or less than 10 percent by weight. If gas samples are equal to or less than 10 percent VOC by weight for 8 consecutive quarterly samplings, sampling frequency shall only be required annually. [District Rule 2201]

43. VOC content of gas streams shall be determined by ASTM D1945, EPA Method 18 referenced as methane, or equivalent test method with prior District approval. [District Rule 2201]

44. All sampling connections, open-ended valves, and lines shall be equipped with two closed valves or be sealed with blind flanges, caps, or threaded plugs except during actual use. [District Rule 2201]

45. Permittee shall maintain records of the VOC content test results for a period of five years and make such records available for inspection upon request. [District Rule 1070]

46. For valves and connectors attributed to this unit, a leak shall be defined as a reading of methane in excess of 100 ppmv above background when measured per EPA Method 21. For pump and compressor seals attributed to this unit, a leak shall be defined as a reading of methane in excess of 500 ppmv above background when measure per EPA Method 21. [District Rule 2201]

47. The operator shall audio-visually inspect for leaks all accessible operating pumps, compressors and Pressure Relief Devices (PRDs) in service at least once every 24 hours, except when operators do not report to the facility for that given 24 hours. Any identified leak that cannot be immediately repaired shall be reinspected within 24 hours using a portable analyzer. If a leak is found, it shall be repaired as soon as practical but not later than the time frame specified in Rule 4455 Table 3. [District Rule 2201]

48. The operator shall inspect all components at least once every calendar quarter, except for inaccessible components, unsafe-to-monitor components and pipes. Inaccessible components, unsafe-to-monitor components and pipes shall be inspected in accordance with the requirements set forth in Rule 4455 Sections 5.2.5, 5.2.6, and 5.2.7. New, replaced, or repaired fittings, flanges and threaded connections shall be inspected immediately after being placed into service. Components shall be inspected using EPA Method 21. [District Rule 2201]

49. The operator may apply for a written approval from the APCO to change the inspection frequency from quarterly to annually for a component type, provided the operator meets all the criteria specified in Rule 4455 Sections 5.2.8.1 through 5.2.8.3. This approval shall apply to accessible component types, specifically designated by the APCO, except pumps, compressors, and PRDs which shall continue to be inspected on a quarterly basis. [District Rule 2201]

50. An annual inspection frequency approved by the APCO shall revert to quarterly inspection frequency for a component type if either the operator inspection or District inspection demonstrates that a violation of the provisions of Rule 4455 Sections 5.1, 5.2 and 5.3 of the rule exists for that component type, or the APCO issued a Notice of Violation for violating any of the provisions of Rule 4455 during the annual inspection period for that component type. When the inspection frequency changes from annual to quarterly inspections, the operator shall notify the APCO in writing within five (5) calendar days after changing the inspection frequency, giving the reason(s) and date of change to quarterly inspection frequency. [District Rule 2201]

51. The operator shall initially inspect a process PRD that releases to the atmosphere as soon as practicable but not later than 24 hours after the time of the release. To insure that the process PRD is operating properly, and is leak-free, the operator shall re-inspect the process PRD not earlier than 24 hours after the initial inspection but not later than 15 calendar days after the date of the release using EPA Method 21. If the process PRD is found to be leaking at either inspection, the PRD leak shall be treated as if the leak was found during quarterly operator inspections. [District Rule 2201]

52. Except for process PRD, a component shall be inspected within 15 calendar days after repairing the leak or replacing the component using EPA Method 21. [District Rule 2201]

53. Upon detection of a leaking component, the operator shall affix to that component a weatherproof readily visible tag that contains the information

specified in Rule 4455 Section 5.3.3. The tag shall remain affixed to the component until the leaking component has been repaired or replaced; has been re-inspected using EPA Method 21; and is found to be in compliance with leak, inspection, and maintenance requirements. [District Rule 2201]

54. An operator shall minimize all component leaks immediately to the extent possible, but not later than one (1) hour after detection of leaks in order to stop or reduce leakage to the atmosphere. [District Rule 2201]

55. If the leak has been minimized but the leak still exceeds the applicable leak standards of this DOC, an operator shall repair or replace the leaking component, vent the leaking component to a closed vent system, or remove the leaking component from operation as soon as practicable but not later than the time period specified in Rule 4455 Table 3. For each calendar quarter, the operator may be allowed to extend the repair period as specified in Rule 4455 Table 3, for a total number of leaking components, not to exceed 0.05 percent of the number of components inspected, by type, rounded upward to the nearest integer where required. [District Rule 2201]

56. If the leaking component is an essential component or a critical component and which cannot be immediately shut down for repairs, the operator shall minimize the leak within one hour after detection of the leak. If the leak has been minimized, but the leak still exceeds any of the applicable leak standards of the DOC, the essential component or critical component shall be repaired or replaced to eliminate the leak during the next process unit turnaround, but in no case later than one year from the date of the original leak detection, whichever comes earlier. [District Rule 2201]

57. For any component that has incurred five repair actions for major gas leaks or major liquid leaks, or any combination of major gas leaks and major liquid leaks within a continuous 12-month period, the operator shall comply with at least one of the requirements specified in Rule 4455 Sections 5.3.7.1, 5.3.7.2, 5.3.7.3, or 5.3.7.4 by the applicable deadlines specified in Sections 5.3.7.5 and 5.3.7.6. If the original leaking component is replaced with a new like-in-kind component before incurring five repair actions for major leaks within 12-consecutive months, the repair count shall start over for the new component. An entire compressor or pump need not be replaced provided the compressor part(s) or pump part(s) that have incurred five repair actions as described in Section 5.3.7 are brought into compliance with at least one of the requirements of Sections 5.3.7.1 through 5.3.7.6. [District Rule 2201]

58. All records required by this DOC shall be retained for a period of at least 5 years and shall be made available to the District upon request. [District Rules 1070 and 2201]

59. The permittee shall obtain written District approval for the use of any equivalent equipment not specifically approved by this Determination of Compliance. Approval of the equivalent equipment shall be made only after the District's determination that the submitted design and performance of the proposed

alternate equipment is equivalent to the specifically authorized equipment. [District Rule 2201]

60. The permittee's request for approval of equivalent equipment shall include the make, model, manufacturer's maximum rating, manufacturer's guaranteed emission rates, equipment drawing(s), and operational characteristics/parameters. [District Rule 2201]

61. Alternate equipment shall be of the same class and category of source as the equipment authorized by the Determination of Compliance. [District Rule 2201]

62. No emission factor and no emission shall be greater for the alternate equipment than for the proposed equipment. No changes in the hours of operation, operating rate, throughput, or firing rate may be authorized for any alternate equipment. [District Rule 2201]

63. The air quality modeled impacts of the proposed alternative equivalent equipment shall not result in any more adverse impacts than the equipment it replaces. [District Rule 2201]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-33-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-18-15**, **-16**, **-38**, and **-39**); 2) portable analyzer test results (Conditions **AQ-18-20** through **-23**); and 3) non-compliance events and associated corrective maintenance (Condition **AQ-18-58**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Condition **AQ-18-15**, to the CPM within 60 days of testing. (Conditions **AQ-18-24** and **-25**)

The project owner shall provide a summary of the fugitive emissions LDAR program, per Conditions **AQ-18-37** through **-57**, in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit the written request for the use of alternate equipment, if necessary, to both the District and CPM for approval in accordance with, and that meets the standards of, Conditions **AQ-18-59** through **-63**.

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-18** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-18-11** through **-63**)

AQ-19 The following conditions cover permit unit S-7616-34-0.

UREA UNIT WITH UREA PASTILLATION SYSTEM: UREA UNIT WITH HIGH-PRESSURE AND LOW-PRESSURE ABSORBERS; PASTILLATION UNIT WITH A DROP FORMER, MOVING BELT, OSCILLATING SCRAPER, AND BUCKET ELEVATOR SERVED BY A DUST COLLECTOR

8. All equipment shall be maintained in good operating condition and shall be operated in a manner to minimize emissions of air contaminants into the atmosphere. [District Rules 2201 and 2410]

9. Operation shall include the following dust collectors serving the following operations: urea bucket elevator. [District Rule 2201]

10. All conveyors and crushers shall be fully enclosed and shall vent only to dust collectors. [District Rule 2201]

11. All processing and conveying equipment, storage systems, and transfer and loading systems shall be dust-tight (to prevent visible emissions in excess of 5 percent opacity) and shall vent only to dust collectors. [District Rule 2201]

12. Each dust collector shall be equipped with dust-tight (to prevent visible emissions in excess of 5 percent opacity) provisions to return collected material to process equipment. [District Rule 2201]

13. Each dust collector shall be equipped with operational differential pressure indicators, and during fabric collector operation read in the proper range specified by the manufacturer. [District Rule 2201]

14. The differential pressure across each compartment of the dust collectors shall be checked and the results recorded quarterly. If the differential pressure across each compartment of the dust collectors is not within the proper range specified by the manufacturer, corrective action is required prior to further operation of the equipment. Corrective action means that the cause of the improper pressure differential is corrected before operation of the equipment is resumed. [District Rule 2201]

15. Each dust collector shall automatically activate whenever process equipment served is activated. [District Rule 2201]

16. Material shall not be conveyed or crushed unless ventilation system and dust collectors are operating and functioning properly. [District Rule 2201]

17. Permittee shall maintain daily records of the hours of operation of material processed and records shall be made available for District inspection upon request. [District Rule 2201]

18. Airflow for the following dust collector(s) shall not exceed: urea bucket elevator: 1,500 cfm. [District Rule 2201]

19. Particulate matter emissions from the dust collectors shall not exceed 0.001 grains/dscf in concentration. [District Rule 2201]

20. PM10 emissions shall not exceed any of the following emissions for the following operations: urea bucket elevator: 0.3 lb/day. [District Rule 2201]

21. PM10 emissions shall not exceed any of the following emissions for the following operations: urea bucket elevator: 113 lb/yr. [District Rule 2201]

22. The maximum process rates of material on a weight basis shall not exceed any of the following: urea bucket elevator: 1,720 ton/day. [District Rule 2201]

23. The maximum process rates of material on a weight basis shall not exceed any of the following: urea bucket elevator: 627,800 ton/yr. [District Rule 2201]

24. Dust collector filters shall be completely inspected annually while not in operation for tears, scuffs, abrasives or holes which might interfere with PM collection efficiency and shall be replaced as needed. [District Rule 2201]

25. Visible emissions from the operation shall be checked and record results quarterly. If visible emissions are observed, corrective action is required prior to further loading. Corrective action means that visible emissions are eliminated before next loading event. [District Rule 2201]

26. Records of dust control device maintenance, inspection, and repairs shall be maintained. The records shall include identification of equipment, date of inspection, corrective action taken, and identification of individual performing inspection. [District Rule 2201]

27. Testing for particulate matter concentration for each dust collector shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 12 calendar months of the date the previous performance test was required to be completed thereafter. If the results of the most recent performance test demonstrate that emissions from the affected facility are 50 percent or less of the applicable emissions standard, a new performance test must be conducted within 24 calendar months of the date that the previous performance test was required to be completed. [District Rule 1081]

28. Testing for compliance with particulate matter concentration limit shall be conducted using EPA method 5. The sampling time and sample volume for each run shall be at least 60 minutes and 0.85 dscm (30 dscf). Sampling shall begin no less than 30 minutes after startup and shall terminate before shutdown procedures begin. A minimum of three valid test runs are needed to comprise a PM performance test. [District Rule 1081]

29. Testing for the opacity standards for the operations shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 90 operating days of the date the

previous performance test was required to be completed thereafter. If all 6-minute average opacity readings in the most recent performance test are equal to or less than half the applicable opacity limit, a new performance test must be conducted within 12 calendar months of the date that the previous performance test was required to be completed. [District Rule 1081]

30. Source testing to determine opacity shall be conducted using EPA method 9. [District Rule 1081]

31. The permittee shall conduct monthly visual observations of all process and control equipment. If any deficiencies are observed, the necessary maintenance must be performed as expeditiously as possible. [District Rule 1081]

32. Permittee shall conduct testing for compliance with the particulate matter concentration limit and particulate matter emissions limit within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility. [District Rule 1081]

33. Permittee shall provide the District at least 30 days prior notice of any performance test, except as specified under other subparts, to afford the Administrator the opportunity to have an observer present. [District Rule 1081]

34. Permittee shall maintain a logbook (written or electronic) with the records specified in this document on-site and make it available upon request. [District Rule 1081]

35. All records required by this DOC shall be retained for a period of at least 5 years and shall be made available to the District, ARB, and USEPA upon request. [District Rules 1070 and 2201]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-34-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-19-20** through **-23**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-19-26**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-19-19** and **-20**, to the CPM within 60 days of testing. (Condition **AQ-19-27**)

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-19** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-19-8** through **-35**)

AQ-20 The following conditions cover permit unit S-7616-35-0.

NITRIC ACID UNIT FOR THE PRODUCTION OF NITRIC ACID FROM AMMONIA OXIDATION, NITRIC OXIDE OXIDATION, AND ABSORPTION SERVED BY: SELECTIVE CATALYTIC REDUCTION (SCR) TO CONTROL NOX, AND TERTIARY CATALYTIC DECOMPOSITION TO CONTROL N2O

8. All equipment shall be maintained in good operating condition and shall be operated in a manner to minimize emissions of air contaminants into the atmosphere. [District Rule 2201]

9. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, 10 percent opacity. [District Rules 2201]

10. The production rate of nitric acid shall not exceed 501 tons of nitric acid in one day. [District Rule 2201]

11. The selective catalytic reduction system shall be operated at all times that nitric acid production is occurring. [District Rule 2201]

12. NOx emissions from the nitric acid unit shall not exceed 100.2 lb-NOx/day. [District Rule 2201]

13. NOx emissions from the nitric acid unit shall not exceed 33,617 lb-NOx per calendar year. [District Rule 2201]

14. The ammonia slip emissions (NH3) shall not exceed either of the following limits: 1.0 lb/hr or 10.0 ppmvd @15 percent O2 (based on a 24 hour rolling average). [District Rule 2201]

15. N2O emission rate shall not exceed 0.54 lb-N2O per ton of HNO3 produced. [District Rule 2410]

16. Source testing to quantify N2O emissions (lb-N2O/ton of HNO3 produced) shall be conducted within 60 days after initial start-up, and once every twelve (12) months thereafter, with equipment in operation at 90 percent or more of the rated capacity when the analysis is conducted. [District Rules 1081, 2201, and 2410]

17. Source testing shall be conducted using the methods and procedures approved by the District. The District must be notified at least 30 days prior to any compliance source test, and a source test plan must be submitted for approval at least 15 days prior to testing. [District Rule 1081]

18. Sampling facilities for source testing shall be provided in accordance with the provisions of Rule 1081 (Source Sampling). [District Rule 1081]

19. The results of each source test shall be submitted to the District within 60 days thereafter. [District Rule 1081]

20. The nitric acid unit shall not discharge into the atmosphere any gases which contained NOx, expressed as NO2, in exceed of 0.20 lb-NOx per ton of nitric acid produced (24-hour rolling average, expressed as 100 percent nitric acid). [District Rule 2201 and 40 CFR 60 Subpart Ga]

21. The nitric acid plant shall comply with the requirements of 40 CFR Part 60, Subpart Ga. [40 CFR 60 Subpart Ga]

22. The permittee shall install, calibrate, maintain, and operate a continuous emission monitoring system (CEMS) for measuring and recording the concentration of NOx emissions in accordance with the provisions of Section 60.13 and Performance Specification 2 of Appendix B and Procedure 1 of Appendix F of part 60. [District Rules 2201, 1080, and 40 CFR 60 Subpart Ga]

23. The permittee shall install, calibrate, maintain, and operate a stack gas flow rate monitoring system. [40 CFR 60 Subpart Ga]

24. The permittee shall determine hourly NOx emissions rate and calculate emissions in units of the applicable emissions limit (lb/ton of 100 percent acid produced). [40 CFR 60 Subpart Ga]

25. The CEMS shall be in continuous operation during all operating periods including unit startup and shutdown, and malfunction. [District Rule 1080 and 40 CFR 60 Subpart Ga]

26. The permittee must use cylinder gas audits to fulfill the quarterly auditing requirement. [40 CFR 60 Subpart Ga]

27. For the NOx concentration CEMS, the permittee must use a span value, as defined in Performance Specification 2, Section 3.11, of Appendix B of this part, of 500 ppmv (as NO2). If the NOx concentrations emitted is higher than 600 ppmv (e.g., during startup or shutdown periods), the permittee must apply a second CEMS or dual range CEMS and a second span value equal to 125 percent of the maximum estimated NOx emission concentration to apply to the second CEMS or to the higher of the dual analyzer ranges during such periods. [40 CFR 60 Subpart Ga]

28. The permittee shall perform a relative accuracy test audit (RATA) for the NOx CEMS as specified by 40 CFR Part 60, Appendix F, 5.11, at least once every four calendar quarters. The permittee shall comply with the applicable requirements for quality assurance testing and maintenance of the continuous emission monitor equipment in accordance with the procedures and guidance specified in 40 CFR Part 60, Appendix F. [District Rule 1080 and 40 CFR 60 Subpart Ga]

29. The permittee must operate and certify the continuous emissions rate monitoring system (CERMS) in accordance with the provisions of §60.13 and Performance Specification 6 of Appendix B of part 60 and the specifications of Section 60.73a (Subpart Ga). [District Rule 1080 and 40 CFR 60 Subpart Ga]

30. The permittee must conduct an initial performance test to demonstrate compliance with the NOx emissions limit under §60.72a(a) beginning in the calendar month following initial certification of the NOx and flow rate monitoring CEMS. The initial performance test consists of collection of hourly NOx average concentration, mass flow rate recorded with the certified NOx concentration and flow rate CEMS and the corresponding acid generation (tons) data for all of the hours of operation for the first 30 days beginning on the first day of the first month following completion of the CEMS installation and certification as described above. The permittee must assure that the CERMS meets all of the data quality assurance requirements as per §60.13 and Appendix F, Procedure 1, of this part and you must use the data from the continuous emissions rate monitoring system (CERMS) for this compliance determination. [District Rule 1080 and 40 CFR 60 Subpart Ga]

31. The permittee shall calculate the 24-hour day rolling arithmetic average emission rate in units of the applicable emissions standard (lb-NOx/ton 100 percent acid produced) at the end of each operating day using all the quality assured hourly average CEMS data for the previous 24 operating hours according to the procedures specified in Section 60.75a. [District Rule 2201 and 40 CFR 60 Subpart Ga]

32. The permittee shall maintain records of the following information for each operating day period: (1) hours of operation; (2) production rate of nitric acid, expressed as 100 percent nitric acid; (3) 24-hour average NOx emissions rate values. [District Rule 2201 and 40 CFR Subpart Ga]

33. The permittee shall maintain records of the following time periods: (1) times when the equipment is not in compliance with the emissions standards; (2) times when the pollutant concentration exceeded full span of the NOx monitoring equipment; (3) times when the volumetric flow rate exceeded the high value of the volumetric flow rate monitoring equipment. [40 CFR 60 Subpart Ga]

34. The permittee shall maintain records of any modifications to CEMS which could affect the ability of the CEMS to comply with applicable performance specifications. For each malfunction, the permittee shall maintain records of the following information: (1) records of the occurrence and duration of each malfunction of operation (i.e., process equipment) or the air pollution control and monitoring equipment; (2) records of actions taken during periods of malfunction to minimize emissions in accordance with section 60.11(d), including corrective actions to restore malfunctioning process and air pollution control and monitoring equipment to its normal or usual manner of operation. [District Rule 1080 and 40 CFR 60 Subpart Ga]

35. The permittee shall submit performance test data from the initial and subsequent performance tests and from performance evaluations of the continuous monitors to the Administrator at the appropriate address as shown in 40 CFR 60.4. The permittee shall report to the Administrator for each 30 operating day period where the nitric acid plant was not in compliance with the emissions standard: (1) Time period; (2) NOx emission rates (lb/ton of acid produced); (3) Reasons for

noncompliance with the emissions standard; and (4) Description of corrective actions taken. The permittee shall also report the following whenever they occur: (1) Times when the pollutant concentration exceeded full span of the NOx pollutant monitoring equipment; and (2) Times when the volumetric flow rate exceeded the high value of the volumetric flow rate monitoring equipment. [District Rule 1080 and 40 CFR 60 Subpart Ga]

36. The permittee shall report any modifications to CERMS which could affect the ability of the CERMS to comply with applicable performance specifications. [40 CFR 60 Subpart Ga]

37. Within 60 days of completion of the relative accuracy test audit (RATA) required by this subpart, the permittee must submit the data from that audit to EPA's WebFIRE database by using the Compliance and Emissions Data Reporting Interface (CEDRI) that is accessed through EPA's Central Data Exchange (CDX) (https://cdx.epa.gov/SSL/cdx/EPA_Home.asp) in the format specified in 40 CFR 60 Subpart Ga, Section 60.77a. [40 CFR 60 Subpart Ga]

38. If a malfunction occurred during the reporting period, the permittee must submit a report that contains the following: (1) The number, duration, and a brief description for each type of malfunction which occurred during the reporting period and which caused or may have caused any applicable emission limitation to be exceeded; (2) A description of actions taken by an owner or operator during a malfunction of an affected facility to minimize emissions in accordance with §60.11(d), including actions taken to correct a malfunction. [40 CFR 60 Subpart Ga]

39. Source testing to measure the NOx and NH3 emission rates (lb/hr and ppmvd @ 15 percent O2) and PM10 emission rate (lb/hr) shall be conducted within 60 days after the conclusion of the commissioning period and at least once every twelve months thereafter. [District Rules 1081]

40. The following test methods shall be used: NOx - EPA Method 7E or 20, PM10 - EPA Method 5/202 (front half and back half), CO - EPA Method 10 or 10B, O2 - EPA Method 3, 3A, or 20, VOC - EPA Method 18 or 25, and ammonia - EPA Method 206. EPA approved alternative test methods as approved by the District may also be used to address the source testing requirements of this DOC. The request to utilize EPA approved alternative source testing methods must be submitted in writing and written approval received from the District prior to the submission of the source test plan. [District Rules 1081]

41. NH3 emissions for source test purposes shall be determined using BAAQMD method ST-1B. [District Rule 1081]

42. All records required by this DOC shall be retained for a period of at least 5 years and shall be made available to the District, ARB, and USEPA upon request. [District Rules 1070 and 2201]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-35-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Condition **AQ-20-10** and **-13**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-20-33**) in the Annual Compliance Reports.

The project owner shall provide the results and field data collected during the air pollutant source tests conducted per the requirements of these conditions shall be submitted to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-20-12** through **-15**, and **-20**, shall be submitted to the CPM within 60 days of testing. (Conditions **AQ-20-16** through **-19** and **-39** through **-41**).

The project owner shall provide a summary of the CEMS and CERMS data collected in compliance with **AQ-20** Conditions, showing compliance with the emissions limits of Conditions **AQ-20-12**, **-13**, **-15**, and **-20**, shall be submitted to the CPM in the Annual Compliance Reports (**AQ-SC8**). (Conditions **AQ-20-22** and **-29**).

The project owner shall provide any other CEMS and CERMS data (design, performance tests, RATA tests) collected to comply with **AQ-20** conditions in the Quarterly or Annual Compliance Reports (**AQ-SC8**) upon CPM request.

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-20** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-20-8** through **-42**)

AQ-21 The following conditions cover permit unit S-7616-36-0.

AMMONIUM NITRATE UNIT THAT PRODUCES AMMONIUM NITRATE, CONSISTING OF: NEUTRALIZER WITH INTEGRAL SCRUBBER TO CONTROL AMMONIA; PROCESS CONDENSATE TANK WITH VENT SCRUBBER TO CONTROL PARTICULATE MATTER EMISSIONS; AMMONIUM NITRATE COOLER, AND PROCESS PUMP(S)

8. All equipment shall be maintained in good operating condition and shall be operated in a manner to minimize emissions of air contaminants into the atmosphere. [District Rule 2201]

9. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, Ringelmann 1 or 20 percent opacity. [District Rule 4101]

10. The permittee shall calibrate, maintain and operate the wet scrubber according the manufacturer's specifications and recommendations. The permittee shall keep records on-site for a period of five years of the calibration and maintenance activities. [District Rule 2201]

11. PM10 emissions from scrubber vent shall not exceed 0.20 lb-PM10/hr. [District Rule 2201]

12. PM10 emission from scrubber vent shall not exceed 0.0075 lb-PM10 per ton of ammonium nitrate produced. [District Rule 2201]

13. Production of ammonium nitrate shall not exceed 636 tons per day nor 212,000 tons during any consecutive 12-month period. [District Rule 2201]

14. Operation of the ammonium nitrate unit shall not exceed 8,000 hours per calendar year. [District Rule 2201]

15. The permittee shall keep records of daily ammonium nitrate production. These records shall contain each month's total and a rolling total for the previous 12 months. [District Rule 2201]

16. Source testing to quantify PM10 emissions (lb-PM10/hr and lb-PM10/ton of ammonium nitrate produced) from scrubber vent shall be conducted within 60 days after initial start-up, and once every twelve (12) months thereafter, with equipment in operation at 90 percent or more of the rated capacity when the analysis is conducted. [District Rules 1081 and 2201]

17. Source testing shall be conducted using the methods and procedures approved by the District. The District must be notified at least 30 days prior to any compliance source test, and a source test plan must be submitted for approval at least 15 days prior to testing. [District Rule 1081]

18. The following test methods shall be used PM10: EPA method 5 (front half and back half). Alternative test methods as approved by the District may also be used to address the source testing requirements of this permit. [District Rules 1081 and 2201]

19. Sampling facilities for source testing shall be provided in accordance with the provisions of Rule 1081 (Source Sampling). [District Rule 1081]

20. The results of each source test shall be submitted to the District within 60 days thereafter. [District Rule 1081]

21. All records required by this DOC shall be retained for a period of at least 5 years and shall be made available to the District, ARB, and USEPA upon request. [District Rules 1070 and 2201]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-36-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-21-13** through **-14**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-21-10**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans in compliance with Condition **AQ-21-17** to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-21-11** and **-12**, to the CPM within 60 days of testing. (Condition **AQ-21-16)**

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-21** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-21-8** through **-21**).

AQ-22 The following conditions cover permit unit S-7616-37-0.

UREA STORAGE AND HANDLING OPERATION CONSISTING OF FOUR 20,000-TON STORAGE CAPACITY ENCLOSED UREA STORAGE DOMES EACH WITH ONE UREA TRANSFER TOWER, WITH EACH TRANSFER TOWER SERVED BY ONE DUST COLLECTOR; ENCLOSED UREA RECLAIM BUILDING WITH RECLAIM HOPPERS AND GRIZZLIES; ENCLOSED, TUBULAR RECLAIM CONVEYOR (THAT TRANSFERS MATERIAL TO UREA TRANSFER TOWER #5); UREA TRANSFER TOWER #5 SERVED BY DUST COLLECTOR; ENCLOSED, TUBULAR LOADOUT FEED CONVEYOR (THAT TRANSFERS MATERIAL TO LOADOUT BUILDING); UREA LOADOUT BUILDING SERVED BY BAGHOUSE DUST COLLECTOR, WITH RAIL LOADOUT CONVEYOR, ONE TRUCK AND ONE TRAIN LOADOUT WEIGH SYSTEM, ONE TRUCK AND ONE TRAIN LOADING SPOUT AND VENT SYSTEM

8. Operation shall include the following dust collectors serving the following operations: urea bucket elevator to conveyor, five urea transfer towers, urea loading building vent. [District Rule 2201]

9. All conveyors shall be fully enclosed and shall vent only to dust collectors. [District Rule 2201]

10. All transfer towers, conveyors, urea domes, and urea handling buildings shall be dust-tight (to prevent visible emissions in excess of 5 percent opacity) and shall vent only to dust collectors. [District Rule 2201]

11. Each dust collector shall be equipped with dust-tight (to prevent visible emissions in excess of 5 percent opacity) provisions to return collected material to process equipment. [District Rule 2201]

12. Each dust collector shall be equipped with operational differential pressure indicators, and during fabric collector operation read in the proper range specified by the manufacturer. [District Rule 2201]

13. The differential pressure across each compartment of the dust collectors shall be checked and the results recorded quarterly. If the differential pressure across each compartment of the dust collectors is not within the proper range specified by the manufacturer, corrective action is required prior to further operation of the equipment. Corrective action means that the cause of the improper pressure

differential is corrected before operation of the equipment is resumed. [District Rule 2201]

14. Each dust collector shall automatically activate whenever process equipment served is activated. [District Rule 2201]

15. Material shall not be conveyed or crushed unless ventilation system and dust collectors are operating and functioning properly. [District Rule 2201]

16. Permittee shall maintain daily records of the hours of operation of material unloading at the enclosed truck receiving hoppers and records shall be made available for District inspection upon request. [District Rule 2201]

17. Airflow for the following dust collector(s) shall not exceed: urea transfer tower 1: 1,500 cfm; urea transfer tower 2: 1,500 cfm; urea transfer tower 3: 1,500 cfm; urea transfer tower 4: 1,500 cfm; urea transfer tower 5: 1,500 cfm; urea loading building: 20,000 cfm. [District Rule 2201]

18. Particulate matter emissions from the dust collectors shall not exceed 0.001 grains/dscf in concentration. [District Rule 2201]

19. PM10 emissions shall not exceed any of the following emissions for the following operations: urea transfer tower 1: 0.3 lb/day; urea transfer tower 2: 0.3 lb/day; urea transfer tower 3: 0.3 lb/day; urea transfer tower 4: 0.3 lb/day; urea transfer tower 5: 0.3 lb/day; urea loading building: 4.1 lb/day. [District Rule 2201]

20. PM10 emissions shall not exceed any of the following emissions for the following operations: urea transfer tower 1: 113 lb/yr; urea transfer tower 2: 28 lb/yr; urea transfer tower 3: 56 lb/yr; urea transfer tower 4: 28 lb/yr; urea transfer tower 5: 27 lb/yr; urea loading building baghouse: 357 lb/yr. [District Rule 2201]

21. The maximum process rates of material on a weight basis shall not exceed any of the following: urea bucket elevator to conveyor: 1,720 ton/day; urea transfer tower 1: 1,720 ton/day; urea transfer tower 2: 1,720 ton/day; urea transfer tower 3: 1,720 ton/day; urea transfer tower 4: 1,720 ton/day; urea transfer tower 5: 1,720 ton/day; urea loading building: 1,720 ton/day. [District Rule 2201]

22. The maximum process rates of material on a weight basis shall not exceed any of the following: urea transfer tower 1: 627,800 ton/yr; urea transfer tower 2: 156,950 ton/yr; urea transfer tower 3: 313,900 ton/yr; urea transfer tower 4: 156,950 ton/yr; urea transfer tower 5: 627,800 ton/yr; urea loading building baghouse: 627,800 ton/yr. [District Rule 2201]

23. Dust collector filters shall be completely inspected annually while not in operation for tears, scuffs, abrasives or holes which might interfere with PM collection efficiency and shall be replaced as needed. [District Rule 2201]

24. Visible emissions from the operation shall be checked and record results quarterly. If visible emissions are observed, corrective action is required prior to

further loading. Corrective action means that visible emissions are eliminated before next loading event. [District Rule 2201]

25. Records of dust control device maintenance, inspection, and repairs shall be maintained. The records shall include identification of equipment, date of inspection, corrective action taken, and identification of individual performing inspection. [District Rule 2201]

26. Testing for particulate matter concentration for each dust collector shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 12 calendar months of the date the previous performance test was required to be completed thereafter. If the results of the most recent performance test demonstrate that emissions from the affected facility are 50 percent or less of the applicable emissions standard, a new performance test must be conducted within 24 calendar months of the date that the previous performance test was required to be completed. [District Rule 1081]

27. Testing for compliance with particulate matter concentration limit shall be conducted using EPA method 5. The sampling time and sample volume for each run shall be at least 60 minutes and 0.85 dscm (30 dscf). Sampling shall begin no less than 30 minutes after startup and shall terminate before shutdown procedures begin. A minimum of three valid test runs are needed to comprise a PM performance test. [District Rule 1081]

28. Testing for the opacity standards for the operations shall be conducted within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility, and within 90 operating days of the date the previous performance test was required to be completed thereafter. If all 6-minute average opacity readings in the most recent performance test are equal to or less than half the applicable opacity limit, a new performance test must be conducted within 12 calendar months of the date that the previous performance test was required to be completed. [District Rule 1081]

29. Source testing to determine opacity shall be conducted using EPA method 9. [District Rule 1081]

30. The permittee shall conduct monthly visual observations of all process and control equipment. If any deficiencies are observed, the necessary maintenance must be performed as expeditiously as possible. [District Rule 1081]

31. Permittee shall conduct testing for compliance with the particulate matter concentration limit and particulate matter emissions limit within 60 days after achieving the maximum production rate, not later than 180 days after initial startup of such facility. [District Rule 1081]

32. Permittee shall provide the District at least 30 days prior notice of any performance test, except as specified under other subparts, to afford the Administrator the opportunity to have an observer present. [District Rule 1081]

33. Permittee shall maintain a logbook (written or electronic) with the records specified in this document on-site and make it available upon request. [District Rule 1081]

34. All records required by this DOC shall be retained for a period of at least 5 years and shall be made available to the District, ARB, and USEPA upon request. [District Rules 1070 and 2201]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-37-0:

The project owner shall provide a summary of: 1) operations throughput and annual emissions estimates (Conditions **AQ-22-19** through **-22**); and 2) non-compliance events and associated corrective maintenance (Condition **AQ-22-25**) in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit source test plans to the District for approval and the CPM for review at least 15 days prior to testing. The project owner shall provide the results of the source tests to the District and a summary of the source test results, showing compliance with the emissions limits of Conditions **AQ-22-18** and **-19**, to the CPM within 60 days of testing. (Condition **AQ-22-26**)

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-22** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-22-8** through **-34**)

AQ-23 The following conditions cover permit unit S-7616-38-0.

2,922 BHP CUMMINS MODEL QSK60-G6 INTERIM TIER 4 (OR THE HIGHEST TIER RATING APPLICABLE AT THE TIME OF INSTALLATION, WHICHEVER TIER IS HIGHER) CERTIFIED DIESEL-FIRED EMERGENCY STANDBY IC ENGINE POWERING A 2,000 KW CUMMINS MODEL DQKC ELECTRIC GENERATOR, #1 (OR EQUIVALENT)

8. Particulate matter emissions shall not exceed 0.1 grains/dscf in concentration. [District Rule 4201]

9. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, Ringelmann 1 or 20 percent opacity. [District Rule 4101]

10. The exhaust stack shall vent vertically upward. The vertical exhaust flow shall not be impeded by a rain cap (flapper ok), roof overhang, or any other obstruction. [District Rule 4102]

11. Only CARB certified diesel fuel containing not more than 0.0015 percent sulfur by weight is to be used. [District Rules 2201 and 4801 and 17 CCR 93115]

12. This engine shall be equipped with an operational non-resettable elapsed time meter or other APCO approved alternative. [District Rule 4702, 17 CCR 93115, and 40 CFR 60 Subpart IIII]

13. This engine shall be operated and maintained in proper operating condition as recommended by the engine manufacturer or emissions control system supplier. [District Rule 4702 and 40 CFR 60 Subpart IIII]

14. An emergency situation is an unscheduled electrical power outage caused by sudden and reasonably unforeseen natural disasters or sudden and reasonably unforeseen events beyond the control of the permittee. [District Rule 4702]

15. Emissions from this IC engine shall not exceed any of the following limits: 0.5 g-NOx/bhp-hr, 2.6 g-CO/bhp-hr, or 0.3 g-VOC/bhp-hr. [District Rule 2201 and 13 CCR 2423 and 17 CCR 93115]

16. Emissions from this IC engine shall not exceed 0.07 g-PM10/bhp-hr based on USEPA certification using ISO 8178 test procedure. [District Rules 2201 and 4102 and 13 CCR 2423 and 17 CCR 93115]

17. The engine EPA Tier rating shall be the highest applicable Tier rating at the time of installation. [District Rules 2201 and 2410, and 13 CCR 2423 and 17 CCR 93115]

18. This engine shall be operated only for testing and maintenance of the engine, required regulatory purposes, and during emergency situations. Operation of the engine for maintenance, testing, and required regulatory purposes shall not exceed 50 hours per calendar year. [District Rules 4702 and 2410, and 17 CCR 93115]

19. The permittee shall maintain monthly records of emergency and non-emergency operation. Records shall include the number of hours of emergency operation, the date and number of hours of all testing and maintenance operations, and the purpose of the operation (for example: load testing, weekly testing, rolling blackout, general area power outage, etc.). For units with automated testing systems, the operator may, as an alternative to keeping records of actual operation for testing purposes, maintain a readily accessible written record of the automated testing schedule. [District Rule 4702 and 17 CCR 93115]

20. All records shall be maintained and retained on-site for a minimum of five (5) years, and shall be made available for District inspection upon request. [District Rule 4702 and 17 CCR 93115]

21. The permittee shall obtain written District approval for the use of any equivalent equipment not specifically approved by this Determination of Compliance. Approval of the equivalent equipment shall be made only after the District's determination that the submitted design and performance of the proposed alternate equipment is equivalent to the specifically authorized equipment. [District Rule 2201]

22. The permittee's request for approval of equivalent equipment shall include the make, model, manufacturer's maximum rating, manufacturer's guaranteed emission rates, equipment drawing(s), and operational characteristics/parameters. [District Rule 2201]

23. Alternate equipment shall be of the same class and category of source as the equipment authorized by the Determination of Compliance. [District Rule 2201]

24. No emission factor and no emission shall be greater for the alternate equipment than for the proposed equipment. No changes in the hours of operation, operating rate, throughput, or firing rate may be authorized for any alternate equipment. [District Rule 2201]

25. The air quality modeled impacts of the proposed alternative equivalent equipment shall not result in any more adverse impacts than the equipment it replaces. [District Rule 2201]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-38-0:

The project owner shall submit the engine specifications at least 30 days prior to purchasing the engines to the District for review and approval and to the CPM for review demonstrating that the engines meet highest engine tier requirement and meet NSPS and ARB ATCM emission limit requirements at the time of engine purchase and the emission limit requirements of Conditions **AQ-23-8**, **-15**, and **-16**; and the design requirements of Conditions **AQ-23-10** and **-12**. (Condition **AQ-23-17**)

The project owner shall provide a summary of the hours of operation showing compliance with Condition **AQ-23-18** and **-19**, and summary of annual emissions in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit the written request for the use of alternate equipment, if necessary, to both the District and CPM for approval in accordance with, and that meet the standards of, Conditions **AQ-23-21** through **-25**.

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-23** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-23-8** through **-25**)

AQ-24 The following conditions cover permit unit S-7616-39-0.

2,922 BHP CUMMINS MODEL QSK60-G6 INTERIM TIER 4 (OR THE HIGHEST TIER RATING APPLICABLE AT THE TIME OF INSTALLATION, WHICHEVER TIER IS HIGHER) CERTIFIED DIESEL-FIRED EMERGENCY STANDBY IC ENGINE POWERING A 2,000 KW CUMMINS MODEL DQKC ELECTRIC GENERATOR, #2 (OR EQUIVALENT)

8. Particulate matter emissions shall not exceed 0.1 grains/dscf in concentration. [District Rule 4201]

9. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, Ringelmann 1 or 20 percent opacity. [District Rule 4101]

10. The exhaust stack shall vent vertically upward. The vertical exhaust flow shall not be impeded by a rain cap (flapper ok), roof overhang, or any other obstruction. [District Rule 4102]

11. Only CARB certified diesel fuel containing not more than 0.0015 percent sulfur by weight is to be used. [District Rules 2201 and 4801 and 17 CCR 93115]

12. This engine shall be equipped with an operational non-resettable elapsed time meter or other APCO approved alternative. [District Rule 4702, 17 CCR 93115, and 40 CFR 60 Subpart IIII]

13. This engine shall be operated and maintained in proper operating condition as recommended by the engine manufacturer or emissions control system supplier. [District Rule 4702 and 40 CFR 60 Subpart IIII]

14. An emergency situation is an unscheduled electrical power outage caused by sudden and reasonably unforeseen natural disasters or sudden and reasonably unforeseen events beyond the control of the permittee. [District Rule 4702]

15. Emissions from this IC engine shall not exceed any of the following limits: 0.5 g-NOx/bhp-hr, 2.6 g-CO/bhp-hr, or 0.3 g-VOC/bhp-hr. [District Rule 2201 and 13 CCR 2423 and 17 CCR 93115]

16. Emissions from this IC engine shall not exceed 0.07 g-PM10/bhp-hr based on USEPA certification using ISO 8178 test procedure. [District Rules 2201 and 4102 and 13 CCR 2423 and 17 CCR 93115]

17. The engine EPA Tier rating shall be the highest applicable Tier rating at the time of installation. [District Rules 2201 and 2410, and 13 CCR 2423 and 17 CCR 93115]

18. This engine shall be operated only for testing and maintenance of the engine, required regulatory purposes, and during emergency situations. Operation of the engine for maintenance, testing, and required regulatory purposes shall not exceed 50 hours per calendar year. [District Rules 4702 and 2410, and 17 CCR 93115]

19. The permittee shall maintain monthly records of emergency and non-emergency operation. Records shall include the number of hours of emergency operation, the date and number of hours of all testing and maintenance operations, and the purpose of the operation (for example: load testing, weekly testing, rolling blackout, general area power outage, etc.). For units with automated testing systems, the operator may, as an alternative to keeping records of actual

operation for testing purposes, maintain a readily accessible written record of the automated testing schedule. [District Rule 4702 and 17 CCR 93115]

20. All records shall be maintained and retained on-site for a minimum of five (5) years, and shall be made available for District inspection upon request. [District Rule 4702 and 17 CCR 93115]

21. The permittee shall obtain written District approval for the use of any equivalent equipment not specifically approved by this Determination of Compliance. Approval of the equivalent equipment shall be made only after the District's determination that the submitted design and performance of the proposed alternate equipment is equivalent to the specifically authorized equipment. [District Rule 2201]

22. The permittee's request for approval of equivalent equipment shall include the make, model, manufacturer's maximum rating, manufacturer's guaranteed emission rates, equipment drawing(s), and operational characteristics/parameters. [District Rule 2201]

23. Alternate equipment shall be of the same class and category of source as the equipment authorized by the Determination of Compliance. [District Rule 2201]

24. No emission factor and no emission shall be greater for the alternate equipment than for the proposed equipment. No changes in the hours of operation, operating rate, throughput, or firing rate may be authorized for any alternate equipment. [District Rule 2201]

25. The air quality modeled impacts of the proposed alternative equivalent equipment shall not result in any more adverse impacts than the equipment it replaces. [District Rule 2201]

Verification: The following verification requirements apply to applicable conditions for permit unit S-7616-39-0:

The project owner shall submit the engine specifications at least 30 days prior to purchasing the engines for review and approval demonstrating that the engines meet highest engine tier requirement and meet NSPS and ARB ATCM emission limit requirements at the time of engine purchase and the emission limit requirements of Conditions **AQ-24-8**, **-15**, and **-16**; and the design requirements of Conditions **AQ-24-10** and **-12**. (Condition **AQ-24-17**).

The project owner shall provide a summary of the hours of operation showing compliance with Condition **AQ-24-18** and **-19**, and summary of annual emissions in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit the written request for the use of alternate equipment, if necessary, to both the District and CPM for approval in accordance with, and that meets the standards of, Conditions **AQ-24-21** through **-25**.

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-24** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-24-8** through **-25**)

AQ-25 The following conditions cover permit unit S-7616-40-0.

556 BHP CUMMINS MODEL CFP-15E-F40 INTERIM TIER 4 (OR THE HIGHEST TIER RATING APPLICABLE AT THE TIME OF INSTALLATION, WHICHEVER TIER IS HIGHER) CERTIFIED DIESEL-FIRED EMERGENCY STANDBY IC ENGINE POWERING A FIREWATER PUMP (OR EQUIVALENT)

8. Particulate matter emissions shall not exceed 0.1 grains/dscf in concentration. [District Rule 4201]

9. No air contaminant shall be discharged into the atmosphere for a period or periods aggregating more than three minutes in any one hour which is as dark as, or darker than, Ringelmann 1 or 20 percent opacity. [District Rule 4101]

10. The exhaust stack shall vent vertically upward. The vertical exhaust flow shall not be impeded by a rain cap (flapper ok), roof overhang, or any other obstruction. [District Rule 4102]

11. Only CARB certified diesel fuel containing not more than 0.0015 percent sulfur by weight is to be used. [District Rules 2201 and 4801 and 17 CCR 93115]

12. This engine shall be equipped with an operational non-resettable elapsed time meter or other APCO approved alternative. [District Rule 4702, 17 CCR 93115, and 40 CFR 60 Subpart IIII]

13. This engine shall be operated and maintained in proper operating condition as recommended by the engine manufacturer or emissions control system supplier. [District Rule 4702 and 40 CFR 60 Subpart IIII]

14. An emergency situation is an unscheduled electrical power outage caused by sudden and reasonably unforeseen natural disasters or sudden and reasonably unforeseen events beyond the control of the permittee. [District Rule 4702]

15. Emissions from this IC engine shall not exceed any of the following limits: 1.5 g-NOx/bhp-hr, 2.6 g-CO/bhp-hr, or 0.14 g-VOC/bhp-hr. [District Rule 2201 and 13 CCR 2423 and 17 CCR 93115]

16. Emissions from this IC engine shall not exceed 0.01 g-PM10/bhp-hr based on USEPA certification using ISO 8178 test procedure. [District Rules 2201 and 4102 and 13 CCR 2423 and 17 CCR 93115]

17. The engine EPA Tier rating shall be the highest applicable Tier rating at the time of installation. [District Rules 2201 and 2410, and 13 CCR 2423 and 17 CCR 93115]

18. This engine shall be operated only for testing and maintenance of the engine, required regulatory purposes, and during emergency situations. For testing purposes, the engine shall only be operated the number of hours necessary to comply with the testing requirements of the National Fire Protection Association (NFPA) 25 - "Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems". Total hours of operation for all maintenance, testing, and required regulatory purposes shall not exceed 100 hours per calendar year. [District Rule 4702 and 2410, and 17 CCR 93115]

19. The permittee shall maintain monthly records of emergency and non-emergency operation. Records shall include the number of hours of emergency operation, the date and number of hours of all testing and maintenance operations, and the purpose of the operation (for example: load testing, weekly testing, rolling blackout, general area power outage, etc.). For units with automated testing systems, the operator may, as an alternative to keeping records of actual operation for testing purposes, maintain a readily accessible written record of the automated testing schedule. [District Rule 4702 and 17 CCR 93115]

20. All records shall be maintained and retained on-site for a minimum of five (5) years, and shall be made available for District inspection upon request. [District Rule 4702 and 17 CCR 93115]

21. The permittee shall obtain written District approval for the use of any equivalent equipment not specifically approved by this Determination of Compliance. Approval of the equivalent equipment shall be made only after the District's determination that the submitted design and performance of the proposed alternate equipment is equivalent to the specifically authorized equipment. [District Rule 2201]

22. The permittee's request for approval of equivalent equipment shall include the make, model, manufacturer's maximum rating, manufacturer's guaranteed emission rates, equipment drawing(s), and operational characteristics/parameters. [District Rule 2201]

23. Alternate equipment shall be of the same class and category of source as the equipment authorized by the Determination of Compliance. [District Rule 2201]

24. No emission factor and no emission shall be greater for the alternate equipment than for the proposed equipment. No changes in the hours of operation, operating rate, throughput, or firing rate may be authorized for any alternate equipment. [District Rule 2201]

25. The air quality modeled impacts of the proposed alternative equivalent equipment shall not result in any more adverse impacts than the equipment it replaces. [District Rule 2201]

__**Verification:**__ The following verification requirements apply to applicable conditions for permit unit S-7616-40-0:

The project owner shall submit the engine specifications at least 30 days prior to purchasing the engines for review and approval demonstrating that the engines meet highest engine tier requirement and meet NSPS and ARB ATCM emission limit requirements at the time of engine purchase and the emission limit requirements of Conditions **AQ-25-8**, **-15**, and **-16**; and the design requirements of Conditions **AQ-25-10** and **-12**. (Condition **AQ-25-17**)
The project owner shall provide a summary of the hours of operation showing compliance with Condition **AQ-25-18** and **-19**, and summary of annual emissions in the Annual Compliance Reports (**AQ-SC8**).

The project owner shall submit the written request for the use of alternate equipment, if necessary, to both the District and CPM for approval in accordance with, and that meets the standards of, Conditions **AQ-25-21** through **-25**.

The project owner shall make the site available for inspection of equipment and records kept to show compliance with all **AQ-25** Conditions by representatives of the District, ARB, U.S. EPA, and the Commission upon request. (Conditions **AQ-25-8** through -**25**).

ACRONYMS

AADT	Annual Average Daily Trip
AAQS	Ambient Air Quality Standard
ACEC	Area of Critical Environmental Concern
AER	Actual Emissions Reductions
AERMOD	ARMS/EPA Regulatory Model
AFC	Application for Certification
AGR	Acid Gas Removal
AIR	Association of Irritated Residents
APCO	Air Pollution Control Officer (SJVAPCD)
AQ	Air Quality
AQCMM	Air Quality Construction Mitigation Manager
AQCMP	Air Quality Construction Mitigation Plan
AQI	Air Quality Index
AQMP	Air Quality Management Plan
AQRVs	Air Quality Related Values
ARB/CARB	California Air Resources Board
ASU	Air Separation Unit
ASTM	ASTM International, formerly known as American Society for Testing and Materials.
ATC	Authority to Construct
ATCM	Air Toxics Control Measure
BAAQMD	Bay Area Air Quality Management District
BACT	Best Available Control Technology
bhp or BHP	Brake Horsepower
bhp-hr	Brake Horsepower Hours
BOP	Balance of Plant
Btu	British Thermal Units
CAA	Clean Air Act
CAAQS	California Ambient Air Quality Standards
CAPCOA	California Air Pollution Controls Officers Association
CCPI	Clean Coal Power Initiative
CCR	California Code of Regulations
CDX	Central Data Exhange (U.S. EPA Online Data Resource)
CEC	California Energy Commission (or Energy Commission)
CEDRI	Compliance and Emissions Data Reporting Interface (part of CDX)
CEM	Continuous Emission Monitor
CEMP	Construction Emissions Mitigation Plan
CEMS	Continuous Emissions Monitoring System
CEQA	California Environmental Quality Act
CERMS	Continuous Emissions Rate Monitoring System
cfm	Cubic Feet per Minute
CFR	Code of Federal Regulations
CH_4	Methane
CO	Carbon Monoxide

CO_2 or CO2	Carbon Dioxide
CO2e/CO2E	Carbon Dioxide Equivalent
Coanda effect	Mixing that occurs when a gas is passed over a carefully profiled curved surface creating high efficiency combustion
COS	Carbonyl Sulfide
CPM	Compliance Project Manager (Energy Commission)
Cr^{6+}	Chromium
CS_2	Carbon Disulfide
CTB	Central Tank Battery
CTG	Combustion Turbine Generator
DEIS	Draft Environmental Impact Statement
DELs	Daily Emission Limitations
DOC	Determination of Compliance
DOE	United States Department Of Energy
DPM	Diesel Particulate Matter
dscf	Dry Standard Cubic Foot
dscm	Dry Standard Cubic Meter
EHOF	Elk Hills Oil Field
EIR	Environmental Impact Reports
EOR	Enhanced Oil Recovery
EPA	United States Environmental Protection Agency, also U.S. EPA
ERC	Emission Reduction Credit
ERIP	Emissions Reduction Incentive Program
FDOC	Final Determination Of Compliance
FEIS	Final Environmental Impact Statement
FLM	Federal Land Manager
FMP	Flare Minimization Plan
FSA	Final Staff Assessment
ft/sec	Feet per Second
GEP	Good Engineering Practice
GHG	Greenhouse Gas
GPM	Gallon Per Minute
gr	Grains (1 gr $\cong$ 0.0648 grams, 7000 gr = 1 pound)
GWh	Gigawatt-hour
H_2S or H2S	Hydrogen Sulfide
HAP or HAPs	Hazardous Air Pollutants
HCl	Hydrogen Chloride
HECA	Hydrogen Energy California Project
Hg	Mercury
HHV	Higher Heating Value
HNO_3	Nitric Acid
hp	Horsepower
hr	Hour
HRA	Health Risk Assessment
HRSG	Heat Recovery Steam Generator
HSC	Health and Safety Code
IC	Internal Combustion

IGCC	Integrated Gasification Combined Cycle
ISO	International Organization for Standardization
km	Kilometer
kW	Kilowatt
LAER	Lowest Achievable Emission Rate
lb or lbs	Pound or Pounds
LDAR	Leak Detection and Repair
LHV	Lower Heating Value
LORS	Law, Ordinances, Regulations, and Standards
LPG	Liquefied Petroleum Gas
LTGC	Low Temperature Gas Cooling
MATS	Mercury And Air Toxics Standards
MCR	Monthly Compliance Report
$\mu g/m^3$	Microgram per cubic meter
mg	Milligram
mg/m^3	Milligram per cubic meter
MHI	Mitsubishi Heavy Industries
MMBtu	Million British Thermal Units
MMBtu/hr	Million British Thermal Units per Hour
MMscfd	Million Standard Cubic Feet Per Day
mol	Mole
MRV	Monitoring, Reporting and Verification
MW	Megawatts (1,000,000 Watts)
MWh	Megawatt-hour
N_2O or N2O	Nitrous Oxide
NAAQS	National Ambient Air Quality Standards
ND	No Data
NEPA	National Environmental Policy Act
NESHAPs	National Emission Standards for Hazardous Air Pollutants
NFPA	National Fire Protection Association
NH_3 or NH3	Ammonia
NMHC	Non-methane Hydrocarbons
NMOC	Non-methane Organic Compounds
NNSR	Nonattainment New Source Review
NO	Nitric Oxide
NO_2 or NO2	Nitrogen Dioxide
NOx	Oxides of Nitrogen *or* Nitrogen Oxides
NRU	Nitrogen Reinjection Unit
NSPS	New Source Performance Standard
NSR	New Source Review
O_2 or O2	Oxygen
O_3	Ozone
OEHI	Occidental of Elk Hills, Inc
PAMS	Photochemical Assessment Monitoring Station
Pb	Lead
PDOC	Preliminary Determination Of Compliance
petcoke	Petroleum Coke

PM	Particulate Matter
PM10	Particulate Matter less than 10 microns in diameter
PM2.5	Particulate Matter less than 2.5 microns in diameter
ppm	Parts Per Million
ppmv	Parts Per Million by Volume
ppmvd	Parts Per Million by Volume, Dry
ppmw	Parts Per Million by Weight
PRD	Pressure Release Device
PS	Performance Specification
PSA	Pressure Swing Absorption
PSA/DEIS	Preliminary Staff Assessment/Draft Environmental Impact Statement
PSD	Prevention of Significant Deterioration
psig	Pounds per Square Inch Gauge
PTO	Permit to Operate
PUC	California Public Utility Commission
PVMRM	Plume Volume Molar Ratio Method
Q/d	Emissions over Distance ratio
RACM	Reasonably Available Control Measure
RACT	Reasonably Available Control Technology
RATA	Relative Accuracy Test Audit
RCF	Reinjection Compression Facility
RICE	Reciprocating Internal Combustion Emissions
Ringlemann	A standard measure of opacity (opaqueness of plumes)
SB	Senate Bill
scf	Standard Cubic Feet
SCR	Selective Catalytic Reduction
SF6	Sulfur Hexafluoride
SILs	Significant Impact Levels
SIP	State Implementation Plan
SJVAB	San Joaquin Valley Air Basin

General Conformity Evaluation and Determination

NATIONAL ENERGY TECHNOLOGY LABORATORY
Albany, OR • Morgantown, WV • Pittsburgh, PA
U.S. DEPARTMENT OF ENERGY

April 25, 2013

Robert Worl
Siting Project Manager
California Energy Commission
1516 Ninth Street
Sacramento, CA 95814-5512

Dear Mr. Worl:

As we have discussed, the United States Department of Energy (DOE) is considering providing financial assistance for the construction and operation of the Hydrogen Energy California Project (HECA). DOE's proposed action is subject to the Clean Air Act's General Conformity Rule (GCR) set forth in section 176(c) of the Act and 40 CFR Part 93.

DOE's practice is to coordinate its compliance with the GCR with its preparation of the analyses of potential impacts required by the National Environmental Policy Act (NEPA), in particular the GCR's requirements for public participation in 40 CFR § 93.156. Accordingly, DOE requests that the staff of the California Energy Commission (CEC) incorporate the attached *General Conformity Evaluation* into appropriate section of the Preliminary Staff Assessment/Draft Environmental Impact Statement (PSA/DEIS). In addition, DOE requests that CEC staff incorporate into the PSA/DEIS the text DOE provided earlier regarding its adoption of this evaluation.

DOE intends to publish a Notice of Availability in the Federal Register announcing that the PSA/DEIS is available for public review and comment. This notice will state that the draft *General Conformity Evaluation* is included in the PSA/DEIS and invite the public to comment on the evaluation as well as the other information presented in the PSA/DEIS. DOE will also send copies of its draft evaluation to federal, tribal, state, and local organizations as required by 40 CFR § 93.155.

The applicant, HECA LLC, has negotiated enforceable commitments with the San Joaquin Valley Air Pollution Control District (SJVAPCD) that call for HECA to provide funds to the District's Emission Reduction Incentive Program (ERIP), which the SJVAPCD will disburse as grants to emission reduction projects. The SJVAPCD will administer the projects and verify the emission reductions. The SJVAPCD will fund projects within the San Joaquin Valley Air Basin (SJVAB) that produce real, quantifiable and enforceable emission reductions that will occur contemporaneously with the emissions from the project that are subject to the GCR. The District intends to fund enough projects to more than offset the HECA project's anticipated GCR emissions (that is, the SJVAPCD is requiring the applicant to provide funding for a surplus of emission reductions in the SJVAB). Through this mechanism, the District will ensure that construction and operational emissions of nitrogen oxide and volatile organic compounds from the project that exceed the GCR thresholds will be more than offset by the emission reductions achieved by the District's ERIP. On the basis of these agreements and the analysis in the attached

626 Cochrans Mill Road, P.O. Box 10940, Pittsburgh, PA 15236
paul.detwiler@netl.doe.gov • Voice (412) 386-4839 • Fax (412) 386-5949 • www.netl.doe.gov

General Conformity Evaluation, DOE believes that the project will conform to the applicable state implementation plans and that DOE's proposed federal action of providing financial assistance to the applicant would comply with the requirements of the GCR. DOE consulted with the applicant and the SJVAPCD regarding the *General Conformity Evaluation* and the emission reduction agreements.

If you should have any questions, please contact Cliff Whyte, Environmental Compliance Division Director, at (304)285-2098 at your convenience.

Sincerely,

R. Paul Detwiler
Chief Counsel

Hydrogen Energy California LLC (HECA LLC) is proposing an Integrated Gasification Combined Cycle (IGCC) polygeneration project located approximately 7 miles west of the outermost edge of the City of Bakersfield, and 1.5 miles northwest of the unincorporated community of Tupman, in western Kern County, California, as seen in Figure 1 (the "Project" or "HECA Project"). The Project will gasify a fuel blend of 75 percent coal and 25 percent petroleum coke (petcoke) to produce synthesis gas (syngas). Syngas produced via gasification will be purified to hydrogen-rich fuel, and used to generate a nominal 300 megawatts (MW) of low-carbon baseload electricity in a Combined Cycle Power Block, low-carbon nitrogen-based fertilizer in an integrated Manufacturing Complex, and carbon dioxide (CO_2) for use in enhanced oil recovery (EOR).

Section 176(c)(1) of the Clean Air Act (CAA) requires any entity of the federal government that engages in, supports, or in any way provides financial support for, licenses, or permits, or approves any activity, to demonstrate that the action conforms to the applicable State Implementation Plan (SIP) for achieving and maintaining the National Ambient Air Quality Standards (NAAQS) for criteria pollutants before the action is otherwise approved (General Conformity Rule). The HECA Project will receive financial support from the United States Department of Energy (U.S. DOE), and will be subject to the National Environmental Policy Act (NEPA) environmental review process by the U.S. DOE. Therefore, the HECA Project is subject to the requirements of the Federal Clean Air Act General Conformity Rule for all nonattainment and maintenance areas affected by the direct and indirect emissions from the Project.

An evaluation of General Conformity was performed for the HECA Project for all the affected nonattainment and maintenance areas in the states of California, Arizona, and New Mexico. Criteria pollutant emissions generated in each Project-affected area from activities associated with Project construction and operation were estimated and compared to the General Conformity *de minimis* thresholds to assess whether a General Conformity Determination (GCD) is required.

The estimated emissions indicate that the total direct and indirect construction and operational emissions of carbon monoxide (CO), particulate matter less than 10 microns in diameter (PM_{10}), particulate matter less than 2.5 microns in diameter ($PM_{2.5}$), and sulfur dioxide (SO_2) are below the applicable General Conformity thresholds for all years of construction and operation in all nonattainment and maintenance areas. Construction and operational emissions of nitrogen oxides (NO_x) exceed the General Conformity threshold each year of construction and operation in the San Joaquin Valley Air Basin (SJVAB). Construction emissions of volatile organic compounds (VOCs) exceed the General Conformity threshold in years 2014 and 2015 in the SJVAB. This requires a General Conformity Evaluation and Determination in the SJVAB for NO_x for construction and operation; and for VOC during construction.

HECA has entered into an enforceable commitment with the San Joaquin Valley Air Pollution Control District (SJVAPCD) to provide funds to the SJVAPCD's Emission Reduction Incentive Program (ERIP), which would be disbursed in the form of grants for emission reduction projects. The SJVAPCD serves as both the administrator of the projects and the verifier of the emission reductions. The SJVAPCD will fund projects within the SJVAB that will produce real, quantifiable, enforceable, and surplus emission reductions, contemporaneously with Project emission increases. Through this mechanism, construction and operational emissions of NO_x and VOC from the Project which exceed the General Conformity thresholds will be fully offset and the federal action will conform to the SIP pursuant to Title 40, Code of Federal Regulations, Part 93, Subpart B, Section 93.158(a)(2) and/or Section 93.158(a)(5)(iii).

The HECA IGCC polygeneration project is located near the community of Tupman, as shown in Figure 1. The Project will gasify a fuel blend of 75 percent coal and 25 percent petroleum coke (petcoke) to produce synthesis gas (syngas). Syngas produced via gasification will be purified to hydrogen-rich fuel, and used to generate a nominal 300 megawatts (MW) of low-carbon baseload electricity in a Combined Cycle Power Block, low-carbon nitrogen-based fertilizer in an integrated Manufacturing Complex, and carbon dioxide (CO_2) for use in enhanced oil recovery (EOR). The HECA Project Site comprises a 453-acre parcel of land on which the HECA IGCC electrical generation facility, low-carbon nitrogen-based fertilizer Manufacturing Complex, and associated equipment and processes (excluding off-site portions of linear facilities), will be located. HECA has an agreement to purchase the HECA Project Site, as well as an additional 653 acres adjacent to the HECA Project Site, herein referred to as the Controlled Area. HECA will have control over public access and future land use on this property. In addition, the HECA Project will include the following linear facilities, which extend off the Project Site.

- Electrical transmission line. An approximately 2-mile-long electrical transmission line will interconnect the Project to a future Pacific Gas and Electric Company (PG&E) switching station east of the Project Site.
- Natural gas supply pipeline. An approximately 13-mile-long natural gas interconnection will be made with PG&E natural gas pipelines north of the Project Site.
- Water supply pipelines and wells. An approximately 15-mile-long process water supply line and up to five new groundwater wells will be installed by the Buena Vista Water Storage District (BVWSD) to supply brackish groundwater from northwest of the Project Site. An approximately 1-mile-long water supply linear from the West Kern Water District (WKWD) east of the Project Site will provide potable water.

A fleet of trucks and trains will be used for the transportation of feedstock and product to/from the Project Site on a regular basis during commercial operation. HECA is considering two alternatives for transporting the feedstock coal to the Project Site.

- Alternative 1, rail transportation. An approximately 5-mile-long new industrial railroad spur will connect the Project Site to the existing San Joaquin Valley Railroad (SJVRR) Buttonwillow railroad line, north of the Project Site. This railroad spur will also be used to transport some HECA products to market.
- Alternative 2, truck transportation. An approximately 27-mile-long truck transport route via existing roads from an existing coal transloading facility northeast of the Project Site.

Based on the transportation alternatives, the Project impact area will include the states of California, Arizona, and New Mexico for the General Conformity Determination (GCD) purposes. However, only the areas that are currently designated by the United States Environmental Protection Agency (U.S. EPA) as nonattainment or maintenance areas are required to be analyzed.

The construction of HECA is anticipated to start in 2013 and to be completed in 2017. The anticipated Project commercial operation start date is September 2017. During calendar year 2017, both construction activities and operational activities will occur.

Section 176(c)(1) of the Clean Air Act (CAA) requires any entity of the federal government that engages in, supports, or in any way provides financial support for, licenses, or permits, or approves any activity, to demonstrate that the action conforms to the applicable State Implementation Plan (SIP) for achieving and maintaining the National Ambient Air Quality Standards (NAAQS) for criteria pollutants before the action is otherwise approved. The General Conformity requirement is implemented pursuant to regulations set forth at Title 40, Code of Federal Regulations, Part 93 (General Conformity Rule).

A SIP is a state's compilation of its air quality control plans and rules that will be implemented to achieve compliance with the NAAQS. Criteria pollutants are six major air pollutants for which the U.S. EPA has established NAAQS. These pollutants are ozone (O_3), particulate matter (particulate matter less than 10 microns in diameter [PM_{10}] and particulate matter less than 2.5 microns in diameter [$PM_{2.5}$]), carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), and lead. This analysis examines emissions from all criteria pollutants and their precursors except lead and ammonia (a $PM_{2.5}$ precursor), because these are not emitted from the non-exempt General Conformity sources (i.e., transportation sources).

Section 176(c)(1) also assigns primary oversight responsibility for conformity assurance to the agencies themselves, not to the U.S. EPA or the states. Specifically, for there to be conformity, a federal action must not contribute to new violations of standards for ambient air quality, increase the frequency or severity of existing violations, or delay timely attainment of standards in the area of concern.

Due to the financial support from the United States Department of Energy (U.S. DOE), the General Conformity Rule is applicable in the San Joaquin Valley Air Basin (SJVAB) and all other nonattainment and maintenance areas affected by the direct and indirect emissions from the Project. HECA has estimated annual Project emissions of nonattainment and maintenance pollutants and their precursors to determine if emissions of these pollutants are above the General Conformity *de minimis* thresholds, and thus subject to the General Conformity Rule, and to determine whether the proposed action conforms to the SIP. This General Conformity evaluation for HECA was prepared to confirm that the proposed action would conform to the SIP.

The General Conformity Rule establishes certain procedural requirements that must be followed when preparing a General Conformity evaluation. This section addresses the regulatory background, requirements, and processes of the General Conformity Rule.

2.1 GENERAL CONFORMITY REGULATORY BACKGROUND

The U.S. EPA promulgated the General Conformity Rule on November 30, 1993, in Volume 58 of the Federal Register (FR) Page 63214 (58 FR 63214) to implement the conformity provision of Title I, Section 176(c) of the federal CAA (42 U.S.C. § 7506(c)). Section 176(c)(1) requires that the federal government not engage, support, or provide financial assistance for, permit or license, or approve any activity that fails to conform to an approved SIP.

The General Conformity Rule is codified in 40 Code of Federal Regulations (CFR) Part 93 (40 CFR 93), Subpart B, "*Determining Conformity of General Federal Actions to State or Federal Implementation Plans*". The General Conformity Rule applies to all federal actions, except programs and projects that require funds or approval from the U.S. Department of Transportation (U.S. DOT), the Federal Highway Administration (FHWA), the Federal Transit Administration (FTA), or the Metropolitan Planning Organization (MPO). In lieu of a General Conformity analysis, these latter types of programs and projects must comply with the Transportation Conformity Rule promulgated by U.S. DOT on November 24, 1993 (58 FR 62197).

The federal General Conformity Rule is often incorporated into state and local regulations. For instance, the San Joaquin Valley Air Pollution Control District (SJVAPCD) has adopted the federal General Conformity regulations in its Rule 9110, "*General Conformity.*"

2.2 GENERAL CONFORMITY REQUIREMENTS

As defined in the CAA, Title I, Section 176(c)(1), conformity means to uphold air quality goals through reduction or elimination of NAAQS violations. Accordingly, a proposed action or activity achieves conformity if the associated pollutant emissions would not:

- Cause or contribute to new violations of any NAAQS in any area;
- Increase the frequency or severity of any existing violation of any NAAQS; or
- Delay timely attainment of any NAAQS or interim emission reductions.

The General Conformity Rule establishes conformity in coordination with and as part of the NEPA environmental review process. The General Conformity Rule affects air pollutant emissions associated with actions that are federally funded, licensed, permitted, or approved; and ensures emissions do not contribute to air quality degradation, or prevent the achievement of state and federal air quality goals. In short, General Conformity, if applicable, refers to the process to evaluate plans, programs, and projects to determine and demonstrate that they satisfy the requirements of the CAA and applicable SIP. A positive GCD of a project can be shown through state emission budgets in the SIP, emission offsets, or air quality modeling.

In the SJVAPCD jurisdiction, U.S. EPA approved the 2004 Extreme Ozone Attainment Demonstration Plan for 1-hour ozone on March 8, 2010. However, this SIP is based on the revoked federal 1-hour ozone standard and does not have any projected emissions for milestone years after 2010, as attainment was expected to be achieved by then. On August 30, 2012, U.S. EPA proposed to withdraw its approval of the 2004 ozone plan. This action will require SJVAPCD to develop new plans for attainment of the 1-hour ozone air quality standard. SJVAPCD is preparing this new 1-hour ozone plan currently and expects to finish and submit this to California Air Resources Board (CARB) and U.S. EPA in 2013. On the other hand, the SJVAPCD's Governing Board adopted the 2007 8-hour Ozone Plan and its amendments in 2007 and 2008, and 2011. This SIP was approved by CARB and U.S. EPA on March 1, 2012. Therefore, the SJVAPCD's 2007 8-hour Ozone Plan is the current applicable SIP to be used for the HECA Project.

SJVAPCD has adopted the 2008 $PM_{2.5}$ Plan, although this plan has not yet been approved by U.S. EPA. Therefore, it was determined that the current applicable SIPs to be used in the SJVAPCD jurisdiction area for this General Conformity analysis are the 2007 8-hour ozone plan, the 2008 $PM_{2.5}$ plan, the U.S. EPA-approved 2007 PM_{10} Maintenance Plan and Request for Re-designation, and the U.S. EPA-approved 1996 Carbon Monoxide Re-designation Request and Maintenance Plan for Ten Federal Planning Areas.

2.3 GENERAL CONFORMITY PROCESSES

This General Conformity analysis was prepared based on guidance from two documents: the U.S. EPA General Conformity Guidance (40 CFR 93, Subpart B) and the U.S. DOE CAA General Conformity Requirements and the NEPA Process (DOE, 2000).

The process to evaluate General Conformity for a proposed federal action involves two major phases or processes: the General Conformity Applicability Review process, and the GCD process. Applicability review process is required for any action that is federally funded, licensed, permitted, or approved, where the total direct and indirect emissions for criteria pollutants and precursors in a nonattainment or maintenance area exceed the General Conformity *de minimis* rates specified in 40 CFR 93.153(b)(1) and (2). If emissions exceed these rates, then a GCD is required.

Based on the definitions from 40 CFR 93.153 and U.S. EPA General Conformity Guidance, direct emissions are caused by the action itself, such as the emissions from the construction of a facility. Indirect emissions are also caused by the action, but are removed from the action in either time or space. For example, emissions from employees commuting to a facility are indirect emissions. Both direct and indirect emissions have to be reasonably foreseeable, meaning that the emissions can be estimated based on acceptable techniques using reasonable assumptions about the type and quantity of equipment used.

The General Conformity requirements and the NEPA Process Guide from the U.S. DOE provide four steps for the General Conformity Applicability process to determine whether the next phase of General Conformity evaluation requirements apply to a federal action, and therefore, that a GCD may be needed. The four steps are:

- Step 1 – Determine whether criteria pollutants and their precursors would be emitted.
- Step 2 – Determine whether emissions of criteria pollutants and precursors would occur in a nonattainment or maintenance area.
- Step 3 – Determine whether the action is exempt from the General Conformity Rule.
- Step 4 – Estimate emissions and compare them with the General Conformity *de minimis* threshold emissions rates.

After completing the General Conformity Applicability review process, if the General Conformity Rule is applicable for the proposed action, then a GCD process is required. The GCD process is an assessment of whether the proposed action conforms to the applicable SIP. Positive General Conformity can be shown through state emission budgets, emission offsets, air quality modeling, or any combination of these three processes.

Per 40 CFR 51.859(d) the Conformity Analysis must be based on the total direct and indirect emissions from the action for:

- nonattainment areas, the year mandated in the CAA for attainment; for maintenance areas, the farthest year for which emissions are projected in the approved maintenance plan;
- the year during which the emissions for the proposed action are projected to be the greatest on an annual basis; and
- any year for which the applicable SIP specifies an emission budget.

2.4 EXEMPTION FROM GENERAL CONFORMITY ANALYSIS

As noted previously, the General Conformity requirements apply to a federal action if the net project emissions equal or exceed the General Conformity *de minimis* emission thresholds. The only exceptions to this applicability criterion are the topical exemptions included in 40 CFR 93.153 (c), (d), and (e). However, the emissions caused by the HECA Project do not meet any of these exempt categories, except the portion of an action that includes major or minor new or modified stationary sources that require a permit under the new source review (NSR) program or the prevention of significant deterioration program (40 CFR 93.153 (d)(1)). In addition to these topical exemptions, the General Conformity regulations allow each federal agency to establish a list of activities that are presumed to conform (40 CFR 93.153 (f)). The U.S. DOE has not established any other exemption actions or activities for HECA.

Emissions from the operation of the HECA Project stationary sources will be permitted through the SJVAPCD under NSR, and are therefore exempt from the GCD, and thus are not included in the total General Conformity evaluation emission analysis.

A Conformity Determination is required for each criteria pollutant and its precursors where the total of direct and indirect annual emissions of the criteria pollutant or its precursors in a federal nonattainment or maintenance area would equal or exceed the General Conformity *de minimis* thresholds. The CAA defines nonattainment areas as geographic regions designated as not meeting one or more of the NAAQS. It requires that a SIP be prepared for each nonattainment area, and a maintenance plan be prepared for each former nonattainment area that has subsequently demonstrated compliance with the standards. The nonattainment or maintenance status and the applicable General Conformity *de minimis* thresholds in all the areas potentially affected by the HECA Project are shown in Table 1. The pollutant with the most nonattainment areas in the state of California is ozone; these areas are shown on Figure 1.

The *de minimis* thresholds are based on the severity of the nonattainment status. In the SJVAB, for example, U.S. EPA has designated the basin as extreme nonattainment for O_3, thus the applicable *de minimis* thresholds for O_3 precursors (VOC and nitrogen oxides (NO_x)) are set to 10 tons per year. For other pollutants (PM_{10}, SO_2, and $PM_{2.5}$), the thresholds are set at 100 tons per year. Although Project-related activities may occur in other regions than those listed in Table 1, those regions are in attainment for all pollutants, and thus are not included in the General Conformity evaluation.

References: U.S. EPA Greenbook (U.S. EPA, July 20, 2012)

Nonattainment and maintenance criteria pollutant and precursor emissions were calculated for each calendar year of the construction and operation phases of the Project, as well as the year when construction and operational activities overlap. The calculations used methodologies recommended and approved by the CARB and the U.S. EPA. The following are calculation methodologies used for both the construction and operational emissions.

On-road construction and operational vehicles emissions were estimated by multiplying the emission factors generated from the CARB's EMFAC2007 (CARB, 2007a) model by the numbers of vehicles and the mileage driven. Although EMFAC2011 (CARB, 2011) was released in September 2011, it is not yet approved by U.S. EPA for use in federal projects for NEPA and federal conformity analyses; thus, emission factors from EMFAC2007 were applied. Fugitive dust emissions generated in both the construction and operation phases were estimated by using the emission factors obtained from the U.S. EPA AP-42 publication (U.S. EPA, 1995). It should be noted that all the calculated emissions are mitigated emissions that incorporate the Project-committed feasible emission control measures. Detailed construction and operational emissions calculation methodologies are discussed in Section 4.1 and 4.2.

4.1 CONSTRUCTION EMISSIONS

The primary emission sources during construction will include heavy construction equipment, construction vehicles, and fugitive dust from disturbed areas due to grading, excavating, and construction of Project structures. Different areas within the Project Site will be disturbed at different times during the 49-month overall construction period, which includes site preparation, construction, and up to 18 months of commissioning. Each phase has some overlap, but all construction activities are included in the emission estimates. Construction activities will occur 22 days per month, with a single-shift 10-hour workday.

Construction emissions were calculated from sources in three different categories: on-site sources, sources associated with linear construction (e.g., pipelines, transmission line, rail spur, etc.), and off-site sources. On-site sources include construction equipment, delivery trucks entering and exiting the site, and commuter vehicles entering and exiting the site. Linear sources include all construction equipment required for the total linear construction. Off-site sources include worker commuting vehicles and delivery trucks while traveling off-site. Trip distances were based on the assumption that worker commuting vehicles and delivery trucks would travel within Kern County.

The schedule of equipment needed during construction and the estimated number of pieces of equipment that would operate during each month of the construction effort are presented in Appendix A. Emissions from equipment will occur over a 49-month construction period. The list of fueled equipment needed during each month of the construction effort served as the basis for estimating pollutant emissions throughout the term of construction.

Construction equipment and vehicle exhaust emissions were estimated using equipment lists and construction scheduling information provided by the Project design engineering firm. The off-road construction equipment emissions were estimated by multiplying the emission factors generated from CARB's OFFROAD2007 model (CARB, 2007b) by the amount of power produced and by the operating hours, for each equipment type. Emission factors specific to Kern County in calendar year 2013 were used.

Fugitive dust emissions resulting from on-site soil disturbances were estimated using the U.S. EPA AP-42 emission factors for dirt piling, grading, bulldozing and dirt-pushing, and travel on unpaved roads. Dust control efficiencies from 61 to 93 percent for Project Site and linear construction activities were assumed to be achieved by frequent watering, speed control, or application of dust suppressant on unpaved roads.

Emissions from on-road delivery trucks and worker commute trips were estimated using trip generation information presented in Appendix A, and emission factors provided by the EMFAC2007 model for on-road vehicles. Construction workers were assumed to commute to the Project Site from within Kern County.

Table 2 presents the estimated construction emissions by calendar year, from the start of construction in 2013 through the estimated completion in 2017. Emissions were calculated for each year of construction to determine the year with the highest emissions for each pollutant. It is important to note that all the emissions in Table 2 are generated within SJVAB, because the Project is not expected to have delivery trucks or worker commuting vehicles traveling outside of the boundary of SJVAB during construction. Emissions from commissioning of the stationary sources permitted under NSR are not included in the summary in Table 2, because these are exempt from GCD requirements, although emissions from worker commuter vehicles and delivery trucks associated with commissioning are included in the construction emissions. Detailed calculation spreadsheets are provided in Appendix A, which show the calculated emissions for all construction activities and equipment, as well as the data and assumptions used for the calculations.

4.2 OPERATIONAL EMISSIONS

The criteria pollutant emissions generated during operation of the Project will come from the onsite stationary, area, fugitive, mobile sources, and the offsite transportation sources. However, the onsite stationary, area, and fugitive sources will be required to obtain NSR permits from SJVAPCD, and therefore are exempt from the General Conformity analysis pursuant to 40 CFR 93.153.

4.2.1 Onsite Emissions Covered by NSR

The HECA Project will produce low-carbon baseload electricity, low-carbon nitrogen–based fertilizer in an integrated Manufacturing Complex, and CO_2 for EOR. The Gasification Block will feature Mitsubishi Heavy Industries, Ltd. (MHI) oxygen-blown dry-feed gasifier, Shift, Low Temperature Gas Cooling (LTGC), Mercury Removal, Acid Gas Removal (AGR), Sulfur Recovery, Tail Gas Treating, EOR CO_2 Compression Units, and associated utilities to produce hydrogen-rich fuel. Sulfur and mercury components will be removed, and CO_2 will be captured and compressed for EOR and resulting sequestration.

The Combined Cycle Power Block will generate approximately 405 MW of gross power, and will provide approximately 300 MW output of low-carbon baseload electricity. The Power Block will feature one MHI 501 GAC® (Granular-Activated Carbon) combustion turbine generator (CTG) that will be fueled with hydrogen-rich fuel from the gasification plant, and natural gas as a backup fuel; a heat recovery steam generator (HRSG) with duct firing on a combination of hydrogen-rich fuel and Pressure Swing Adsorption (PSA) off-gas; and a condensing steam turbine-generator.

The Manufacturing Complex is an integrated complex that will produce approximately 1 million tons per year of nitrogen-based fertilizer. Process units used in producing the low-carbon, nitrogen-based fertilizer are the PSA, Carbon Dioxide Purification, and Compression, Ammonia Synthesis, Urea, Urea Pastillation and Storage, Nitric Acid, Ammonium Nitrate, UAN Units, and associated utilities.

The operational emissions from the Project are mainly generated from the combustion of the hydrogen-rich fuel in the Combined Cycle Power Block. Other emission sources are outlined in Table 3. Each emission source can be categorized as part of the Power Block, Gasification Block, Manufacturing Complex, or ancillary equipment as shown in Table 3. Annual emissions from the operation of the sources listed in Table 3 are presented in Table 4.

Table 3
Operational NSR Permitted Emissions Sources

Power Block	Gasification Block	Manufacturing Complex	Ancillary Equipment
• Combustion Turbine (MHI 501GAC®) • Power Block Cooling Tower	• Coal Dryer • Auxiliary Boiler • Gasification Flare • Sulfur Recovery Unit (SRU) Flare • Rectisol® Flare • Tail Gas Thermal Oxidizer • Air Separation Unit (ASU) and Process Cooling Towers • CO_2 Vent • Material Handling Dust collection (Feedstock) • Fugitive Leaks from piping	• Nitric Acid Unit • Urea Absorbers • Urea Pastillation • Ammonium Nitrate Unit • Ammonia Synthesis Unit Start-Up Heater • Material Handling Dust collection (Urea) • Fugitive leaks from piping	• Two Emergency Diesel Generators • Emergency Diesel Firewater Pump

Emissions from the operation of the stationary sources at HECA will be permitted through the SJVAPCD under NSR, and therefore are exempt from GCD, and thus are not included in the total General Conformity evaluation emission analysis. These emissions are presented in Table 4 for reference.

4.2.2 Transportation Emissions

The on-site and off-site mobile sources include the trucks and trains delivering feedstock and removing products that would travel from and to the Project Site on a regular basis, plus the worker commuter vehicles. The emissions from these transportation sources are considered indirect emissions, and are required to be included in the General Conformity analysis. Therefore, all the operational transportation-related emissions of the Project were quantified using similar concepts and techniques used in the construction emissions estimations. These emissions were evaluated for the first full year of operation, as this year will have the highest operational emissions, as more stringent transportation related standards and emission controls will be mandated in later years. The emissions presented in Tables 5-8 represent Project refinements since the initial General Conformity Analysis submission in September 2012.

HECA evaluated two alternatives for the transportation of the feedstock and products to and from the Project Site. Alternative 1, the rail alternative, will transport coal to the Project Site along a new industrial railroad spur that will connect the Project Site to the existing SJVRR Buttonwillow railroad line, north of the Project Site. This railroad spur will also be used to transport some HECA products to market. Alternative 2, the truck alternative, would transport coal to an existing transloading facility in Wasco, then transfer it onto trucks for delivery to the Project Site. In Alternative 2, all products would be transported by truck, and the railroad spur would not be developed.

Table 4
Operational Criteria Pollutant Emissions from the NSR Permitted Sources

Pollutant / Equipment	CO	NO_X	PM_{10}	$PM_{2.5}$	SO_2	VOC
	tons per year					
HRSG/CTG	89.0	106.5	54.0	54.0	17.1	15.1
Coal Dryer	12.7	17.0	5.6	5.6	2.8	2.4
Auxiliary Boiler	8.6	1.4	1.2	1.2	0.5	0.9
Tail Gas Thermal Oxidizer	11.2	13.4	0.4	0.4	8.3	0.3
CO_2 Vent	124.1	N/A	N/A	N/A	N/A	2.4
Gasification Flare	18.5	2.5	0.03	0.03	0.02	0.01
Rectisol Flare	0.8	0.7	0.03	0.03	0.3	0.01
SRU Flare	0.2	0.1	0.006	0.006	0.4	0.003
Cooling Towers[1]	N/A	N/A	25.5	15.3	N/A	N/A
Emergency Generators[2]	0.8	0.2	0.02	0.02	0.001	0.1
Fire Water Pump	0.2	0.09	0.001	0.001	0.0003	0.01
Nitric Acid Unit	N/A	17	N/A	N/A	N/A	N/A
Urea Pastillation Unit	N/A	N/A	0.2	0.2	N/A	N/A
Ammonium Nitrate Unit	N/A	N/A	0.8	0.8	N/A	N/A
Ammonia Start-Up Heater	0.14	0.04	0.02	0.02	0.01	0.02
Material Handling[3]	N/A	N/A	2.3	2.3	N/A	N/A
Fugitives	6.0	0.005	0.1	0.03	0.1	16.7
Total Annual Emissions[4]	**272.1**	**158.8**	**90.2**	**79.9**	**29.5**	**38.0**

Notes:
1 Includes contributions from all three cooling towers
2 Includes contributions from both emergency generators
3 Material handling emissions are shown as the contribution of all dust collection points.
Total annual emissions represent the maximum annual emissions during operations plus start-up and shut-down emissions
HRSG = Heat Recovery Steam Generator
CTG = combustion turbine generator
CO = carbon monoxide
N/A = not applicable
NO_X = nitrogen oxides
PM_{10} = particulate matter less than 10 microns in diameter
$PM_{2.5}$ = particulate matter less than 2.5 microns in diameter ($PM_{2.5}$ is assumed to equal PM_{10})
SO_2 = sulfur dioxide
VOC = volatile organic compound

The main difference between Alternatives 1 and 2 is the approximately 5-mile railroad spur that would connect the Project Site to the existing SJVRR Buttonwillow railroad line, north of the Project Site, would not be built would not be built under Alternative 2; thus, no feedstock or product would be transported to or from the Project Site via train. The coal would still be transported from New Mexico via train, but would be offloaded at the transloading facility in Wasco, then trucked to the Project Site. There would be no changes to the stationary sources.

Detailed operational emission estimation techniques are described below for Alternatives 1 and 2, separately. The detailed calculations can be found in Appendices B and C for Alternatives 1 and 2, respectively.

Alternative 1

The petcoke trucks will enter the Project Site from Station Road, at Tupman Road, and then proceed south to the truck-unloading station. At the truck-unloading area, each truck will idle for no more than 5 minutes while unloading, and then loop back around through the truck scales and wash rack to exit the Project Site onto Station Road. The product trucks and trains are loaded in the product loading area in the center of the Project Site. The product trucks will also enter and exit the Project Site from Station Road at Tupman Road, and pass through the truck scales and wash rack.

Coal will be transported to the Project Site by train, and a portion of the product will be transported off-site via train. The trains will enter and exit the northwestern corner of the Project Site near Dairy Road and Adohr Road. The train feedstock unloading and product loading stations will be located in the center of the Project Site. In addition to the feedstock and product trains, there will be one dedicated switching engine on site to move either the feedstock or product rail cars.

Emissions associated with the truck movement were calculated using heavy-heavy duty diesel truck emission factors for all trucks, except the operations and maintenance trucks, which were calculated with the light-heavy-duty gasoline and diesel emission factors from EMFAC2007. EMFAC2007 factors vary depending on the calendar year for which the model is run, because the emission factors reflect adopted CARB engine and fuel standards, and are also based on the vehicle fleet age and composition. The vehicle fleet used by EMFAC2007 is based on an analysis of California Department of Motor Vehicles (DMV) registration data, which vary by calendar year and geographic area. Thus, EMFAC2007 runs for earlier calendar years will produce higher emission factors because of older, higher-polluting vehicles still in the vehicle fleet. In addition, the anticipated Project commercial operation date is late 2017. HECA has committed to use a fleet mix of delivery trucks that meets the emission standards from 2010; thus, EMFAC2007 emissions factors for the fleet vehicles for calendar year 2010 were used here in the operational emission calculations.

The fleet mix of line-haul engines that will be used to move feedstock and products for HECA will meet or exceed the U.S. EPA Tier 2+ or 3 standards. Tier 2+ engines are remanufactured engines that meet the revised 2008 standards, and have the same emission limits as new Tier 3 engines. The emissions factors for criteria pollutants for line-haul and switch locomotives were obtained from the U.S. EPA document "Technical Highlights: Emission Factors for Locomotives" for Tier 2+ or 3 engines (U.S. EPA, 2009). The trains' emissions were calculated by multiplying the locomotive emission factors by the numbers of locomotive engines, hours of operations, horsepower, and engine load factor.

On-site feedstock and product train emissions were calculated on the basis that the line-haul engines will operate in Notch 1 or idling mode while on-site; therefore, emissions were conservatively estimated for Notch 1 horsepower. The percentage of total engine horsepower used at Notch 1 was obtained from the "Port of Long Beach Air Emissions Inventory for 2007" (Port of Long Beach, 2010), which was based on data derived from the U.S. EPA (U.S EPA, 1998). Emissions from the switching engine were based on U.S. EPA Tier 3 emission factors and maximum switching engine horsepower of 260 hp.

The off-site feedstock transportation-related emissions are associated with coal transportation by rail, and petcoke transportation by truck. The Project will gasify a blend of 75 percent coal and 25 percent petcoke to produce a hydrogen-rich gas that will be used to produce low-carbon nitrogen-based fertilizer and electricity in a Combined Cycle Power Block. Western sub-bituminous coal will be supplied from mines in New Mexico and transported by rail. The coal trains will travel through New Mexico, Arizona, Mojave Desert Air Quality Management District (MDAQMD), and Eastern Kern Air Pollution Control District (EKAPCD), to the HECA facility in SJVAPCD. Off-site feedstock and product train exhaust emissions were calculated based on an average locomotive load factor from the Port of Long Beach study. Off-site exhaust emissions are based on an average travel speed of 40 miles per hour and the distance of the train route. Empty trains require 76 percent of the horsepower that full trains require.

Fugitive dust emissions from coal trains were calculated using AP-42, Section 13.2.5, Industrial Wind Erosion. Emissions were calculated based on a train speed of 40 miles per hour, the average exposed area of coal in each car, the expected number of coal cars travelling to the Project Site per year, and roughness parameters (roughness height, z_0, and threshold friction velocity, u_t*) appropriate for coal (from AP-42). It has been assumed that all emitted particulate matter will be lost during the first 100 miles of the trip; therefore all particulate matter emissions have been assigned to transportation emissions in New Mexico.

Petcoke most likely will be supplied from refineries in the Los Angeles or Santa Maria areas and transported by trucks. Therefore, the petcoke trucks will travel in SJVAPCD and South Coast Air Quality Management District (SCAQMD).

As a polygeneration facility, the Project is designed to produce several types of products. The products and byproducts that will be shipped off site by either truck or train include:

- Degassed liquid sulfur: Most of the sulfur will be transported by truck to existing buyers, but some will also be transported by rail (approximately 75 percent by truck and 25 percent by rail). Rail is expected to travel on routes only within SJVAPCD, and trucks would travel in both SJVAPCD and SCAQMD.
- Gasification solids: Most of the gasifier solids will be transported by rail for beneficial reuse by regional industries. A smaller portion can be transported to nearby industries by truck. It is estimated that movements would be approximately 75 percent by rail and 25 percent by truck. Rail is expected to travel on routes in SJVAPCD, EKAPCD, and MDAQMD; and trucks would travel within SJVAPCD.
- Urea pastilles: Urea pastilles are small, solid “pellets” of urea. The estimated movements are 75 percent by rail and 25 percent by truck. Rail is expected to travel through SJVAPCD, Sacramento Metro area, Yuba City-Marysville area, Chico area, and other areas in northern California. Trucks would be routed only within SJVAPCD.
- UAN: The UAN solution is expected to be sold to regional users. The estimated movements are 50 percent by rail and 50 percent by truck. Both rail and trucks would be routed only within SJVAPCD.

In addition, trucks carrying the zero-liquid-discharge solids and miscellaneous equipment and supplies would travel to and from the Project Site to various facilities in Kern County. All truck and train routes are calculated to be round-trip routes, and are differentiated by the air basin in which they occur to aid in the conformity evaluation calculations, which are presented in Appendix B. For purposes of the General Conformity evaluation, it should be noted that not all of the affected air districts are nonattainment or maintenance for the same pollutants. Because the General Conformity Rule does not apply to attainment areas, only emissions generated in nonattainment or maintenance areas were calculated.

As expected, the majority of the transportation-related emissions are in the SJVAB. The Project-related transportation emissions in this air basin, as well as in the other Project-affected nonattainment or maintenance areas, are summarized in Table 5. The detailed on-site and off-site transportation emission calculations are included in Appendix B.

Alternative 2

Under the truck alternative, coal would be transported via existing roads from the existing coal transloading facility in Wasco. Under this alternative, the on-site railroad spur would not be developed. Therefore, there would be no trains on-site for feedstock delivery or product removal. All products would be transported by truck.

Compared to Alternative 1, the coal train under Alternative 2 will travel approximately 7 more miles extra in SJVAPCD in order to get to the transloading facility. The coal truck route distance from the transloading facility in Wasco to HECA is 26.5 miles. All product truck routes will remain the same as Alternative 1, with increased truck volume to account for the lack of trains. Emissions were estimated for the on-site and off-site vehicles transporting feedstock and products. Emission factors and calculation techniques described in Alternative 1 were also used to estimate the emissions from the vehicles for Alternative 2.

Table 6 presents the on-site and off-site transportation emissions of criteria pollutants for Alternative 2 in all Project-affected nonattainment or maintenance areas. Detailed transportation emissions and calculations for Alternative 2 are included in Appendix C.

4.3 CONSTRUCTION AND OPERATION OVERLAP YEAR EMISSIONS

Commercial operation of the HECA Project will start in late 2017, and the construction phase of the Project is expected to end in 2017. Therefore, during 2017, both construction and operation activities are expected to occur. To estimate the construction and operation overlap year emissions, the full-year operational emissions were scaled to 4 months, and resulting emissions were added to the 2017 construction emissions. Because there are no construction emissions outside of the SJVAB, and operational emissions in all other nonattainment and maintenance areas are less than the General Conformity thresholds, only emissions in SJVAB are presented in Tables 7 and 8. These tables show the estimated construction and operation overlap year emissions in the SJVAB for Alternatives 1 and 2, respectively. Detailed transportation emissions and calculations for Alternatives 1 and 2 are included in Appendices B and C, respectively.

VOC = volatile organic compound

The general conformity applicability reviews for Alternatives 1 and 2 from HECA are presented below in Tables 9 and 10, respectively. These tables summarize and compare the emissions by year associated with the HECA Project, with the different applicable General Conformity *de minimis* thresholds in each of the affected nonattainment and maintenance areas.

As shown in Tables 9 and 10, for both Alternatives 1 and 2, the annual emissions from the HECA Project are below the applicable General Conformity *de minimis* thresholds for CO, PM_{10}, $PM_{2.5}$, and SO_2 for each year of construction, construction and operation overlap, and operation, in all nonattainment and maintenance areas. Construction emissions of NO_x exceed the General Conformity *de minimis* threshold each year of construction in the SJVAB. Construction emissions of VOC exceed the General Conformity *de minimis* threshold in years 2014 and 2015 of construction in the SJVAB. Operational emissions of NO_x exceed the General Conformity *de minimis* threshold each year of operation in the SJVAB. NO_x emissions also exceed the General Conformity *de minimis* threshold during the construction and operation overlap year. Therefore, a GCD is required for NO_x for construction and operation in the SJVAB. A GCD in the SJVAB is also required for VOC during construction.

Notes:
CO = carbon monoxide
NA = Not Applicable
NOX = nitrogen oxides
PM10 = particulate matter less than 10 microns in diameter
PM2.5 = particulate matter less than 2.5 microns in diameter (PM2.5 is assumed to equal PM10)
SO2 = sulfur dioxide
VOC = volatile organic compound

As indicated in Section 5, a GCD is required for NO_x for construction and operation, and for VOCs during construction in the SJVAB, for both Alternatives 1 and 2.

According to the U.S. EPA and U.S. DOE General Conformity Guidance, a full GCD is only required for the federal agency approved alternative. As of the writing of this GCD report, the U.S. DOE has not approved an alternative yet. Therefore, a General Conformity evaluation was conducted for both alternatives. Both Alternatives 1 and 2 have identical NO_x and VOC construction emissions for all calendar years of the construction phase. NO_x emissions during the construction and operation overlap year and the operation years are different for Alternatives 1 and 2. Alternative 2 NO_x emissions are higher than those of Alternative 1 in SJVAB, although both Alternatives are greater than the GCD threshold for all years. Regardless of the Alternative, HECA has identified the criteria and options that can be used to demonstrate that the federal action conforms to the applicable SIP.

The SJVAPCD staff was consulted, and it was determined that the adopted 2007 8-hour O_3 plan does not include HECA construction or operational direct or indirect emissions in the emission inventory, nor do the growth forecasts account for the emissions from HECA. Therefore, to achieve General Conformity for the HECA project, it is necessary to incorporate the HECA emissions in the next SIP revision, develop additional positive mitigation measures, or obtain emissions offsets in the SJVAB.

SJVAPCD staff recommended that the Project emissions of NO_x and VOC be fully offset through the SJVAPCD's Emission Reduction Incentive Program (ERIP). The ERIP is a thoroughly audited and highly respected grant-based program that contracts with third parties receiving grant funds to implement emission reduction projects, and then assures tracks and enforces those reductions. The SJVAPCD serves as both the administrator of the projects and the verifier of the emission reductions. Examples of projects funded in the past include electrification of stationary internal combustion engines; replacement of old heavy-duty trucks with new, cleaner trucks; and replacement of old farm tractors. The SJVAPCD will fund projects within the SJVAB that will produce real, quantifiable, enforceable, and surplus emission reductions, contemporaneously with Project emission increases.

Therefore the Project has entered into an enforceable commitment with the SJVAPCD to participate in the ERIP. A copy of the Mitigation Agreement setting forth this commitment is attached as Appendix D. The HECA Project's participation in the ERIP will provide pound-for-pound offsets of emissions that exceed the General Conformity thresholds to offset all emissions subject to General Conformity down to zero. The offsets will cover NO_x emissions during all years of construction and operations, as well as VOCs during all years of construction, as the threshold is exceeded in 2014 and 2015. The required offsets will be based on the maximum potential emissions for either Alternative 1 or 2. Through this mechanism, construction and operational emissions of NO_x and VOC from the Project which exceed the General Conformity thresholds will be fully offset and the federal action will conform to the SIP pursuant to Title 40, Code of Federal Regulations, Part 93, Subpart B, Section 93.158(a)(2) and/or Section 93.158(a)(5)(iii). An explanation of the basis of the fees to be paid into the ERIP is provided below.

Emission fees to be paid by HECA into the ERIP are based on the SJVAPCD's Indirect Source Control (ISR) rule, Rule 9510, and include a 4% administration fee to cover SJVAPCD costs related to contracting and enforcing the actual emission reductions resulting from the ERIP. The amount of the fee for both NO_x and VOC emissions is \$9,350 per ton per year. Based on the emissions information presented in Section 5 above, the amount of the fees to be paid by HECA into the ERIP is presented in Table 11.

Table 11
ERIP Conformity Mitigation Fee

Emissions Subject to General Conformity Mitigation					
	NOx	VOC	Mitigation Fee[1]	Administration Fee[2]	
HECA Project	(tpy)	(tpy)	($/ton)		Cost
Construction (total)	243.6	39.5	9,350	4%	$ 2,752,864
Operations (max year)[3]	43.6	0	9,350	4%	$ 4,238,692
Total:					**$ 6,991,556**

Notes:

1. Mitigation Fee defined in SJVAPCD Rule 9510 (ISR)
2. Administration Fee set forth in SJVAPCD Rule 3180
3. Construction emissions are the same in both Alternatives; for Operational emissions, the higher emissions from Alternative 2 have been used.

As required by 40 CFR 93 Subpart B, an evaluation of the General Conformity was performed for the HECA Project for all the affected nonattainment and maintenance areas in the states of California, Arizona, and New Mexico. Criteria pollutant emissions generated in each Project-affected area from activities associated with the Project construction and operation were calculated and compared to the General Conformity *de minimis* thresholds to assess whether a GCD is required.

The estimated emissions indicate that the total direct and indirect construction and operational emissions of CO, PM_{10}, $PM_{2.5}$, and SO_2 are below the applicable General Conformity thresholds for all years of construction and operation in all nonattainment and maintenance areas. Construction and operational emissions of NO_x exceed the General Conformity threshold during construction and operation in the SJVAB. Construction emissions of VOC exceed the General Conformity threshold in the SJVAB. Thus a GCD for NO_x for during construction and operation and for VOC during construction in the SJVAB is required.

The Project has entered into an enforceable commitment with the SJVAPCD to participate in its Emission Reduction Incentive Program (ERIP). The HECA Project's participation in the ERIP will provide pound-for-pound offsets of emissions that exceed the General Conformity thresholds to offset all emissions subject to General Conformity down to zero. The offsets will cover NO_x emissions during all years of construction and operations, as well as VOCs during all years of construction, as the threshold is exceeded in 2014 and 2015. Through this mechanism, construction and operational emissions of NO_x and VOC from the Project which exceed the General Conformity thresholds will be fully offset and the federal action will conform to the SIP pursuant to Title 40, Code of Federal Regulations, Part 93, Subpart B, Section 93.158(a)(2).

Notes:

1. According to schedules provided by Fluor, Linear construction (except rail) takes place in months 11-22.
2. According to schedules provided by Fluor, Rail construction occurs in months 13-17.
3. According to schedule on "onsite equipment" tab, site prep/pilling occurs in months 1-8. Assume onsite covered storage piles are only present during these months.
4. Assume linear covered storage piles are present during entire 12 months of linear construction, months 11-22.

Hydrogen Energy California, Kern County Power Project
PM2.5 Emissions by Month - from Fugitive Sources

Notes:

1. According to schedules provided by Fluor, Linear construction (except rail) takes place in months 11-22.
2. According to schedules provided by Fluor, Rail construction occurs in months 13-17.
3. According to schedule on "onsite equipment" tab, site prep/pilling occurs in months 1-8. Assume covered storage piles are only present during these months.
4. Assume linear covered storage piles are present during entire 12 months of linear construction, months 11-22.

Onsite distance for worker vehicles based on parking areas of 100m x 250 m. Assume average one way trip is 175m, round trip of 350 m, or 0.22 miles.
Emission factors from EMFAC2007 (version 2.3) for year 2010
Emission factors for personal commuting vehicles are based on the assumption 50% LDA and 50% LDT
CH_4 and N_2O emission factor for personal commuting vehicles is based on the average factor for gasoline and diesel passenger vehicles from CCAR, GRP Version 3.0, Table C.5
CH_4 and N_2O emission factor for light delivery trucks is based on the factor for diesel light duty trucks from CCAR, GRP Version 3.0, Table C.5
CH_4 and N_2O emission factor for heavy duty tucks is based on the factor for diesel heavy duty trucks from CCAR, GRP Version 3.0, Table C.5

Number of workers per commuter vehicle = 1.3
Actual worker schedule data updated 4/3/12 with data from Table 2-28 HECA Manpower R5 04 02 12.xls
Vehicle occupancy rate is based on information from Section 2.0 Project Description.

Assumptions:
Assumed average distance traveled off site for all employees commuting will be 20 miles
times 2 for return trip = 40 miles
22 days per month of construction, average

CO_2 GWP (SAR, 1996) = 1
CH_4 GWP (SAR, 1996) = 21
N_2O GWP (SAR, 1996) = 310

Hydrogen Energy California, Kern County Power Project
Onsite Fugitive Dust Emissions
1/29/2013

ASSUMPTIONS:
1 month of dirt moving
22 construction days per month
10 construction hours per day
19 M, moisture content of surface material (%) (average of soil borings taken onsite at 5 ft)
50 s, silt content of surface material (%) (from soil boring B-4)

Dirt Piling or Material Handling

$E = k * 0.0032 * (U/5)^{1.3} / (M/2)^{1.4}$ USEPA AP42 Chapter 13.2.4 (Aggregate Handling And Storage Piles)

0.35 k for PM_{10}
0.053 k for $PM_{2.5}$
6.25 U = Mean Wind speed (mph) average for Bakersfield Airport 2000-2004
19 M = Moisture content of surface material (%)
0.00006 lb of PM_{10}/ ton of material
0.00001 lb of $PM_{2.5}$/ ton of material

Do not include capacity factor because emissions are based on material handled.

6,136 yd^3/day 7,241 ton/day 2,360 density of soil (lb/yd^3)
135,000 yd^3 159,300 tons (USDA NRCS Physical Soil Properties from Kern County for Lockern-Buttonwillow clay)

Excavation 850,000 Cubic yds
Imported Fill 500,000 Cubic yds (assume 10% of entire site in any given month; with equipment present over 35 months, this is a conservative estimate of the max amount of material handled)

Scraping Emissions Factor - Topsoil Removal by Scraper

E = 0.058 lb TSP/ton material handled USEPA AP42 Chapter 11.9 (Western Surface Coal Mining), Table 11.9-4
Material 850,000 cubic yards, total excavation
0.31 fraction of total excavation handled by scrapers 0.31 <-- fraction of all earth moving equipment in months 1-7 that are scrapers
1705 cubic yards per day, for all scrapers, based on 7 months of scrapers
2012 tons/day

TSP 116.7 lb TSP/day
fraction of TSP that is PM10 0.489 from CEIDARS database for construction fugitives
fraction of TSP that is PM2.5 0.102 from CEIDARS database for construction fugitives
PM10 57.1 lb/day
PM2.5 11.9 lb/day
Mitigation for watering 61% (the emission factor does not account for soil moisture)
Mitigated PM10 22.3 lb/day
Mitigated PM2.5 4.6 lb/day

Scrapers in Travel **AP42 Table 11.9-1 (from Table 13.2.3-1)**

$E = 0.051(S)^{2.0}$ for particles ≤ 15 um USEPA AP42 Chapter 13.2.3 (Heavy Construction Operations), Table 13.2.3-1 - refers to
$E = 0.040(S)^{2.5}$ for TSP ≤ 30 um USEPA AP42 Chapter 11.9 (Western Surface Coal Mining), Table 11.9-1

multiply by 0.60 for PM_{10}
multiply TSP equation by 0.031 for $PM_{2.5}$
S = mean vehicle speed (mph)
S = 15.0 mph COC will limit vehicles to 15 mph onsite
34.86 lb ≤ 30 μm/VMT
11.48 lb ≤ 15 μm/VMT
PM_{10} = 6.89 lb PM_{10}/VMT
$PM_{2.5}$ = 1.08 lb $PM_{2.5}$/VMT
Mitigated PM_{10} = 2.69 lb PM_{10}/VMT
Mitigated $PM_{2.5}$ = 0.42 lb $PM_{2.5}$/VMT

Equipment	Daily VMT	Mitigation Efficiency[1]	PM10 Emissions (lb/day)	PM2.5 Emissions (lb/day)
Excavator - Earth Scraper 637	0.9	61%	2.4	0.38

Formula based on lbs per VMT, not hours, so no capacity factor included.

Scrapers Unloading

AP42 Table 11.9-4

0.04 lb TSP / ton material
2012 tons material handled per day
80.5 lb TSP /day

fraction of TSP that is PM10 0.489 from CEIDARS database for construction fugitives
fraction of TSP that is PM2.5 0.102 from CEIDARS database for construction fugitives

PM10 39.4 lb PM10/day
PM2.5 8.2 lb PM2.5/day
Mitigation 61%

Mitigated PM10 15.3 lb PM10/day
Mitigated PM2.5 3.2 lb PM2.5/day

Hydrogen Energy California, Kern County Power Project
Onsite Fugitive Dust Emissions
1/29/2013

Grading Emissions Factor — **To be used for all grading activities**

$E = 0.051(S)^{2.0}$ for particles ≤ 15 um — USEPA AP42 Chapter 13.2.3 (Heavy Construction Operations), Table 13.2.3-1 - refers to
$E = 0.040(S)^{2.5}$ for TSP ≤ 30 um — USEPA AP42 Chapter 11.9 (Western Surface Coal Mining), Table 11.9-1

multiply PM15 equation by 0.60 for PM_{10}
multiply TSP equation by 0.031 for $PM_{2.5}$
S = mean vehicle speed (mph)
S = 5.5 mph — the Cat Motor Grader Application Guide states typical operation speed is 4-7 mph; take midpoint of 5.5 mph
2.84 lb ≤ 30 μm/VMT
1.54 lb ≤ 15 μm/VMT
PM_{10} = 0.93 lb PM_{10}/VMT — percent of day operational: 0.5
$PM_{2.5}$ = 0.09 lb $PM_{2.5}$/VMT — VMT: 27.5
Mitigated PM_{10} = 0.36 lb PM_{10}/VMT
Mitigated $PM_{2.5}$ = 0.03 lb $PM_{2.5}$/VMT

Equipment	Daily VMT	Mitigation Efficiency[1]	PM10 Emissions (lb/day)	PM2.5 Emissions (lb/day)
Excavator - Motor Grader (CAT140H)	27.500	61%	9.928	0.943
		Total	**9.93**	**0.94**

Formula based on lbs per VMT, not hours, so no capacity factor included.

Bulldozing/Earth clearing

$E = 1.0(s)^{1.5}/(M)^{1.4}$ for particles ≤ 15 um — USEPA AP42 Chapter 13.2.3 (Heavy Construction Operations), Table 13.2.3-1 - refers to
$E = 5.7(s)^{1.2}/(M)^{1.3}$ for TSP ≤ 30 um — USEPA AP42 Chapter 11.9 (Western Surface Coal Mining), Table 11.9-1, 11.9-3

multiply PM15 equation by 0.75 for PM_{10}
multiply TSP equation by 0.105 for $PM_{2.5}$
50 s = Silt content (%)
19 M = Moisture content of surface material (%)
4.30 lb/hr of PM_{10}
1.42 lb/hr of $PM_{2.5}$
4.30 lb/hr of PM_{10} (mitigated)
1.42 lb/hr of $PM_{2.5}$ (mitigated)

Equipment	Hours per day	Activity Factor	Mitigation Efficiency[1]	PM10 Emissions (lb/hr)	PM10 Emissions (lb/day)	PM2.5 Emissions (lb/hr)	PM2.5 Emissions (lb/day)
Bulldozer D10R	6	100.0%		4.30	25.79	1.42	8.54
Bulldozer D6C	6	100.0%		4.30	25.79	1.42	8.54
			Total	**8.60**	**51.58**	**2.85**	**17.09**

Covered Storage Piles

SCAQMD Table A9-9-E
E = 1.7 * G/1.5 * (365-H)/235 * I/15 * J
PM10 Emission factor from wind erosion of storage piles per day per acre
50 G = Silt content (%)
37 H = Mean number of days per year with at least 0.01 inches of precipitation (from WRCC for Bakersfield Airport Station)
0.3 I = Percentage of time that the unobstructed wind speed exceeds 12 mph at mean pile height (wind speed percentage and average based on 2000-04 (5 yrs) of wind speed data as recorded at Bakersfield Airport station)
0.5 J = Fraction of TSP that is PM_{10} = 0.5
0.791 lb PM_{10}/acre/day
0.08 Mitigated lb PM_{10}/acre/day

Source	Quantity	Size of Pile (acre)	Hours/Day	Mitigation Efficiency[1]	PM10 Emissions (lb/hr)	PM10 Emissions (lb/day)	PM2.5 Emissions (lb/hr)	PM2.5 Emissions (lb/day)
Cover Storage Pile	25	0.25	24	90%	0.02	0.49	0.004	0.103

Pile size and number are assumed
Assume PM2.5 is 20.8% of PM10

Hydrogen Energy California, Kern County Power Project
Onsite Fugitive Dust Emissions
1/29/2013

Travel onsite - paved and unpaved roads

USEPA AP42 Chapter 13.2.2 (Unpaved Roads)

E = k * (s/12)^a * (W/3)^b

Size specific emission factor for vehicle travel on unpaved roads at industrial sites (eqn 1a; lb/VMT)

Constants:	PM2.5	PM10	TSP
k (lb/VMT)	0.15	1.5	4.9
a	0.9	0.9	0.7
b	0.45	0.45	0.45

4 s = Surface material silt content (%) (value for gravel road)
50 s = Surface material silt content (%) (value for dirt surfaces)
value listed in table W = Mean vehicle weight (ton) * weighted mean based on monthly equipment schedule in "onsite equipment" tab

AP 42 13.2.1 Paved Roads, updated January 2011

For a daily basis,
E = [k (sL)^0.91 x (W)^1.02](1-P/4N) equation (2)

	SOURCE
P = number of "wet" days with at least 0.254 mm (0.01 in) of precipitation during the averaging period	Days/year Buttonwillow Station 1940-2011, WRCC
W = average weight (tons) of vehicles traveling the road	"Avg vehicle weight" tab
k = particle size multiplier for particle size range and units of interest	Values from Table 13.2.1-1, PARTICLE SIZE MULTIPLIERS FOR PAVED ROAD EQUATION
sL = road surface silt loading (g/m^2)	Default value from URBEMIS 9.2 for Kern County
N = number of days in the averaging period	

	P	**k**	**sL**	**N**
	#	**lb/VMT**	**g/m2**	**#**

Mitigation Measure[1]	Control Efficiency	
Apply water every three hours to disturbed surfaces[3]	61%	
Traffic speeds on all unpaved roads to be reduced to 15 mph or less	57%	
Apply chemical dust suppressant annually to unpaved parking areas/disturbed areas	84%	*CEC stated in the background to DR A132 that they will be requiring the use of soil binders on all onsite unpaved roads, including gravel
Combined Mitigation Efficiency - reduced speed + suppressants	**93%**	
Combined Mitigation Efficiency - reduced speed + watering	**83%**	
Water the storage pile by hand or apply cover when wind events are declared.	90%	

Notes:

1. Mitigation efficiencies from SCAQMD Table XI-A and Table XI-E (South Coast Air Quality Management District, Air Quality Analysis Handbook (under development), accessed at http://www.aqmd.gov/ceqa/handbook/mitigation/fugitive/MM_fugitive.html).
2. Equipment weight from SCAQMD Table A9-9-D-3 and various websites.
3. Water trucks operate at least 4 times per day.

Hydrogen Energy California, Kern County Power Project
Off-Site Linears Fugitive Dust Emissions
1/29/2013

ASSUMPTIONS:
12 months of soil disturbance
10 total construction hours per work day
22 construction days per month

Dirt Piling or Material Handling

E = k * (0.0032) * (U/5)^1.3 / (M/2)^1.4 PM Emissions from Dirt Piling or Material Handling (lb/ton) from USEPA AP42, Chapter 13.2.4 (Aggregate Handling and Storage Piles)

0.053 k for PM2.5
0.35 k for PM10
6.25 U = Mean Wind speed (mph) average for Bakersfield Airport 2000-2004
15 M = Moisture content of surface material (%) (from SCAQMD Table A9-9-G-1 for moist dirt)
0.00001 lb of $PM_{2.5}$/ ton of material
0.00009 lb of PM_{10}/ ton of material

Potable water pipeline	1.2	10	63360	1.45
Railway	5.3	60	1679040	38.54
Sources:			TOTAL:	**252.11**

Lengths: email from William Becktel, 3/26/12
ROW Width: Table 2-01 March 20 from Fluor.doc

Assume tons/day of material is evenly split among the number of pieces of equipment operating in a given month.
Do not include capacity factor because emissions are based on material handled, not hours of operation.

4622 yd^3/day   5454 ton/day
1,220,222 yd^3 1,439,862 tons   2360 density of soil (lb/yd^3)
(USDA NRCS Physical Soil Properties from Kern County
Lockern-Buttonwillow clay soil)
252.11 acres =   1,220,222 cubic yds, assume depth of soils moved is   1 yd

Scraping Emissions Factor

E = 0.058 lb/ton material handled   USEPA AP42 Chapter 11.9 (Western Surface Coal Mining), Table 11.9-4
Material 1,220,222 cubic yards, total excavation
0.17 fraction of total excavation handled by scrapers   0.17 <-- fraction of all earth moving equipment in months 11-22 that are scrapers
4622 cubic yards per day, for all scrapers, based on two months of scrapers in use
5454 tons/day

TSP 316.3 lb TSP/day
fraction of TSP that is PM10 0.489 from CEIDARS database for construction fugitives
fraction of TSP that is PM2.5 0.102 from CEIDARS database for construction fugitives
PM10 154.7 lb/day
PM2.5 32.3 lb/day
Mitigation for watering 61% (the emission factor does not account for soil moisture)
Mitigated PM10 60.3 lb/day
Mitigated PM2.5 12.6 lb/day

Grading Emissions Factor   To be used for all scraping and grading activities

$E = 0.051(S)^{2.0}$ for particles ≤ 15 um   USEPA AP42 Chapter 13.2.3 (Heavy Construction Operations), Table 13.2.3-1 - refers to
$E = 0.040(S)^{2.5}$ for TSP ≤ 30 um   USEPA AP42 Chapter 11.9 (Western Surface Coal Mining), Table 11.9-1

multiply by 0.60 for PM_{10}
multiply TSP equation by 0.031 for $PM_{2.5}$
S = mean vehicle speed (mph)

S = 5.5 mph   the Cat Motor Grader Application Guide states typical operation speed is 4-7 mph; take midpoint of 5.5 mph
2.84 lb ≤ 30 μm/VMT
1.54 lb ≤ 15 μm/VMT
PM_{10} = 0.93 lb PM_{10}/VMT
$PM_{2.5}$ = 0.09 lb $PM_{2.5}$/VMT

Equipment	Daily VMT	Mitigation Efficiency[1]	PM10 Emissions (lb/day)	PM2.5 Emissions (lb/day)
CAT MODEL 12 MOTOR GRADER	27.5	61%	9.928	0.943
		Total	**9.93**	**0.94**

* mileage based on assumed maximum for scrapers in CalEEMod calculations

Formula based on lbs per VMT, not hours, so no capacity factor included.

Off-Site Linears Fugitive Dust Emissions
1/29/2013

Storage Piles
SCAQMD Table A9-9-E
E = 1.7 * G/1.5 * (365-H)/235 * I/15 * J
PM10 Emission factor from wind erosion of storage piles per day per acre

50 G = Silt content (%) (from Geotechnical Investigaion, AFC Appendix P)
37 H = Mean number of days per year with at least 0.01 inches of precipitation (from WRCC for Bakersfield Airport Station)
0.3 I = Percentage of time that the unobstructed wind speed exceeds 12 mph at mean pile height (based on 2000-04 (5 yrs) of wind speed data as recorded at Bakersfield Airport station)
0.5 J = Fraction of TSP that is PM_{10} = 0.5
0.791 lb/acre/day

Source	Quantity	Size of Pile (acre)	Mitigation Efficiency[1]	PM_{10} Emissions (lbs/day)	$PM_{2.5}$ Emissions (lbs/day)
Storage Piles	8	0.25	90%	0.16	0.033

Pile size and number are assumed
Days per year accounts for weekend days also, not just work days
Assume PM2.5 is 20.8% of PM10

Travel on unpaved roads
E = k * (s/12)^a * (W/3)^b — USEPA AP42 Chapter 13.2.2 (Unpaved Roads)
Size specific emission factor for vehicle travel on unpaved roads at industrial sites (eqn 1a; lb/VMT)

Constants:	PM2.5	PM10	TSP
k (lb/VMT)	0.15	1.5	4.9
a	0.9	0.9	0.7
b	0.45	0.45	0.45

4 s = Surface material silt content (%) (value for gravel road)
value listed in tableW = Mean vehicle weight (ton)

Vehicle Type	Round Trips /Day/ Unit	Round Trip Distance on Dirt Surface (mile)	Mean Vehicle Weight (tons)[2]	PM2.5 EF[5] (lbs/VMT)	PM_{10} EF (lbs/VMT)	Mitigation Efficiency[1]	If weight = 0, where is source included

Mitigation Measure[1]	Unpaved Roads
Apply water every three hours to disturbed surfaces[3]	61%
Traffic speeds on all unpaved roads to be reduced to 15 mph or less	57%
Combined Mitigation Efficiency	**83%**
Water the storage pile by hand or apply cover when wind events are declared.	90%

Notes:

1. Mitigation efficiencies from SCAQMD Table XI-A and Table XI-E (South Coast Air Quality Management District, Air Quality Analysis Handbook (under development), accessed at http://www.aqmd.gov/ceqa/handbook/mitigation/fugitive/MM_fugitive.html).
2. Equipment weight from SCAQMD Table A9-9-D-3 and various websites.
3. Water trucks operate at least 4 times per day.
4. Assumed maximum travel speed is 5 mph.

5. An emission factor based on mean vehicle weight could not be calculated for the linear equipment since the equipment will be scattered over various linears at different locations. Therefore, emissions remain calculated based on the weight of each piece of equipment; this is a more conservative estimate.

Hydrogen Energy California, Kern County Power Project
Fugitive Dust on Paved Roads
1/29/2013

AP 42 13.2.1 Paved Roads, updated January 2011

For a daily basis,
E = [k (sL)^0.91 x (W)^1.02](1-P/4N) equation (2)

P = number of "wet" days with at least 0.254 mm (0.01 in) of precipitation during the averaging period
W = average weight (tons) of vehicles treaveling the road
k = particle size multiplier for particle size range and units of interest
sL = road surface silt loading (g/m^2)
N = number of days in the averaging period

Notes:

[1] Capacity factors from SCAQMD Table A9-8-D

[2] Assuming ROGs are equivalent to VOCs

- Emission factors for on-road vehicles are based on results from Emfac Emissions Model 2007 Version 2.3 (HHDT-DSL=heavy heavy-duty trucks-diesel; MHD-DSL=medium heavy duty-diesel). EMFAC scenario year was 2010 and the selected area was Kern County. PM_{10} values include break wear and tire wear.

- Emission factors for off-road vehicles are based on output from Offroad 2007, calendar year 2013 for Kern County.

On-Road Vehicles:

- $PM_{2.5}$ Fraction of PM_{10}, Diesel: 0.920

Off-Road Vehicles:

- PM2.5 Fraction of PM10, Diesel: 0.920

- CH_4 and N_2O factors are derived from California Climate Action Registry General Reporting Protocol Version 3.0 (April 2008), Table C.5 for LDT, MHD, and HHD diesel fueled trucks in the San Joaquin Valley Air Basin (MHD =HHD). These emissions are in g/mile. On-road vehicles are limited to 10 mph, which is used to convert to lb/hr. (See GHG Reference Info tab)

- N_2O factors for off-road vehicles are derived from California Climate Action Registry General Reporting Protocol Version 3.0 (April 2008), Table C.5 (distillate fuel factors for the industrial sector) using the following to convert from kg/gallon to lb/hp-hour, and then multiplying by the rated horsepower rating: 1 gallon/137,000 Btu, 7,000 Btu/hp-hour, and 2.2046 lb/kg. CH_4 factors are from the SCAQMD data.

CO_2 GWP (SAR, 1996) =	1
CH_4 GWP (SAR, 1996) =	21
N_2O GWP (SAR, 1996) =	310

Notes:

[1] Capacity factors from SCAQMD Table A9-8-D

[2] Assuming ROGs are equivalent to VOCs

- Emission factors for on-road vehicles are based on results from Emfac Emissions Model 2010 Version 2.3 (LDT-DSL=light duty class II trucks-diesel; HHDT-DSL=heavy heavy-duty trucks-diesel; MHD-DSL=medium heavy duty-diesel). EMFAC scenario year was 2010.

- Emission factors for off-road vehicles are based on output from Offroad 2007, calendar year 2013 for Kern County.
  On-Road Vehicles:
    - $PM_{2.5}$ Fraction of PM_{10}, Diesel: 0.920
  Off-Road Vehicles:
    - PM2.5 Fraction of PM10, Diesel: 0.920

- CH_4 and N_2O factors are derived from California Climate Action Registry General Reporting Protocol Version 3.0 (April 2008), Table C.5 for LDT, MHD, and HHD diesel fueled trucks in the San Joaquin Valley Air Basin (MHD =HHD). These emissions are in g/mile. On-road vehicles are limited to 10 mph, which is used to convert to lb/hr. (See GHG Reference Info tab)

- N_2O factors for off-road vehicles are derived from California Climate Action Registry General Reporting Protocol Version 3.0 (April 2008), Table C.5 (distillate fuel factors for the industrial sector) using the following to convert from kg/gallon to lb/hp-hour, and then multiplying by the rated horsepower rating: 1 gallon/137,000 Btu, 7,000 Btu/hp-hour, and 2.2046 lb/kg. CH_4 factors are from the SCAQMD data.

CO_2 GWP (SAR, 1996) =	1
CH_4 GWP (SAR, 1996) =	21
N_2O GWP (SAR, 1996) =	310

				Less Than Thresholds?	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**
NAAs in State of New Mexico	PM10 Nonattainment - Moderate - Anthony, NM (Dona Ana County) CO Maintenance (Bernalillo County) SO2 Maintenance - Grant Co, NM	NMED-AQB	Entire NMED-AQB jurisdiction area (one way trip: trains = 102 miles to coal mine site)	Offsite Train	1.81		1.40		0.13	
				Offsite Truck	0.00		0.00		0.00	
				Total Emissions	**1.81**		**1.40**		**0.13**	
				Applicable General Conformity *de minimis* Thresholds	**100**		**100**		**100**	
				Less Than Thresholds?	**Yes**		**Yes**		**Yes**	

Notes:

1. The associated emissions from the onsite worker travel are negligible
2. To simplify the analysis, the biggest area among all detailed NAA areas was conservativly used to estimate the emissions in each main NAA category area.
   For State of Arizona and New Mexico the total distances accross each state along the train routes were conservativly used to estimate the emissions in NAA.
3. The distance for trains and trucks are varied depending on the type to materials transporting and their destinations.
4. In MDAQMD, it is important to note that the size of the ozone NAA and PM10 NAA area are different and the ozone NAA is smaller than PM10 NAA. Therefore, the train route (distance) within MDAQMD in ozone nonattainment area is smaller than the distance in PM10 nonattainment area.
5. ACRONYMS AND ABBREVIATIONS
   MDAQMD = Mojave Desert Air Quality Management District
   SCAQMD = South Coast Air Quality Management District
   EKAPCD = East Kern County Air Pollution Control District
   SMAQMD = Sacramento Metro Air Quality Management District
   BCAQMD = Butte County Air Quality Management District
   FRAQMD = Feather River Air Quality Management District
   ADEQ = Arizona Department of Environmental Quality
   NMED-AQB = New Mexico Environment Department - Air Quality Bureau
6. Construction of the project is expected to complete in June 2017 and the operation will start from September. Therefore, the operational emissions were scaled from the entire year of project operation.

Emission Factors For all Locomotives
SOx [3]
g/gal
1.88

Locomotive Application	Conversion Factor (bhp-hr/gal)
Large Line-haul & Passenger	20.8
Small Line-haul	18.2
Switching	15.2

Note:

(1) EPA's Technical Highlights: Emission Factors for Locomotives, 2009 (http://www.epa.gov/nonroad/locomotv/420f09025.pdf).

(2) Line-haul engine emissions of CO, NOx, PM, and HC are based on EPA Tier 2+ and Tier 3 emission factors.

(3) Based on 300 ppm sulfur diesel fuel.

(4) VOC emissions can be assumed to be equal to 1.053 times the HC emissions

(5) $PM_{2.5}$ Fraction of PM_{10}, = 0.97

(6) No off-site switching or idling was assumed for train transportation.

(7) Average line haul locomotive load factor was obtained from Table 5.12 of The Port Of Long Beach - 2007 Air Emissions Inventory (http://www.polb.com/civica/filebank/blobdload.asp?BlobID=6021)

Summary of Truck Emissions - HECA

3/05/2013 revision

Calculations for Trucks Operations

Data Supplied By Client							
Parameter	**Coke Trucks (Max @ 50 or 60 mph)**	**Liquid Sulfur Product Trucks (Max @ 50 or 60 mph)**	**Gasification Product Trucks (Max @ 50 or 60 mph)**	**Ammonia Product Trucks (Max @ 50 or 60 mph)**	**Urea Product Trucks (Max @ 50 or 60 mph)**	**UAN Sulfur Product Trucks (Max @ 50 or 60 mph)**	**Equipment and Miscellaneous Trucks (Max @ 50 or 60 mph)**
	Running Emissions	**Running Emissions**	**Running Emissions**	**Running Emissions**	**Running Emissions**	**Running Emissions**	**Running Emissions**
Distance traveled per truck in San Joaquin Valley, CA (mi)	104	104	160	0	80	80	92
Distance traveled per truck in Los Angeles-South Coast Air Basin, CA (mi)	176	180	0	0	0	0	151
Maximum number of trucks or loads:							
Annual average trucks or loads	15,200	1,020	3,170	0	5,730	9,340	4,690

No off-site idling was assumed for truck transportation.
Distance traveled per truck is based on round-trip.

EMFAC2007 Emission Factors + Fugitive Dust (g/mi) For Truck Model year 2010, Scenario year 2015

Pollutant	Coke and Coal Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	Liquid Sulfur Product Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	Gasification Product Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	Ammonia Product Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	Urea Product Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	UAN Sulfur Product Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	Equipment and Miscelleneous Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)

PM10 *	0.60	0.60	0.60	0.60	0.60	0.60	0.60
PM2.5 *	0.18	0.18	0.18	0.18	0.18	0.18	0.18

EMFAC2007 is the approved federal model for vehicle combustion emissions
* PM10 and PM2.5 includes fugitive dust factor for paved roads obtained from AP-42 Ch. 13 plus PM factors from EMFAC 2007
PM factors from EMFAC = combustion exhaust + tire wear + break wear
The maximum emission factor from either truck speed at 50 mph or 60 mph was used.
Most California highways have speed limits of 60 or 70 mph and large trucks travel more slowly than the speed limit.

Annual Emission Rates in ton/yr all trucks

Summary of Worker Commute Vehicle Emissions - HECA

3/05/2013 revision

Calculations for Worker Commute Vehicle Operation

OFFSITE - 50 MPH								EF (g/mile)					
Onroad Vehicle	Fuel Type	Vehicle Type	Total Number of Workers per day	Daily Vehicle Count	Round Trip Distance (miles/vehicle/day)	Trips per day	VMT (Annual)	CO	NOx	PM_{10}	$PM_{2.5}$	SO_2	TOC
Personal Commuting Vehicles	G/D	LDA/ LDT	200	154	40.0	1	2,246,154	1.6825	0.1930	0.4234	0.1134	3.50E-03	0.0540

Assumptions:

Assumed average distance traveled off site for all employees commuting will be 20 miles

times 2 for return trip = 40 miles

365 days per year

Number of workers per commuter vehicle = 1.3

EMFAC2007 emissions are for fleet mix years 1971-2015 travelling at 50 mph.

Area	Description	CO	NOx	PM10	PM2.5	SO2	VOC
		Annual Emission Rates (tons/year) all worker commute vehicles					
San Joaquin Valley, CA	Personal Commuting Vehicles	4.17	0.48	1.05	0.28	0.01	0.13

Fugitive Dust on Paved Road

3/05/2013 revision

AP 42 13.2.1 Paved Roads, updated January 2011

For a daily basis,
E = [k (sL)^0.91 x (W)^1.02](1-P/4N) (2)

P = number of "wet" days with at least 0.254 mm (0.01 in) of precipitation during the averaging period
W = average weight (tons) of vehicles traveling the road
k = particle size multiplier for particle size range and units of interest
sL = road surface silt loading (g/m^2)

	k
	g/VMT
PM2.5	0.25
PM10	1.00

Table 13.2.1-1
PARTICLE SIZE MULTIPLIERS FOR PAVED ROAD EQUATION

Fleet mix on highway

W=	9.1	tons, average	
sL=	0.031	g/m2	Default value from URBEMIS 9.2 for Kern County
P=	36	days/year Buttonwillow Station 1940-2011, WRCC	

E=

0.09836	g/VMT PM2.5
0.39344	g/VMT PM10

Vehicle weight (tons)		fraction of each vehicle type
1.6	passenger vehicles	0.75
40	large trucks	0.18
9	2-4 axle trucks	0.07

9.1 weighted average for all vehicles (ton)

On I-5 near the Project, 75% of all vehicles are passenger vehicles,
of the remaining vehicle, 73% are 5-axle trucks and the remainder are 2-4 axle trucks.
From information provided by California Department of Transportation for the traffic analysis.

Industrial Wind Erosion, AP-42 Section 13.2.5

Emission factor (g/m^2-yr) = k Σ P_i (from i=1,N) (Equation 2) *3/05/2013 revision*

Erosion Potential (P_i) (g/m^2) = 58 (u* - u_t*)^2 + 25(u* - u_t*) (Equation 3)

0.5	k =	PM_{10} particle size multiplier
0.075	k =	$PM_{2.5}$ particle size multiplier
1	N =	number of disturbances per year
33.76	A =	exposed area of coal, m^2, per car (Table 4.1, Jan 2008 Connell Hatch: exposed area = 33.76 m^2)

Use Equation (1) to determine friction velocity:

$u(z) = u^* / 0.4 \times \ln(z/z_0)$

17.88	u(z) =	fastest mile (m/s) (based on speed of train)
0.2	z =	distance at which wind speed is measured (m) (based on the height above the coal cars at which wind flow would be laminar; assumed this height is equal to the difference between the height of the locomotive engine and the trailing coal cars)
0.003	z_0 =	roughness height for uncrusted coal pile (m), from Table 13.2.5-2
1.70	u* =	friction velocity (m/s), solved for using Equation 1
0.55	u_t* =	threshold friction velocity (m/s); Table 13.2.5-2 value for ground coal (surrounding coal pile)

Erosion Potential

	P =	105.9	g/m^2	erosion potential corresponding to the observed (or probable) fastest mile of wind for the ith period between disturbances, g/m^2
Annual	A =	442,256.0	m^2/yr	exposed area of coal per car (m^2) times number of cars per year

Unmitigated Emissions

Emission factor (g/m^2-yr) = k Σ P_i (from i=1,N)

E =	23,423,432	grams PM_{10} / year
	25.82	tons PM_{10} / year
E =	3,513,515	grams $PM_{2.5}$ / year
	3.87	tons $PM_{2.5}$ / year

Mitigation Efficiency of Surfactant: 85%

* HECA will be requiring the coal supplier to apply a surfactant to the coal transported by rail to reduce fugitive losses during transport. Surfactant achieves at least an 85% control efficiency.

Mitigated PM_{10}: 3.87 tons PM_{10} / year

Mitigated $PM_{2.5}$: 0.58 tons $PM_{2.5}$ / year

* It has been assumed that all emitted PM will be lost during the first 100 miles of the trip and has thus all been assigned to New Mexico. Maximum train speed (and thus wind speed) will certainly be reached within this time, and according to AP-42 Section 13.2.5.1, "particulate emission rates tend to decay rapidly (half-life of a few minutes) during an erosion event."

40	train speed, mph
0.447	m/s per 1 mph
453.6	grams per pound
2000	pounds per ton
13,100	Required rail car loads per year at normal operation (cars/yr)

Summary of Transportation Vehicles and Routes

Notes

1) Equipment Maintenance Trucks are considered to be 2% of the total trucks per day for the feed and product operation.
2) Miscellaneous trucks are considered to be 3% of the total trucks per day for the feed and product operation plus a small number of additional trucks to provide additives to the gasification.
3) The maximum flow rate of coke is ratioed up from the normal flow rate at 25% to 30% of feed
4) The maximum daily transfer rate of coal is based on supplying 7-days of normal coal required feed (75% of feedstock on a heat input basis) in 5 days and rounded upward to 2 significant figures.
5) The maximum flow rate of sulfur is 2 times the normal production
6) The maximum flow rate of these commodities is 2 times the normal production
7) The sources of flow data used in the Production Rate calculation were based on the flow rates provided in "Conference Note: Rail and Truck Traffic - Planning Session" and the "FertilizerProductMovement Update", 01-25-12.

Calculations for Trucks Operation onsite

Assumed Number of Unit Trains (incoming/outgoing)

Averaging Period	Coal Unit Trains (incoming)	Unit Trains of Product (outgoing)	Maximum Total Trains per period
Annual average unit trains	119	165	284
# Cars Per train	111	60	
maximum # Cars Per day	200-240	42-46	

	Switching Enigne/ Rail car movers	Line-Haul Engine for Coal Train	Line-Haul Engine for Product Trains
Engine Power Rating (hp)		4400	3000
Notch Operation		1	1
Notch percentage of hp		5.0%	5.0%
Avg Notch horsepower	260	220	150
# of engines per train	1	2	2
hours to unload/load each train		2	1
max operating hours (hrs/day)	8		
max operating hours (hrs/year)	1248		

The majority of the time the line-haul engine will operate in Notch 1 or idling, therefore emissions were conservatively estimated for Notch 1 horsepower.

Notch percentage presented in PORT OF LONG BEACH AIR EMISSIONS INVENTORY for 2007 (POLB, Jan 2009) derived from EPA data.

For each coal train it takes 2 hours to complete the onsite loop to unload

For each product train it takes 1 hour to load

	CO	NOx	PM10	PM2.5	SO2	VOC

Fugitive Dust on Paved Road

3/05/2013 revision

AP 42 13.2.1 Paved Roads, updated January 2011

Calculations for Trucks Operation onsite

For a daily basis,

E = [k (sL)^0.91 x (W)^1.02](1-P/4N) (2)

P = number of "wet" days with at least 0.254 mm (0.01 in) of precipitation during the averaging period
W = average weight (tons) of vehicles traveling the road
k = particle size multiplier for particle size range and units of interest
sL = road surface silt loading (g/m^2)

	k
	g/VMT
PM2.5	0.25
PM10	1.00

Table 13.2.1-1
PARTICLE SIZE MULTIPLIERS FOR PAVED ROAD EQUATION

Large Trucks

			Empty truck	full truck	Load Capacity	
W=	17.5	tons, average	5	30	0	tons
sL=	0.031	g/m2 Default value from URBEMIS 9.2 for Kern County				
P=	36	days/year Buttonwillow Station 1940-2011, WRCC				

E=

0.19149 g/VMT PM2.5 large delivery trucks
0.76594 g/VMT PM10 large delivery trucks

Operation and Maintenance Vehicles

W=	3	tons
sL=	0.031	g/m2 Default value from URBEMIS 9.2 for Kern County
P=	36	days/year Buttonwillow Station 1940-2011, WRCC

E=

0.03169 g/VMT PM2.5 O&M trucks
0.12675 g/VMT PM10 O&M trucks

APPENDIX C

HECA Project

3/05/2013 revision

Federal NAAQS Nonattainment or Maintenance Area General Name and State	Detailed Status in Nonattainment or Maintenance Area	Authority Agency	Basis to Estimate the Offsite Transportation Distance	Emission Sources / Applicable General Conformity Thresholds / Comparisons	Project Operational Annual Emission Rates - for General Conformity (tpy)					
					CO	**NOx**	**PM10**	**PM2.5**	**SO2**	**VOC**
NAAs in State of Arizona	8-Hour Ozone (2008) Nonattainment - Marginal - Phoenix-Mesa, AZ (Part of Maricopa and Pinal County) PM10 Nonattainment (Moderate, Serious, or Maintenance) (12 Counties) PM2.5 Nonattainment - Nogales, AZ (Part of Santa Cruz County), West Central Pinal, AZ (West Pinal County) SO2 Nonattainment - Hayden (Pinal County), AZ (Part of Pinal County), Maintenance - San Manual (Pinal County), AZ, Ajo (Pima County), AZ, Douglas (Cochise County), AZ, Miami (Gila County), AZ CO Maintenance - Serious - Phoenix, AZ. (Part of Maricopa)	ADEQ	Entire ADEQ jurisdiction area (one way trip: trains = 364 miles)	Offsite Train	6.48	25.08	0.41	0.39	0.46	0.69
				Offsite Truck	0.00	0.00	0.00	0.00	0.00	0.00
				Total Emission	**6.48**	**25.08**	**0.41**	**0.39**	**0.46**	**0.69**
				Conformity De minimis (ton/yr)	**100**	**100**	**70**	**100**	**100**	**100**
				Less than De minimis?	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**
NAAs in State of New Mexico	PM10 Nonattainment - Moderate - Anthony, NM (Dona Ana County) CO Maintenance (Bernalillo County) SO2 Maintenance - Grant Co, NM	NMED-AQB	Entire NMED-AQB jurisdiction area (one way trip: trains = 102 miles to coal mine site)	Offsite Train	1.81		1.40		0.13	
				Offsite Truck	0.00		0.00		0.00	
				Total Emission	**1.81**		**1.40**		**0.13**	
				Conformity De minimis (ton/yr)	**100**		**100**		**100**	
				Less than De minimis?	**Yes**		**Yes**		**Yes**	

Notes:

1. The associated emissions from the onsite worker travel are negligible
2. To simplify the analysis, the biggest area among all detailed NAA areas was conservativly used to estimate the emissions in each main NAA category area.
   For State of Arizona and New Mexico the total distances accross each state along the train routes were conservativly used to estimate the emissions in NAA.
3. The distance for trains and trucks are varied depending on the type to materials transporting and their destinations.

ozone nonattainment area is smaller than the distance in PM10 nonattainment area.

5. ACRONYMS AND ABBREVIATIONS
   MDAQMD = Mojave Desert Air Quality Management District
   SCAQMD = South Coast Air Quality Management District
   EKAPCD = East Kern County Air Pollution Control District
   SMAQMD = Sacramento Metro Air Quality Management District
   BCAQMD = Butte County Air Quality Management District
   FRAQMD = Feather River Air Quality Management District
   ADEQ = Arizona Department of Environmental Quality
   NMED-AQB = New Mexico Environment Department - Air Quality Bureau
6. Construction of the project is expected to complete in June 2017 and the operation will start from September. Therefore, the operational emissions were scaled from the entire year of project operation.

NAAs in State of Arizona	8-Hour Ozone (2008) Nonattainment - Marginal - Phoenix-Mesa, AZ (Part of Maricopa and Pinal County) PM10 Nonattainment (Moderate, Serious, or Maintenance) (12 Counties) PM2.5 Nonattainment - Nogales, AZ (Part of Santa Cruz County), West Central Pinal, AZ (West Pinal County) SO2 Nonattainment - Hayden (Pinal County), AZ (Part of Pinal County), Maintenance - San Manual (Pinal County), AZ, Ajo (Pima County), AZ, Douglas (Cochise County), AZ, Miami (Gila County), AZ CO Maintenance - Serious - Phoenix, AZ. (Part of Maricopa)	ADEQ	Entire ADEQ jurisdiction area (one way trip: trains = 364 miles)	Offsite Train	19.45	75.23	1.22	1.18	1.37	2.08
				Offsite Truck	0.00	0.00	0.00	0.00	0.00	0.00
				Total Emission	**19.45**	**75.23**	**1.22**	**1.18**	**1.37**	**2.08**
				Conformity De minimis (ton/yr)	**100**	**100**	**70**	**100**	**100**	**100**
				Less than De minimis?	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**
NAAs in State of New Mexico	PM10 Nonattainment - Moderate - Anthony, NM (Dona Ana County) CO Maintenance (Bernalillo County) SO2 Maintenance - Grant Co, NM	NMED-AQB	Entire NMED-AQB jurisdiction area (one way trip: trains = 102 miles to coal mine site)	Offsite Train	5.42		4.21		0.38	
				Offsite Truck	0.00		0.00		0.00	
				Total Emission	**5.42**		**4.21**		**0.38**	
				Conformity De minimis (ton/yr)	**100**		**100**		**100**	
				Less than De minimis?	**Yes**		**Yes**		**Yes**	

Notes:

1. The associated emissions from the onsite worker travel are negligible
2. To simplify the analysis, the biggest area among all detailed NAA areas was conservativly used to estimate the emissions in each main NAA category area.
   For State of Arizona and New Mexico the total distances accross each state along the train routes were conservativly used to estimate the emissions in NAA.
3. The distance for trains and trucks are varied depending on the type to materials transporting and their destinations.

nonattainment area is smaller than the distance in PM10 nonattainment area.

5. ACRONYMS AND ABBREVIATIONS
   MDAQMD = Mojave Desert Air Quality Management District
   SCAQMD = South Coast Air Quality Management District
   EKAPCD = East Kern County Air Pollution Control District
   SMAQMD = Sacramento Metro Air Quality Management District
   BCAQMD = Butte County Air Quality Management District
   FRAQMD = Feather River Air Quality Management District
   ADEQ = Arizona Department of Environmental Quality
   NMED-AQB = New Mexico Environment Department - Air Quality Bureau

EPA Estimated Locomotive Average Emission Rates by Tiers

Tier	Emission Factor (g/bhp-hr)			
	CO	NO_X	PM	HC
Uncontrolled	1.28	13.00	0.32	0.48
Tier 0	1.28	8.60	0.32	0.48
Tier 0+	1.28	7.20	0.20	0.30
Tier 1	1.28	6.70	0.32	0.47
Tier 1+	1.28	6.70	0.20	0.29
Tier 2	1.28	4.95	0.18	0.26
Tier 2+ and Tier 3	1.28	4.95	0.08	0.13
Tier 4	1.28	1.00	0.015	0.04

Emission Factors For all Locomotives
SOx (3)
g/gal
1.88

Locomotive Application	Conversion Factor (bhp-hr/gal)
Large Line-haul & Passenger	20.8
Small Line-haul	18.2
Switching	15.2

Note:

(1) EPA's Technical Highlights: Emission Factors for Locomotives, 2009 (http://www.epa.gov/nonroad/locomotv/420f09025.pdf).

(2) Line-haul engine emissions of CO, Nox, PM, and HC are based on EPA Tier 3.

(3) Based on 300 ppm sulfur diesel fuel.

(4) VOC emissions can be assumed to be equal to 1.053 times the HC emissions

(5) $PM_{2.5}$ Fraction of PM_{10}, = 0.97

(6) No off-site switching or idling was assumed for train transportation.

(7) Average line haul locomotive load factor was obtained from Table 5.12 of The Port Of Long Beach - 2007 Air Emissions Inventory (http://www.polb.com/civica/filebank/blobdload.asp?BlobID=6021)

Summary of Truck Emissions - HECA

3/05/2013 revision

Calculations for Trucks Operation

Data Supplied By Client							
Parameter	Coke Trucks (Max @ 50 or 60 mph)	Coal Trucks (Max @ 50 or 60 mph)	Liquid Sulfur Product Trucks (Max @ 50 or 60 mph)	Gasification Product Trucks (Max @ 50 or 60 mph)	Urea Product Trucks (Max @ 50 or 60 mph)	UAN Sulfur Product Trucks (Max @ 50 or 60 mph)	Equipment and Miscellaneous Trucks (Max @ 50 or 60 mph)
	Running Emissions	Running Emissions	Running Emissions	Running Emissions	Running Emissions	Running Emissions	Running Emissions
Distance traveled per truck in San Joaquin Valley, CA (mi)	104	53	104	160	80	80	92
Distance traveled per truck in Los Angeles-South Coast Air Basin, CA (mi)	176	0	180	0	0	0	151
Maximum number of trucks or loads:							
Annual average trucks or loads	15,200	61,040	1,360	12,680	22,920	18,680	4,690

No off-site idling was assumed for truck transportation.
Distance traveled per truck is based on round-trip.

EMFAC2007 Emission Factors + Fugitive Dust (g/mi) For Truck Model year 2010, Scenario year 2015

Pollutant	Coke Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	Coal Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	Liquid Sulfur Product Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	Gasification Product Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	Urea Product Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	UAN Sulfur Product Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)	Equipment and Miscelleneous Trucks (Max @ 50 or 60 mph) Running Emissions (g/mile/trk)
CO	1.32	1.32	1.32	1.32	1.32	1.32	1.32
NOx	2.17	2.17	2.17	2.17	2.17	2.17	2.17
ROG	0.18	0.18	0.18	0.18	0.18	0.18	0.18
SOx	0.02	0.02	0.02	0.02	0.02	0.02	0.02
PM10 *	0.60	0.60	0.60	0.60	0.60	0.60	0.60
PM2.5 *	0.18	0.18	0.18	0.18	0.18	0.18	0.18

EMFAC2007 is the approved federal model for vehicle combustion emissions
* PM10 and PM2.5 includes fugitive dust factor for paved roads obtained from AP-42 Ch. 13 plus PM factors from EMFAC 2007
PM factors from EMFAC = combustion exhaust + tire wear + break wear
The maximum emission factor from either truck speed at 50 mph or 60 mph was used.
Most California highways have speed limits of 60 or 70 mph and large trucks travel more slowly than the speed limit.

Annual Emission Rates in ton/yr all trucks

Pollutant	Coke Trucks (Max @ 50 or 60 mph) Running Emissions	Coal Trucks (Max @ 50 or 60 mph) Running Emissions	Liquid Sulfur Product Trucks (Max @ 50 or 60 Running Emissions	Gasification Product Trucks (Max @ 50 or 60 Running Emissions	Urea Product Trucks (Max @ 50 or 60 mph) Running Emissions	UAN Sulfur Product Trucks (Max @ 50 or 60 mph) Running Emissions	Equipment and Miscelleneous Trucks (Max Running Emissions	Total Truck Emission Rates (tons/yr)

Summary of Worker Commute Vehicle Emissions - HECA

3/05/2013 revision

Calculations for Worker Commute Vehicle Operation

OFFSITE - 50 MPH								EF (g/mile)					
Onroad Vehicle	Fuel Type	Vehicle Type	Total Number of Workers per day	Daily Vehicle Count	Round Trip Distance (miles/vehicle/day)	Trips per day	VMT (Annual)	CO	NOx	PM_{10}	$PM_{2.5}$	SO_2	TOC
Personal Commuting Vehicles	G/D	LDA/ LDT	200	154	40.0	1	2,246,154	1.6825	0.1930	0.4234	0.1134	3.50E-03	0.0540

Assumptions:

Assumed average distance traveled off site for all employees commuting will be 20 miles

times 2 for return trip = 40 miles

365 days per year

Number of workers per commuter vehicle = 1.3

EMFAC2007 emissions are for fleet mix years 1971-2015 travelling at 50 mph.

Area	Description	Annual Emission Rates (tons/year) all worker commute vehicles					
		CO	NOx	PM10	PM2.5	SO2	VOC
San Joaquin Valley, CA	Personal Commuting Vehicles	4.17	0.48	1.05	0.28	0.01	0.13

Fugitive Dust on Paved Road

3/05/2013 revision

AP 42 13.2.1 Paved Roads, updated January 2011

For a daily basis,
E = [k (sL)^0.91 x (W)^1.02](1-P/4N) (2)

P = number of "wet" days with at least 0.254 mm (0.01 in) of precipitation during the averaging period
W = average weight (tons) of vehicles traveling the road
k = particle size multiplier for particle size range and units of interest
sL = road surface silt loading (g/m^2)

	k
	g/VMT
PM2.5	0.25
PM10	1.00

Table 13.2.1-1
PARTICLE SIZE MULTIPLIERS FOR PAVED ROAD EQUATION

Fleet mix on highway

W= 9.1 tons, average
sL= 0.031 g/m2 Default value from URBEMIS 9.2 for Kern County
P= 36 days/year Buttonwillow Station 1940-2011, WRCC

E=
0.09836 g/VMT PM2.5
0.39344 g/VMT PM10

Vehicle weight (tons)		fraction of each vehicle type
1.6	passenger vehicles	0.75
40	large trucks	0.18
9	2-4 axle trucks	0.07

9.1 weighted average for all vehicles (ton)

On I-5 near the Project, 75% of all vehicles are passenger vehicles,
of the remaining vehicle, 73% are 5-axle trucks and the remainder are 2-4 axle trucks.
From information provided by California Department of Transportation for the traffic analysis.

Industrial Wind Erosion, AP-42 Section 13.2.5

Emission factor (g/m^2-yr) = k Σ P_i (from i=1,N) (Equation 2) 3/05/2013 revision

Erosion Potential (P_i) (g/m^2) = $58 (u^* - u_t^*)^2 + 25(u^* - u_t^*)$ (Equation 3)

0.5	k =	PM_{10} particle size multiplier
0.075	k =	$PM_{2.5}$ particle size multiplier
1	N =	number of disturbances per year
33.76	A =	exposed area of coal, m^2, per car (Table 4.1, Jan 2008 Connell Hatch: exposed area = 33.76 m^2)

Use Equation (1) to determine friction velocity:

$u(z) = u^* / 0.4 \times \ln(z/z_0)$

17.88	u(z) =	fastest mile (m/s) (based on speed of train)
0.2	z =	distance at which wind speed is measured (m) (based on the height above the coal cars at which wind flow would be laminar; assumed this height is equal to the difference between the height of the locomotive engine and the trailing coal cars)
0.003	z_0 =	roughness height for uncrusted coal pile (m), from Table 13.2.5-2
1.70	u^* =	friction velocity (m/s), solved for using Equation 1
0.55	u_t^* =	threshold friction velocity (m/s); Table 13.2.5-2 value for ground coal (surrounding coal pile)

Erosion Potential

	P =	105.9	g/m^2	erosion potential corresponding to the observed (or probable) fastest mile of wind for the i^{th} period between disturbances, g/m^2
Annual	A =	442,256.0	m^2/yr	exposed area of coal per car (m^2) times number of cars per year

Unmitigated Emissions

Emission factor (g/m^2-yr) = k Σ P_i (from i=1,N)

E =	23,423,432	grams PM_{10} / year
	25.82	tons PM_{10} / year
E =	3,513,515	grams $PM_{2.5}$ / year
	3.87	tons $PM_{2.5}$ / year

Mitigation Efficiency of Surfactant: **85%**

* HECA will be requiring the coal supplier to apply a surfactant to the coal transported by rail to reduce fugitive losses during transport. Surfactant achieves at least an 85% control efficiency.

Mitigated PM_{10}: **3.87 tons PM_{10} / year**

Mitigated $PM_{2.5}$: **0.58 tons $PM_{2.5}$ / year**

* It has been assumed that all emitted PM will be lost during the first 100 miles of the trip and has thus all been assigned to New Mexico. Maximum train speed (and thus wind speed) will certainly be reached within this time, and according to AP-42 Section 13.2.5.1, "particulate emission rates tend to decay rapidly (half-life of a few minutes) during an erosion event."

40	train speed, mph
0.447	m/s per 1 mph
453.6	grams per pound
2000	pounds per ton
13,100	Required rail car loads per year at normal operation (cars/yr)

Summary of Transportation Vehicles and Routes

Notes
1) Equipment Maintenance Trucks are considered to be 2% of the total trucks per day for the feed and product operation.
2) Miscellaneous trucks are considered to be 3% of the total trucks per day for the feed and product operation.
3) The maximum flow rate of coke is ratioed up from the normal flow rate at 25% to 30% of feed
4) The maximum flow rate of coal is ratioed up from the normal flow rate at 75% to 100% of feed
5) The maximum flow rate of sulfur is 2 times the normal production
6) The maximum flow rate of these commodities is 2 times the normal production
7) The sources of flow data used in the Production Rate calculation were based on the flow rates provided in "Conference Note: Rail and Truck Traffic - Planning Session" and the "FertilizerProductMovement Update", 01-25-12.

APPENDIX D

MITIGATION AGREEMENT

MITIGATION AGREEMENT 20130092

This Mitigation Agreement ("Agreement") is entered into as of April 18, 2013 by and between Hydrogen Energy California LLC ("Developer") and the SAN JOAQUIN VALLEY UNIFIED AIR POLLUTION CONTROL DISTRICT ("District"), an air pollution control district formed pursuant to California Health and Safety Code section 40150, et seq.

RECITALS

WHEREAS, District is an air pollution control district formed by the counties of Fresno, Kern, Kings, Madera, Merced, San Joaquin, Stanislaus and Tulare, pursuant to California Health and Safety Code section 40150, et seq.; and

WHEREAS, District is responsible for developing and implementing air quality control measures within the District Boundaries, including air quality control measures for stationary sources, and indirect sources; and

WHEREAS, Developer submitted an Amended Application for Certification (08-AFC-8A) seeking licensing from the California Energy Commission (CEC) which will permit the development of a Project located in the County of Kern, California, as more particularly described on Exhibit A attached hereto and incorporated herein (the "Project"); and

WHEREAS, the Project will cause impacts on air quality within the geographical boundaries of the San Joaquin Valley Unified Air Pollution Control District, as depicted on Exhibit B attached hereto and incorporated herein (the "District Boundaries"); and

WHEREAS, the term "indirect" emissions as used in this Agreement refers to emissions from construction and transportation activities, as opposed to emissions from permitted stationary sources; and

WHEREAS, as a result of funding provided to the Project by the U.S. Department of Energy ("DOE"), the Project is subject to District Rule 9110 and Clean Air Act Section 176(c)(1) as implemented by 40 CFR Part 93 Subpart B, "Determining Conformity of Federal Actions to State or Federal Implementation Plans" (General

SJVUAPCD
1990 E. Gettysburg
Fresno, CA 93726
(559) 230-6000

Conformity); and

WHEREAS, Developer has prepared, and District staff has reviewed and concurred in, a General Conformity Evaluation for the Project, including air quality impact modeling for assessing indirect air quality emission impacts associated with construction and operation of the Project; and

WHEREAS, the General Conformity Evaluation demonstrates indirect emissions are expected to exceed the following Conformity Thresholds in the San Joaquin Valley Air Basin: 10 tons/year NOx, and 10 tons/year ROG/VOC; and

WHEREAS, District has determined that Developer's payment of fees into District's Emission Reduction Incentive Program (ERIP) will provide pound-for-pound offsets of Project indirect emissions that exceed the General Conformity thresholds and result in DOE's federal action conforming to the applicable state implementation plan (SIP), all as set forth in the General Conformity Evaluation for the Project; and

WHEREAS, the emission offsets that will be provided pursuant to this Agreement for purposes of satisfying the General Conformity requirements are distinct from and in addition to any new source review emission offsets that Developer is required to provide pursuant to District Rule 2201; and

WHEREAS, the Project is subject to review pursuant to the California Environmental Quality Act ("CEQA") codified at California Public Resources Code Section 21000, et seq.; and

WHEREAS, pursuant to its certified regulatory program, the CEC acts as CEQA lead agency for the Project and the District is a CEQA responsible agency for the Project; and

WHEREAS, District has determined, in its role as a CEQA responsible agency, that Project indirect emissions are expected to exceed the District CEQA Significance Thresholds of 10 tons/year NOx, 10 tons/year ROG/VOC and 15 tons/year PM10 and that additional mitigation measures beyond those proposed by Developer are necessary to mitigate Project indirect emissions below a level of significance; and

SJVUAPCD
1990 E. Gettysburg
Fresno, CA 93726
(559) 230-6000

WHEREAS, District has determined that Developer's payment of fees into District's Emission Reduction Incentive Program (ERIP) will further mitigate Project indirect emissions that exceed the District CEQA Significance Thresholds and result in Project indirect emissions being mitigated below the level of significance; and

WHEREAS, District has determined that with appropriate funding, District can provide additional reductions of emissions from certain projects in types and in sufficient quantities which, when combined with other measures proposed by Developer, will offset and mitigate Project criteria pollutant emissions for construction and operation , such that the Project will not result in significant impacts to air quality and the DOE action with respect to the Project will conform to the applicable SIP; and

WHEREAS, Developer and District desire to enter into this Agreement in order to develop and implement air quality control measures which, when combined with other measures proposed by Developer, will offset and mitigate the emissions for the Project, so that the development of such Project will not result in an increase in criteria pollutant emissions over those which would otherwise exist without the development thereof; and

WHEREAS, District has determined that compliance with the terms of this Agreement will ensure that the Project will have no significant adverse impacts to air quality, and that DOE's action with respect to the Project will conform to the applicable SIP as more fully set forth in the General Conformity Evaluation prepared for the Project.

AGREEMENT

NOW, THEREFORE, in exchange of the mutual covenants herein contained, Developer and District hereby agree as follows:

1. **Offsetting and Mitigation of Project Related Impacts on Air Quality**

Project related indirect emissions from construction and operation that exceed applicable CEQA and General Conformity thresholds shall be offset and mitigated by achieving real, surplus, quantifiable and enforceable reductions of ROG/VOC, NOx,

SJVUAPCD
1990 E. Gettysburg
Fresno, CA 93726
(559) 230-6000

and PM_{10} through implementation of Emission Reduction Measures in accordance with this Agreement. The determination of whether proposed emission reductions are real, surplus, quantifiable and enforceable shall be performed by the District through its Strategy and Incentives Department. Estimated Project related indirect source emissions that exceed applicable CEQA and General Conformity thresholds are set forth in Exhibit C, which is attached hereto and incorporated herein, and shall be offset and mitigated as demonstrated in Exhibit C. For construction emission impacts, indirect emissions of any criteria pollutant exceeding the applicable General Conformity Threshold or District CEQA Significance Threshold in any given year will be fully offset and mitigated for that pollutant for the entire project construction period. For operational emission impacts, indirect emissions of any criteria pollutant exceeding the applicable General Conformity Threshold or District CEQA Significance Threshold will be fully offset and mitigated for that pollutant, as specified in Exhibit C.

2. **Payment of Air Quality Mitigation Fees**

No later than five months prior to breaking ground for construction of the Project, Developer shall pay Air Quality Mitigation Fees to District in the amount of three million three hundred twenty seven thousand three hundred thirty four dollars ($3,327,334) for implementation of Emission Reduction Measures to offset and mitigate Project construction emissions as specified in Exhibit C. The amount specified above includes a 4% administration fee to cover the District's costs of administering this Agreement.

No later than six months prior to the commercial operation date (COD) for the Project, Developer shall pay additional Air Quality Mitigation Fees to the District in the amount of four million two hundred thirty eight thousand six hundred ninety two dollars ($4,238,692) for implementation of Emission Reduction Measures to offset and mitigate Project indirect operational emissions as specified in Exhibit C. The amount specified above includes a 4% administration fee to cover the District's costs of administering this Agreement.

///

3. **Implementation of Emission Reduction Measures**

Upon Developer's submission to District of the Air Quality Mitigation Fees specified in paragraph 2 above, District shall (1) use diligent efforts to enter into Funding Agreements with owners and/or operators of pollution source equipment to implement the Emission Reduction Proposals within 150 days (in the case of Emission Reduction Measures to offset and mitigate construction emissions) and 180 days (in the case of Emission Reduction Measures to offset and mitigate indirect operational emissions); (2) determine the types and quantities of permanent reduction in emissions which would be realized by the Emission Reduction Measures; (3) perform the determination of surplus emission reductions of ROG/VOC, NOx, and PM10; and (4) advise Developer of such determinations in writing.

District shall notify Developer or designee in writing of Funding Agreements entered into by the District. In the event District is unable to achieve the required reductions District shall provide Developer a written statement of the amount of reductions that have been achieved. Developer shall have a reasonable time, not to exceed ninety (90) days, within which to submit to District additional Emission Reduction Proposal(s) or provide District additional Air Quality Mitigation Fees.

4. **Refunds**

Upon verification by District that Project indirect emissions have been fully offset and mitigated in accordance with this Agreement, District shall refund Developer any unused Air Quality Mitigation Fees. District shall have reasonable time, not to exceed sixty (60) days, to refund Developer.

5. **CEQA & General Conformity Compliance**

District hereby confirms that with implementation of this Agreement: i) Project construction emissions of any criteria pollutant exceeding the General Conformity Threshold or District CEQA Significance Threshold in any given year will be fully offset and mitigated for that pollutant for the entire project construction period; and ii) Project indirect operational emissions of any criteria pollutant exceeding the General

SJVUAPCD
1990 E. Gettysburg
Fresno, CA 93726
(559) 230-6000

Conformity Threshold or District CEQA Significance Threshold will be fully offset and mitigated for that pollutant.

6. **District's Obligations**

6.1 **Acknowledgement Regarding Full Offset and Mitigation**

Upon successful implementation of the Emission Reduction Measures pursuant to Paragraph 3, District shall verify in writing to Developer, the CEC and the DOE that the Project related impacts on air quality have been fully offset and mitigated as set forth in Paragraph 5. For the purpose of this Agreement, fully offset and mitigated means that the reductions specified in Exhibit C have been achieved.

6.2 **Oversight of Funding Agreements**

District shall ensure that the owners/operators of equipment subject to Funding Agreements perform all obligations to be performed on the part of such parties under said Funding Agreements.

6.3 **Oversight of Air Quality Mitigation Monitoring Plan**

Upon request of the CEC, District shall oversee that portion of the mitigation monitoring plan adopted by CEC which relates to the mitigation brought about by this Agreement. Alternatively, upon request of the CEC, District shall cooperate with the CEC in the oversight of that portion of the mitigation monitoring plan adopted by the CEC for the Project which relates to the mitigation brought about by this Agreement.

6.4 **Documentation, Record Keeping and Monitoring**

District shall document, keep adequate records on and monitor the emission reductions brought about as a result of this Agreement, and shall, upon written request by Developer, the CEC or the DOE, provide Developer, the CEC or the DOE written reports verifying achieved emission reductions and/or emission reductions being brought about to fully offset and mitigate Project related impacts on air quality.

6.5 **Achievement of Emission Reductions**

For and in exchange of Developer's payment of funds pursuant to Paragraph 2 above, District shall ensure, by way of entering into, funding and enforcing the Funding

SJVUAPCD
1990 E. Gettysburg
Fresno, CA 93726
(559) 230-6000

Agreements in accordance with the provisions of this Agreement, that the Project achieves the required emission reductions to the extent specified in this Agreement. District shall ensure that implementation of Emission Reduction Measures to offset Project indirect operational emissions as specified in Exhibit C shall result in emission reductions in a timeframe complying with the general conformity mitigation requirements of 40 CFR 93.163.

7. **Subsequent Litigation, Legislation and/or Administrative Action / Credit to Developer**

In the event that despite this Agreement, Developer is required as a result of a final judgment or District Approved Settlement (as defined below) in any subsequent third party litigation, to pay monies in addition to the monies to be paid by Developer pursuant to Paragraph 2 above, then District shall acknowledge and credit Developer with the emission reductions achieved pursuant to this Agreement and any additional emission reductions achieved to mitigate the Project related impacts on air quality that will result from Developer's payment of such additional monies. To the extent that monies paid by Developer pursuant to Paragraph 2 above, when combined with monies paid pursuant to a District Approved Settlement, result in emission reductions in excess of those required to fully offset and mitigate Project related emissions as required by this Agreement, District shall refund to Developer any remaining Air Quality Mitigation Fees in excess of those required to achieve the emission reductions contemplated by this Agreement. For purposes of this Paragraph, a "District Approved Settlement" shall mean a settlement of a lawsuit filed pursuant to CEQA, the National Environmental Protection Act or other applicable environmental law which (i) provides for Developer's payment of monies in exchange for a dismissal or settlement of such lawsuit, (ii) provides for the use of such monies by the petitioner in such lawsuit in such a manner as to mitigate adverse air quality impacts of the Project, and (iii) is approved in writing by District.

///

1990 E. Gettysburg
Fresno, CA 93726
(559) 230-6000

8. **Term of Agreement**

This Agreement shall be effective upon the date first written above, and shall terminate upon District's meeting its obligation to implement Emission Reduction Measures that provide necessary emissions reductions to fully offset and mitigate the indirect Project related air impacts, including any associated monitoring, recordkeeping and reporting. Developer may, at any time by written notice to District, terminate this Agreement, whereupon, (i) District shall acknowledge in writing to the CEC and DOE that Developer has offset and mitigated indirect air quality impacts of the Project to the extent and in the types and quantities brought about by Funding Agreements and Emission Reduction Measures implemented as of the date of termination, (ii) District shall refund to Developer any unused portion of Developer's Air Quality Mitigation Fees less any unpaid administrative fees incurred; and (iii) neither Developer nor District shall have any further rights or obligations under this Agreement except as expressly provided. District's obligations to oversee implementation of Funding Agreements pursuant to Paragraph 9 and to ensure that required emission reductions are achieved, pursuant to Paragraph 9, shall remain effective for as long as necessary to ensure that the anticipated emission reductions continue to be achieved to the extent specified in this Agreement.

9. **Representations, Covenants and Warranties**

9.1. **Developer's Representations, Covenants and Warranties**.

Developer represents, covenants and warrants to District, as of the date of this Agreement, as follows:

9.1.1. The undersigned representatives of Developer are duly authorized to execute, deliver and perform this Agreement, and upon Developer's execution and delivery of this Agreement, this Agreement will have been duly authorized by Developer.

9.1.2. Upon execution and delivery of this Agreement by Developer, Developer's obligations under this Agreement shall be legal, valid and binding obligations of Developer, duly enforceable at law and in equity in accordance with the terms and conditions of this Agreement.

9.1.3. There is no lawsuit, legal action, arbitration, legal or administrative proceeding, legislative or quasi-legislative action or claim existing, pending, threatened or anticipated which would render all or any portion of this Agreement invalid, void or unenforceable in accordance with the terms and conditions thereof.

9.1.4. Other than the execution and delivery of this Agreement by the undersigned representatives of Developer, there are no approvals, consents, confirmations, proceedings, or other actions required by Developer or any third party, entity or agency in order to enter into and carry out the terms, conditions and intent of the parties with respect to this Agreement.

9.2. **District's Representations, Covenants and Warranties**

District represents, covenants and warrants to Developer, as of the date of this Agreement, as follows:

9.2.1. The undersigned representatives of District are duly authorized to execute, deliver and perform this Agreement, and upon District's execution and delivery of this Agreement, this Agreement will have been duly authorized by District.

9.2.2. Upon execution and delivery of this Agreement by District, District's obligations under this Agreement shall be legal, valid and binding obligations of District, duly enforceable at law and in equity in accordance with the terms and conditions of this Agreement.

9.2.3. There is no lawsuit, legal action, arbitration, legal or administrative proceeding, legislative, quasi-legislative or administrative action or claim existing, pending, threatened or anticipated which would render all or any portion of this Agreement invalid, void or unenforceable in accordance with the terms and conditions thereof.

9.2.4. Other than the execution and delivery of this Agreement by the undersigned representatives of District, there are no approvals, consents,

SJVUAPCD
1990 E. Gettysburg
Fresno, CA 93726
(559) 230-6000

confirmations, proceedings, or other actions required by District or any third party, entity or agency in order to enter into and carry out the terms, conditions and intent of the parties with respect to this Agreement.

9.2.5. The monies paid by Developer under this Agreement shall be sufficient to ensure that the emission reduction contemplated by this Agreement shall occur, and District shall utilize such monies in such a manner as to ensure that such emission reduction shall occur.

9.2.6. Upon the approval of this Agreement by the governing board of District, the Air Pollution Control Officer of District, or equivalent representative, or a delegee of such officer, shall have the authority to approve, deliver, verify, enter into, acknowledge and/or accept any communication, notice, notification, verification, agreement and/or other document to be issued or entered into by District under the terms and conditions of this Agreement, without further approval of the governing board of District.

10. **Indemnification**

Developer agrees to indemnify, defend and hold harmless District for, from and in connection with any third party claims, losses and/or liabilities arising from or in connection with District's performance of this Agreement, excluding only such claims, losses and/or liabilities which result from or in connection with District's sole negligence, act or omission.

11. **Inurement**

Developer's rights and obligations under this Agreement, or applicable portions thereof, shall inure to the benefit of and be binding upon the heirs, successors and assigns of Developer. Upon Developer's conveyance of all or any portion of the Project, the rights and obligations of Developer under this Agreement shall, to the extent applicable, be transferred to the transferee thereof, and Developer shall thereupon be released by District from, all obligations and liabilities so assigned, except for such obligations and liabilities arising prior to such transfer.

///

12. **Assignment**

Developer shall have the right to assign all or any part of its rights and/or obligations under this Agreement. Upon any such assignment, Developer shall deliver to District a written assignment and assumption agreement specifying the fact and extent of the assignment, the name and address of the assignee, and the assignee's assumption of all obligations of Developer thereby assigned. Developer shall have the right to assign all or any part of its rights and/or obligations under this Agreement to a third party for use in connection with the mitigation of air quality impacts resulting from one or more projects other than the Project, so long as (i) the project is located within the District Boundaries, (ii) the air quality impacts of such project(s) will in fact be mitigated, as verified by District, by the emission reductions brought about by this Agreement, and (iii) the project(s) consist of residential, commercial, industrial and/or mixed use real estate projects. Upon any such assignment by Developer, District shall enter into an amendment of this Agreement which acknowledges the assignment and conforms the various provisions of this Agreement as may be required to be conformed in order to provide to the assignee the rights and benefits of this Agreement as if such assignee and its project were the original party and project contemplated in this Agreement.

13. **Recitals Incorporated**

The recitals set forth hereinabove are hereby incorporated into this Agreement and acknowledged, agreed to and adopted by the parties to this Agreement.

14. **Further Assurances**

Developer and District agree to execute and deliver any documents and/or perform any acts which are reasonably necessary in order to carry out the intent of the parties with respect to this Agreement.

15. **No Joint Venture or Partnership**

District and Developer agree that nothing contained in this Agreement or in any document executed in connection with this Agreement shall be construed as making

District and Developer joint venturers or partners.

16. **Notices**

Any notices or communications relating to this Agreement shall be given in writing and shall be deemed sufficiently given and served for all purposes when delivered, if (a) in person, (b) by facsimile (with the original delivered by other means set forth in this paragraph, (c) by generally recognized overnight courier or (d) by United States Mail, certified or registered mail, return receipt requested, postage prepaid, to the respective addresses set forth below, or to such other addresses as the parties may designate from time to time by providing written notice of the change to the other party.

DEVELOPER	**DISTRICT**
Hydrogen Energy California, LLC 30 Monument Square, Suite 235 Concord, MA 01742 Fax: (978)287-9529 Attn: Marisa Mascaro	Seyed Sadredin Executive Director/APCO 1990 E. Gettysburg Avenue Fresno, CA 93726 (559) 230-6000 Fax: (559) 230-6061

17. **Entire Agreement**

The terms of this Agreement, together with all attached exhibits, are intended by the parties as the complete and final expression of their agreement with respect to such terms and exhibits and may not be contradicted by evidence of any prior or contemporaneous agreement. This Agreement specifically supersedes any prior written or oral agreements between the parties with respect to the subject matter of this Agreement.

18. **Amendments and Waivers**

No addition to or modification of this Agreement shall be effective unless set forth in writing and signed by the party against whom the addition or modification is sought to be enforced. The party benefited by any condition or obligation may waive the same, but such waiver shall not be enforceable by another party unless made in writing and signed by the waiving party.

19. **Invalidity of Provisions**

If any provision of this Agreement as applied to either party or to any circumstance shall be adjudged by a court of competent jurisdiction to be void or unenforceable for any reason, the same shall in no way affect (to the maximum extent permissible by law) any other provision of this Agreement, the application of any such provision under circumstances different from those adjudicated by the court, or the validity or enforceability of this Agreement as a whole. The parties further agree to replace any such invalid, illegal or unenforceable portion with a valid and enforceable provision, which will achieve, to the maximum extent legally possible, the economic, business or other purposes of the invalid, illegal or unenforceable portion.

20. **Construction**

Unless otherwise indicated, all paragraph references are to the paragraph of this Agreement and all references to days are to calendar days. Whenever, under the terms of this Agreement the time for performance of a covenant or condition falls upon a Saturday, Sunday or California state holiday, the time for performance shall be extended to the next business day. The headings used in this Agreement are provided for convenience only and this Agreement shall be interpreted without reference to any headings. Wherever required by the context, the singular shall include the plural and vice versa, and the masculine gender shall include the feminine or neuter genders, or vice versa. This Agreement may be executed in one or more counterparts, each of which shall be deemed an original, but all of which together shall constitute one and the same instrument. The language in all parts of this Agreement shall be construed as a whole in accordance with its fair meaning, and shall not be construed against any party solely by virtue of the fact that such party or its counsel was primarily responsible for its preparation.

21. **Governing Law**

This Agreement shall be governed by the laws of the State of California applicable to contracts made and to be performed in California.

22. **No Third-party Beneficiaries**

Nothing in this Agreement, express or implied, is intended to confer any rights or remedies under or by reason of this Agreement on any person other than the parties to it and their respective permitted successors and assigns, nor is anything in this Agreement intended to relieve or discharge any obligation of any third person to any party hereto or give any third person any right of subrogation or action over or against any party to this Agreement.

23. **Exhibits**

The exhibits attached to this Agreement shall be deemed to be a part of this Agreement and are fully incorporated herein by reference.

24. **Force Majeure**

The time within which any party shall be required to perform under this Agreement shall be extended on a day-per-day basis for each day during which such performance is prevented or delayed by reason of events reasonably outside of the control of the performing party, including, without limitation, acts of God, events of destruction, acts of war, civil insurrection, strikes, shortages, governmental delays, moratoria, civil litigation and the like, and/or delays caused by the non-performing party's act or omission.

EXHIBIT A

DESCRIPTION OF THE PROJECT

The HECA IGCC polygeneration project is located near the community of Tupman, as shown in Figure 1. The Project will gasify a fuel blend of 75 percent coal and 25 percent petroleum coke (petcoke) to produce synthesis gas (syngas). Syngas produced via gasification will be purified to hydrogen-rich fuel, and used to generate a nominal 300 megawatts (MW) of low-carbon baseload electricity in a Combined Cycle Power Block, low-carbon nitrogen-based fertilizer in an integrated Manufacturing Complex, and carbon dioxide (CO_2) for use in enhanced oil recovery (EOR). The HECA Project Site comprises a 453-acre parcel of land on which the HECA IGCC electrical generation facility, low-carbon nitrogen-based fertilizer Manufacturing Complex, and associated equipment and processes (excluding off-site portions of linear facilities), will be located. HECA has an agreement to purchase the HECA Project Site, as well as an additional 653 acres adjacent to the HECA Project Site, herein referred to as the Controlled Area. HECA will have control over public access and future land use on this property. In addition, the HECA Project will include the following linear facilities, which extend off the Project Site.

- Electrical transmission line. An approximately 2-mile-long electrical transmission line will interconnect the Project to a future Pacific Gas and Electric Company (PG&E) switching station east of the Project Site.

- Natural gas supply pipeline. An approximately 13-mile-long natural gas interconnection will be made with PG&E natural gas pipelines north of the Project Site.

- Water supply pipelines and wells. An approximately 15-mile-long process water supply line and up to five new groundwater wells will be installed by the Buena Vista Water Storage District (BVWSD) to supply brackish groundwater from northwest of the Project Site. An approximately 1-mile-long water supply linear from the West Kern Water District (WKWD) east of the Project Site will provide potable water.

BIOLOGICAL RESOURCES

Amy Golden

SUMMARY OF CONCLUSIONS

Hydrogen Energy California, LLC (applicant) is proposing to build Hydrogen Energy California (HECA or project), an Integrated Gasification Combined Cycle (IGCC) power generating facility, on 544 acres of actively farmed agricultural lands in western Kern County, including 453 acres for the IGCC facility and 91 acres for temporary staging (**Biological Resources Table 2**). An additional 229 acres of agricultural and disturbed natural lands would be developed for five linear routes including four buried pipelines, an above ground transmission line and PG&E electrical switchyard, and optional railroad spur.

Construction of the project would primarily impact agricultural lands and intermixed non-native grassland, allscale scrub habitats that provide habitat for a number of upland species covered under the U.S. Fish and Wildlife Service's *Recovery Plan for Upland Species of the San Joaquin Valley* (Recovery Plan, USFWS 1998). HECA would impact approximately 33 acres of allscale scrub habitat, which would mostly occur along the carbon dioxide pipeline route. The proposed carbon dioxide pipeline route located on the lower flanks of the Elk Hills Oil Field and immediately north of the Elk Hills mitigation parcels, is the linear route that supports the most contiguous natural, non-farmland type of habitat in the project area and staff believes this linear route represents the highest quality natural habitat and poses the highest threat for construction impacts to upland species (**Biological Resources Figure 2**). In addition, five sites along the natural gas pipeline route also support areas of disturbed allscale scrub and some of these sites represent similar habitat values as the nearby Buttonwillow Ecological Reserve, located north of the project area. Approximately 740 acres of additional impacts would occur to various agricultural land types (alfalfa, orchards, and row crops) and existing disturbed lands. Collectively, these habitats provide forage, breeding, dispersal and movement, and cover values to a number of special-status wildlife including San Joaquin kit fox, blunt-nosed leopard lizard, giant kangaroo rat, Tipton kangaroo rat, San Joaquin antelope squirrel, San Joaquin pocket mouse, short-nosed kangaroo rat, Swainson's hawk, and burrowing owl as well as a number of rare, declining special-status plant species.

HECA is proposed for an area located in a San Joaquin kit fox Core Recovery Area known as natural lands of western Kern County, which include critical dispersal and connection points between the Elk Hills, Buena Vista Valley, and Lokern Natural Areas, and urban Bakersfield satellite populations of kit fox. The Recovery Plan states that the Carrizo Plain and western Kern County San Joaquin kit fox populations are important for kit fox recovery and preliminary population viability analyses indicate that the possibility of the extinction of this species dramatically increases if either the Carrizo Plain or western Kern County populations are eliminated (USFWS 1998). Staff estimates the project's impacts to 773 acres of habitat represents a loss of denning and regional movement lands for San Joaquin kit fox. HECA would not result in the construction of any new roads although certain intersections would need improvements such as the addition of turn lanes; however, construction and operation would contribute considerable amounts of increased traffic on several local and collector roads that intersect with other irrigation canals that kit fox are known to use for movement. Staff believes increased vehicle traffic from the project, especially non-peak traffic during dawn, dusk and nighttime hours, could result in a considerable increase in vehicle-fox strike mortality and all wildlife that occurs on or near roadways. Staff has proposed Condition of Certification **BIO-7**, which requires that the applicant conduct focused den surveys prior to construction for San Joaquin kit fox and American badger, establish exclusion zones, and continue monitoring the activity of potential dens identified in active construction areas. Condition of Certification **BIO-7** also requires that the applicant follow the USFWS's *Standardized Recommendations for Protection of the San Joaquin Kit Fox Prior to or during Ground Disturbance* for avoiding impacts to this species (USFWS 2011). Staff's proposed Condition of Certification **BIO-12** requires that the applicant prepare and implement a Small Mammal Relocation Plan. In addition, staff has proposed Conditions of Certification **BIO-13** (giant kangaroo rat) and **BIO-14** (Tipton kangaroo rat and San Joaquin antelope squirrel) which requires that the applicant perform focused preconstruction surveys and mapping for giant kangaroo rat precincts and small mammal burrows, preconstruction trapping and relocation in order to minimize and avoid take of small burrowing mammals in active construction areas, and burrow excavation once burrows and precincts have been completely trapped and evaluated for small mammal presence.

Blunt-nosed leopard lizard (BNLL) is a California Fully Protected species under California Fish and Game Code Section 5050 and therefore, incidental take of the species is not legally permitted as defined bySection 86 of the Fish and Game Code. This species is present at the Elk Hills Oil Field and has a high potential to occupy the proposed carbon dioxide pipeline route as well as disturbed allscale scrub areas along the natural gas pipeline. The construction of the project would impact approximately 192 acres of natural allscale scrub and disturbed lands which provide small mammal burrow habitat for BNLL; this poses a threat to BNLL in the form of mortality from vehicles and equipment on roadways, entrapment in construction-related trenches or pipes, burial in burrows by equipment, avoidance of certain habitats, modification to breeding and/or foraging behaviors, and reduced carrying capacity of natural scrub habitat and neighboring lands known to be occupied by BNLL. Staff has proposed Condition of Certification **BIO-8** which requires that the applicant prepare and implement a Blunt-nosed Leopard Lizard Impact Avoidance and Minimization Plan to further minimize the potential for take during construction and operation of the project. In particular, this plan would take into consideration the phasing of linear construction and how clearance surveys, exclusion fencing, and fence and burrow monitoring would also be phased in order to ensure BNLL remain clear of active construction areas. Condition of Certification **BIO-8** also requires that various impact avoidance measures be incorporated including scheduling surface ground disturbing during the BNLL's active season (approximately April 15 to October 15) to the greatest extent practicable, particularly in habitat areas where this species is mostly likely to be encountered, minor shifts in proposed pipeline alignments in order to avoid potentially occupied small mammal burrows, and presence of biological monitor(s) in active construction areas. Scheduling surface ground- disturbing activities during the BNLL active season would make it more likely to guarantee that BNLL are above ground, active, and able to escape from construction activities. Staff concludes that even with the implementation of staff's proposed take avoidance and minimization measures, incidental take of blunt-nosed leopard lizard would likely occur over the life of the project. Therefore, staff considers this impact significant and unavoidable under CEQA even with the incorporation of mitigation. It is also unclear whether the project would comply with Fish and Game Code Section 5050 relating to Fully Protected Reptile and Amphibian Species and the California Endangered Species Act since avoiding take of this species cannot be guaranteed for the life of the project.

During protocol-level surveys performed for Swainson's hawk, 12 active raptor nests were found within the surveyarea, six of which were confirmed Swainson's hawk nests. All six Swainson's hawk nests appear to be within a 0.25 mile of either the project site or a proposed linear facility and therefore could be affected by construction noise or other construction disturbances during the nesting season. The majority of these nest trees occur along canal levees of the Kern River Flood Control Channel, West Side Canal and other smaller unnamed agricultural canals and ditches and are likely supplied to some extent by irrigation runoff that accumulates in irrigation canals as well as groundwater. In addition, valley sink scrub, a sensitive vegetation community identified by the California Natural Diversity Database, potentially occurs in these same areas in association with the Kern River Flood Control Channel. Staff believes that a more definitive analysis is needed on the water source of the nest trees that occur in the project area and pre- and post-project groundwater drawdown around the proposed well field. Staff also believes the loss of approximately 571 acres of agricultural lands including alfalfa, wheat, onion fields, and other low-growing crop types that provide forage value is a significant loss of foraging habitat for Swainson's hawk. More definitive analysis is needed on the baseline groundwater levels and water source of the nest trees and sensitive vegetation communities that occur in the project area. Staff's proposed Condition of Certification **BIO-9** (Swainson's Hawk Impact Avoidance Measures) requires that the applicant perform focused, preconstruction surveys within 0.50-mile of all project facilities and a minimum construction avoidance buffer of 0.50 mile must be implemented around any active Swainson's hawk nests following the recommended survey protocol for this species. Condition of Certification **BIO-9** also requires the applicant to prepare and implement a Swainson's Hawk Monitoring and Mitigation Plan which would account for the phasing of construction and need to phase preconstruction surveys. With the incorporation of the above conditions of certification, the project's impacts to Swainson's hawk habitat would be reduced; however, until additional data is provided regarding the project's impacts and overall mitigation strategy, staff cannot determine if the project's impacts to Swainson's hawk habitat would be reduced to below a level of significance. If groundwater drawdown from HECA's proposed well field and along the 15-mile processed water pipeline is consistent enough over the course of several years, staff believes the decrease in water supply to the tree's root system could result in gradual decline and eventually nest tree failure which may constitute take under the California Endangered Species Act, the Migratory Bird Treaty Act, and California Fish and Game Code 3503; therefore, it is unknown if HECA complies with these LORS at this time.

Staff has proposed several impact avoidance and minimization measures to reduce the potential for impacts to special-status plants and wildlife primarily during construction of the project. Specifically, staff has proposed Conditions of Certification **BIO-1** through **BIO-6** which would apply to all species that could be impacted by the project by requiring the applicant to appoint a Designated Biologist and Biological Monitors for routine monitoring and reporting of the project during construction and implementation of a worker awareness training program. Conditions of Certification **BIO-7** through **BIO-17** are species-specific conditions, which in essence require the applicant to perform focused, preconstruction surveys in suitable habitat areas, implement species-specific construction impact avoidance measures, and monitor for signs of disturbance during construction following wildlife agency protocols. These conditions also require the applicant to prepare species-specific mitigation and monitoring plans specifically for blunt-nosed leopard lizard, Swainson's hawk, burrowing owl, and listed small mammals (giant kangaroo rat, Tipton kangaroo rat, San Joaquin antelope squirrel) outlining construction avoidance procedures while considering a phased construction schedule along linear routes when implementing clearance surveys.

Energy Commssion staff, the California Department of Fish and Wildlife (CDFW), and U.S. Fish and Wildlife Service (USFWS) have determined that permanent protection and perpetual management of compensatory habitat is necessary and required in accordance with CEQA and biological laws, ordinances, regulations, and standards (LORS). This determination is based on factors including an assessment of the importance of the habitat in the project area and the extent to which project activities would impact the habitat. There remains much uncertainty regarding the applicant's overall compensatory mitigation proposal for the project. The applicant submitted a Section 7 Biological Assessment for HECA including the OEHI component of the project on March 1, 2013, (URS 2013b**, Biological Resources Appendix A**). The applicant has proposed to mitigate for permanent and temporary habitat impacts to federally and state listed species at a 0.1:1 and 2.1:1 ratio, respectively, which staff believes would not suffice as adequate habitat compensation for project impacts to special-status species (HECA 2012b, URS 2013b). The applicant has also proposed to purchase habitat credits from the Kern Water Bank as mitigation for the project, which the wildlife agencies have indicated is not a feasible option for mitigating HECA's impacts to special-status wildlife species. The CDFW and USFWS have indicated that while it may be possible to purchase some mitigation credits for a portion of the listed species that would be impacted, it is not feasible to mitigate HECA entirely at the Kern Water Bank, given the nature of the project's impacts to listed wildlife species from project traffic road mortality and habitat loss. During May 2013, the applicant submitted a Section 2081 Incidental Take Permit application for project impacts to state-listed wildlife species for which the applicant would be seeking incidental take coverage which staff has preliminarily reviewed (URS 2013d). Staff has inserted Condition of Certification **BIO-20** (Compensatory Habitat Mitigation for Upland Species) as a placeholder. Staff will continue to work with the applicant, CDFW, and USFWS to develop an appropriate mitigation strategy for HECA that is consistent with the goals and objectives of the *Recovery Plan for Upland Species of the San Joaquin Valley*. Additional conditions of certification, and modifications to currently proposed conditions of certification including Condition of Certification **BIO-20**, are likely to be necessary based on further consultation with the wildlife agencies and information provided by the applicant. With the implementation of staff's proposed Conditions of Certification **BIO-1** through **BIO-20**, impacts to special-status species would be reduced; however, without an adequate mitigation proposal, staff cannot make a determination whether the project would comply with all applicable LORS or that project impacts to sensitive biological resources would be reduced to less than significant levels in accordance with CEQA.

INTRODUCTION

This section of the Preliminary Staff Assessment and Draft Environmental Impact Statement (PSA/DEIS) presents the preliminary conclusions of the California Energy Commission (Energy Commission) staff and the Department of Energy (DOE), hereafter jointly referred to as staff unless otherwise noted, regarding the potential impacts to biological resources from construction and operation of the proposed Hydrogen Energy California (HECA) project. As discussed in the **Introduction** section of the PSA, this document analyzes the project's impacts pursuant to both the National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA). The two statutes are similar in their requirements concerning analysis of a project's impacts. Therefore, unless otherwise noted, staff's use of, and reference to, CEQA criteria and guidelines also encompasses and satisfies NEPA requirements for this environmental document.

The HECA project will capture 3 million tons per year of CO_2 and 2.6 million tons per year will be compressed and used for Enhanced Oil Recovery (EOR) at the Elk Hills Oil Field (EHOF) located approximately three miles south of the site. The CO_2 EOR component of HECA (referred to as the OEHI component throughout the remainder of this document) would be permitted by the Division of Oil, Gas and Geothermal Resources (DOGGR) under a Class II Underground Injection Control (UIC) permit. The Class II UIC permit application identifies phase 1 of the OEHI component, which would include 25 injection patterns. OEHI estimates the entire OEHI component would consist of over 200 injection patterns and each injection well would function as a central injection point surrounded by three to five offsetting production wells. OEHI indicated that subsequent pattern areas would be submitted under subsequent UIC permit applications as the OEHI component of HECA proceeds (OEHI 2012c). Staff has analyzed the effects of the OEHI component to the physical environment in accordance with CEQA. Where significant impacts have been identified, staff has provided recommended mitigation measures to the applicable permitting authorities in order to reduce an impact to biological resources to less than significant levels.

The project would impact approximately 773 acres (453 acres for the IGCC facility, 91 acres for staging areas, and 229 acres for linear facilities) of agricultural lands and disturbed natural lands in western Kern County, California (**Biological Resources Table 2**). Information provided in this document addresses potential impacts to special-status species, their habitats, and areas of critical biological concern for all impact areas mentioned above. This document explains the need for mitigation, evaluates the adequacy of mitigation proposed by the applicant, and specifies additional mitigation measures to reduce the project's impacts. It also describes compliance of the project with applicable laws, ordinances, regulations, and standards and recommends conditions of certification for the project.

This analysis is based, in part, upon information provided in the Amended Application for Certification for Hydrogen Energy California, Kern County (HECA 2012b), several responses to staff's data requests from the applicant and OEHI regarding the proposed carbon dioxide pipeline, public issue resolution workshops conducted on behalf of the project on April 12, 2010, September 27, 2012, and November 7, 2012; site visits performed by biology staff on April 12, 2010, May 12, 2012, and October 17, 2012 of the proposed HECA facilities and EHOF; review of the USFWS's *Recovery Plan for Upland Species of the San Joaquin Valley* (Recovery Plan, USFWS 1998); Section 7 Biological Assessment submitted for HECA (**Biological Resources Appendix A**, URS 2013b); and communications and correspondence with representatives from CDFW and USFWS.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

The project will need to abide by the Laws, Ordinances, Regulations, and Standards (LORS) listed in **Biological Resources Table 1** during project construction and operation.

Biological Resources Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable Law	Description
Federal	
Endangered Species Act (Title 16, United States Code, section 1531 et seq., and Title 50, Code of Federal Regulations, part 17.1 et seq.)	Designates and provides for protection of threatened and endangered plant and animal species and their critical habitat. "Take" of a federally listed species is prohibited without an incidental take permit, which may be obtained through Section 7 consultation (between federal agencies) or a Section 10 Habitat Conservation Plan.
Migratory Bird Treaty Act (Title 16, United States Code, sections 703 through 711)	Makes it unlawful to take or possess any migratory nongame bird (or any part of such migratory nongame bird) as designated in the Migratory Bird Treaty Act.
Clean Water Act Section 404 (Code of Federal Regulations Title 33, Chapter 26, Subchapter 4 Section 1344)	Requires the permitting and monitoring of all discharges to surface water bodies. Section 404 requires a permit from the U.S. Army Corps of Engineers (Corps) for a discharge of dredged or fill materials into waters of the U.S., including wetlands. Section 401 requires a permit from a regional water quality control board (RWQCB) for the discharge of pollutants. By federal law, every applicant for a federal permit or license for an activity that may result in a discharge into a California water body, including wetlands, must request state certification that the proposed activity will not violate state and federal water quality standards.
Bald and Golden Eagle Protection Act (Title 16, United States Code section 668)	Provides for the protection of the bald eagle and the golden eagle by prohibiting, except under certain specified conditions, the take, possession, and commerce of such birds. The 1972 amendments increased penalties for violating provisions of the act or regulations issued pursuant thereto and strengthened other enforcement measures. Rewards are provided for information leading to arrest and conviction for violation of the act.
Eagle Act (Title 50, Code of Federal Regulations, section 22.26)	Would authorize limited take of bald eagles (*Haliaeetus leucocephalus*) and golden eagles (*Aquila chrysaetos*) under the Eagle Act, where the taking is associated with, but not the purpose of activity, and cannot practicably be avoided.
Eagle Act (Title 50, Code of Federal Regulations, section 22.27)	Would provide for the intentional take of eagle nests where necessary to alleviate a safety hazard to people or eagles; necessary to ensure public health and safety; the nest prevents the use of a human–engineered structure, or; the activity, or mitigation for the activity, will provide a net benefit to eagles. Only inactive nests would be allowed to be taken except in the case of safety emergencies.

State	
California Endangered Species Act of 1984 (Fish and Game Code, sections 2050 through 2098)	Protects California's rare, threatened, and endangered species. "Take" of a state-listed species is prohibited without an Incidental Take Permit.
Definition of "Take" (Fish and Game Code section 86)	Defines take as to hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill.
Protected furbearing mammals (Title 14, California Code of Regulations, section 460)	Fisher, marten, river otter, desert kit fox and red fox may not be taken at any time.
California Code of Regulations (Title 14, sections 670.2 and 670.5)	Lists the plants and animals of California that are declared rare, threatened, or endangered.
Fully Protected Species (Fish and Game Code, sections 3511, 4700, 5050, and 5515)	Designates certain species as fully protected and prohibits the take of such species or their habitat unless for scientific purposes (see also Title 14 California Code of Regulations, section 670.7).
Nest or Eggs (Fish and Game Code section 3503)	Protects California's birds by making it unlawful to take, possess, or needlessly destroy the nest or eggs of any bird.
Birds of Prey (Fish and Game Code section 3503.5	Unlawful to take, possess, or destroy any birds in the orders Falconiformes and Strigiformes or to take, possess, or destroy the nest or eggs of any such bird.
Migratory Birds (Fish and Game Code section 3513)	Protects California's migratory birds by making it unlawful to take or possess any migratory nongame bird as designated in the Migratory Bird Treaty Act or any part of such migratory nongame birds.
Nongame mammals (Fish and Game Code section 4150)	Makes it unlawful to take or possess any non-game mammal or parts thereof except as provided in the Fish and Game Code or in accordance with regulations adopted by the commission.
Ecological Reserves (Fish and Game Code Section 1580 et seq)	Designates land or land and water areas that are to be preserved in a natural condition, or which are to be provided some level of protection, for the benefit of the general public to observe native flora and fauna and for scientific study or research.

Streambed Alteration Agreement (Fish and Game Code sections 1600 et seq.)	Regulates activities that may divert, obstruct, or change the natural flow of the bed, channel, or bank of any river, stream, or lake in California designated by CDFW in which there is at any time an existing fish or wildlife resource or from which these resources derive benefit. Impacts to vegetation and wildlife resulting from disturbances to waterways are also reviewed and regulated during the permitting process.
Porter-Cologne Water Quality Control Act	Regulates discharges of waste and fill material to waters of the State, including “isolated” waters and wetlands through regional water boards, their basin plans, and Waste Discharge Requirements (WDRs). WDRs protect pre-identified beneficial uses that often include rare, threatened, and endangered species and wildlife habitat. California establishes its regulations to comply with CWA under the Porter-Cologne Water Quality Act.
California Native Plant Protection Act of 1977 (Fish and Game Code section 1900 et seq.)	Designates state rare, threatened, and endangered plants.

Kern County General Plan Land Use, Open Space, and Conservation Element (Kern County 2007)	Directs the county to work closely with state and federal agencies to assure that discretionary projects avoid or minimize impacts to fish, wildlife, and botanical resources.

PROPOSED PROJECT

SETTING AND EXISTING CONDITIONS

<u>Proposed Project</u>

HECA proposes to construct and operate an integrated gasification combined cycle (IGCC) facility in western Kern County, California on 453 acres (project site). In addition to the IGCC facility, there are five proposed linear facilities that would require construction in order for the project to operate and two additional alternatives for coal transportation to the project site, a proposed railroad spur or a trucking route. Collectively, the project site and linear facility footprints are defined as the project area throughout the remainder of this document. The linear facility routes include a proposed transmission line and PG&E switching station, potable water pipeline, processed water pipeline and well field, natural gas pipeline, and carbon dioxide pipeline. HECA would also include a controlled buffer area, a 653-acre area immediately adjacent to the project site that is open for purchase by the applicant with the intent that the applicant would be able to control public site access and ownership surrounding the project site. An additional 91 acres would be usedfor temporary construction staging and would be located between Adohr Road and the northern boundary of the project site (HECA 2012b). In addition, OEHI is proposing to inject high volumes of compressed carbon dioxide (CO_2) to facilitate oil production, increase recoverable oil reserves, and ultimately extend the productive life of the Elk Hills Unit. This portion of HECA is known as the OEHI component.

Regional Setting

HECA is proposed for an area in western Kern County, which is located in the San Joaquin Valley basin, the southern portion of the Great Central Valley of California. The San Joaquin Valley basin is defined by the Coast Ranges to the west, the San Emigdio and Tehachapi Mountains to the south, the Sierra Nevada mountain range to the east, and the delta of the San Joaquin and Sacramento Rivers to the north. Kern County extends beyond the southern slope of the Sierra Nevada range into the Mojave Desert towards the western portion of the county. The Carrizo Plain National Monument is located approximately 23 miles west of the project area and the Kern and Pixley National Wildlife Refuge is located approximately 34 miles northwest of the project area.

Water supply within Kern County is primarily provided by groundwater, the Kern River and other surface water features and imports, which include inputs from the California State Water Project via the Friant-Kern Canal and the Central Valley Project via the California Aqueduct. In Kern County, approximately 60 percent of water used for agricultural and residential uses is pumped from groundwater and agriculture uses almost 90 percent of the water consumed in the region.

The project occurs in a very rural, agricultural setting. HECA is proposed for an area northeast of the former Elk Hills Naval Petroleum Reserve-1 (NPR-1) and NPR-2, presently the EHOF. This area supports several water diversion structures and bypass channels including the California Aqueduct, the Kern River Flood Control Channel, the West Side Canal, and the Kern River and Kern River Drainage floodplain area, among several other unnamed ditches and canals associated with these water diversion facilities. Topographically, the EHOF consists of an east-west trending ridge about 16 miles long by 6 miles wide and is located approximately 26 miles southwest of Bakersfield in western Kern County in the southern San Joaquin Valley. The EHOF is an approximate-48,000 acre active oil field with significant levels of disturbance in high production areas. Past disturbances which have altered habitat conditions on EHOF include grazing, wild fires, and ongoing oil and gas operations. Elevations across the EHOF range from approximately 300 to 1,550 feet above mean sea level; steep ephemeral drainages with incised banks are found within the interior of the EHOF with flat valleys and alluvial plains on the perimeter (HECA 2012b, Appenidx A). The EHOF consists of NPR-1 and NPR-2. NPR-1 consists of approximately 47,409 acres and is surrounded on three sides by oil and gas fields and agricultural lands.

On the north side, NPR-1 is contiguous with a large area of relatively undisturbed habitat known as the Lokern Road area (URS 2012d). Also located north of EHOF, is the Lokern Ecological Preserve (LEP), approximately 3,900 acres in size. McKittrick Valley and portions of Buena Vista Valley with Highway 33 running northwest-southeast are to the west of the EHOF. The cities of McKittrick and Derby Acres are located along Highway 33 and approximately ten miles farther to the west and across the Temblor Range is the Carrizo Plain National Monument, an Area of Critical Environmental Concern. To the south and partially contiguous with NPR-1 is the Buena Vista Valley

and NPR-2; the NPR-2 is approximately 30,000 acres in size and was recently transferred from DOE ownership to the Bureau of Land Management. Natural vegetation on NPR-1 consists primarily of valley saltbush scrub, sink scrub, and non-native grassland habitat (HECA 2012b, Appendix A). Lands to the east include Coles Levee Ecological Preserve (approximately 6,059 acres), the Kern Water Bank Authority (approximately 19,900 acres), the Tule Elk State Reserve and the Kern River. The Buena Vista Lake Bed is located immediately southeast of Highway 119.
Several natural resource conservation areas occur in the project area including the following (**Biological Resources Figure 1**):

- The EHOF has been heavily studied and monitored for biological resources for over 30 years. Currently, a California Endangered Species Act (CESA) Memorandum of Understanding (MOU) between CDFW and OEHI in conjunction with a 1995 USWFS Biological Opinion (BO, URS 2012d) prescribe measures to avoid, minimize, and mitigate adverse effects to listed plant and wildlife species, one measure of which is the designation of a 7,075-acre conservation area on and adjacent to the Elk Hills Unit. Populations of special-status wildlife species known to occur at Elk Hills include San Joaquin kit fox, giant kangaroo rat, Tipton kangaroo rat, blunt-nosed leopard lizard, San Joaquin antelope ground squirrel, burrowing owl, among other wildlife and many plants considered rare, threatened, or endangered by the California Native Plant Society (CNPS) are known to occur on the EHOF and are essential to the continued existence of these species;

- The approximate 950-acre Tule Elk State Reserve is located south of the community of Buttonwillow between HECA and the Kern Water Bank and has been a refuge for tule elk for over 60 years. In the San Joaquin Valley, the remaining elk range was limited to the willow and tule-filled marshes between Buena Vista and Tulare Lakes; however gradually these lands disappeared as the area was diked, drained, and cleared for agriculture. As early as 1912, proposals were made to provide a fenced preserve near Buena Vista Lake in Kern County and protect the depleting elk population from local agricultural interests. In 1932, the State Park Commission purchased 953 acres near the town of Tupman and the new Tupman Reserve was completely fenced to enclose the elk. In 1954, management of the 41 surviving elk in the Tupman Reserve was turned over to California State Parks which devised a feeding program and constructed artificial ponds for the elk to use (California State Parks 2004, Harrison et al 1987); however, past management practices have resulted in a degraded ecosystem unable to support the elk herd without supplemental feeding. Funding has been secured to keep the park open and an endowment has been set up to feed the elk herd (pers. comm.California State Parks). Presently, tule elk have access to approximately 600 acres inside the Tule Elk State Reserve (Pers. comm. California State Parks). Long-term monitoring surveys indicate the Tule Elk State Reserve also supports the following special-species: western burrowing owl, San Joaquin kit fox, blunt-nosed leopard lizard, Tipton kangaroo rat, San Joaquin pocket mouse, San Joaquin antelope squirrel, a large population of slough thistle, among many other common and special-status plant and wildlife species (Pers. comm. California State Parks);

- The Lokern Ecological Reserve (LER) is comprised of parcels previously designated as mitigation lands under the Bakersfield Metropolitan Habitat

Conservation Plan that were in time deeded over to CDFW as conservation lands. The LER consists of several disjunct parcels along both sides of the California Aqueduct between Elk Hills Road and 7th Standard Road. The LER is part of the much larger Lokern Natual Area which includes over 40,000 acres of high-quality habitat for various wildlife and plant species of the San Joaquin Valley. The LER supports similar species as those discussed above as well as occurrences of western pond turtle, California tiger salamander, tricolored blackbird, short-nosed kangaroo rat, giant kangaroo rat, and slough thistle, a sensitive plant that occurs in alkali meadows and flats in the southern San Joaquin Valley are also known from the LER;

- The Buttonwillow Ecological Reserve (BER) is known to support several rare plant species including heartscale, lesser saltscale, Lost Hills crownscale, Kern mallow, and San Joaquin woolythreads and sensitive wildlife species such as blunt-nosed leopard lizard, California horned lizard, Swainson's hawk, San Joaquin antelope squirrel, Tipton kangaroo rat, Buena vista lake shrew, and San Joaquin kit fox;

- The Department of Water Resources is pursuing a Habitat Conservation Plan (HCP) and a companion State Incidental Take (Section 2081) Permit, collectively the draft California Aqueduct Habitat Conservation Plan area, for the entire length of the California Aqueduct that occurs between Kettleman City and the Grapevine area along Interstate 5. The HCP is in draft form and not permitted, to date.

- The Kern Water Bank, operated by the Kern Water Bank Authority recharges, stores, and recovers groundwater in the Bakersfield area and includes several thousand acres of recharge basins and recovery wells (HEI 2009a). A portion of the Kern Water Bank is also a mitigation bank that is permitted and authorized to sell mitigation credits to developers as project mitigation for impacts to a select number of species; and

- The Coles Levee Ecosystem Preserve (CLEP) is located approximately 3.5 miles southeast of the project area. CLEP, a working oil field, is a preserve that was established through an agreement between ARCO, CDFW, and USFWS. It was an operating mitigation bank for projects that impacted threatened and endangered species in the project area vicinity, but the mitigation bank credits have been sold out for some time. CLEP is currently managed by Aera Energy and CDFW holds a permanent conservation easement over all of CLEP. CLEP supports grassland, alkali marsh, and saltbush scrub habitats and there are known occurrences of special-status plants including slough thistle, oil nest straw, San Joaquin bluecurls, Hoover's eriastrum, recurved larkspur, and gypsum-loving larkspur. Wildlife species known from CLEP include San Joaquin antelope squirrel, Heerman's kangaroo rat, Tipton kangaroo rat, short-nosed kangaroo rat, American badger, San Joaquin pocket mouse, blunt-nosed leopard lizard, western spadefoot toad, golden eagle, burrowing owl, and prairie falcon among many other common and rare wildlife species.

Habitat Types

The project area supports five main habitat communities as discussed in more detail below and summarized in **Biological Resources Table 2**.

Biological Resources Table 2:
Upland Habitat Types within Project Area[1]

Vegetation Community/Cover Type in project area	Project Site and construction laydown	Linear Facility	Total
Allscale scrub/natural vegetation	0	32.7	32.7
Alfalfa	177.8	25.54	203.34
Other row crops	337.3	31.13	368.43
Orchards	0	8.91	8.91
Developed/disturbed	28.9	130.85	159.75
Total	**544.0**	**229.13**	**773.13**

Project Setting

Vegetation and Wildlife

Allscale scrub and several agricultural crop types characterize the biological communities within the project area. Although the individual crop types do not translate into habitat types identified by resource databases or agencies, farmed agricultural land still provides biological value to wildlife as described in more detail below.

Areas along Stockdale Highway and Highway 58 are characterized primarily by almond orchards, farmed lands of alfalfa, cotton, and corn, and occasional dairy farms and homesteads with irrigation canals and raised levee roads between fields. Natural habitat areas of allscale scrub are interspersed between actively cultivated areas and lower elevation erosional drainages. Besides pistachio and almond orchards, alfalfa and other row crops are generally dense and low growing.

The proposed carbon dioxide pipeline route located on the lower flanks of the Elk Hills and immediately north of a portion of the Elk Hills conservation area is the linear route that supports the most contiguous natural, non-farmland type of habitat in the project area. The low-lying washes on the lower flanks of the Elk Hills where the carbon dioxide pipeline route is proposed supports sparse allscale scrub habitat and primarily alkaline soils (HECA 2012b, Appendix A, Attachment A). Non-native annual grassland seems to dominate the carbon dioxide pipeline route although vegetation associated with valley sink scrub is intermixed in low-lying washes. Most of the mammal species on NPR-1 are

[1] These acreages were developed from Data Request Table A56-1, area of habitats and existing land use types within the project area (URS 2013b) and Table A211-1 Disturbed Acreages (URS 2013b) and do not include habitat disturbances associated with the OEHI component which are discussed in the Carbon Capture and Sequestration Enhanced Oil Recovery Project on Elk Hills Unit portion of this PSA section.

rodents; however, the coyote (*Canis latrans*) population on EHOF significantly increased from 1979 to 84 and predation on San Joaquin kit fox (*Vulpes macrotis mutica*) prompted a coyote control program. Most of the bird species that utilize the oil field are either permanent or seasonal residents, with several transient migrant bird species as well. In addition, portions of the natural gas pipeline route also support areas of disturbed, natural allscale scrub primarily Sites 1 through 5 shown on **Biological Resources Figure 2**. Some of these sites represent similar habitat values as the nearby Buttonwillow Ecological Reserve, generally located north of the project site.

Allscale Scrub

Allscale scrub habitat is the dominant natural community in the project area, which is interspersed with non-native annual grasslands and farmed agricultural lands. The proposed linear facilities support approximately 33 acres of natural allscale scrub habitat; however, the project site itself does not support any allscale scrub since it is in active cultivation. Generally, the few natural areas in the project area that are not farmlands, support patches of natural allscale scrub vegetation intermixed with non-native annual grasslands with varying levels of disturbance. The applicant identified natural scrub habitat occurring south of the proposed processed water pipeline between the West Side Canal and Kern River Flood Control Channel (KRFCC), along portions of the natural gas pipeline along Highway 58 and north (HECA 2012b). The KRFCC, Kern Water Bank, Tule Elk State Reserve, the lower flanks of the Elk Hills south of the California Aqueduct, and other interspersed areas support native allscale scrub habitat. Some of the wetter areas with more alkaline soils support alkali sink scrub; however, these areas are not located within the project's footprint of the linear facilities and would not be developed for the project. Previously, the applicant identified the habitat between the canals and south of the water pipeline as allscale riparian scrub (HEI 2009a). These habitats are described in more detail below, but most closely characterize the allscale scrub community and the *Atriplex polycarpha* shrubland alliance and allscale scrub series described in the *Manual of California Vegetation,* Second Edition (URS 2010k).

Allscale scrub is characterized as a low-growing, gray-colored, microphyllous shrub community with succulent shrubs with a height ranging from 0.3 to 1 meter (Holland 1986). Total shrub cover is low, with much bare ground between widely spaced shrubs. The allscale scrub community within the biological survey area is dominated by allscale (*Atriplex polycarpha*) and other associate species including bladderpod (*Isomeris arborea),* and cheesebush (*Hymenoclea salsola*). This vegetation community is equivalent to the *Atriplex polycarpha* shrubland alliance described in the *Manual of California Vegetation,* Second Edition (URS 2010k), which characterizes an *Atriplex polycarpa*-dominated community as the allscale series (Sawyer-Keeler Wolfe 1995). The allscale series has allscale as the sole or dominant shrub in the canopy along with bladderbod, bush buckwheat (*Eriogonum fasciculatum*), cheesebush, honey mesquite (*Prosopis glandulosa*), saltbush (*Atriplex* sp.), and salt grass (*Distichlis spicata*). These communities are also consistent with the San Joaquin saltbush vegetation community described in *Terrestrial Vegetation of California* (Barbour et al 2007). Barbour (2007) describes this community occurring mainly on the southern and western part of the San Joaquin Valley as an open, broad-leaved evergreen or deciduous shrub community with a herbaceous layer that varies from medium density to absent with the structure varying in short distances.

The proposed carbon dioxide pipeline route also supports natural allscale scrub interspersed with non-native grasses and forbes and as indicated above, this facility represents the largest block on non-farmland scrub habitat in the project area, mostly due to its location on the lower flanks of Elk Hills. Non-native annual grassland seems to dominate the carbon dioxide pipeline routealthough vegetation associated with valley sink scrub is intermixed in low-lying washes. Plant species observed along the carbon dioxide route during February 2011 field surveys include non-native grasses and forbs including fiddleneck (*Amsinckia menziesii* var. *intermedia*), red brome (*Bromus madritensis* spp. *rubens*), pepperweed (*Lepidium* sp.), valley popcorn-flower (*Plagiobothrys* sp.), red-stemmed filaree (*Erodium cicutarium*), annual sunflower (*Helianthus annus*), and tidy-tips (*Layia glandulosa*) with occasional saltbush shrubs but shrub density increased in steeper, higher elevations of Elk Hills (HECA 2012b, Volume 2, Appendix A-2 of Appendix A).

Alfalfa, Other Row Crops, and Orchards

The project area supports approximately 203 acres of alfalfa (*Medicago sativa*) fields. Alfalfa occurs in association with neighboring cotton and orchards. Several agricultural ditches conveying irrigation water and farm roads transverse the project area between fields. The project area also supports approximately 368 acres of actively farmed fields of other crop types including cotton, dry onion, safflower, wheat, grape, and corn (**Biological Resources Table 2)**. Various non-native plant species also occur in the project area in association with cultivated agricultural lands that include, in part, curly dock (*Rumex crispus*), plantain grass (*Plantago* sp.), Russian thistle (*Salsola tragus*), fescue (*Vulpia* sp.), and storksbill (*Erodium botrys*) (URS 2009c). Agricultural fields, row crops, orchards, and intermixed irrigation ditches provide a wealth of habitat values to locally common and rare wildlife species. These habitats provide various food, cover, and foraging habitat components for several species of birds, amphibians, reptiles, and small mammals. Common wildlife species observed during various field surveys include common side-blotched lizard (*Uta stansburiana*), bullfrog (*Rana catesbiana*), western toad (*Bufo boreas*), great egret (*Ardea alba*), mourning dove (*Zenaida macroura*), black phoebe (*Sayornis nigricans*), western kingbird (*Tyrannus verticalis*), northern mockingbird (*Mimus polyglottos*), horned lark (*Eremophila alpestris*), raccoon (*Procyon lotor*), and coyote. Several raptor species are known to forage and nest in association with agricultural fields including Swainson's hawk, a state-threatened species that forages primarily over alfalfa fields and other low-growing crop types.

Developed or Disturbed Areas

Approximately 160 acres of disturbed or developed lands occur in the project area, primarily along named canals and channels and farm roads, canal maintenance roads. Areas not designated as row crop, orchard, alfalfa, or natural allscale scrub are considered developed or disturbed (URS 2013b)

Sensitive Vegetation Communities

The California Natural Diversity Database (CNDDB) identifies three sensitive vegetation communities occurring within a 10-mile radius of the project area including Great Valley mesquite scrub, valley saltbush scrub, and valley sink scrub (CDFG 2012, HECA 2012b). These vegetation communities have a global and state rank of either G1 or G2 and S1 or S2 indicating that the communities are critically imperiled globally and very threatened statewide.

Alkali sinks are drainage basins that have soils high in soluble salts and the basins are typically dominated by halophytes (plants tolerant of alkaline and saline soils) (USFWS 1998). Alkali sinks in the San Joaquin Valley typically support scrub plant communities such as alkali playa and valley sink scrub. Valley sink scrub is characterized by low, open dense succulent plants dominated by alkaline-tolerant chenopod shrubs (e.g. *Allenrolfea occidentalis* and *Sueda* sp.) with little understory or a sparse herbaceous layer. In these communities, high groundwater supplies water to perennial plants; historically, perennial plant species drew water from the high groundwater table associated with Kern, Buena Vista, Tulare, and Goose Lakes in the San Joaquin Valley (Garcia and Associates 2006). Several anthropogenic activities have caused the loss and degradation of these natural communities and species associated with them since the mid-1800s from livestock grazing, water impoundment, diversion, and stream channelization primarily due to urbanization and agricultural development (USFWS 1998).

Sections of the KRFCC that run adjacent to the proposed processed water pipeline support areas of valley sink scrub and valley saltbush scrub; however, this linear facility would not directly impact the KRFCC although gradual groundwater drawdown could potentially cause a long-term decline in these rare plant communities. In addition, small, interrupted sections of willow (*Salix* sp.), Fremont's cottonwood (*Populus fremontii*), and tamarisk occur along the KRFCC and the West Side Canal and between agricultural fields; however these areas are not considered well-developed riparian scrub communities due to lack of developed, multi-layered canopy, low cover, and low species diversity. Fremont cottonwoods are the single-most important riparian species in California since this species dominates the few remaining riparian forests in the Central Valley and other riparian areas throughout cismontane and transmontane California (Warner and Hendrix, ed. 1984). However, due to water diversion and reclamation projects, stream channelization, and unregulated clearing of riparian areas since the early 1900s and even early since the pre-settlement era due to gold mining, riparian communities have drastically declined in acreage and habitat quality and typically only occur in small stands. Extant riparian communities in the San Joaquin Valley are estimated to be approximately 7,000 acres and exist as degraded, narrow stands of riparian vegetation along channelized streams (USFWS 1998).

Waters of the United States (including Wetlands)

For purposes of DOE, this section of the PSA/DEIS describes wetlands potentially affected by the construction and operation of HECA. This section also analyzes the potential direct and indirect effects of the proposed project on wetlands. This section provides the required wetland assessment and this PSA/DEIS provides an opportunity for public review in compliance with regulations promulgated at 10 CFR 1022, "Compliance with Floodplain and Wetland Environmental Review Requirements." These regulations provide a guide for DOE compliance with Executive Order (EO) 11990, “Protection of Wetlands.” EO 11990 requires that federal agencies, while planning their actions, consider alternatives to affecting wetlands, if applicable, and limit adverse impacts to the extent practicable if impacts cannot be avoided.

The applicant mapped a total of 187.91 acres of water features within the project area, of which 92.51 acres were identified as potential waters of the U.S. including portions of the West Side Canal/Outlet Canal; Kern River Flood Control Channel; East Side Canal; California Aqueduct; several agricultural ditches, canals, and stock ponds that connect to these features; and depressional wetland areas (URS 2012a). The following features were identified as potential Waters of the U.S. (URS 2013c):

- Seasonally ponded depressions (2.93 acres);
- California Aqueduct (1.70 acres); and
- Kern River Flood Control Channel (87.88 acres).

The applicant performed formal wetland delineation surveys of the project area during December 2010 and March 2012 and submitted revised waters of the U.S. maps to staff showing the location of delineated waters of the U.S. (URS 2012a); likewise, the applicant submitted a Jurisdicitonal Delineation report and Nationwide Permit Preconstruction Notification 33 during March 2013 (URS 2013c) which staff has prelimarily reviewed.

Several depressional wetland areas were mapped along disturbed, shoulder areas north and south of Highway 58 where the natural gas pipeline linear is proposed. This area is highly disturbed from development of Highway 58, the San Joaquin Valley Buttonwillow Railroad line, and farmland harvest activities and farm roads south of the highway. Generally speaking, these features do not support all three wetland criteria parameters (hydrophytic vegetation, hydric soils, and wetland hydrology) to be classified as wetlands and were therefore identified as non-jurisdictional waters. The majority of these features support sufficient hydrology to sustain ponded water for a sufficient period of time and exhibit hydric soil indicators due to ponding; however, most features do not support hydrophytic vegetation. One feature, WL-1 located north of Highway 58, does support hydrophytic vegetation and was identified as a wetland feature. However, the extent of Corps jurisdiction over these delineated features under Section 404 of the Clean Water Act has not been determined at this time.

The Kern River flows west to southwest through the city of Bakersfield and under Highway 119 in the project area. The Kern River occurs approximately five miles southeast of the project area and therefore would not be directly affected by the project. The KRFCC supports natural, alkali scrub habitat and is an overflow channel to the Kern River. In previous Jurisdictional Determinations made by the Corps in the project vicinity, the Corps has taken jurisdiction over the Kern River and the KRFCC since it is tributary to the Kern River. The applicant has identified the West Side Canal, East Side Canal, and all connecting basins and drainage ditches as non-jurisdictional; however, since these two named canals connect to the Kern River and two lakes in the Buena Vista Aquatic Recreation Area, Lake Evans and Lake Webb (HECA 2012b), the Corps may have Section 404 jurisdiction over these features as well. Typically, the U.S. Army Corps of Engineers (Corps) would not have Clean Water Act Section 404 jurisdiction over irrigation ditches or canals excavated in uplands that drain uplands; however, the Corps often determines its extent of jurisdiction while taking into consideration the local hydrology and surface water connections specific to the project area.

Waters of the State

Some or all of the potential federally jurisdictional waters described above may also fall under state jurisdiction. CDFW typically does not have jurisdiction over agricultural stock ponds or detention basins; however, some canals do fall under Fish and Game Code Section 1600 jurisdiction. CDFW has taken jurisdiction over portions of the Kern River Flood Control Channel for other projects primarily due to the presence of a defined bed and bank with alkali sink habitat and direct overland flow connection to the Kern River. Since the West Side Canal was constructed to convey irrigation water from the Kern River to nearby fields, this feature would not likely fall under Section 1600 jurisdiction (CDFW, pers comm. October 2012). The applicant has proposed HDD for the carbon dioxide pipeline under the West Side Canal, KRFCC, and California Aqueduct (HECA 2012b). CDFW has indicated since the proposed HDD activities could result in a frac-out into waterways during drilling, a HDD plan is needed along with submittal of the project's notification of a Lake or Streambed Alteration to CDFW (CDFW, pers comm. October 2012). The applicant submitted a Notification of a Lake or Streambed Alteration package to the agencies including a draft HDD Plan during May 2013 which staff has preliminarily reviewed (URS 2013d).

Ephemeral Drainages

The carbon dioxide pipeline route occurs in a transitional area between higher topographic areas from the Elk Hills towards the lower flanks of the Elk Hills and lowland valley areas. As a result, the proposed route supports several ephemeral drainages with a defined bed and bank that likely convey water for a short period following rain events, but otherwise remain dry. Drainages in the higher foothill elevation areas consist of defined washes approximately 3 to 10 feet wide with very little vertical erosion while lowland area drainages consist of low (sink) zones with approximately 4 to 10 feet of vertical erosion and steeply incised channels (HECA 2012b, Appendix A, Attachment A). The ephemeral drainages may fall under Fish and Game Code Section 1600 jurisdiction.

Special-Status Species

Special-status species are plant and wildlife species that have been afforded special protection and recognition by federal, state, or local agencies and environmental protection laws such as those identified in **Biological Resources Table 1**. Listed and special-status species are of relatively limited distribution and often times require specialized habitat conditions. Special-status species are defined as meeting one or more of the following criteria:

- listed as Threatened or Endangered or candidates for future listing under the California Endangered Species Act (CESA) or Federal Endangered Species Act (FESA);
- protected under other regulations (e.g. Migratory Bird Treaty Act);

- listed as Species of Concern by CDFW;
- a plant species considered by the California Native Plant Society (CNPS) to be "rare, threatened, or endangered in California" (CNPS List 1A, 1B, and 2) as well as CNPS List 3 and 4 plant species[2];
- a plant listed as rare under the California Native Plant Protection Act ;
- considered a locally significant species, that is, a species that is not rare from a statewide perspective but is rare or uncommon in a local context such as within a county or region or is so designated in local or regional plans, policies, or ordinances; or
- any other species receiving consideration during environmental review under CEQA Section 15830, including species not protected through state or federal listing but nonetheless demonstrable as "endangered" or "rare" under CEQA.

Special-status species considered for this analysis are based on information provided in the Amended AFC (HECA 2012b), species queries of the California Natural Diversity Database (CDFG 2012), species list provided in the 1997 Final SEIS/PEIR for the sale of Naval Petroleum Reserve-1 (OXY 2012c), USFWS's online list for federally listed species, and CNPS online list for potentially occurring rare plants on the *East Elk Hills, CA* 7.5-minute topographic quadrangle map (USGS 1954, photorevised 1974) and nine surrounding quadrangles, plant and wildlife species known to occur or potentially occurring on EHOF, correspondence with the applicable resource agencies, and species covered under the Recovery Plan (USFWS 1998).

Biological Resources Table 3 lists special-status species that are known to occur or could potentially occur in the project area and vicinity and therefore, could potentially be impacted by the project. Several special-status plant species were found during biological surveys along the linear facilities, primarily along the proposed carbon dioxide pipeline route as indicated in **Biological Resources Table 3**.

As indicated in **Biological Resources Table 4**, several special-status wildlife species were either detected during field surveys performed in support of the currently proposed project or former project versions of HECA or are known to occur in the project area and therefore considered present or highly likely to occur, primarily in association with the Elk Hills region.

---

[2] List 3 plants may be analyzed under CEQA §15380 if sufficient information is available to assess potential impacts to such plants. Factors such as regional rarity vs. statewide rarity should be considered in determining whether cumulative impacts to a List 4 plant are significant even if individual project impacts are not. CNPS List 3 and 4 may be considered regionally significant if, e.g., the occurrence is located at the periphery of the species' range, or exhibits unusual morphology, or occurs in an unusual habitat/substrate. For these reasons, CNPS List 3 and 4 plants should be included in the field surveys and impact analyses. List 3 and 4 plants are also included in the California Natural Diversity Database's (CNDDB) Special Plants, Bryophytes, and Lichens List. [Refer to the current online published list available at: http://www.dfg.ca.gov/biogeodata.]

Biological Resources Table 3
Special-Status Plant Species Known or Potentially Occurring in the Project Area

Common Name	Scientific Name	Status State/Fed/CNPS
Alkali mariposa lily	*Calochortus striatus*	--/--/1B.2
Bakersfield cactus	*Opuntia basilaris* var. *treleasei*	SE/FE/1B.1

Status Codes:

Federal:
FE - Federally listed, endangered: species in danger of extinction throughout a significant portion of its range
FT - Federally listed, threatened: species likely to become endangered within the foreseeable future
FC = Federal candidate for listing
BCC: Fish and Wildlife Service: Birds of Conservation Concern: Identifies migratory and non-migratory bird species (beyond those already designated as federally threatened or endangered) that represent highest conservation priorities <www.fws.gov/migratorybirds/reports/BCC2002.pdf>
BLM Sensitive= Bureau of Land Management Sensitive species

State
CSC = California Species of Special Concern. Species of concern to CDFW because of declining population levels, limited ranges, and/or continuing threats have made them vulnerable to extinction.
SE - State listed as endangered
ST = State listed as threatened
R = State listed as rare.
SFP = Fully protected
WL = State Watch List: includes species formerly on California Species of Special Concern List

Special-status Plant Species

Botanical surveys were performed on various dates during March 2009, April and May 2010, and March 2012 for the project areain support of the currently proposed project or former project versions of HECA; non-protocol level botanical surveys for the current carbon dioxide pipeline route were performed during February 2011 and April 2011. Rare plant surveys were performed in suitable habitat areas on previously unsurveyed areas of the linear facilities on March 27 through March 30, 2012; however, rainfall was below average during the late 2011/2012 season and many spring annuals either did not germinate or failed to flower and therefore the 2012 survey season was not a satisfactory season for determining growth and presence or absence of special-status plant species (URS 2012a). Moreover, the majority of unsurveyed areas of Sites 1, 2, 3, and 5 along the natural gas pipeline route were not surveyed in 2012 due to access restrictions (URS 2012a).

The following special-status plant species were either observed during spring 2009, 2010, or 2011 botanical surveys and/or were considered to have a high potential to occur in the project area due to confirmed observations from ongoing long-term monitoring surveys performed on EHOF since 1998:

- Hoover's eriastrum (*Eriastrum hooveri*)
- Gypsum-loving larkspur (*Delphinium gypsophilum* spp*. gypsophilum*)
- Lost Hill's crownscale (*Atriplex vallicola*)
- Cottony buckwheat (*Eriogonum gossypinum*)
- Oil nest straw (*Stylocline citroleum*)
- Recurved larkspur (*Delphinium recurvatum*)
- San Joaquin bluecurls (*Trichostema ovatum*)
- Tejon poppy (*Eschscholzia lemmonii* ssp. *kernensis*)

Hoover's Eriastrum (Eriastrum hooveri, **California Native Plant Society List 4.2*)***

Hoover's eriastrum is an annual herb species on CNPS List 4.2 that grows within chenopod scrubs, grasslands, and gently growing terrain or flats with alkaline, sandy soils from approximately 150 to 2,700 feet elevations in foothill regions (CNPS 2013) but also commonly occurs below 600 feet in elevation (Garcia and Associates 2006). Hoover's eriastrum is known to occur throughout the EHOF in several parcels and sections and has been monitored annually since 1998 (Quad Knopf 2001). A large population of Hoover's eriastrum occurs in the Coles Levee Ecosystem Preserve on the historic Buena Vista Lake bed and on the Elk Hills (Garcia and Associates 2006). Originally, this species was known from 39 historical locations, although by 1986 only 22 of these locations were believed to be extant. Surveys conducted between 1986 and 1990 identified an additional 91 populations and surveys conducted since 1990 have resulted in the identification of even additional populations. It is believed that most extant occurrences of Hoover's eriastrum occur in the following areas: the Lokern-Elk Hills-Buena Vista Hills-Coles Levee-Maricopa-Taft area, the Antelope Plain-Lost Hills-Semitropic area, and the Carrizo Plain-Elkhorn Plain-Temblor Range-Caliente Mountains-Cuyama Valley-Sierra Madre Mountains area (Garcia and Associates 2006).

CNDDB records for this species occur in the vicinity of the Buttonwillow Airfield and the base of Elk Hills from saltbush scrub habitats within existing oil and gas development areas (CDFG 2012). There are 63 records of this species from the Consortium of California Herbaria mostly from Kern, Los Angeles, Fresno, San Luis Obispo, and Santa Barbara counties. Records from Kern County for Hoover's eriastrum are from the general vicinity of Highway 58, Highway 46, Lokern Road, Highway 119, Buttonwillow, and Lost Hills (CCH 2010).

Year 2001 marked the last year of comprehensive floristic surveys at EHOF; however, annual monitoring of changes in Hoover's eriastrum woolly-star abundance relative to other vegetative parameters in response to abiotic factors has been conducted on six sites throughout Elk Hills since 1993. Sites were randomly selected during 1993 based on the then 110 known occurrences of this species on ElK Hills. Annual monitoring of the six sites was completed during April 2011 and mean densities of this species ranged from zero to 9.97 individual plants per square foot. The frequency of occurrence ranged from zero to 70 percent on the six plots. Site #5 is the closest monitoring site to the proposed carbon dioxide pipeline route and the average density was 1.33 plants per square foot at this location (Western Kern Environmental Consulting 2012).

Allscale scrub communities within the project area are potential habitat for Hoover's eriastrum. This species was observed during focused botanical surveys and reconnaissance-level biological surveys. This species was also found during surveys performed for previous versions of the HECA project. A population of approximately 1,000 individuals of Hoover's eriastrum was observed during spring 2009 surveys near the Elk Hills School (URS 2009c) in close proximity to the current carbon dioxide pipeline route. In addition, approximately 100,000 individual plants were found during April and May 2010 field surveys within the formerly proposed natural gas/potable water linear facility and carbon dioxide routes (URS 2010k). Additionally, this species was observed along a roadside during a survey performed on April 14, 2011 along the currently proposed carbon dioxide route (HECA 2012b, Appendix A Attachment A).

***Gypsum-loving Larkspur* (*Delphinium gypsophilum* ssp. *gypsophilum,* California Native Plant Society List 4.2)**

Gypsum-loving larkspur is a CNPS List 4.2 species that the California Native Plant Society considers a species of limited distribution although fairly endangered in California (CNPS 2013); this species typically occurs in chenopod scrubs, cismontane woodland, and foothill grasslands from 300 to 2,500 feet above mean sea level (CNPS 2013). Gypsum-loving larkspur is considered a common plant species on Elk Hills and has been found in 72 sections of Elk Hills since monitoring surveys began in 1995. On Elk Hills, this species commonly occurs on north facing slopes and has not been observed on flat terrain during surveys performed since 1995 in the Elk Hills (Quad Knopf 2001). There are 118 records of this species from the Consortium of California Herbaria primarily from Kern, San Luis Obispo, Fresno, and Merced counties. The nearest records from Kern County are from the Temblor Range of the Coast Ranges near Bitter Creek National Wildlife Refuge, Kettleman Hills, Wheeler Ridge, and along Tupman Road northwest of Taft (CCH 2010).

Allscale scrub habitat in the project area is potential habitat for gypsum-loving larkspur. This species was found during surveys performed along former project linear routes; however, this plant has not been observed within the construction footprints of any current linear routes. During April and May 2010, approximately 100 plants were found within the formerly proposed natural gas/potable water and carbon dioxide route (URS 2010k), although this area is located east of the currently proposed carbon dioxide pipeline and would not be directly impacted.

***Lost Hills Crownscale (Atriplex coronata var.vallicola,* California Native Plant Society List 1B.2)**

Lost Hills crownscale is a CNPS List 1B.2 species indicating that the California Native Plant Society has determined that the species is rare, threatened, or endangered in California. This small, annual herb also occurs in chenopod scrub habitats and valley and foothill grasslands and has also been reported occurring from valley saltbush scrub in the Elk Hills area (CNPS 2013, CDFG 2012). Lost Hills crownscale is considered an uncommon species on the EHOF and has been observed in nine sections since monitoring surveys began in 1995. This species was last surveyed for on Elk Hills during the 2001 comprehensive floristic survey and was primarily found to grow on the southern and eastern flanks of Elk Hills following 1999, 2000, and 2001 surveys (Quad Knopf 2001).

Lost Hills crownscale is a covered species under the Recovery Plan (USFWS 1998) and occurs in valley sink scrubs, saltbush scrubs, non-native grasslands, and alkali meadows. The CNPS reports this species occurs from 150 feet to 1,900 feet elevation (CNPS 2013). However, valley-floor populations occur at elevations of 165 to 280 feet elevation whereas those on the Carrizo Plain range from approximately 1,300 to 2,000 feet in elevation (USFWS 1998). Lost Hills crownscale has been reported from the margins and beds of dried ponds on alkaline soils below 650 feet elevation in the San Joaquin Valley and possibly in the Carrizo Plain of San Luis Obispo County, but plants from the latter location are undescribed (Garcia and Associates 2006). Prior to the 1980s, this species was reported from three general areas: north of Lost Hills, Mendota in Fresno County, and the Carrizo Plain in San Luis Obispo County. In the 1980s, a number of new sites were discovered near the Lost Hills and on the Carrizo Plain and the current distribution and centers of concentration are currently known as: Lost Hills to extreme southern Kings County; Kerman Ecological Reserve in Fresno County; Soda Lake region of the Carrizo Plain; the Lokern-McKittrick area of Kern County; and southwestern Merced County. Additionally, the Lost Hills and Carrizo Plain areas represent the largest metapopulations (USFWS 1998).

There are 68 records of this species from the Consortium of California Herbaria most of which are from Kern, Fresno, and San Luis Obispo counties. The nearest records for this species to the project area include fairly recently reported records (late 1980s) near Buena Vista Slough, Lost Hills, and west of Elk Hills near McKittrick (CCH 2010).

Approximately 80 plants of Lost Hills crownscale were found within the formerly proposed natural gas/potable water pipeline route (URS 2010k), although this species has not been observed within current HECA linear routes. Allscale scrub habitat in the project area is potential habitat for this species.

Cottony Buckwheat (Eriogonum gossypinum, California Native Plant Society List 4.2)

Cottony buckwheat is a CNPS List 4.2 indicating it is of limited distribution and fairly endangered in California (CNPS 2013). Cottony buckwheat occurs in chenopod scrub habitat. Cottony buckwheat is known to occur throughout the EHOF and has been found most prevalently from the northwestern portion of Elk Hills since monitoring surveys began in 1995. On the Elk Hills, this species commonly occurs on south facing slopes in association with wild oat (*Avena* sp.), red brome (*Bromus madritensis* ssp. *rubens*), red-stem filaree (*Erodium botrys*), allscale, bladderpod, and mousetail grass (*Vulpia myros*) (Quad Knopf 2001).

There are 71 records of this species from the Consortium of California Herbaria most of which are from Kern County; the nearest records for cottony buckwheat are from Hart Memorial Park near the Kern River in Bakersfield, Oil City and McKittrick areas, Maricopa Hills, and Elk Hills (CCH 2010). Approximately 500 plants of this species were found during April and May 2010 in a previously proposed route for the carbon dioxide pipeline (URS 2010k); however, this species has not been observed within current linear routes. Due to the presence of suitable habitat, identified occurrences during field surveys and known occurrences from the EHOF, allscale scrub communities in the project area are potential habitat for cottony buckwheat.

Oil Neststraw (*Stylocline citroleum,* California Native Plant Society List 1B.1)

Oil neststraw is a CNPS List 1B.1 indicating it is of limited distribution and the California Native Plant Society considers this species to be rare, threatened, or endangered in California (CNPS 2013). This species is an inconspicuous, low-growing annual herb that lacks showy flowers. Presently, oil nest straw is known from Elk Hills and the Coles Levee Ecosystem Preserve in western Kern County from petroleum-producing areas; however, extant occurrences are known from saltbush scrub communities in undeveloped areas as well. One occurrence of oil nest straw from EHOF is from a steep wash bank with a well-developed cryptobyotic crust (USFWS 1998). Oil nest straw has been found in 61 sections in Elk Hills since monitoring surveys began in 1995 and most prevalently in the northwestern and southeastern portions; it was found most commonly in areas with reduced annual grass cover and sandy soils (Quad Knopf 2001). This species grows in flats and on slopes within valley and foothill grassland and chenopod scrubs from approximately 150 to 1,200 feet elevation and has been reported from both sandy and clay soils. There are ten records of this species in the Consortium of California Herbaria, eight of which are from Kern County; the nearest records are from the Taft and McKittrick areas and two records from the Naval Petroleum Reserve in Elk Hills (CCH 2010).

Approximately 15,000 oil nest straw plants were found during April and May 2010 in the formerly proposed natural gas/potable water pipeline routes and carbon dioxide route (URS 2010k). Additionally, this plant and Hoover's eriastrum were observed along a roadside during a survey performed on April 14, 2011 on the currently proposed carbon dioxide route (HECA 2012b, Appendix A Attachment A). Due to the presence of suitable habitat, identified occurrences during field surveys and known occurrences from the EHOF, all allscale scrub habitat in the project area is potential habitat for oil neststraw.

Recurved Larkspur **(*Delphinium recurvatum,* California Native Plant Society List 1B.2)**

Recurved larkspur is a CNPS List 1B.2 species that the California Native Plant Society considers to be rare, threatened and fairly endangered in California. This species occurs in valley and foothill grasslands, cismontane woodlands, and chenopod scrubs from approximately sea level to 2,300 feet elevation. This species occurs on poorly drained, fine alkaline soils in valley saltbush and alkali sink scrub below 2,000 feet elevation, from Glenn and Butte counties southward to Kern County in the Central Valley. Recurved larkspur is known from several widely scattered occurrence areas, a few which include areas between the Kern National Wildlife Refuge and Interstate 5, west of the Tule Elk Reserve near the base of the Elk Hills, northeast of the Lokern Natural Area, and east of Coles Levee Ecosystem Preserve (Garcia and Associates 2006). There are 159 records (34 records from Kern County) of this species for the entire state from the Consortium of California Herbaria (CCH 2010); the majority of the Kern County occurrences are from the Wasco-Corcoran Highway, Bakersfield, and Elk Hills areas. The nearest CNDDB record is approximately 1.5 miles west of the project site from loamy, saltbush scrub habitat during 1998 (CDFG 2012) and recurved larkspur has been found but is considered uncommon on the northern flank of Elk Hills since monitoring surveys began in 1995 (Quad Knopf 2001). This species was not observed during field surveys performed for the project from 2009 to 2012. Due to the presence of suitable habitat, identified occurrences during field surveys and known occurrences from the EHOF, allscale scrub habitat I the project area is potential habitat for recurved larkspur.

San Joaquin Bluecurls **(*Trichostema ovatum,* California Native Plant Society List 4.2)**

San Joaquin bluecurls is a CNPS List 4.2 species indicating it is fairly endangered in California although of limited distribution (CNPS 2013). This species is known to occur in chenopod scrub and grassland habitats. This species has been found although is considered uncommon on the EHOFsince monitoring surveys begin in 1995 (Quad Knopf 2001).

There are no CNDDB records for this species within a nine topographic quadrangle search around the project site (CDFG 2012). There are 79 records in the Consortium of California Herbaria, 33 of which are from Kern County and the closest records to the project site are approximately five miles north of the Lost Hills, Buena Vista Hills, Wasco, and east Bakersfield areas (CCH 2010). Approximately 250 plants of San Joaquin bluecurls were identified along the formerly proposed natural gas/potable route during April and May 2010 (URS 2010k, URS 2010n); however, this species has not been observed along current linear routes. Allscale scrub habitat in the project area is potential habitat for this species.

Tejon Poppy (*Eschscholzia lemmonii ssp. kernensis,* California Native Plant Society List 1B.1)

Tejon poppy is a CNPS List 1B.1 species that the California Native Plant Society considers to be rare, threatened and fairly endangered in California. Tejon poppy occurs in chenopod scrubs and valley foothill grasslands from approximately 500 feet to 3,000 feet elevation. This species is also a covered plant species in the Recovery Plan. Tejon poppy remains extant in the Elk Hills and possibly six other locations that historically supported this species which surround the lower hills of the southern tip of the San Joaquin Valley. Tejon poppy grows in adobe clay soils and often times only following above-average rain years (USFWS 1998). Tejon poppy has been found in 28 sections of Elk Hills since monitoring surveys began in 1995 and occurred most commonly in foothill grassland habitat at Elk Hills (Quad Knopf 2001).

The nearest CNDDB record is from an area south of the California Aqueduct approximately 3.5 miles west of the project site from valley saltbush scrub habitat and there are many records from the EHOF (Quad Knopf 2001, CDFG 2012). There are six records for this species in the CCH, mostly from eastern Kern County and the Tejon Ranch area (CCH 2010). This species was not observed during surveys performed for HECA from 2009 or 2012; however, due to the presence of suitable habitat, identified occurrences during field surveys and known occurrences from the EHOF, allscale scrub habitat I the project area is potential habitat for Tejon poppy.

Special-status Wildlife Species

The following special-status wildlife species were either observed during field surveys, known to occur, or have a high probability of occurring in the project area:

- Blunt-nosed leopard lizard (*Gambelia sila*)
- Western spadefoot toad (*Spea hammondii*)
- Giant garter snake (*Thamnophis gigas*)
- San Joaquin kit fox (*Vulpes macrotis mutica*)
- San Joaquin antelope squirrel (*Ammospermophilus nelsoni*)
- Tipton kangaroo rat (*Dipodomys nitratoides nitratoides*)
- Short-nosed kangaroo rat (*Dipodomys nitratoides brevinasus*)
- Giant kangaroo rat (*Dipodomys ingens*)
- Buena Vista lake shrew (*Sorex ornatus relictus*)
- Western burrowing owl (*Athene cunicularia*)
- Swainson’s hawk (*Buteo swainsoni*)
- Golden eagle (*Aquila chrysaetos*)

***Blunt-nosed Leopard Lizard* (*Gambelia sila*, Federally Endangered, California Endangered and Fully Protected)**

Blunt-nosed leopard lizard (BNLL), a federally endangered species, state endangered, and CDFW Fully Protected species occurs in open, sparsely vegetated open plains; grasslands; alkali playa sink scrub habitats; canyon floors; broad and sandy washes; and arroyos in the San Joaquin Valley and low-lying foothills (USFWS 1985). Areas with greater than 50 percent ground cover are typically avoided since it is believed that dense vegetation interferes with thermoregulation, hunting ability, mating behavior, and predator defense mechanisms (Garcia and Associates 2006). Their primary food source is insects, but may opportunistically consume other lizards and occasionally plant material. This species' current distribution is generally on undeveloped parcels on the southern San Joaquin Valley floor from primarily the following areas: Kern and Pixley National Wildlife Refuge; Liberty Farms (Antelope and Allensworth); Carrizo and Elkhorn Plains; Buttonwillow, Elk Hills, and Tupman Essential Habitat Areas; north of Bakersfield around Poso Creek; and western Kern County near the towns of Maricopa, McKittrick, and Taft (USFWS 2009). Inventory data of this species in the Elk Hills Naval Petroleum Reserve No. 1 indicate that this species is absent or rare in hilly terrain, but favor adjacent lower slopes and wash systems with variable soil types from gravel, hardpan, or sandy loam (USFWS 1985).

Leopard lizards use small rodent burrows (e.g., abandoned ground squirrel tunnels, or occupied or abandoned kangaroo rat tunnels) for shelter from predators and temperature extremes. Density of BNLL may be correlated with abundance of mammal burrows. When small mammal populations were compared to BNLL abundance in the Kern National Wildlife Refuge, kangaroo rat abundance and frequency of BNLL directly coincided; however similar studies performed in the Pixley National Wildlife Refuge or on BLM-administered lands in southwestern Kern County did not identify a strong correlation between BNLL abundance and rodent burrow density (USFWS 1985). In a study conducted in southwestern Kern County near Maricopa, BNLL population density estimates ranged from 0.47 to 0.53 BNLL per acre in "optimal" habitats and remaining habitats averaged approximately 0.16 BNLL per acre. Additionally, on a two-acre study site not subjected to oil and gas development near Taft in Kern County, BNLL density ranged from 0.1 and 0.5 BNLL per acre (USFWS 1985).

BNLL emerge from hibernation during April and May and remain active above ground through October; adult breeding activity peaks in May and June with eggs being laid in June and July; after about two months of incubation, young hatch from late July through early August and rarely into September. Adult, aboveground activity greatly decreases after June and lizards enter into hibernation into late September and early October (Garcia and Associates 2006). Aboveground activity is largely dependent on ground surface temperatures; lizards are most active on the ground when air temperatures are between 74 and 104 degrees Fahrenheit, with soil temperatures between 72 and 97 degrees Fahrenheit. Habitat disturbance, destruction and fragmentation, especially conversion to agriculture, are the greatest threats to BNLL populations (USFWS 2009).

Surveys for BNLL have been conducted since 2008 in support of former proposals of HECA. Non-protocol-level surveys were performed for BNLL during 2008 in support of the original AFC, a portion of which occurs within the currently proposed carbon dioxide pipeline route. During these surveys, a total of 25 BNLL sitings were documented during July and August 2008 surveys in the area south of the California Aqueduct within the carbon dioxide pipeline corridor (URS 2009c, URS 2012a Figure A45-1). In addition, one first-year male BNLL was observed during May 2009 near the Coles Levee Preserve and one adult BNLL was found near Magnolia Road during August and September 2010 surveys west of the proposed natural gas pipeline (URS 2009 b,c and URS 2010p). BNLL is known to occupy Elk Hills, Coles Levee Preserve, Tule Elk State Reserve, and Kern Water Bank. Given known occurrences at Tule Elk State Reserve and current CNDDB records for this area, BNLL have the potential to occur along the proposed potable water/transmission line route located immediately north of the reserve. BNLL are known to occur on the lower flanks of the EHOF, primarily the northern and southern habitat conservation areas that support low-gradient drainages with sparse saltbush scrub habitat. The carbon dioxide pipeline route occurs most closely to the North Flank monitoring route of the Elk Hills conservation areas. No BNLL were observed along the North Flank monitoring route during 2007 to 2010 monitoring years (OEHI 2012b). Following the 2011 Elk Hills monitoring year, no BNLL were observed during spring and fall road surveys along the North Flank Road route although five BNLL were observed during spring 2011 walking surveys of the North Flank route (Western Kern Environmental Consulting 2012).

Portions of the natural gas pipeline route along Highway 58 support suitable BNLL habitat (**Biological Resources Figure 2**). The applicant identified five areas along the route as potential habitat areas and conducted protocol-level BNLL surveys during 2012. Presently, no BNLL have been observed on the five sites along the natural gas pipeline route although staff has not been provided a final survey report (URS 2012a). All five locations are potential BNLL habitat, primarily Site 1 which resembles habitat quality of the nearby Buttonwillow Ecological Preserve located further west. Several observations of side-blotched (*Uta stansburiana*) and western whiptail (*Cnemidophorus tigris mundus*) were recorded at all five sites; however, more observations of these lizards were found along Site 1 than the other four sites which may indicate Site 1 provides more suitable lizard habitat than the other sites.

The processed water pipeline route itself does not provide suitable habitat for BNLL; however, the adjacent KRFCC supports allscale scrub habitat and more open areas of the KRFCC with lower shrub density may support BNLL individuals. The northern extension of the railroad spur/natural gas pipeline route do not support potential habitat given the surrounding agricultural fields on all sides. Active cultivation of row crops precludes occupancy by BNLL (USFWS 1998); therefore, the project’s alfalfa and row crop acreage is not considered potential habitat for this species. In summary, BNLL are assumed present within the carbon dioxide pipeline route and potentially present within Sites 1 through 5 along the natural gas pipeline route.

Western Spadefoot Toad (*Spea hammondii*, California Species of Concern)

Western spadefoot toads, a California species of concern, occur primarily in grassland habitats but can also be found in valley foothill woodlands and require vernal pools or other seasonally inundated wetlands for breeding. This distribution of this near endemic California species is from Redding, Shasta County southward into northwestern Baja, California and entirely west of the Sierran-desert range axis. Spadefoot toads are almost completely terrestrial and enter ponds only to breed. Spadefoot toads breed in temporary rain-filled pools with water temperatures ranging from 9 to 30 ºC that remain filled with rainwater for a minimum of 3 weeks in order to completely metamorphose (CDFG 1994). Suitable breeding pools must lack non-native species such as crayfish, bullfrogs, and introduced fishes. They occupy seasonal pools and seasonal ponds from sea level to approximately 4,100 feet elevation. Western spadefoot toads spend the majority of time burrowed below ground and only emerge above ground to breed following relatively warm (> 10.0-12.8ºC) rains in late winter-spring and fall. Spadefoot toads emerge from burrows in loose soil to a depth of at least one meter, but surface activity may occur in any month between October and April if enough rain has fallen (CDFG 1994).

There are several CNDDB records from the Lost Hills area approximately 30 miles north of the project site. One record is from 1998 on the east side of the California Aqueduct, 2.5 miles southeast of Lost Hills; one adult was found in valley saltbush scrub habitat with scattered mesquite trees. Another CNDDB record is from 2005 from the Semitropic Ridge approximately 7 miles east of Lost Hills from a seasonal pool along a dirt road. A third CNDDB record from 2005 found tadpoles and post-metamorphs from a wide muddy-bottomed section of the Kern River inundated with approximately three feet of water (CDFG 2012).

Western spadefoot tadpoles were found in a seasonal wetland depression between the Westside Canal and California Aqueduct during 2009 surveys (HEI 2009a). Staff considers this and other seasonally wet, depressional areas of the irrigation ditches, channels, and spillways that occur in the project area potential habitat for this species, including seasonally ponded areas, assuming these areas do not remain inundated long enough to support non-native bullfrogs and other tadpole predators. Additionally, the disturbed seasonal wetlands identified along Highway 58 with sufficient hydrology may represent potential habitat for western spadefoot toad.

Giant Garter Snake (*Thamnophis gigas*, Federally Threatened, California Threatened)

The giant garter snake is a large aquatic snake and is endemic to wetland habitats of the Central Valley. Extant records coincide with historic occurrences and follow large floodplain regions, freshwater marshes, and tributary streams of the Central Valley. Historically, this species is known from Butte County in the north to Buena Vista Lake in the south and was probably absent from the northern San Joaquin Valley where the floodplain of the San Joaquin River narrows. This species is presumed extant in 11 counties and Kern County is not one of the 11 counties where this species is currently presumed to occur; the largest extant occurrences include the rice fields of the Sacramento and Colusa National Wildlife Refuge in the Colusa Basin; Gilsizer Slough in the Sutter Basin; Badger Creek area of the Cosumnes River Preserve; the Badger Creek/Willow Creek area, and the American Basin. The USFWS currently identifies 13 separate populations of GGS all within isolated areas with no protected dispersal corridors between the 13 populations (USFWS 1999a). The 13 extant, isolated populations generally range from Butte County in the north to just southwest of Fresno along the Central Valley. There are four CNDDB records for this species from the nine USGS topographic quadrangles surrounding the project site near Buttonwillow, Tupman, and west of Taft where giant garter snake was observed prior to but not during a giant garter snake study by G. Hansen (CDFG 2012).

Giant garter snake populations are distributed in portions of the rice production zones on the Central Valley. The life cycle of giant garter snake coincides well with the man-altered ecosystem of rice fields and associated water conveyance system because the spring and summer flooding and fall dry-down of rice production coincides with the biological needs of this species. This species inhabits marshes, sloughs, ponds, small lakes and agricultural wetlands such as irrigation and drainage canals, rice fields, and adjacent uplands. Suitable upland refugia habitat must be located in close proximity to its summer aquatic, foraging habitat. Essential habitat components include: adequate water during the snake's active period (early spring through mid-fall) to provide prey base and cover; emergent wetland vegetation such as cattails (*Typha* sp.) and bulrush (*Scirpus* sp.) for cover and forage; upland habitat for basking, cover, and retreat sites; and adjacent uplands for cover and refuge from floodwaters (USFWS 1999a).

San Joaquin Kit Fox (*Vulpes macrotis mutica*, Federally Endangered, California Threatened)

The San Joaquin kit fox, a federally endangered and state threatened species, is primarily nocturnal, but are commonly seen during the day in late spring and early summer (Orloff et al. 1986). Generally, kit fox are small, slim-bodied foxes with a long, bushy, black-tipped tail and large ears (USFWS 1998). This species typically occurs in valley and foothill grassland, or mixed shrub/grassland habitats throughout low, rolling hills and valleys often times utilizing habitats that have been altered by humans (e.g., agricultural land, oil fields, etc). San Joaquin kit foxes can inhabit the margins and fallow lands near irrigated row crops, orchards, and vineyards, and may forage occasionally within these agricultural areas (Cypher et al 2007). Another study found that San Joaquin kit foxes in an agricultural setting typically denned in small patches of grassland but that 40 to 50 percent of their nocturnal locations were in row crops or orchards. Kit fox often enlarge ground squirrel burrows for use as a den and may use vacant badger dens for shelter (USFWS 1998), both of which occur within the project area. Kit fox change dens frequently, sometimes only using a den for two or three days. Bjurlin (2004) estimates home range sizes vary from 1.66 square miles (1,063 acres) to 4.48 square miles (2,867 acres) making it difficult to estimate the minimum amount of habitat space or land necessary to support a small population.

The historic distribution of San Joaquin kit fox covered most of the San Joaquin Valley. Current research data and sightings indicate that the San Joaquin kit fox currently inhabit various areas of suitable habitat on the San Joaquin Valley floor and in the surrounding foothills of the Coastal Range, Sierra Nevada, Tehachapi Mountains, from southern Kern County north to Contra Costa, Alameda, and in San Joaquin counties on the west and Stanislaus County on the east. The largest extant population of kit fox occur from Elk Hills and Buena Vista Valley in western Kern County and the Carrizo Plain Natural Area in San Luis Obispo County (USFWS 1998).

While the effects of roadways on San Joaquin kit fox have not been directly studied, the relatively large space requirements, home range, high mobility, and crepuscular (active primarily at dawn and dusk) behavior of this species makes road crossings necessary throughout much of their current range (Bjurlin 2004). Loss and conversion of natural lands into agricultural, industrial, and urban development and associated practices continue to decrease available habitat. Other identified threats include habitat degradation from increased noises, noxious gases, and release of wastewater; traffic mortality; pesticides and rodenticides; competition and predation by non-native foxes; and to a lesser extent, disease (USFWS 1998).

The Recovery Plan states that a sound, conservative strategy for this species hinges on the enhanced protection and management of three geographically distinct core populations. Within the core population areas, several smaller satellite populations occur. The three core populations for San Joaquin kit fox conservation and recovery are 1) the Carrizo Plain Natural Area in San Luis Obispo County, 2) the natural lands of western Kern County (i.e. Elk Hills, Buena Vista Hill and Valley, Lokern Natural Area, and adjacent land) inhabited by kit fox, and 3) the Ciervo-Panoche Natural Area of western Fresno and eastern San Benito counties. HECA is proposed in a core population area for San Joaquin kit fox, natural lands of western Kern County including areas which support critical connection points between satellite populations. The Recovery Plan states that the Carrizo Plain and western Kern County San Joaquin kit fox populations are important for kit fox recovery and preliminary population viability analyses indicate that the possibility of the extinction of this species dramatically increase if either the Carrizo Plain or western Kern County populations are eliminated (USFWS 1998).

Due to the project occurring in a San Joaquin kit fox core recovery area and diverse habitat use of this species ranging from natural, allscale scrub to farmed agricultural lands, staff considers all habitat types in the project area suitable habitat for San Joaquin kit fox. Potential kit fox dens have been found along the natural gas pipeline route along Highway 58 and northward as well as the potable water/transmission line route. These potential dens have either shown active burrowing owl sign and/or kit fox sign which both species are known to occupy the same type of burrow; therefore all known or potential burrowing owl burrows are also potential kit fox dens. Approximately ten potential kit fox dens were found at Site 1 along the natural gas pipeline route during 2012 field surveys, none of which showed any current kit fox use. Few potential kit fox dens or burrowing owl burrows were found at Site 2 which also support California ground squirrels (*Spermophilus beecheyi*). Sites 3, 4, and 5 also support potential kit fox or burrowing owl burrows during 2012 field surveys (URS 2012c). Since San Joaquin kit fox is known to occupy the Kern Water Bank and Tule Elk State Reserve, the potential for fox to utilize habitats within the project areaand potable water/transmission line route is likely. San Joaquin kit fox are also known to occur along the California Aqueduct and other irrigation canals and adjacent uplands and agricultural areas; therefore this species is likely to occur along the processed water line. San Joaquin kit fox is known to occur on Elk Hills and along the carbon dioxide pipeline route. Field surveys were conducted during February 2011 along the proposed route and several large mammal dens (coyote, American badger, kit fox) were observed although did not show sign of active occupancy (HECA 2012b, Volume 2 Appendix A); follow-up surveys performed along the proposed carbon dioxide pipeline route in 2012 identified two potential kit fox dens (OEHI 2013b). No active natal kit fox dens were identified following 2011 monitoring of the Elk Hills Conservation Areas (Western Kern Environmental Consulting 2012); however, active natal kit fox dens were observed along the north flank Elk Hills area, west of the proposed carbon dioxide pipeline route from 2007 to 2010 monitoring of the Elk Hills Conservation Areas (OEHI 2012b).

San Joaquin Antelope Squirrel (*Ammospermophilus nelsoni*, California Threatened)

San Joaquin antelope squirrel occur in valley saltbush scrub habitats ranging in elevation from approximately 160 feet on the San Joaquin Valley floor side to approximately 3,600 feet in the Temblor Range. This species' range is unevenly distributed and only occurs in a few localities, including the Lokern and Elk Hills region of western Kern County as well as the Carrizo and Elkhorn Plains in eastern San Luis Obispo County (Garcia and Associates 2006). Over 80 percent of their original geographic range had been converted to agriculture by 1979 with relatively no prime, undisturbed habitat remaining within the San Joaquin Valley for this species.

In the southern and western San Joaquin Valley, this species is associated with arid, open gently sloping grasslands with scattered shrubs in areas free of flooding. This species requires loose, friable soils for digging their own burrows; otherwise they will often co-occur and utilize burrows of giant kangaroo rats where soils are otherwise too coarse for San Joaquin antelope squirrel to burrow laterally into banks. In areas with sparse shrub cover, this species commonly co-occurs with giant kangaroo rats; the distribution of Nelson's antelope squirrel and abundance appears to be positively related to low rainfall, loose soil texture, shrub cover, and presence of giant kangaroo rats (Garcia and Associates 2006).

Several San Joaquin antelope squirrels were observed during 2009 biological field surveys near the Town of Tupman and Elk Hills area performed for previous versions of the HECA project (HEI 2009a, URS 2009b). Focused surveys and small mammal trapping have not been conducted for this species in the project area; surveys for this species for the current linear alignments were completed in conjunction with 2012 wetland delineation, botanical, Swainson's hawk, and blunt-nosed leopard lizard surveys during which no San Joaquin antelope squirrel were observed (URS 2012a). This species is assumed present in allscale scrub habitats east and west of the California Aqueduct. San Joaquin antelope squirrel was not captured following 2011 monitoring of the Elk Hills conservation areas (Western Kern Environmental Consulting 2012); the last time this species was trapped on Elk Hills was during the 2008 monitoring year. This species is known to occur at Kern Water Bank, Tule Elk State Reserve, and several CNDDB records occur for this species east of the California Aqueduct. Since this species is known to occur in the project area, all scrub habitat in the project area is considered potential habitat for San Joaquin antelope squirrel.

Tipton Kangaroo Rat **(*Dipodomys nitratoides nitratoides,* Federally Endangered, California Endangered)** ***and Short-nosed Kangaroo Rat*** **(*Dipodomys nitratoides brevinasus,* California Species of Concern)**

The Tipton kangaroo rat (*Dipodomys nitratoides nitratoides)* is one of three subspecies of San Joaquin kangaroo rat (*D. nitratoides*) and is restricted to the Tulare sub-basin. Within *D. nitratoides*, individuals from the western edge of the San Joaquin Valley and west of the California Aqueduct are genetically distinct as short-nosed kangaroo rats (*D. nitratoides brevinasus*) based on morphology, chromosome number, and habitat preference. The short-nosed kangaroo rat is a California species of concern and a Bureau of Land Management Sensitive species. Construction of flood control and water diversion structures removed some of the genetic barriers, a narrow zone of seasonal and permanent wetlands around Kern and Buena Vista lakes, and probably allowed for genetic exchange between short-nosed and Tipton kangaroo rat subspecies; however, today the California Aqueduct and large expanses of irrigated farmlands have genetically isolated these populations (USFWS 1998). Tipton kangaroo rat mostly occurs east of the California Aqueduct and occupies scrub and grassland communities near level terrain with the alluvial floodplain soils. Important natural communities for Tipton kangaroo rat are iodine bush shrubland and valley saltbush scrub. In areas subject to occasional flooding, Tipton kangaroo rat will construct burrows on elevated ground (Garcia and Associates 2006). Sparse to moderate shrub cover in terraced grasslands typically supports higher densities of this species, although burrow systems are often situated in more open habitats. Terrain not subject to permanent flooding is essential for permanent occupancy by this species (USFWS 1998).

Focused surveys and small mammal trapping were not performed for this species; however, this species is assumed present within portions of the project east of the California Aqueduct. Tipton kangaroo rat is known to occur in the Coles Levee Ecosystem Preserve, Kern Water Bank, and likely the Tule Elk State Reserve. This species is assumed present east of the California Aqueduct within saltbush scrub or alkali sink scrub habitats, although there are CNDDB records of this species west of the California Aqueduct as well. Tipton kangaroo rat does not occur on Elk Hills since short-nosed kangaroo is the genetically distinct subspecies known to occur on Elk Hills. Following 2011 monitoring of the Elk Hills conservation areas, short-nosed kangaroo rat was the most commonly trapped small mammal on trap gridlines (Western Kern Environmental Consulting 2012). All allscale scrub habitats associated with linear facility routes east of the California Aqueduct are suitable habitat for Tipton kangaroo rat.

Giant Kangaroo Rat **(*Dipodomys ingens*, Federally Endangered, California Endangered)**

Up until the 1950s, colonies of giant kangaroo rats were spread over hundreds of thousands of acres of gently rolling, continuous grasslands habitat along the western edge of the San Joaquin Valley, Carrizo Plain, and Cuyama Valley. Presently, this species is known from six major geographic sub-units including the Panoche region in western Fresno and eastern San Benito counties; Kettleman Hills in Kings County; San Juan Creek and Carrizo Plain in San Luis Obispo County; the Elk Hills, Taft, Maricopa, McKittrick, and other upland areas in western Kern County; and Cuyama Valley in

Santa Barbara and San Luis Obispo counties. Giant kangaroo rats occupy both grassland and low-density shrub communities in a variety of soil types and on slopes up to approximately 2,800 feet above mean sea level yet preferred habitats of this species are annual grassland communities of less than 10 percent slope with friable, sandy loam soils (USFWS 1998). In lower elevation areas (less than 1,300 feet) in the southern San Joaquin Valley, giant kangaroo rats occupy annual grasslands and alkali scrub and saltbush communities with an herbaceous community of red brome, red-stemmed filaree, and annual fescue. Several studies indicate that this species prefers flat terrain with low shrub cover; one study indicated that this species selected sites with dense grass cover and low shrub cover in disturbed areas more times than bare areas or areas with dense shrub cover and that giant kangaroo rats spent little to no time under shrubs (Harris et al 1987). In the southern San Joaquin Valley, giant kangaroo rats are primarily known to occur on the south or west side of the California Aqueduct although a recent discovery of a giant kangaroo rat was found during small mammal trapping for the Buena Vista Water Storage Pipeline on the east side of the California Aqueduct which suggests this species does occur east of the aqueduct (CDFW, pers comm. October 2012). This discovery was between the California Aqueduct and Kern Water Flood Control Channel in the vicinity of the processed water pipeline and west of HECA.

Giant kangaroo rats are active all year and do not become dormant during certain seasons or weather patterns. This species is primarily nocturnal although has been observed during daylight hours during hot summer temperatures. The greatest value of the former Naval Petroleum Reserves (formerly known as NPR-1 and NPR-2) in California to giant kangaroo rats is the large extent of habitat of varying quality and its connectivity to adjacent habitat in the Lokern area (USFWS 1998). Giant kangaroo rats are granivores (seed-eaters) and cut the ripening heads off of grasses and forbs and gather individual seed heads and store them in small, above-ground surface pits over their burrow systems, called precincts, which is then covered by loose debris and dirt. Precincts (individual territories in which 2 to 1,000 precincts can signify a territory) are specific to the species and mapping precincts can allow for the identification of specific sign and presence of the species in areas where they are expected to occur.

Concerning the recent discovery of giant kangaroo rat during small mammal trapping for the Buena Vista Water Storage Pipeline on the east side of the California Aqueduct, a precinct was not present which further supports the notion that the absence of precincts does not preclude the presence of giant kangaroo rat. Estimated home ranges can range in size from 60 to 350 square meters and the core area of the territory is located over the precinct. A single individual or several individuals of females and offspring may occupy precincts. Burrows are typically located on flat to gently sloping terrain and areas preferred for permanent colonies of this species include areas not subject to seasonal flooding. In areas of suitable habitat and soil burrowing conditions, populations may exceed 20 individuals per acre (USFWS 1998).

This species was not targeted during surveys and small mammal trapping was not conducted; however, this species is known to occur in high population numbers along the eastern flank of Elk Hills. In support of a former carbon dioxide pipeline route, the applicant conducted a walking survey of the carbon dioxide pipeline route and a 1,000-foot buffer during April 2010 for giant kangaroo precincts and none were found within the survey that included southern sections 16, 21, and 28 within Township 30, Range 24 (URS 2010k) of the *East Elk Hills* topographic quadrangle map. Following the 2007, 2009, and 2011 monitoring years, giant kangaroo rat precincts were identified in Elk Hills Section 22S and in the immediate vicinity of the carbon dioxide pipeline route (OEHI 2012b) among other areas of the Elk Hills Conservation Area. Following the 2010 monitoring survey season, a total of 1,946 active precincts were identified in 2011, which represents a 142 percent increase from the 805 active precincts reported the previous year of Elk Hills Conservation Areas (Western Kern Environmental Consulting 2012). Following 2012 field surveys, four giant kangaroo rat precincts were identified within 50 feet of the proposed carbon dioxide pipeline route (OEHI 2013b). Given the known high population numbers from Elk Hills of giant kangaroo rat and their precincts, staff considers the entire eastern flank of Elk Hills and carbon dioxide pipeline route occupied habitat of this species. Due to recent discoveries of this species east of the California Aqueduct in the immediate project area, staff also considers allscalle scrub and intermixed disturbed grassland communities within the project area and linear facilities potential habitat for this species.

***Buena Vista Lake Shrew* (*Sorex ornatus relictus*, Federally Endangered, California Species of Concern)**

Buena Vista Lake shrew is one of nine subspecies of the ornate shrew, *Sorex ornatus*. Historically, this shrew occurred in wetlands and sloughs around the Buena Vista Lake and Goose Lake beds and presumably throughout the Tulare Basin other historic Tulare Lake Bed. This species historically inhabited mesic habitats associated with the Tulare Sub-basin including wet meadows, riparian corridors, freshwater marshes, and alkali sink scrubs. This species inhabits densely vegetated areas around the margins of marshes, lakes, and sloughs although little is understood about the current range of Buena Vista Lake shrew and a few extant populations are know from the Tulare Basin and the Buena Vista Lake slough area further south of the project site.

Live small mammal trapping that was conducted at six sites within the Tulare Basin during 1999 and 2000, resulted in nine Buena Vista Lake shrews collected at the Coles Levee Preserve, one of the six trapping sites, among others trapped at the Kern Fan Recharge Area and the Kern National Wildlife Refuge (Garcia and Associates 2006). The USFWS designated final critical habitat for this species on January 24, 2005 (USFWS 2005). The Kern Lake Preserve Unit, totaling approximately 84 acres, was designated as final critical habitat for this species. Presently, critical habitat is proposed for Buena Vista Lake shrew south of the Tule Elk State Reserve at the confluence with the Cross Valley Canal. The nearest CNDDB record is a historic record from 1969 near Tejon Creek in the Tejon Hills, approximately four miles south of the project site. This species is known to occur on Coles Levee Ecosystem Preserve.

This species was not observed during field surveys although small mammal trapping has not been conducted which is the only definitive method for determining presence or absence in the project area. There is a low potential for Buena Vista Lake shrew to occur in wet areas along the West Side Canal and East Side Canal during years with adequate rainfall and adequate vegetative cover. Although this species generally has a low potential to occur in the project area, the greatest potential for occurrence of Buena

Vista Lake shrew is along the project's proposed processed water pipeline and railroad spur.

Western Burrowing Owl **(*Athene cunicularia*, California Species of Concern)**

Western burrowing owls are a California Species of Concern and yearlong resident in suitable habitats throughout California, although some populations undergo local movements. In California, burrowing owls range from the Central Valley extending from Redding to the Grapevine area in the Central Valley; east through the Mojave Desert and west to San Jose, San Francisco Bay area, and the outer coastal foothill area from Monterey south to San Diego; and the Sonoran Desert. Agricultural areas and canal systems provide important burrowing habitat for this species. Grasslands and desert shrub stepped habitats are considered naturally occurring habitats of this species, while burrowing owls may also occur in agricultural or grassy areas, or vacant lots and pastures, if the vegetation is low and suitable forage and burrowing sites are available nearby (CDFG 2012b). In recent years, their numbers have drastically declined in southern California and remnant populations persist in isolated agricultural areas and grasslands, particularly in the high desert in the Chino Hills/Prado Basin, rural areas of San Bernardino, Riverside, and San Diego counties. However, they are still fairly common in and around agricultural areas of the Imperial Valley (Small 1994).

Burrowing owls are unique among the North American owls in that they nest and roost in burrows, especially those created by California ground squirrels (*Spermophilus beecheyi*), kit fox (*Vulpes macrotis*), desert tortoise (*Gopherus agassizii*), and other wildlife as well as man-made structures such as culverts, exposed pipes, and debris piles as artificial burrows. Their home range is distinctly tied to the location of their burrow system and there are differences in their diurnal and nocturnal home ranges. The best available scientific data indicates that foraging occurs primarily within a 600 meter radius (estimated 300 acres) of the nest burrow during the breeding season (CDFG 2012b). Diurnal home range for owls can be 150 feet on both sides of burrow; the nocturnal home range is typically much larger, one square mile per owl pair, and several owls can overlap in that one square mile (Pers. Comm. Peter Bloom). The mean home range for 11 male burrowing owls in 1998 and 22 males in 1999 was 177 ha (437 acres) and 189 hectares (467 acres), respectively, at naval Air Station in Lemoore, California which is located south of Fresno (Bloom 2003). Male burrowing owls often move greater than 1,000 meters when foraging during the breeding season (Bloom 2003). Intra-specific aggressive displays for defending breeding territories can occur and breeding territories can range from 250 to 600 meters (500 feet to 1,970 feet).

The availability of burrows is an essential component of burrowing owl habitat since the burrows provide protection, shelter, and nest sites. Essential habitat for burrowing owls in California includes suitable year-round habitat for breeding, foraging, wintering, and dispersal of owls consisting of shore or sparse vegetation, presence of suitable burrows, or fossorial mammals, and availability of abundant prey within close proximity to the burrow system (CDFG 2012b). Burrowing owls have a strong affinity for previously occupied nesting and wintering habitats. They often return to burrows or at least the same burrow area used in previous years to nest, especially if they were successful at reproducing there in previous years (Gervais *et al.* 2008, CDFG 2012b). Burrowing owls are known to use satellite burrows which typically occur within 75 meters of the nest burrow and owl pairs use on average approximately five satellite burrows (CDFG 2012b). The southern California breeding season (defined as from pair bonding to fledging) generally occurs from February to August with peak breeding activity from April through July (Haug et al. 1993).

Burrowing owls were detected along the formerly proposed carbon dioxide pipeline and natural gas linear during August 2008 and August 2010 surveys, respectively (URS 2010o). During 2011 field surveys, burrowing owls were observed immediately south of the potable water/transmission line route; during these surveys which coincided with the burrowing owl nesting season, three individual adult owls were observed, including a pair of adults with no young observed along Morris Road (HECA 2012a).

Following 2012 field surveys, burrowing owls and several potential burrows were also observed at Site 1 along the natural gas linear where two individual owls were found during May through July BNLL surveys. Burrowing owl sign was also found during BNLL surveys at sites 2 and 3 along the natural gas route. A known burrowing owl pair with successful breeding was documented during 2012 from the Buttonwillow Ecological Reserve along Brandt Road, approximately 0.50 mile west of the proposed natural gas linear route (URS 2012a). This species is known to occur at Kern Water Bank, Tule Elk State Reserve, Elk Hills, and the Buttonwillow Ecological Reserve. During 2011 monitoring year of Elk Hills Conservation Areas, burrowing owls were observed throughout spring and fall kit fox and BNLL surveys; during pre-activity surveys, four owls and 24 owl burrows were found, of which 7 burrows were active (Western Kern Environmental Consulting 2012). In addition, two burrowing owls were observed along the carbon dioxide pipeline route following 2012 field surveys (OEHI 2013b). Suitable habitat occurs within the project area for this species, primarily within the allscale scrub habitat of the project's linear facilities.

***Swainson's Hawk* (*Buteo swainsoni*, Caifornia Threatened)**

Swainson's hawks, a state threatened species, require large areas of open landscape for foraging, including grasslands and agricultural lands that provide low-growing vegetation for hunting and high rodent prey populations. This species has suffered a decline in the Central Valley as with other North American raptor populations, largely due to the conversion of native communities to agricultural lands, the southern San Joaquin Valley in particular which is devoid of suitable nest trees and well-developed riparian areas due to agricultural conversion. Swainson's hawks typically nest in large native trees such as valley oak (*Quercus lobata*), cottonwood (*Populus fremontii*), walnut (*Juglans hindsii*), and willow (*Salix* spp.), and occasionally in non-native trees, such as eucalyptus (*Eucalyptus* spp.) within riparian woodlands, roadside trees, trees along field borders, isolated trees, small groves, and on the edges of remnant oak woodlands (CDFG 1993). The present-day agriculture in the southern San Joaquin Valley, primarily cotton and vineyards, are not compatible with Swainson's hawk hunting style (Estep 1989).

Two populations comprise the current Swainson's hawk range in California: northeastern counties of Modoc, Siskiyou, and Lassen of upland juniper-sage/steppe communities, and the more isolate Central Valley population in intensively farmed agricultural regions of the Sacramento and San Joaquin valleys (Estep 1989). A study of four study sites located between Sacramento and Stockton in the Central Valley to investigate home ranges, foraging behavior, use of agricultural fields, and nest site selection, showed the foraging ranges of some radio-tagged Swainson's hawks had an elastic pattern and fluctuated with the pattern of crop maturity and harvest. Results showed evidence that as some crop types mature, vegetative cover increases which reduced prey availability and causes Swainson's hawks to spend less time foraging over mature, non-harvested crop fields. Unless farming activities attracted hunting Swainson's hawks, birds only spent a few minutes foraging over a field before moving on; this highly active foraging behavior often resulted in birds traveling as far as 18 miles from the nest in search of prey. Swainson's hawks responded, however, to the abundance of prey that became available during harvest. During typical crop harvest times of year (generally late July through September), daily foraging ranges were as small as 30 acres and Swainson's hawks often restricted hunting activities to a single field (Estep 1989).

In this study, of the 30 cover types that occurred in the project area discussed above, Swainson's hawks were observed using 17 cover types. Cover types that had less overall vegetative cover and greater prey availability ranked the highest (alfalfa, disced fields, fallow, and dryland pasture). Alfalfa was preferred across all 12 hawks that were radio-tagged and the foraging use of alfalfa occurred continuously from March through September. The alfalfa fields that occurred in the project area were mowed and bailed once a month generally, keeping its vegetative cover less than that of maturing row and grain crops. Unlike row and grain crops that are harvested and replanted annually, a single alfalfa planting may remain and continue to produce hay in a particular field for up to six years in the Central Valley (Estep 1989). While beet and tomato fields supported the largest prey populations, dense cover appeared to preclude hawk foraging during most of the year; however, during harvest these crop types were hunted regularly. Swainson's hawk used tomato and beet fields for foraging a high percentage of time, primarily due to a high frequency of harvesting. In some cases, in large fields of beets and tomatoes being harvested, Swainson's hawks would feed in groups and would remain for the length of the harvest and up to several days. Other row crops such as corn, sunflowers, safflower, beans, and peppers were less preferred since these crops create an impenetrable barrier for hunting Swainson's hawks during maturity. Dryland pastures, the land cover type that most resembles the physical characteristics of historic grassland habitat in the Central Valley, were also frequented often by hunting hawks usually in response to farming activities (Estep 1989).

The applicant performed protocol-level surveys for Swainson's hawk nesting activity during 2010, 2011, and 2012. The survey area included a five-mile radius around the project site, a one-mile radius to the northeast to cover more agricultural areas, and a half-mile radius into the Elk Hills region. Staff and CDFW agreed that although this survey buffer area strays from the survey protocol (Swainson's Hawk Technical Advisory Committee 2000), the modified survey area was adequate to allow for the identification of nesting pairs that have the potential to be impacted by construction within the project area. Potential Swainson's hawk nest trees were considered all living trees of approximately 20 feet and taller. All trees meeting this criterion were recorded by species and the presence of farmhouses, homesteads, agricultural areas, and developed areas were also noted. Several tree units representing possibly hundreds of suitable raptor nests trees were identified within the survey area. During 2012 focused surveys for nesting Swainson's hawks, 19 active raptor nests were identified in the survey area described above, six of which were Swainson's hawk nests and four of which were confirmed to have successfully fledged young. The remaining 13 active nests were either common raven, great-horned owl, red-tailed hawk, or red-shouldered hawk nests (URS 2012a).

The project area supports approximately 203 acres of alfalfa and 368 acres of other row crops. The five most common crop types in the project area are alfalfa, cotton, pistachio, wheat, and dry onion (HECA 2012b, Land Use Table 5.4-3). Staff considers the 203 acres of alfalfa as suitable foraging habitat for this species and depending on the frequency of farming and crop rotation of the other low-growing rowcrops such as cotton and dry onion, these fields may support an adequate prey base for Swainson's hawk, which increases the foraging habitat value for this species.

Golden Eagle (*Aquila chrysaetos*, California Fully Protected)

Golden eagles are typically year-round residents found throughout most of their western United States range. They breed from late January through August with peak activity from March through July (Kochert et al. 2002). Migratory patterns are fairly local in California where adults are relatively sedentary, but dispersing juveniles sometimes migrate south in the fall. This species is considered to be more common in southern California than in the northern part of the state (USFS 2008). Habitats for this species typically include rolling foothills, mountain areas, and deserts. Golden eagles need open terrain for hunting and prefer grasslands, deserts, savanna, and early successional stages of forest and shrub habitats. Golden eagles primarily prey on lagomorphs and rodents but will also take other mammals, birds, reptiles, and some carrion (Kochert et al. 2002). This species prefers to nest in rugged, open habitats with canyons and escarpments, with overhanging ledges and cliffs and large trees used as cover.

The status of golden eagle populations in the United States is not well known, although there are indications that populations may be in decline (USFWS 2009b, Kochert et al. 2002). Accidental death from collision with manmade structures, electrocution, gunshot, and poisoning are the leading causes of mortality for this species, and loss and degradation of habitat from agriculture, development, and wildfire continues to put pressure on golden eagle populations (Kochert et al. 2002; USFWS 2009b).

Absent interference from humans, golden eagle breeding density is determined by either prey density or nest site availability, depending upon which is more limiting (USFWS 2009b). A compilation in Kochert et al (2002) of breeding season home ranges from several western United States studies showed an average home range of 20 to 33 square kilometers (7.7 to 12.7 square miles). In San Diego, a study of 27 nesting pairs found breeding ranges to be an average of 36 square miles with a range from 19 to 59 square miles (Dixon 1937). Other studies from within and outside the United States include ranges from nine to 74.2 square miles (McGahan 1968; Watson et al. 1992 [range of 14.7 to 26.1 pairs per 1,000 square kilometers]). An Environmental Assessment (EA) and Implementation Guidance for take permits have been issued under the Bald Eagle and Golden Eagle Protection Act (USFWS 2009c). The EA specifies that in implementing the resource recovery permit for take of inactive golden eagle nests (50 CFR 22.25), data within a 10-mile radius of the nest provides adequate information to evaluate potential effects.

There are three CNDDB records for golden eagles nests for the entire County of Kern, although this species is rarely reported in the CNDDB due to sensitivity of nest locations: one record is from 1995 along the south fork of oil canyon creek, approximately 16 miles north of Mojave in foothill/pinyon pine woodland; a second record is from 1991 in Sequoia National Forest, 0.5 mile north of Cottonwood Creek from Jeffrey pine and white fir habitat; and a third nest location from Red Rock Canyon State Park during 1988 (CDFG 2012). There are no known golden eagle nest sites within 30 miles of the project area. Golden eagles have been reported in the project area, but mostly as transients. At least five golden eagles were observed on the edge of Elk Hills approximately five years ago and a deceased female golden eagle hit by a vehicle was picked up on the western side of the Tule Elk State Reserve during October 2010; other reports from local birding experts indicate golden eagles are commonly observed in eastern Kern County and have been observed in western Kern County as transients (URS 2012a). Since there are no known nest sites in the immediate project vicinity and high agricultural use of the project area, golden eagles are not expected to utilize the site's agricultural fields for forage and likely only occur as transients during migration.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

METHODS AND THRESHOLD FOR DETERMINING SIGNIFICANCE

The determination of whether a project has a significant effect on biological resources is based on the best scientific and factual data that staff could review for the project. CEQA requires a list of criteria that are used to determine the significance of identified impacts. A significant impact is defined by CEQA as "a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (CEQA Guidelines Section 15382).

Thresholds for determining CEQA significance in this section are based on Appendix G of the CEQA Guidelines (CCR 2012) and performance standards or thresholds identified by staff. In this analysis, the following impacts to biological resources are considered significant if the project would:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFW or USFWS;
- Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, or regulations, or by the CDFW or USFWS;
- Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means;

- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites;
- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance;
- Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan;
- Conflict with applicable federal, state, or local laws, ordinances, regulations, and standards (LORS) protecting biological resources, as listed in **Biological Resources Table 1**; and
- Have a substantial adverse effect on any other species receiving consideration during environmental review under CEQA Section 15830, including species not protected through state or federal listing but nonetheless demonstrable as "endangered" or "rare" under CEQA.

The CEQA Guidelines define "direct" impacts as those impacts that result from the project and occur at the same time and place. "Indirect" impacts are defined as those that are caused by the project, but can occur later in time or farther removed in distance while still reasonably foreseeable and related to the project. The significance of impacts is generally determined by compliance with applicable LORS; however, guidelines adopted by resource agencies may also be used. Staff has also evaluated the potential for cumulative effects of the project on biological resources when considered with all past, currently proposed, and future projects in the region.

Impact analyses typically characterize effects to plant communities as temporary or permanent, with a permanent impact referring to areas that are paved or otherwise precluded from restoration to a pre-project state. For the purpose of this analysis, an impact is considered temporary if there is evidence to indicate that pre-disturbance levels of biomass, cover, density, community structure, and soil characteristics could be achieved within five years through revegetation activities.

Biological Resources Table 5 summarizes the acreages of direct habitat loss for special-status wildlife species which would require compensatory habitat mitigation outlined in staff's proposed Condition of Certification **BIO-20**. Once the applicant submits a comprehensive mitigation plan for the project and based on further coordination with staff, CDFW, and USFWS, these acreages may change in preparation of the FSA/FEIS. This section analyzes the potential for direct and indirect impacts of construction and operation of HECA to biological resources and provides suggested mitigation measures to reduce the severity of potentially adverse impacts as summarized in **Biological Resources Table 6.**

Biological Resources Table 5
Direct Habitat Impact Acreages for Upland Wildlife Species

Vegetation Community/Cover Type in project area (Total Direct Habitat Impact for Project)	San Joaquin kit fox	Giant kangaroo rat	Tipton kangaroo rat	San Joaquin antelope squirrel	Burrowing owl	Blunt-nosed leopard lizard	Swainson's hawk
Allscale scrub/natural vegetation (**32.7 acres**)	32.7	32.7	32.7	32.7	32.7	32.7	0
Alfalfa (**203.34** acres)	203.34	0	0	0	0	0	203.34
Other row crops (**368.43**)	368.43	0	0	0	0	0	368.43
Orchards (**8.91**)	8.91	0	0	0	0	0	0
Developed/disturbed (**159.75**)	159.75	159.75	159.75	159.75	159.75	159.75	0
Total	**773.13**	**192.45**	**192.45**	**192.45**	**192.45**	**192.45**	**571.77**

Biological Resources Table 6
Summary of Impact/Proposed Mitigation

Biological Resource	Impact/Proposed Mitigation
Vegetation Communities & Associated Wildlife	**Direct impacts:** Permanent and temporary loss of 30 acres of allscale scrub/non-native grassland habitat and loss of approximately 580 acres of alfalfa, orchards, and other row crops which provide habitat for a number of plants and wildlife (**Biological Resources Tables 7,8**). **Indirect impacts:** Disturbance (noise, lights, dust) to surrounding plant and wildlife communities; spread of non-native invasive weeds and disruption of plant community composition; changes in drainage patterns; erosion and sedimentation of disturbed soils. **Mitigation:** Impact avoidance and minimization measures, worker awareness and education training, species-specific preconstruction clearance surveys, biological monitoring, and reporting outlined in **BIO-1** through **BIO-18**. Staff has outlined a compensatory habitat mitigation strategy for listed species in **BIO-20**.
Sensitive Vegetation Communities	**Direct impacts:** None anticipated. **Indirect impacts:** Valley sink scrub and small, patchy riparian habitat occurs north of the proposed well field along the processed water pipeline. If these communities are supported by shallow groundwater or other sub-surface water flows through adjacent irrigation canals, groundwater pumping for the project at the proposed BVWSD well field could cause a gradual decline of riparian nest trees and sensitive vegetation communities such as valley sink scrub and more analysis is required. **Mitigation:** Additional information needed on the water supply and water use of valley sink scrub and riparian habitats in the project area; staff has not proposed mitigation until further analysis has been performed.

Biological Resource	Impact/Proposed Mitigation
Potential waters of the State and Waters of the United States	**Direct impacts:** The extent of Corps jurisdiction over potential Waters of the U.S. identified in the site are unknown at this time; the occurrence of and impacts to potential state waters within the project area and ephemeral drainages along the carbon dioxide route are unknown at this time. CDFW has indicated that proposed HDD (HDD) activities under water conveyance features would require the applicant submit a Notification of a Streambed Alternation Agreement describing the proposed work and the applicant submitted this application during May 2013 (URS 2013d). **Indirect impacts**: Potential for frac-out (escape of drilling mud to the water surface as a result of a spill or tunnel collapse) from HDD and indirect effects to water quality and contamination during construction of the project. **Mitigation:** Implementation of **SOIL& SURFACE WATER – 1** (Drainage, Erosion Sedimentation Control Plan), and **BIO-19** (state waters) including the requirement to prepare a Horizontal Directional Drilling Plan would minimize the potential for indirect impacts to potentially jurisdictional state waters and waters of the U.S. including drainages and irrigation canals; however, a determination of the extent of Corps and CDFW Section 1600 jurisdiction over the project is unknown at this time.
Special-status plant species: • Hoover's eriastrum (CNPS List 4.2) • Gypsum-loving larkspur (CNPS List 4.2) • Lost Hills crownscale (CNPS List 1B.2) • Oil nest straw (CNPS List 1B.1) • San Joaquin bluecurls (CNPS List 4.2) • Cottony buckwheat (CNPS List 4.2) • Vernal barley (CNPS List 3.2)	**Direct Impacts:** Loss of individual plants (Hoover's eriastrum, oil nest straw and possibly others) during site grading along carbon dioxide pipeline route. Potential loss of populations of vernal barley along the natural gas pipeline route. Permanent and temporary loss of allscale scrub habitat. Loss of exact number of individuals is unknown since the mapping of rare plant occurrences has not been provided to staff. **Indirect impacts:** Introduction and spread of invasive plants; erosion and sedimentation of disturbed soils; alteration of drainage patterns; herbicide drift; disruption of photosynthesis and other processes from dust. **Mitigation:** Implementation of **BIO-17** requires the applicant to conduct focused preconstruction surveys for additional special-status plant occurrences in suitable habitat areas, including mapping and avoidance of populations as Environmentally Sensitive Areas. Additional focused botanical surveys, field data collection, and GPS mapping are needed along the carbon dioxide and natural gas pipeline routes (primarily Sites 1 through 5) following *Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities* (CDFG 2009).

Biological Resource	Impact/Proposed Mitigation
San Joaquin kit fox and American badger	**Direct impacts:** Loss of approximately 773 acres of allscale scrub/disturbed non-native grasslands and agricultural lands (**Biological Resources Table 5**) that provide foraging, denning, and dispersal values and promote movement opportunities and genetic exchange for San Joaquin kit fox between the Western Kern Core Recovery Area and adjacent satellite population in urban Bakersfield and Semitropic satellites farther north and east; fragmentation and degradation of habitat; increased risk of traffic collision and vehicle strikes from construction and operation traffic; crushing or entombing animals in burrows during construction. **Indirect impacts:** Disturbance from project noise including construction pile driving and lighting; habitat alteration from introduction and spread of weeds. **Mitigation:** Implementation of biological monitoring reporting, worker awareness program, in **BIO-1** through **BIO-6**; implementation of impact avoidance and minimization measures in **BIO-7** including preconstruction den surveys, den exclusion zone and monitoring during construction. Staff has outlined a compensatory habitat mitigation strategy for listed species in **BIO-20**.
Giant kangaroo rat, San Joaquin antelope squirrel, and Tipton kangaroo rat	**Direct:** Loss of approximately 192 acres of disturbed and natural lands (**Biological Resources Table 5**) that support potential small mammal burrowing habitat; fragmentation and degradation of occupied habitat; increased risk of traffic mortality from construction and operation traffic; crushing or entombing animals in burrows during construction. **Indirect:** Disturbance from project noise including construction pile driving and lighting; habitat alteration from introduction and spread of weeds. **Mitigation:** Implementation of biological monitoring reporting, worker awareness program, in **BIO-1** through **BIO-6**; implementation of **BIO-12** requiring the preparation of a Small Mammal Relocation Plan for preconstruction small mammal trapping and salvage; implementation of **BIO-13** including preconstruction giant kangaroo rat precinct survey, mapping, trapping and relocation from active construction areas; implementation of **BIO-14** including a Tipton kangaroo rat, San Joaquin antelope squirrel preconstruction small mammal burrow survey, mapping, trapping and relocation from active construction areas. Staff has outlined a compensatory habitat mitigation strategy for these listed upland species in **BIO-20**.

Biological Resource	Impact/Proposed Mitigation
Blunt-nosed leopard lizard and other reptiles	**Direct impacts:** Permanent and temporary loss of approximately 192 acres of disturbed natural lands (**Biological Resources Table 5**) which provide small mammal burrow habitat for blunt-nosed leopard lizard; increased risk of take of a California Fully Protected species (no-take species) from project construction and operation traffic; crushing or entombing animals in burrows during construction. **Indirect impacts:** Disturbance from project noise and lighting; habitat alteration from introduction and spread of weeds. **Mitigation:** Implementation of impact avoidance and minimization measures in **BIO-6;** focused surveys for blunt-nosed leopard lizard prior to ground-disturbing activities in **BIO-8**; requirements to prepare and implement a BNLL Impact Avoidance and Minimization Plan in **BIO-8**. Staff has outlined a compensatory habitat mitigation strategy for listed species in **BIO-20**.
Western Spadefoot Toad	**Direct impacts:** Grading of potential aquatic breeding sites and upland refugia habitat during construction; crushing or entombing animals in upland burrows during construction. **Indirect impacts**: Impacts to water quality from stormwater runoff into potential breeding ponds that are adjacent to construction areas; introduction of invasive species and habitat alteration; disruption of breeding and habitat use from project noise and lighting. **Mitigation:** Impact avoidance and minimization in **BIO-6** and avoidance of all identified potential breeding habitat in **BIO-16.**
Swainson's hawk	**Direct:** Permanent loss of approximately 571 acres of alfalfa and other low-growing row crops (**Biological Resources Table 5**) that provide foraging habitat for Swainson's hawk; disturbance of nesting and foraging activities for nesting pairs during construction of the plant site and linear facilities; potential loss or decline of nest trees due to groundwater drawdown and decreased water supply to tree's root system. **Indirect impacts:** Disturbance of nesting activities from operations; degradation and fragmentation of remaining adjacent habitat from edge effects. **Mitigation:** Impact avoidance and minimization measures in **BIO-6**; pre-construction nest surveys and implementation of non-disturbance buffers around nest trees in **BIO-9**. Staff has outlined a compensatory habitat mitigation strategy for listed species in **BIO-20**. More data is needed regarding the source of water supply and the effects of groundwater drawdown to nest trees.
Western burrowing owl and other MBTA protected migratory birds	**Direct:** Direct impacts to approximately 192 acres of allscale scrub and disturbed, non-native grassland habitat which provide nest and forage values to burrowing owl and other MBTA-protected birds; loss of several hundred acres of agricultural lands that may provide forage opportunities; potential loss of eggs and young; disturbance of nesting and foraging activities of nesting pairs near the plant site and linear facilities during construction; potential impacts to wildlife exposed to high concentrations of selenium from

Biological Resource	Impact/Proposed Mitigation
	operation of retention ponds; bioaccumulation of selenium by foraging waterbirds from ingestion of a variety of organisms used as food resources. **Indirect impacts:** Disturbance of nesting activities from construction and operation activities; degradation and fragmentation of remaining adjacent habitat from edge effects. **Mitigation:** Implementation of impact avoidance and minimization measures in **BIO-6**; pre-construction nesting bird surveys for MBTA-protected species in **BIO-10** and requirement to net and monitor retention ponds for avian mortality; performance of focused burrowing owl surveys in **BIO-11;** requirements to prepare a Burrowing Owl Monitoring and Mitigation Plan in **BIO-11.** Staff has outlined a compensatory habitat mitigation strategy for listed species in **BIO-20**.

Overview of Vegetation Impacts and Mitigation Measures

The permanent and temporary loss of allscale scrub and agricultural lands are expected to partially displace home ranges and reduce carrying capacity for a number of special-status wildlife species including, but not limited to: San Joaquin kit fox, blunt-nosed leopard lizard, western spadefoot toad, American badger, Tipton kangaroo rat, giant kangaroo rat, San Joaquin antelope squirrel, short-nosed kangaroo rat, San Joaquin pocket mouse, western burrowing owl, Swainson's hawk, other birds and raptors protected by the Migratory Bird Treaty Act and various California Fish and Game Codes, in addition to commonly occurring small mammals, reptiles, and amphibians. Allscale scrub and intermixed non-native grasslands also provide habitat for a number of special-status plant species and native habitats. All of the above species utilize habitats in the project area consisting of intermixed agriculture lands, disturbed, non-native grasslands and allscrub scrub in western Kern County for forage, cover, and wildlife movement particularly when they adjoin higher quality habitat such as the preserve lands of the Kern Water Bank, Tule Elk State Reserve, Lokern Natural Area, and Buttonwillow Ecological Reserve (**Biological Resources Figure 1**).

Construction[3] of HECA would result in permanent and temporary impacts to vegetation communities occupied by special-status and common plant and wildlife species. Construction of the project site and linear facilities would permanently impact approximately 453 and 44 acres of habitat, respectively (**Biological Resources Table 7**). Construction of the IGCC facility itself would result in the loss of 453 acres of agricultural lands used for forage, dispersal, and cover by small and large mammals, foraging raptors, and other wildlife. Permanent impacts would result from the construction of linear facility infrastructure such as transmission line pole structural bases, the new railroad spur right-of-way, metering stations, valve boxes, and five groundwater wells for the proposed well field. This permanent loss of habitat values

[3] For the purposes of this staff assessment, project-related construction activities are defined as any pre-construction, construction, or operational activities conducted for the project site or linear facilities including any flagging/surveying to delineate pipeline or transmission line routes, access routes, or storage areas; grading, trenching, and backfilling of pipeline segments, any truck or delivery routes; and power plant site construction or ongoing maintenance activities of the power plant site and linear facilities.

could ultimately contribute to larger ecosystem impacts such as decreased wildlife movement and genetic exchange and an overall reduction in the project area’s capacity to support these species.

Biological Resources Table 7
Summary of Permanent Habitat Impacts (Acres) by Facility Type[4]

Habitat Type	Project Site	Construction Staging Area	Railroad spur and laydown	Transmission Line/PG&E Switchyard/ Potable Water Pipeline	Carbon dioxide pipeline[5]	Processed Water Pipeline and well field	Natural Gas Pipeline	**Total**
Allscale scrub/natural vegetation	0	0	0	0	0.11	0	0	0.11
Orchards	0	0	4.5	0.01	0	0	0	4.51
Alfalfa	118.0	0	5.3	3.29	0	1.15	0	127.74
Other row crop	317.3	0	16.2	0	0	0	0.23	333.73
Disturbed/Developed	17.7	0	12.4	0.85	0	0	0	30.95
Total	453.0	0	38.4	4.15	0.11	1.15	0.23	**497.04**

[4] From Table A56-1 (Revised Table 5.2-6), Area of Habitats and Existing Land Use Types within Project area and rounded to the nearest tenth of an acre (URS 2013b).

[5] From URS 2012a and OEHI 2012b.

Construction of HECA (including staging areas) and the linear facilities would temporarily impact approximately 91 and 185 acres of habitat, respectively (**Biological Resources Table 8)**. Temporary impacts would primarily result during construction and installation of the buried pipelines (carbon dioxide, processed water, potable water, and natural gas). Depending on the level of maintenance and vehicle traffic required for each linear facility during operation, more significant impacts in the form of wildlife-vehicle mortality and decrease road crossing attempts could occur. Although the majority of project impacts to allscale scrub would be temporary, staff considers the temporal loss of this habitat to be a significant impact to special-status species, which would require mitigation. Allscale scrub habitat subject to temporary impacts should be considered for revegetation activities following the impacts from construction; however, linear facilities that would be subject to regular vehicular traffic and disturbance along maintenance roads or agricultural fields that would revert back to active cultivation following construction, may not be appropriate areas for revegetation.

BIOLOGICAL RESOURCES Table 8
Summary of Temporary Habitat Impacts (Acres) by Facility Type

Habitat Type	Project Site	Construction Staging Area	Railroad spur and laydown	Transmission Line/ PG&E Switchyard/ Potable Water Pipeline	Carbon dioxide pipeline	Processed Water Pipeline and well field	Natural Gas Pipeline	**Total**
Allscale scrub/natural vegetation	0	0	0	0	28.9	0	3.7	32.6
Orchards	0	0	1.1	0.7	0	2.0	0.6	4.4
Alfalfa	0	59.8	3.7	2.8	0	5.9	3.4	75.6
Other row crop	0	20.0	3.5	0.1	0	1.7	9.4	34.7
Disturbed/Developed	0	11.2	4.3	3.7	0	79.5	30.1	128.8
Total	0	91.0	12.6	7.3	28.9	89.1	47.2	**276.1**

The proposed carbon dioxide pipeline route, located on the lower flanks of the Elk Hills and immediately north of the Elk Hills Conservation Area, is the linear route that supports the most contiguous natural, non-farmland type of habitat in the project area. Therefore, it is staff's opinion that the proposed carbon dioxide pipeline route along the low-lying washes on the lower flanks of the Elk Hills represents the highest quality natural habitat and subsequently, a high potential impact area for biological resources. Within the EHOF, the carbon dioxide pipeline alignment follows established roads or an existing pipeline right-of-way for most of its length. OEHI would construct, own, operate, and maintain the entire length of the carbon dioxide pipeline (HECA 2012b). In addition, portions of the natural gas pipeline route also support areas of disturbed, natural allscale scrub, primarily Sites 1 through 5 as shown on **Biological Resources Figure 2**. Some of these sites represent similar habitat values as the nearby Buttonwillow Ecological Reserve, located north of the project site. The majority of the proposed natural gas pipeline would be installed in existing unpaved farm roads that occur along canals or between fields or disturbed areas along Highway 58.

Conducting focused pre-construction surveys for various plants and wildlife, installing exclusionary fencing or flashing in appropriate habitat areas, mapping and avoiding identified small burrows, and consistent construction monitoring would be sufficient to ensure that most special-status wildlife species (e.g., San Joaquin kit fox, American badger, San Joaquin antelope squirrel, giant kangaroo rat, Tipton kangaroo rat, Buena Vista Lake shrew, burrowing owl, other MBTA-protected nesting birds) as well as special-status plant species do not occur in active construction areas. Since HECA includes the construction of several new linear facilities, pre-construction clearance surveys would need to be phased to account for construction beginning in previously undisturbed or unsurveyed areas at different times and possibly different years. To account for the phasing of construction, staff has required the applicant to prepare species-specific monitoring and mitigation plans for blunt-nosed leopard lizard, Swainson's hawk, burrowing owl, and other upland small burrowing mammals. Since blunt-nosed leopard lizard, a California Fully Protected species, is known to occur in the project area and incidental take is prohibited by state law, additional take avoidance and minimization measures including site clearance and biological monitoring is required and has been incorporated into Condition of Certification **BIO-8**.

Staff has proposed several other conditions of certification to mitigate the project's effects to biological resources. Staff recommends that a Designated Biologist and Biological Monitors be assigned to ensure that impact avoidance and minimization measures for the protection of the sensitive biological resources are properly being implemented during construction. Selection of the Designated Biologist and Biological Monitor(s) is described in staff's proposed Conditions of Certification **BIO-1** (Designated Biologist Selection and Duties) and **BIO-2** (Biological Monitor Selection and Duties). The Designated Biologist and Biological Monitor(s) would be responsible, in part, for developing and implementing the Worker Environmental Awareness Program (WEAP) (Condition of Certification **BIO-4**), which is a mechanism for training the construction workers and site personnel on the protection of the biological resources during construction and would be repeated routinely throughout the lifetime operation of the project for new employees. Environmental awareness training for workers focused on routes to and from the project site as well as adherence to posted speed limits would help reduce traffic mortality to wildlife along roads that would be used by construction workers, power plant staff, vendors, feedstock trucks and any other project-related traffic. Staff’s Condition of Certification **BIO-5** requires the applicant to prepare and implement a Biological Resources Mitigation Implementation and Monitoring Plan (BRMIMP) that incorporates the mitigation and compliance measures required by local, state, and federal LORS regarding biological resources. Staff’s proposed Condition of Certification **BIO-6** (Impact Avoidance and Minimization Measures) describes general impact avoidance measures including project design measures and several construction best management practices (BMPs) to minimize the spread of noxious weeds, minimize noise and lighting impacts, and fugitive dust which would be incorporated into the project’s BRMIMP (**BIO-5**). The incorporation of all of these conditions, among others, would minimize the potential for impacts to sensitive species and habitat during construction and operation of the project.

PROJECT IMPACTS TO SPECIAL-STATUS SPECIES

San Joaquin Kit Fox and Other Mammals

During construction of the project, San Joaquin kit fox and other special-status mammals (American badger, Tipton kangaroo rat, giant kangaroo rat, San Joaquin antelope squirrel, short-nosed kangaroo rat, San Joaquin pocket mouse, and to a lesser extent Buena Vista lake shrew) may be killed or harmed during clearing, grading, and trenching activities or may become entrapped within open trenches and pipes. There is a low potential for Buena Vista Lake shrew to occur in and around wetland edges of irrigation canals especially during high rainfall years in which sufficient vegetative cover occurs; therefore, although this species has a low potential to occur in the project area, it is more likely to occur near wet, aquatic areas located along the West Side Canal and East Side Canal and could become crushed or entombed in burrows in these areas.

Construction and operation activities could result in direct mortality, injury, or harassment of individuals as a result of encounters with vehicles or heavy equipment. Other direct effects could include individual kit fox, badger, and small mammals being crushed or entombed in their burrows, collection or vandalism, disruption of breeding or social behaviors during construction or operation of facilities, habitat loss, and disturbance by noise or vibrations from the heavy equipment especially pile driving during construction to kangaroo rats. Some of these animals may be able to escape direct injury from project ground disturbing activities, but become displaced into adjacent areas making them vulnerable to increased predation, exposure, and stress due to lack of cover. Increased human activity and vehicle travel would occur from the construction and operational maintenance traffic along linear facilities that could disturb, injure, or kill individual kit fox, badgers, or small mammals. These species could also be affected by increased project traffic such as worker, feedstock delivery, and wastestream removal traffic during operation. Other indirect effects that could occur during operation of the project include disruption to habitat connectivity and regional movement in an area identified for core recovery of San Joaquin kit fox in the Recovery Plan (USFWS 1998).

The Recovery Plan identifies several threats to San Joaquin kit fox survival and reasons for decline including natural mortality factors (e.g., predation, starvation, flooding, disease, and drought) and man-induced mortality factors (shooting, trapping, poisoning, electrocution, roadkill). The primary threat to survival is loss and degradation of remaining habitat due to conversion to agricultural, industrial or other incompatible land uses leading to an overall decrease of carrying capacity of remaining habitat. In order to determine the project's potential for impacts to San Joaquin kit fox and other upland mammals, staff evaluated the threats to survival and causes for decline identified in the Recovery Plan and evaluated the project's potential to contribute to any of those factors.

Habitat Loss and Habitat Conversion

The permanent and temporary loss of allscale scrub habitat known to be occupied by American badger, San Joaquin kit fox, Tipton kangaroo rat, San Joaquin antelope squirrel, and giant kangaroo rat and potentially occupied by Buena Vista lake shrew could result in habitat displacement, disruption of breeding and foraging behaviors, and a decrease in landscape capacity to support these upland species. Throughout much of the San Joaquin kit fox's range, natural lands are often times bordered by agricultural fields. Although kit fox may not be able to occupy agricultural fields due to lack of den sites, kit fox may be able to cross agricultural croplands to travel to more suitable, natural habitats. Research has indicated that kit foxes occasionally travel up to 1.5 km (about one mile) into croplands (Cypher et al 2005), although concluded that due to the absence of dens that provide cover and escape habitat, kit fox are subject to an increase in predation while crossing croplands and may avoid croplands altogether. San Joaquin kit fox have been reported to inhabit the margins and fallow lands near irrigated row crops, orchards, and vineyards, and may forage occasionally within these agricultural areas (Cypher et al 2007).

Staff believes San Joaquin kit fox occur in the project area as transients moving between agricultural fields although, as indicated above, are likely limited by the absence of denning habitat in agricultural fields. Kit fox likely den and forage along linear facility footprints, especially linear facilities located along canals. Staff believes the project's impact to 773 acres of all agriculture, natural non-native grasslands, and disturbed lands is a significant loss of habitat in a San Joaquin kit fox core recovery area (**Biological Resources Table 5**). The permanent conversion of 453 acres of agricultural lands at the project site alone would be a significant loss of habitat value, since conversion of agricultural lands to an industrial power plant would be a non-compatible land use for kit fox (**Biological Resources Table 7**). This loss of habitat could also affect the ability of kit fox to meet its food, cover, movement, and reproductive requirements since kit fox are known to utilize croplands especially in areas where farmed fields connect to more suitable, natural lands for denning. Long-term, indirect effects could include habitat alteration by increasing shrub cover in disturbed areas along linear routes and canal corridors, which could increase depradation by coyotes on San Joaquin kit fox in higher shrub cover areas. However, since most linear routes are proposed for disturbed areas along canals, major roadway and railroad rights-of-way, and the potential for an increase in shrub cover is not expected to significantly increase the coyote population due to existing levels of disturbance.

Staff believes other mammal species including American badger, Tipton kangaroo rat, giant kangaroo rat, and San Joaquin antelope squirrel are less likely to occupy or utilize the agricultural lands in the project area, except for areas where the agricultural lands directly abut expansive natural, native habitat types (e.g. near the Kern Water Bank, Kern River Flood Control Channel, Tule Elk State Reserve, and Buttonwillow Ecological Reserve). Staff believes the project's impacts to approximately 192 acres of disturbed natural lands that provide small burrowing mammal habitat for giant kangaroo rat, Tipton kangaroo rat, San Joaquin antelope squirrel and other uplands species is a significant loss of habitat (**Biological Resources Table 5**). Buena Vista Lake shrew has a low potential to occur within construction rights-of-way along irrigation canals particularly during wet years when emergent vegetative cover for this species would be higher.

Temporary impacts to approximately 33 acres of natural allscale scrub habitat could displace home ranges and disrupt breeding and foraging behaviors of kit fox, giant kangaroo rat, Tipton kangaroo rat, American badger among other common and special-status wildlife species over the course of three and a half years, the estimated construction period. Since this impact would occur almost entirely along the carbon dioxide route (approximately 29 out of 33 acres), the greatest potential for impact to kit fox and other mammals species occurs along the carbon dioxide route (**Biological Resources Table 8**). Therefore, it is important that this linear route be revegetated to pre-project habitat conditions.

Traffic and Road Impacts

Roads have long been recognized for causing a number of environmental effects on wildlife including mammals, reptiles, and amphibians, as well as plant communities and ecosystem dynamics. Some effects are obvious and direct such as vehicle-related mortality, habitat loss, and habitat fragmentation from traffic and new road construction. Others are more subtle, long-term effects such as invasion of non-native plant species and habitat alteration, disturbance and stress from increased human encroachment, changes in prey availability and predator abundance, disrupted social ecology, habitat use, dispersal, and reduced productivity and genetic exchange (Bjurlin 2004). The following discussion of traffic and road impacts largely focuses on road mortality to San Joaquin kit fox due to the availability of data and literature throughout the range of this species; however, the effects of increased traffic can be applied broadly to other wildlife species.

Direct and indirect effects of roadways may be detectable over one kilometer (0.60 mile) resulting in a "road-effect zone." The number and type of roads passing through kit fox habitat areas play a major role in determining the impact that roadways and traffic would have on kit fox populations. Bjurlin et al (2005) studied urban San Joaquin kit fox mortality rates among other population parameters such as den use and location, movements, and spatial analysis in urban Bakersfield. This study concluded vehicle strikes are the single largest source of mortality for Bakersfield kit fox sub-population, an important factor for urbanized foxes. Of 156 kit fox carcasses collected between 1985 and 2004, 78 foxes were actively monitored with radiotelemetry collars (Bjurlin et al 2005). Of the 78 monitored foxes, 27 percent were found to be definite vehicle strikes, 16 percent were due to predation, and 28 percent were unknown cause of death but were not likely to have died of vehicle collision due to lack of broken bones or contusions.

Road type played a role in correlation with fox deaths in this study. Bjurlin et al (2005) also found few impacts of two-lane highways (e.g. Stockdale Highway, SR 119 and 58) on kit fox ecology in natural land areas outside of the highly urbanized Bakersfield area. This study also concluded as road width, traffic volumes and speeds increase, potential for direct impacts and vehicle fox-collision strike rate increases. From January 1998 to August 2004, out of the 18 retrieved kit fox carcasses that were actively being monitored with radiotelemetry collars at time of death, 83 percent of fox strikes occurred along arterial roads and significantly fewer strikes occurred along collector, local roads, and highways. Here, roads with four or more lanes accounted for about 78 percent of roadkill of all collared foxes and approximately 90 percent of roadkill was retrieved from roads with posted speed limits of 45 mph or greater (Bjurlin et al 2005). Arterial roads were defined as roads with one to three lanes in each direction, carried the majority of city traffic and connected local and collector road networks to state highway system, and with speed limit usually between 35 to 55 miles per hour. In contrast, in more natural areas outside of urbanized zones, predators remain the primary cause of mortality instead of vehicle collisions for both adult and juvenile foxes (Bjurlin 2004). Cypher et al (2005) found that predation (most often by coyotes and bobcats) accounted for 57 percent of San Joaquin kit fox deaths while vehicle strike accounted for only 9 percent of 222 kit fox deaths in rural, natural habitat areas.

However, the Waller probabilistic road kill method (2005) suggests that the lethality of linear transportation features (roadways, railways, etc) to wildlife are governed primarily by two factors, traffic volume and animal velocity (amount of time wildlife spends on the roadway in a crossing attempt). Waller et al (2005) also concluded that increasing the number of road lanes does not increase the probability of animals being struck, but it decreases the traffic volume in each lane thereby decreasing the probability of being struck in each lane; therefore, the probability of road kill is the same with a two-lane roadway as it would be with four lanes.

Increased wildlife roadkill has been a commonly expressed concern for this project. HECA would not result in the construction of any new roads although road improvements at some intersections have been identified; however, construction and operation would result in considerable amounts of increased traffic on several local and collector roads in a rural setting. Staff believes increased vehicle traffic from the project, especially non-peak traffic during dawn, dusk and nighttime hours, could result in a considerable increase in vehicle-fox strike mortality and all wildlife that occurs on or near roadways. Increased project traffic could affect kit fox movement and general wildlife movement in the following ways: decreased habitat amount and quality, increased road kill, fewer road crossing attempts, and reduced access to resources on opposite sides of roadways that could contribute to long-term population fragmentation into smaller, more vulnerable populations. Since kit fox are crepuscular in nature and mostly active during dawn, dusk, and nighttime hours, times during which construction worker traffic and truck deliveries could occur, the susceptibility of this species to vehicle strikes is greater.

Construction Traffic

Based on a peak monthly workforce need of 2,500 workers per day and average vehicle occupancy of 1.3 people per vehicle, it is estimated that an average of 2,460 daily vehicle trips (1,230 round trips) would result from construction worker traffic for the HECA project. Construction would generate an estimated 2,460 additional vehicle daily round trips along Highway 119, Interstate-5, Stockdale Highway, State Route 43 (Enos Lane), and Tupman Road for a period of approximately three and a half years. These totals include additional truck deliveries of soil fill and equipment materials estimated at 1,440 daily round trips during construction (HECA 2012b). The applicant estimated 656 of all daily construction trips would occur during peak morning hours (0700-0900) while 1,230 trips would occur during peak evening hours (1600-1800) since construction workers would likely be leaving the site in the afternoon or evening hours (HECA 2012b, Table 5.10-3, Anticipated Project Construction Trip Generation). Nighttime construction activities are not planned for this project and construction would mostly occur during normal daylight hours, although exceptions may be needed to meet the construction schedule (HECA 2012b), such as occasional concrete pours needed during night hours or that may require extension of work hours into night hours. The applicant has estimated that approximately 85 percent of construction traffic would occur during daylight and 15 percent during night hours (URS 2012a).

Construction traffic for HECA would primarily be via Stockdale Highway to Dairy Road for general truck deliveries and heavy haul loads. Regional construction traffic would arrive via Interstate 5, Tupman Road, and State Route 58. Rail deliveries of large pieces of equipment would be off-loaded and transported near Buttonwillow and hauled to the project site (HECA 2012b). Construction workers would travel to the project site via two primary routes dependent on the point of origin from the Metropolitan Bakersfield area: worker route 1 would be along westbound Stockdale Highway, southbound to Morris Road, westbound to Station Road into the project site; and worker route 2 would travel along westbound Highway 119 to northbound Tupman Road into the project site (HECA 2012b).

Operation Traffic

Operation of the project would result in the addition of traffic associated with employees, feedstock deliveries, and operation and maintenance (O&M) trips serving the project. There will be regular deliveries of feedstock (petroleum coke and coal) to sustain project operations. Under coal transportation alternative 1 (rail), it is estimated that approximately 532 vehicle round trips per day would occur during operation as O&M traffic and delivery trips of processed materials and feedstock (HECA 2012b, Table 5.10-4, Project Operations Trip Generation – Alt 1, Train Option). The applicant estimates that 176 trips would occur during morning peak hours and 220 trips would occur during peak evening hours. Nighttime operation traffic is expected to be minimal; the applicant has estimated that under alternative 1 (rail) approximately 80 and 20 percent of traffic would occur during the day and night, respectively. Under coal transportation alternative 2 (truck route), it is estimated that approximately 1,453 vehicle round trips per day would occur during operation as O&M traffic and delivery trips of processed materials and feedstock, 900 trips of which would be for feedstock delivery alone (HECA 2012b, Table 5.10-5, Project Operations Trip Generation – Alt 2, Truck

Option). The applicant estimates that 302 trips would occur during morning peak hours and 256 trips would occur during peak evening hours. Under alternative 2 (truck coal option), approximately 66 and 34 percent of traffic would occur during the day and night, respectively (URS 2012a).

Vehicle Mortality Strike Analysis

The applicant prepared an analysis looking at the potential for San Joaquin kit fox mortality due to vehicle strikes from project traffic. Since construction and operation traffic would pass through portions of the western Kern County Recovery Area, the Antelope Plain/Semitropic/Kern and Urban Bakersfield satellite populations, and habitat linkages throughout these recovery areas, the applicant first evaluated the project's contribution to baseline traffic levels along the primary roadways that construction and operation traffic would be using for the project (i.e. Interstate-5, Tupman Road, SR 46, SR 119, Stockdale Highway). State Route 58 was not identified as a worker construction route by the applicant, so data was not provided for this roadway. However, staff believes that workers would periodically utilize State Route 58. Using known San Joaquin kit fox mortality rates and traffic levels, the applicant then estimated a project-related road mortality (incidental take) amount for each roadway segment to kit fox over the course of 20 years for operation and three years for construction.

The applicant calculated construction-related incidental take to be 2.39 foxes over three years. Operation-related (employee traffic, material, feedstock delivery, etc) take under Alternative 1 (rail) and Alternative 2 (truck route) over the course of 20 years was estimated to be 11.57 foxes and 26.54 foxes, respectively (HECA 2012b). The applicant determined the baseline take estimate for the individual roadway segments using different sources and methods which staff believes make the calculation of incidental take non-comparable between methods. The applicant evaluated roadway segments along I-5, SR 46, SR 119, Tupman Road, and Stockdale Highway that would be utilized for construction and operation, but only evaluated the portion that overlapped with San Joaquin kit fox core recovery areas. Staff disagrees with this approach since kit fox occur outside of core recovery areas and incidental take of kit fox in the form of fox-vehicle collisions would undoubtedly occur beyond the boundaries of the core areas and the roadway segments that the applicant evaluated. The direct and indirect impacts of traffic to this species and all wildlife would extend beyond the finite boundaries of the core recovery areas as described above not only as take in the form of vehicle-fox strikes, but also as the loss of foraging opportunities, a reduction of crossing opportunities, habitat alteration, disturbance and stress, changes in prey availability, predator abundance, and habitat use. The applicant used Figure 9 in Bjurlin et al (2005) to determine a baseline take estimate along the select roadway segments that the project would be using. However, staff believes this figure should not be used as a standard for determining baseline take for the project, since Figure 9 in Bjurlin et al (2005) represents fox strikes in relation to fox-vehicle collisions along arterial and collector roads at intersections with other linear rights-of-way (canals, golf courses, other collector and arterial roads, highways, railroads). Lastly, staff believes operational take should be calculated over the life of the project, not 20 years as the applicant calculated. Staff believes it may be more appropriate to evaluate vehicle-fox mortality impacts considering the project's contribution to existing traffic volumes and intersection of proposed construction and operation routes with other types of linear right-of-ways.

Likewise, staff believes a more applicable method for determining wildlife incidental take would be to determine roadkill probability using Waller et al (2005) methods, which looks at traffic volumes and the time it takes an animal to cross the kill zone.

Regional Movement

As mentioned previously, the project is proposed for an area located within a core recovery area for San Joaquin kit fox, natural lands of western Kern County, which serves as a linkage point between other core areas and satellite populations. For small populations like these identified in the Recovery Plan (USFWS 1998), the effects of habitat fragmentation associated with transportation networks and risk of extinction from catastrophic events is greater for small populations. Therefore, movement of individuals between these metapopulations is critical for maintaining gene flow and avoiding inbreeding effects (Bjurlin et al 2005). For example, the Department of Water Resource's Kern Fan Element (Kern Water Bank) provides an important linkage as a corridor between the Kern River Parkway through Bakersfield and the western Kern County population. Connecting large blocks of isolated lands to larger, core population areas that are naturally more stable is an important element to San Joaquin kit fox recovery (USFWS 1998).

Another potential effect from increased construction and operation traffic is unwillingness for kit fox and other wildlife to cross roads or "road avoidance" if traffic is consistent enough on the same route and over a long period of time. Studies have shown road avoidance and decreased road crossings to be the case with San Joaquin kit fox. However, kit fox have appeared to adapt to urban areas such as Bakersfield and data on the movements of radio-collared animals show that kit foxes frequently cross roads and often do so in a habitual manner. The movements of radio-collared kit foxes in Kern County near I-5 were monitored and several fox utilized habitat in a 1.15 square mile area and most exhibited parallel movements and home range patterns; on only two occasions were foxes located on the opposite side of the highway from their primary area of use. A study of developed (oil fields) and undeveloped sites (Lokern Natural Area) in western Kern County concluded denning, foraging, and home ranges ranged from 1.36 to 6.66 square km (0.76 to 2.57 square mile) in undeveloped plots (Spiegel et al 1991). Bjurlin et al (2005) concluded the majority of crossings occurred on local roads in the metropolitan Bakersfield area but the majority of mortalities occurred on arterial and collector roads with higher traffic volumes indicating that low traffic volumes and slower speeds associated with local roads may decrease the danger to kit fox.

The study also showed that kit foxes did not appear to prefer or avoid dens that were in close proximity to major roadways in urban environments since natal dens were found within 20 meters form roadways in urban Bakersfield but in many cases, animals maintained territories that did not bring them in frequent contact with major roads. Of 327 kit fox dens used from 2001 to 2004, 68 percent of strikes on major roads occurred within two road widths of an intersection (Bjurlin et al 2005). In this same study, kit foxes died more often than expected by chance at intersections of roadways with other types of linear rights-of-way such as other local and collector roads and canals and strikes were often within one road width of the intersection. This is likely because species of the family Canidae (dogs, wolves, foxes, coyotes) use linear features for travel. This is important for HECA since several project worker routes occur along local and collector roads and intersections with canals occur in the project area, intersections where more strikes could occur since kit fox likely utilize canals for movement. In urban Bakersfield, kit fox have shown some preference for den sites with respect to adjacent land uses; of 471 dens assessed from 1997 to 2004, 36 percent were located along the banks of canals or along detention basins. Intersection improvement areas proposed along SR 119, SR 43, Stockdale Highway, Tupman Road, and Dairy Road could therefore endanger kit foxes that use roadside dens. For HECA, if traffic volumes remain large enough along particular roadways for a long enough period of time, kit fox could shift dens to sites that would not bring them in frequent contact with traffic or the roadways, or avoid crossing roadways in general. This could have long-term implications on kit fox movement in the immediate project area particularly along rural, local roads such as Station, Dairy, Tupman, and Morris roads among others where traffic volumes would be significantly increased during operation of the project.

Mitigation for San Joaquin Kit Fox and Small Upland Mammals

Direct impacts to San Joaquin kit fox and other mammals would occur from proposed project construction and operation including individual mortality from vehicles strikes, vegetation removal, loss of habitat, and displacement of individuals. Incorporation of staff's Conditions of Certification **BIO-1** through **BIO-6** would minimize the potential for construction impacts to kit fox and other burrowing small mammal species. The applicant has recommended impact avoidance and minimization measures to reduce the potential for direct and indirect impacts to San Joaquin kit fox and other wildlife, including combined terrestrial wildlife pre-construction surveys covering affected areas and a 200-foot survey buffer; den surveys and unoccupied den excavation; and combined ground disturbance monitoring for terrestrial wildlife. Staff has incorporated portions of these mitigation measures into staff's proposed Condition of Certification **BIO-7**, which requires that the applicant conduct focused den surveys prior to construction for San Joaquin kit fox and American badger, establish exclusion zones, and continue monitoring the activity of potential dens identified in construction areas. **BIO-7** also requires that the applicant follow the USFWS's *Standardized Recommendations for Protection of the San Joaquin Kit Fox Prior to or during Ground Disturbance* for avoiding impacts to this species (USFWS 2011). Staff's proposed Condition of Certification **BIO-12** requires that the applicant prepare and implement a Small Mammal Relocation Plan, which would include the identification of potential release sites, and monitoring and reporting of small mammals at release sites, among other trap and relocation details. Proposed Condtion of Certificaiton **BIO-13** requires the applicant to perform pre-construction precinct surveys and mapping for giant kangaroo rat and trap and relocate any giant kangaroo rats captured within construction areas in order to minimize take and mortality of this species during construction, in accordance with the Small Mammal Relocation Plan. In addition, proposed Condition of Certification **BIO-14** requires the applicant to perform a pre-construction small mammal burrow survey to better define the subsequent trapping area and relocate any trapped Tipton kangaroo rat and San Joaquin antelope squirrel in order to minimize take and mortality of these species during construction. Temporary loss of habitat values would occur during construction, grading, trenching, and backfilling for the various pipelines along linear facilities. After the completion of construction activities, the applicant would be required to restore the natural, relatively undisturbed allscale scrub habitat along linear facilities to pre-project conditions per staff's proposed Condition of Certification **BIO-18** (Revegetation Plan).

As discussed above, Buena Vista Lake shrew has a low potential to occur within construction rights-of-way along irrigation canals particularly during wet years when emergent vegetative cover for this species would be higher. Likewise, staff does not believe the project would significantly impact this species and mitigation specific to this species is not warranted; however, the implementation of **BIO-1** through **BIO-6, BIO-12, BIO-13,** and **BIO-14** in addition to the measures listed above would further reduce the potential for project impacts to Buena Vista Lake shrew.

Staff believes the project's increase in traffic volumes could have an effect on San Joaquin kit fox; however, additional vehicle-kit fox mortality and data analysis is required. Staff believes the project's impacts to approximately 773 acres of allscale scrub, agricultural lands, and disturbed habitats along canal roads that provide habitat to San Joaquin kit fox in a San Joaquin kit fox Core Recovery Area is a significant impact that requires mitigation. The project's impacts to approximately 192 acres of natural allscale scrub and other disturbed lands that support small mammal burrowing habitat is a significant habitat loss to giant kangaroo rat, San Joaquin antelope squirrel, and Tipton kangarro rat and is a significant impact that requires mitigation. Staff has proposed Condition of Certification **BIO-20** which requires the applicant to secure offisite compensatory mitigation lands that meet species habitat criteria for San Joaquin kit fox, giant kangaroo rat, Tipton kangaroo rat and San Joaquin antelope squirrel. Acquistion and preservation of offsite mitigation lands with a conservation easement would also permanently secure lands as habitat for American badger, San Joaquin pocket mouse, short-nosed kangaroo rat and other common and special-status mammals. In order for staff to prepare the FSA/FEIS, staff needs information on the applicant's mitigation proposal to offset the project's direct and indirect effects to these species. This proposal should be based on HECA's specific vehicle-fox mortality analysisand habitat loss in order to determine the amount of incidental take attributable to the project and ultimately the necessary mitigation to offset the project's impacts. With the incorporation of the above conditions of certification, the project's impacts to these species would be reduced; however, until additional data is provided regarding the project's impacts and overall mitigation strategy, staff cannot determine if the project's impacts to San Joaquin kit fox, giant kangaroo rat, Tipton kangaroo rat, and San Joaquin antelope squirrel would be reduced to below a level of significance in accordance with CEQA.

Blunt-nosed Leopard Lizard and Other Reptiles

The greatest threats to blunt-nosed leopard lizard (BNLL) survival include habitat disturbance, destruction, and habitat fragmentation. Construction of facilities related to oil and natural gas production, wells and pads, storage tanks, pipelines and access roads degrade habitat and cause direct mortality to BNLL. The displacement of BNLL and other species of lizards to adjacent lands due to loss or degradation of habitat may result in an inability to survive if the habitat is already occupied or unsuitable for colonization (USFWS 1998).

The potential for direct impacts from project construction activities to BNLL, coast horned lizard, and other reptiles includes individual mortality from vehicles and equipment on roadways, entrapment in construction-related trenches or pipes, buried in burrows by equipment, avoidance of certain habitats, modification to breeding and/or foraging behaviors, and reduced carrying capacity of natural scrub habitat and neighboring lands known to be occupied by BNLL. Regular vehicle traffic and off-road vehicle use are known to be a large source of mortality of blunt-nosed leopard lizard. Typically roads surround, occur in close proximity, and often bisect remaining natural habitat areas, which further increases the risk of mortality to BNLL from vehicles and fragments habitat (USFWS 1998). Other regional threats to survival of this species include livestock overgrazing that results in removal of herbaceous vegetation and shrub cover and destruction of rodent burrows used by lizards for shelter, pesticide use, and vehicle mortality. Unlike cultivation of row crops which precludes BNLL presence, low to moderate livestock may be beneficial since light grazing may help promote low, sparsely growing herbaceous cover which is favored by BNLL (USFWS 1998).

The project’s contribution of 2,460 and 1,453 daily vehicle trips during construction and operation under alternative 2 (coal delivery truck route option), respectively, would increase the potential risk of road mortality to BNLL and other reptiles. Consistently high traffic levels in natural habitat areas where BNLL is known to occur over long periods would cause fragmentation of habitat and reduction of movement, motility, and gene flow of this federally- and state-listed species that is also a California Fully Protected species. In particular, project traffic along the SR-58 northern extension of the natural gas pipeline, Stockdale highway, the transmission line/potable water facilities immediately north of the Tule Elk State Reserve, and carbon dioxide pipeline route south of the California Aqueduct, all proposed in and around allscale scrub habitat, are the project facilities that pose the largest threats to habitat loss and potential for direct road mortality to BNLL. Staff believes the project’s direct loss of approximately 192 acres of natural allscale scrub and disturbed lands which provide small mammal burrow habitat for blunt-nosed leopard lizard is a signicant impact to this species. The construction of the carbon dioxide pipeline represents the greatest risk, habitat loss, and potential for take and impacts to BNLL. Sites 1 through 5 along the natural gas pipeline route also represent potential BNLL habitat although this species has not been found to occupy these sites following protocol-level surveys performed by the applicant (**Biological Resources Figure 2**). In addition, operation and maintenance activities along the carbon dioxide pipeline route, an area immediately south of the EHOF could result in take of BNLL primarily in the form of direct road mortality from project traffic.

Mitigation for BNLL and Other Reptiles

Direct impacts to BNLL would occur from HECA construction and operation including individual mortality from vehicles strikes, loss of habitat and fragmentation, and displacement of individuals. Incorporation of staff’s Conditions of Certification **BIO-1** through **BIO-6** would minimize the potential for construction impacts to BNLL, coast horned lizard, and other reptilian species. Staff has proposed Condition of Certification **BIO-8**, which requires the applicant to prepare a BNLL Impact Avoidance and Minimization Plan to further minimize the potential for take during construction and operation of the project. In particular, this plan would take into consideration the phasing of linear construction and how clearance surveys, exclusion fencing, and fence and burrow monitoring would also be phased in order to ensure BNLL remain clear of active construction areas. Condition of Certification **BIO-8** also requires that various BNLL impact avoidance measures be incorporated including scheduling surface ground disturbing during the BNLL active season (approximately April 15 to October 15) to the greatest extent practicable, in particular along the carbon dioxide pipeline route and within Sites 1 through 5 along the natural gas pipeline route where this species is mostly likely to be encountered, minor shifts in proposed pipeline alignments in order to avoid potentially occupied small mammal burrows, presence of biological monitor(s), and strategic installation of exclusion fence flashing to preclude BNLL presence in construction areas. Staff's proposed Conditions of Certification **BIO-8** and **BIO-20** require the applicant to secure off-site mitigation lands that meet habitat criteria of BNLL as compensatory mitigation to offset the loss of BNLL habitat.

Blunt-nosed leopard lizard is a California Fully Protected species under California Fish and Game Code Section 5050, and therefore incidental take of the species cannot be permitted as defined by Section 86 of the Fish and Game Code. Therefore, take avoidance and minimization measures must be implemented by the applicant throughout construction and operation (as determined in the subsequently prepared BNLL Impact Avoidance and Minimization Plan per **BIO-8**) to ensure take does not occur. Staff concludes that even with the implementation of the identified take avoidance and minimization measures, incidental take of BNLL would likely occur over the life of the project. Since avoiding take of this species cannot be guaranteed for the life of the project, HECA may not comply with California Fish and Game Code Section 5050 and CESA.

Staff considers the project's impacts to BNLL to be significant and unavoidable impacts under CEQA which require mitigation. For BNLL, CDFW and USFWS typically require compensatory mitigation for a project's impacts to habitat loss that is determined significant under CEQA. Staff notes that any impacts due to habitat loss of BNLL even if mitigated as required under CEQA, may violate CESA and the California Fish and Game Code Section 5050 due to the species' status as a California Fully Protected species and the likelihood of take of this species; therefore, it is unclear whether the project will comply with these LORS.

Giant Garter Snake: Impacts and Mitigation

As discussed previously, giant garter snake has a low potential to occur in the project area due to presumed extirpation from the southern-most portion of the San Joaquin Valley, lack of known occurrences and lack of essential habitat components in the project area. However, staff recommends the implementation of impact avoidance and minimization measures during construction activities along any of the project's linear facilty routes proposed along canals, primarily the railroad spur and 15-mile brackish water pipeline to further minimize the potential for impacts to this species during construction. Likewise, staff has incorporated wildlife agency guidance on this species and construction avoidance measures into Condition of Certification **BIO-15**. With the implementation of this measure, the potential for impacts to giant garter snake would be reduced to less than significant levels.

Western Spadefoot Toad: Impacts and Mitigation

The applicant indicates that western spadefoot tadpoles were found in a seasonal depression between the West Side Canal/Outlet Canal and California Aqueduct during 2009 surveys. Western spadefoot toads are historically known from the Central Valley including the southern San Joaquin Valley with a few extant records remaining and can persist in seasonal wetlands and ponds with emergent vegetation that typically do not inundate long enough to support non-native bullfrogs, crayfish, or other non-native predators of tadpoles. Western spadefoot toad is a California Species of Concern that is declining throughout its range primarily due to habitat loss and agricultural conversion of grasslands. Potential impacts that could occur to this species include terrestrial and aquatic habitat loss and direct mortality of individuals during project grading, vegetation clearing, and pipeline trenching for the project's linear facilities as well as disruption of breeding behaviors, disturbance by noise or vibrations from equipment, and introduction of weeds and exotic plant species that can displace native seasonal wetland vegetation.

Staff believes the depressional seasonal wetland areas and upland areas that were identified between the West Side Canal and California Aqueduct could potentially support spadefoot toads and be impacted during project construction. In addition, several small, disturbed mostly unvegetated seasonal wetlands that were identified along State Route 58 could represent habitat for this species and be impacted during construction and grading for the natural gas pipeline. The applicant indicated that during times of increased rainfall, the depressions identified along the State Route 58 natural gas linear inundate and form shallow pools of water that persist for at least 10 to12 days during the growing season and the best evidence for the length of ponding in the shallow depressions was the presence of mature Lindahl's fairy shrimp (*Branchinecta lindahli*) observed during the March 2012 surveys (URS 2013c); however, given that these shallow depressions are mostly unvegetated, the habitat suitability for western spadefoot toad is reduced. Lindahl's fairy shrimp is a non-listed vernal pool crustacean that is common in arid regions of California in turbid and clear-water short-lived pools and live in seasonal depressions that typically last from 5 to 30 or more days before drying (Eriksen and Belk 1999).

The applicant did not provide a habitat assessment, GPS'ed mapped location of the single occupied seasonal pond, or quantified acreage of potential habitat of this species within the project area, nor did the applicant propose any specific mitigation measures or impact avoidance and minimization measures for western spadefoot toad. Staff believes additional baseline field data is needed on the occurrence of other suitable habitat areas in the project area. In preparation of the FSA/FEIS, staff requests that the applicant perform an upland refugia and aquatic habitat assessment(s) preferably during the wet season (defined as October 15 to April 15 of any given year) and following sufficient winter or spring rains in order to identify potential depressional areas and upland refugia that may provide habitat for western spadefoot toad. All linear facility construction rights-of-way should be subject to the habitat assessment. All potential ponding areas should be identified and mapped with a GPS unit and information to be collected at each GPS'ed potential breeding area includes, at a minimum: the specific numbering system of each potential breeding area, presence of tadpoles and species (if any), habitat community, microhabitat features, observed plant species, observed wildlife species including invertebrates, water temperature, approximate depth and surface area, and level of disturbance.

Staff believes that with the project's potential for impacts to potential breeding habitat of this species with its limited range in the southern San Joaquin Valley and at least one identified occurrence of this species in the project area, significant impacts to this species could occur and mitigation is required. Following performance of the western spadefoot toad habitat assessment, any potential habitat areas would be identified and mapped. In order to reduce the potential for effects to this species and habitat areas during construction, staff has proposed Condition of Certification **BIO-16**, which requires the project owner to install fencing and avoid all identified potential breeding wetland depressions and upland areas within a minimum 100 foot buffer from construction activities, specifically the single depressional area in which spadefoot toad was observed between the West Side Canal and California Aqueduct. With the implementation of Condition of Certification **BIO-16** the potential for impacts to western spadefoot toad and potential wetland breeding depressions would be reduced; however, until additional data is provided regarding the occurrence of additional habitat areas, staff cannot determine if the project's impacts to western spadefoot toad would be reduced to below a level of significance.

Swainson's Hawk: Impacts and Mitigation

During protocol-level surveys performed for this species, 12 active raptor nests were found within the survey area, six of which were confirmed Swainson's hawk nests (URS 2012a, Figure A45-2). All six Swainson's hawk nests appear to be within a 0.25 mile of either the project site or a proposed linear facility and therefore could be affected by construction noise or other construction disturbances during the nesting season. Swainson's hawk nest numbers 05, 06, 19, and 21 occur within immediate proximity (less than 0.25-mile) to the 15-mile processed water pipeline; nest #29 occurs within immediate proximity (less than 0.25-mile) of the natural gas pipeline route along Highway 58; and nest #22 is located approximately one mile due east of the project site in the Tule Elk State Reserve (URS 2012a, Figure A45-2). The applicant estimates that construction of the project would span a 42-month period and that construction of the railroad spur under (coal delivery option #1) would begin early in the construction period so that materials and equipment could be delivered to the project site via the proposed rail line; construction of the project's linear facilities each would require approximately six months to construct (HECA 2012a).

The potential for direct impacts to Swainson's hawks include the loss of nest sites, eggs, and/or young; loss or decline of nest trees, abandonment of active nests; permanent loss of foraging habitat; and disturbance of nesting and foraging activities of hawk pairs. Indirect impacts to Swainson's hawks during construction and operation can include increased road kill hazards, and loss of prey items and food sources due to a decreased number of fossorial mammals. Five of the Swainson's hawk nests found during 2012 surveys occur along the 15-mile brackish water pipeline route and staff believes groundwater drawdown around the well field may result in loss or gradual decline in health of these nest trees. In addition, the project would result in the loss of approximately 571 acres of alfalfa and other low-growing row crops potentially used as foraging habitat for this species (**Biological Resources Table 5**).

Impacts to Nest Trees

Six confirmed Swainson's hawk nests and up to six other confirmed raptor nests (great-horned owl and red-tailed hawk) were found in the same survey area during 2012. Tree species identified during Swainson's hawk nest surveys that are being utilized by several raptors and common ravens (*Corvus corvax*) for nesting include willow (*Salix* sp.), tamarisk (*Tamarisk chinensis*), Fremont cottonwood (*Populus fremontii*), fruitless mulberry (*Morus alba*), and eucalyptus (*Eucalyptus* sp.). Many man-made structures such as power poles and a grain silo also provide nesting sites. Staff estimates up to 13 nest trees with either potential or confirmed nests occur within approximately two miles of the applicant's proposed groundwater well field (URS 2012a, Figure A45-2). The majority of these nest trees occur along canal levees of large named canals including the KRFCC and West Side Canal and other smaller unnamed agricultural canals and ditches and are likely supplied to some extent by irrigation runoff that accumulates in irrigation canals.

Most woody vegetation of lower elevation southwest riparian ecosystems are believed to be dominated by phreatophytic species, that rely heavily on alluvial groundwater. Native tree species such as Fremont cottonwood and black willow (*Salix gooddingii*), and non-native tamarisk dominate these lower-elevation riparian habitats in the southwest. Fremont cottonwood is considered a facultative phreatophyte, a plant species that utilizes moisture from groundwater for a portion of their water requirements but can also acquire water from other soil sources. Cottonwoods typically occur in areas with depth to groundwater of less than 5 meters whereas black willow is an obligate phreatophyte that is more shallowly rooted than cottonwoods. Tamarisk is also considered facultative phreatophyte but is much more drought tolerant than the other two native species (Horton et al 2001). A study that evaluated two riparian riverine sites in Arizona, concluded that an increase in depth to groundwater caused a reduction in shoot water potential and increased canopy dieback and mortality in both willows and cottonwoods. Likewise, both species experienced an increased canopy dieback and mortality when depth to groundwater increased above an apparent threshold of 2.5 to 3.0 meter. In this same study, tamarisk was more tolerant of water stress imposed by deeper groundwater depths and Fremont cottonwood was more tolerant of deeper groundwater sources than willows. Horton et al (2001) also concluded that some regulation of surface water flows may benefit mature riparian forests since in this case, riparian trees were in better physiological condition when depths to groundwater ranged between 3.5 to 4.0 meters (approximately 10 to 12 feet) and riparian trees showed signs of decline once groundwater depths fell below 3 meters. Another study that looked at the effects on riparian vegetation from removing water supply and effluent generated by wastewater treatment plants to the Salinas River concluded that it was essential that the existing water table not be lowered beyond the root zone of approximately 10 feet of willows and cottonwoods (Warner and Hendrix 1984). The depth to groundwater in the area of the well field ranges from 25 to 30 feet (BVW 2010a) and staff estimates that the identified nest trees in the two-mile radius around the well field could experience a groundwater drawdown ranging from four to 12 feet over the course of the 25-year licensing of the project.

Since the majority of nest trees in the proposed well field area occur along canal roads of the KRFCC and West Side Canal and the estimated depth to groundwater is 25 to 30 feet in this area, well below the estimated depth of water use by cottonwoods and willows, staff concludes the trees along these canals are supported to some extent by groundwater but also perched subsurface flows. Depth to groundwater in the project area is estimated to range from 20 to 130 feet below ground surface (BVW 2010a). Staff believes the majority of water supported in irrigation ditches between agricultural fields is primarily irrigation source runoff during the growing season and to a lesser extent, stormwater runoff during the rainy season from Kern River overflow since the majority of stormwater is diverted into other flood control channels farther east of the HECA project before reaching the project area and KRFCC. For alfalfa, the primary crop in the project area, the harvest and irrigation windows typically parallel each other with generally four monthly harvests beginning in May to August with irrigation typically following each harvest (USDA website ref). During an October 2012 site visit, portions of the West Side Canal supported sporadic, shallowly ponded water and hydrophytic vegetation (i.e. salt grass, *Distichlis spicata*) was observed in some areas which suggests that these areas may inundate with irrigation runoff for various periods during the growing season. For a full discussion of surface water and groundwater existing conditions in the project area, see the **Soil & Surface Water** and **Water Supply** sections of this PSA/DEIS.

Although water supply to the root system of nest trees in the project area are believed to be sourced by irrigation runoff in agricultural canals, more definitive analysis is needed on the baseline groundwater levels and water source of the nest trees that occur in the project area. If water drawdown is consistent enough over the course of several years, staff believes the decrease in water supply to the tree's root system could result in gradual decline and eventually nest tree failure. If the long-term drawdown of water resulted in nest tree failure or mortality such as canopy dieback, limb failure or other health or structural indicators due to the project's groundwater pumping, this could constitute incidental take of Swainson's hawk under CESA, which would require take authorization and mitigation for loss of Swainson's hawk nest habitat. Given Swainson's hawk high site fidelity with nest sites, lack of suitable raptor nesting habitat in the project area, staff concludes the project could result in a reduction of nesting habitat, which is a significant impact that would require mitigation.

Foraging Habitat

Staff also believes the loss of approximately 571 acres of agricultural lands including alfalfa, wheat, onion fields, and other crop types that provide forage value is a significant loss of foraging habitat for this species (**Biological Resources Table 5**). Nest #22 is within the Tule Elk Reserve and within one mile from the IGCC project site; construction of the IGCC facility alone would result in loss of 453 acres of Swainson's hawk forage habitat. The CDFW guidance on habitat compensation for this species specifies that to mitigate for the loss of foraging habitat, Habitat Management (HM) lands (agricultural lands or other suitable habitats which provide forage habitat) should be provided by the applicant based on the distance of the project facilities (< 1 mile, between 1 and 5 miles, or between 5 and 10 miles) to active nests trees:

- projects within one mile of an active nest should provide 1 acre of HM land for each acre impacted (1:1 ratio) if at least 10 percent of the lands are secured by fee title acquisition for active management of habitat and remaining 90 percent of lands protected by a conservation easement; OR

0.5 acre of HM land for each acre impacted (0.5:1) if 100 percent of lands are met by fee title acquisition or a conservation easement which allows for active management of habitat for prey production.

- projects between one and five miles from an active nest should provide 0.75 acre of HM lands for each acre impacted (0.75:1). All HM lands may be protected through fee title or conservation easement of suitable foraging habitat.
- projects between five and 10 miles from an active nest should provide 0.50 acre of HM lands for each acre impacted (0.50:1). All HM lands may be protected through fee title or conservation easement of suitable foraging habitat.

Swainson's Hawk Mitigation

The applicant has recommended impact avoidance and minimization measures to reduce the potential for impacts to Swainson's hawks, including bird pre-construction surveys within 200 feet of the project disturbance areas, bird nesting activity surveys; and bird nest protection. The applicant has also proposed Swainson's hawk avoidance and minimization measures following the *Recommended Timing and Methodology for Swainson's Hawk Nesting Surveys in the California's Central Valley* (Swainson's Hawk Technical Advisory Committee 2000) as well as predatory bird minimization measures including the removal of predatory bird nests (HECA 2012b). Since several Swainson's hawk nests were confirmed active during 2012 surveys, staff believes that 200 feet would not be a large enough distance to avoid construction impacts to an active Swainson's hawk nest. California Department of Fish and Wildlife's guidance on this species calls for a buffer area of 0.25-mile between an active nest and any new intensive disturbances such as heavy equipment operation during construction or other project-related activities that may cause nest abandonment or premature fledging between March 1st through August 15th; the nest avoidance buffer should be increased to 0.50 mile in nesting areas outside of urban areas (CDFG 1994).

In Condition of Certification **BIO-9** (Swainson's Hawk Impact Avoidance Measures), the applicant would be required to conduct focused, preconstruction surveys within 0.50-mile of all project facilities and a minimum construction avoidance buffer of 0.50 mile around any active Swainson's hawk nests following the recommended survey protocol for this species (Swainson's Hawks Technical Advisory Committee 2000). This impact avoidance buffer could be reduced during the nesting season by the project's Designated Biologist and compliance project manager based on consultation with CDFW along with monitoring of the nest site for signs of stress or disturbance by the project's Designated Biologist.

Staff understands that the construction of all project facilities would not occur simultaneously and it is not feasible for HECA including all linear facilities to be constructed entirely outside of the nesting season. Therefore, staff has included a requirement in Condition of Certification **BIO-9** for the applicant to prepare a Swainson's

Hawk Monitoring and Mitigation Plan that would account for the phasing of construction and need to phase preconstruction surveys. To the extent possible, construction activities would be timed to occur outside of the nesting season of Swainson's hawk, approximately March 1 through August 15 of each construction year. Due to the occurrence of at least five active raptor nests, three of which are Swainson's hawk, along the 15-mile long processed water pipeline, the start of construction on this linear facility outside of the Swainson's hawk nesting season and the implementation of a minimum 0.50-mile buffer is particularly critical to minimize impacts to these nests during construction of this facility. In addition, incorporation of staff's Conditions of Certification **BIO-1** through **BIO-6**, which require monitoring and reporting of nest sites by biological monitors during construction, worker awareness training, and other impact avoidance measures, would help in minimizing impacts to Swainson's hawks.

Given the occurrence of at least six known active Swainson's hawk nests in the project area including linear facilities, presence of suitable foraging agricultural lands and estimated impacts to 571 acres of foraging habitat loss, staff believes habitat mitigation lands that meet foraging habitat criteria by Swainson's hawk should be acquired. Staff's proposed Conditions of Certification **BIO-9** and **BIO-20** require the applicant to secure off-site mitigation lands as compensatory mitigation to offset project impacts to species such as Swainson's hawk. With the incorporation of the above conditions of certification, the project's impacts to Swainson's hawk would be reduced; however, until additional data is provided regarding the project's impacts and overall mitigation strategy, staff cannot determine if the project's impacts to Swainson's hawk habitat would be reduced to below a level of significance. In order for staff to prepare a FSA/FEIS, the applicant must provide a mitigation proposal to offset the project's effects to nest and forage habitat loss for this species as well as additional data on the water supply source and effects of groundwater pumping to nest trees.Until further analysis and consultation with CDFW is performed on the project's potential for impacts to Swainson's hawk nest trees and potential for take, it is unknown whether the project would comply with MBTA, CESA, and Fish and Game Code Section 3503.

Western Burrowing Owl: Impacts and Mitigation

Western burrowing owls and recent sign has been observed immediately north of the project site, southeast of the transmission line/potable water route and project site, and along the natural gas pipeline route. Adults and owlets were observed west of the natural gas alignment along Brandt Road during 2012 and at least six burrowing owls have been observed at one time during July 2012 at Tule Elk State Reserve and appear to be part of the same owl family group (URS 2012a). Focused protocol-level surveys were not performed for burrowing owl and observations of this species presence in the project footprint were combined with other biological surveys (i.e. BNLL, Swainson's hawk and wetland delineation surveys). Therefore, staff does not have information on which pairs or groups of owls are in fact breeding in the project area. The home range of burrowing owls has been reported to range from 280 in irrigated lands of Imperial Valley to 600 acres and may be much larger in non-irrigated grassland areas such as the Carrizo Plain (CDFG 2012b). The mean home range for 11 male burrowing owls in 1998 and 22 males in 1999 was 177 ha (437 acres) and 189 hectares (467 acres), respectively, at Naval Air Station in Lemoore, California which is located south of

Fresno (Bloom 2003). Based on telemetry results, foraging generally occurred within a 600-meter radius around the nest burrow (roughly 300 acres) although home range of burrowing owls can widely range and is not well understood (CDFG 2008). Moreover, diurnal home range for owls can be 150 feet on both sides of burrow while nocturnal home range can be much larger, for example one square mile per owl pair, and several owls can overlap in that one square mile (Bloom pers. comm.). Male burrowing owls often move greater than 1,000 meters when foraging in the breeding season and home ranges can often times overlap (Bloom 2003). Burrowing owls also show relatively high site fidelity and returned to successful nest sites between nesting years. For example, one study concluded adult males and females nesting in formerly used nest sites at 75 percent and 63 percent rates, respectively, and more commonly owls at least return to the same nest area without necessarily reusing the same burrow (CDFG 2012b).

Since burrowing owls were observed in generally the same area following 2011 and 2012 field surveys and given the best available scientific data available on home range and burrow use, the owls observed are likely resident owls or first-year fledglings or family groups that have not entirely dispersed and have returned to the area to nest. The burrows or culverts at which the owls were observed are likely being used for nesting or as satellite burrows which typically occur within 75 meters of nest burrows, year-round cover or roosting, or a combination of any of these. Staff has concluded that burrows and owl habitat occurs along linear facilities that are confirmed to either support owls and/or support fossorial animals with existing burrows and therefore could support owls and area adjacent to other suitable owl habitat.

An assessment of impacts to burrowing owl should evaluate the type and extent of disturbance, duration and timing of disturbance, sensitivity of the affected owls and visibility of the disturbance, among other environmental factors (CDFG 2012b). The potential for direct impacts to burrowing owls include loss of habitat used for nesting, forage, wintering, and dispersal; loss of nest and satellite burrows; disruption of breeding behaviors during the nesting season; and direct mortality to individual birds. Burrowing owls being ground-dwelling species are more susceptible to being directly crushed or displaced during construction activities. In addition, burrowing owls and other raptors would experience a decrease in prey and food sources due to a decreased number of fossorial mammals from grading and habitat loss.

Construction of the IGCC power plant and linear facilities is estimated to occur over a 42-month window and trenching of the linear facilities, the majority of which will be buried pipelines, would be phased and installed in sections; generally, each linear facility is estimated to take six months to construct. Once the IGCC is constructed, owls in the project area would experience a permanent increased expenditure of energy in order to move around the future power plant and may need to disperse or forage greater distances to other suitable owl habitat, especially since there is a large acreage of alfalfa and other row crops surrounding the project site. Operational noise is likely to permanently impact owls that are likely sensitive to industrial noise levels. These impacts in turn may result in the abandonment of some burrow sites in close proximity to the proposed IGCC power plant or creation of new territories in other suitable habitat areas with low or sparse vegetation and burrowing mammal presence. Nonetheless, since the project occurs in a rural setting and subject to routine traffic along rural roads and agricultural activities and noise levels, burrowing owls have likely habituated to ambient noise levels but would be impacted by increased noise and vibration during project construction and operation. The length of time that habitat would be unavailable to owls for construction of the linear facilities is approximately six months and therefore any owls in the vicinity would be subject to temporary impacts of noise, light, and vibrations, all or a portion of which could occur during the burrowing owl nest season (February 1 to August 31).

Burrowing Owl Mitigation

There is much debate among state, federal, local, and private entities over the most practicable and successful relocation methods for burrowing owl and whether relocation should be considered at all. The California Fish and Game Code Section 1002 does not allow the capture and relocation of burrowing owls unless the effort is associated within the context of scientific research or a Natural Community Conservation Plan (NCCP) conservation strategy (CDFG 2012b). Burrow exclusion or closure (also known as passive relocation) is a technique using one-way doors in burrow openings during the non-breeding season to temporarily exclude owls from burrows and then collapsing the burrow once it has been determined that the owl has vacated the burrow by monitoring or scoping. One reason passive relocation has been criticized as a relocation method is because relocated or displaced owls are tenacious about returning to their familiar burrows and are inclined to move back to the impact site if the impact site is still visible to the owl and/or if the impact site is not completely graded (Bloom pers. comm.). Burrowing owls are put at increased risk when they are introduced to a new environment. No documentation is available to statistically evaluate the success of passive relocation in southern California. Reports elsewhere (Trulio 1995, 1997) do not provide long term analyses associated with passive relocation efforts to determine if passively relocated burrowing owls are present in the area after one or more years. The lack of documented success of passive translocations raises concerns regarding the fate of evicted owls. The demographic consequences of passive relocation and eviction of burrowing owls on an ecosystem level have not been studied and the long-term effects are poorly understood. Therefore, all possible impact avoidance and minimization measures should be implemented and exclusion and burrow collapse can only be recommended as a last option in order to avoid take of burrowing owls (CDFG 2012b).

The previous standard for providing burrowing owl mitigation of 6.5 acres per breeding owl pair is no longer recommended by CDFW because it does not adequately compensate for habitat loss since 6.5 acres was a minimum construction avoidance buffer area around a burrow that was thought to be required by owls (CDFG 2008). Presently, CDFW agency guidance recommends that projects impacting owls and owl habitat should mitigate all significant direct and cumulative impacts to nesting, foraging, wintering, and dispersal habitat during breeding and non-breeding seasons. Land acquisition as project mitigation should be based on the number of acres of all suitable habitat destroyed, with consideration of the number of owls present, duration of occupancy by owls and habitat use of the suitable habitat (CDFG 2008). Acquisition of the appropriate acreage of mitigation lands and determining under which circumstances passive relocation should be considered as a last option for take avoidance, should both take into consideration the foraging distance, average home range of breeding and non-breeding owls, various uses of burrows, and land uses of adjacent lands when determining suitability of those lands to support owls and fossorial mammals.

Construction of the project would result in direct loss of burrowing owl breeding, wintering, and dispersal habitat including all natural, allscale scrub habitat and all developed/disturbed acreage occurring along canals and between agricultural fields. Staff has conservatively estimated that the project would result in direct impacts to approximately 192 acres of burrowing owl habitat (**Biological Resources Table 5**). However, additional indirect and cumulative effects to burrowing owls and owl habitat loss may occur. Indirect effects could include impacts to normal breeding behaviors from project noise, light, vibrations, or alteration of vegetation communities, In addition, staff considers a portion of adjacent habitat lands that would be subject to indirect project effects to be habitat loss for burrowing owl as well. Short or sparsely vegetated areas along the KRFCC and West Side Canal of the proposed processed water pipeline are expected to support burrow or dispersal habitat between adjacent breeding or wintering habitat areas. Depending on the level of farming and crop rotation, crop fields that are left fallow for more than one season likely provide suitable burrowing owl habitat as well. Staff considers these effects to be significant which require mitigation.

The CDFW's current guidance on this species outlines a number of impact avoidance and minimization measures which staff has incorporated into Condition of Certification **BIO-11** (Burrowing Owl Impact Avoidance, and Minimization) including avoiding disturbance of occupied burrows during the nesting period of February 1 through August 31st, avoiding the direct destruction of burrows, implementing a worker environmental awareness program, making burrows to be avoided visible with flagging, eliminating small mammal control in the burrowing owl-occupied areas, among others (CDFG 2012b). Staff's proposed Condition of Certification **BIO-11** also requires the applicant to prepare and implement a Burrowing Owl Monitoring and Mitigation Plan that would incorporate CDFW's (CDFG 2012b) most recent mitigation and impact avoidance guidance for this species. In addition, staff's proposed Conditions of Certification **BIO-11** and **BIO-20** require the applicant to secure off-site mitigation lands that meet habitat criteria for burrowing owl as compensatory mitigation for this species. With the incorporation of the above conditions of certification, the project's impacts to burrowing owl would be reduced; however, until additional data is provided regarding the project's impacts and overall mitigation strategy, staff cannot determine if the project's impacts to burrowing owl would be reduced to below a level of significance.

Other MBTA Birds: Impacts and Mitigation

The Audubon Society has classified 145 Important Bird Areas (IBA) that provide millions of acres of essential habitat for breeding, wintering, and migrating birds including 12 IBAs in Kern County. The project area is located due east of the Buena Vista Lake Bed IBA (Jones et al 2008). The Buena Vista Lake Bed IBA in association with the mosaic of thousands of acres of managed wetlands, freshwater marsh, riparian thickets, grassland, and alkali sink habitats in the areas approximately one to six miles north, south, and east of the project area provide ample habitat opportunities for resident and migrating birds. Several bird species protected by the Migratory Bird Treaty Act (MBTA) and California Fish and Game Codes Section 3503 and 3513 are known to occur in the project area and were observed during various field surveys including many species of songbirds, raptors, and over-wintering shorebirds that utilize agricultural lands as migratory stopover sites. Specifically, the following species have been observed: American kestrel, Cooper's hawk, California horned lark, long-billed curlew, great egret (*Ardea abla*), northern harrier (*Circus cyaneus*), sharp-shinned hawk (*Accipiter striatus*), red-shouldered hawk (*Buteo lineatus*), merlin (*Falco sparverius*), California quail (*Callipepla californica*), Wilson's snipe (*Gallinago delicata*), greater yellowlegs (*Tringa melanoleuca*), lesser yellowlegs (*Tringa flavipes*), killdeer (*Charadrius vociferus*), mourning dove (*Zenaida macroura*), greater roadrunner (*Geococcyx californianus*), thrasher (*Toxostoma* spp.), great-horned owl (*Bubo virginianus*), loggerhead shrike, common raven, rock wren (*Salpinctes obsoletus*), cliff swallow (*Petrochelidon pyrrhonata*), northern rough-winged swallow (*Stelgidopteryx serripennis*), barn swallow (*Hirundo rustica*), Brewer's sparrow (*Spizella breweri*), phoebe (*Sayornis* spp.), white-crowned sparrow (*Zonotrichia leucophrys*), American pipit (*Anthus rubescens*), Bullock's oriole (*Icterus bullockii*), western meadowlark (*Sturnella neglecta*), red-winged blackbird (*Agelaius phoeniceus*), and several other species of warblers, sparrows, finches, and blackbirds (HECA 2012b). In addition, during protocol-level Swainson's hawk surveys, 19 active Swainson's hawk nests and 13 other raptor nests (great-horned owl, red-tailed hawk, and red-shouldered hawk) were found in the project area (URS 2012a, Figure A45-2) and therefore all of these species have been confirmed to nest and forage in the immediate project area. Golden eagles are not known to nest in the project area; however, golden eagles have been observed by local birders and Audubon groups as a transient during migration season (URS 2012c). The various songbird and shorebird species listed above could potentially be impacted from the project due to loss of habitat used for nesting, forage, wintering, and dispersal; loss of nest sites; disruption of breeding behaviors during the nesting season due to construction or operation noise and vibration; and direct mortality to individual birds.

The Central Valley is one of the most important regions in western North America for migratory and wintering bird species. Large expansive acreage of flooded farmlands, managed wetlands, agricultural fields especially rice, and agricultural evaporation ponds provide essential habitat for several species of migratory and wintering shorebirds and songbirds throughout the Sacramento and San Joaquin valleys. Agricultural lands naturally flood during winter months from runoff from primary river systems; many species of birds use the vast acreage of flooded farmlands as migratory stopover sites or wintering cover grounds. Species vary their seasonal, geographic, and habitat use of the Central Valley, primarily in response to changes in water availability from rainfall or management practices of agricultural lands and latitudinal variation in habitat availability mediates, in part, by climate (Shuford et al 1998). For example, in the record rainfall year between 1994 to1995, shorebird numbers increased 74 percent between November and January, primarily from coast-to-interior movements of the dunlin (*Calidris alpina*) and long-billed dowitcher (*Limnodromus scolopaceus)* and local habitat shifts of killdeer (*Charadrius vociferus*)(Shuford et al 1998). These species utilize habitats that occur in the project area such as saltbush scrub, agricultural croplands and farmed fields, stock ponds and flooded seasonal and perennial marshes including the Tule Elk State Reserve and Kern Water Bank as habitat for nesting, foraging, wintering, or as migratory stop-over sites during migration.

The project's potential for impacts to nesting birds is a significant impact under CEQA that requires mitigation. Staff has proposed Condition of Certification **BIO-10** (Mitigation for other MBTA-protected Birds) which requires that the applicant perform pre-construction surveys for birds protected by MBTA and California Fish and Game Codes, establish protective buffers around identified nests, and construction monitoring of nests within construction areas and within 200 foot survey buffer. This measure would apply if any construction activities would occur anytime during the nesting season (February 1 through August 31) during any construction year or start of construction in a previously undisturbed area in order to identify nests that may have begun during the interim. In addition, the applicant has proposed mitigation measures to avoid and minimize impacts to nesting birds, portions of which have been incorporated into staff's proposed Condition of Certification **BIO-6** (Impact Avoidance and Minimization Measures) which requires that construction activities that would result in noise levels greater than 60 decibels be conducted outside of the peak nesting bird season (February 15th to June 15th of any given year).

The loss of bird nests, eggs, or young is regulated by the MBTA and California Fish and Game Code Section 3503 and 3503.5 all of which protect active nests and its contents. In addition and as explained previously, the project's potential for loss of nest tree sites or a decline in nest tree health to the point of reducing successful nesting attempts by nesting birds due to groundwater pumping may constitutue take under MBTA and California Fish and Game Code Section 3503 and 3503.5, and further analysis is required. With the incorporation of the above conditions of certification, the project's impacts to other bird species protected under MBTA and Fish and Game Code Section 3503 and 3503.5 would be reduced; however, until additional data is provided regarding the water supply source and effects of groundwater pumping to nest trees, staff cannot determine if the project complies with these LORS.

Special-status Plant Species

As described previously, seven special-status plant species are known to occur on EHOF as a result of long-term monitoring of the Elk Hills Conservation Area:

- cottony buckwheat (CNPS List 4.2);
- Hoover's eriastrum (CNPS List 4.2);
- gypsum-loving larkspur (CNPS List 4.2);
- Lost Hills crownscale (CNPS List 1B.2);
- Tejon poppy (CNPS List 1B.1);
- oil nest straw (CNPS List 1B.1); and
- San Joaquin bluecurls (CNPS List 4.2).

The 2001 monitoring year marked the last year of comprehensive floristic surveys and consequently, Hoover's eriastrum is the only special-status plants species that is regularly surveyed and monitored at the EHOF. Annual monitoring of changes in Hoover's eriastrum density relative to other vegetative parameters has been conducted on six permanent reference plots distributed throughout Elk Hills since 1993 (Western Kern Environmental Consulting 2012). Two of these species, oil nest straw and

Hoover's eriastrum, have been found in the current carbon dioxide pipeline alignment. These plant species were observed during a single survey performed by OEHI on April 14, 2011 and the number of individual plants observed or a figure showing their location along the pipeline were not provided by the applicant. Additional surveys are needed and additional location data is needed for the observed populations of oil nest straw and Hoover's eriastrum plant as well as the occurrences of other plant species listed above in order to determine the impacts of the project on special-status plants. All species listed above have a high likelihood of occurring within the carbon dioxide pipeline alignment and to a lesser extent plant species identified in **Biological Resources Table 3**.

An occurrence of an additional CNPS List 3.2 plant species, vernal barley (*Hordeum intercedens*), was documented during wetland delineation surveys performed at the northern end of the natural gas pipeline route near Site 1; vernal barley was estimated to comprise approximately 40 percent of the absolute vegetative cover in the low-lying areas where it was observed and it is expected that similar low-lying areas may support this species (URS 2012a). Vernal barley is described as occurring in coastal dune scrub, vernal pools, and valley and foothill grasslands from approximately sea level to 3,000 feet elevation (CNPS 2013). The Consortium of California Herbarium lists 145 records of this species most of which occur in San Diego, Los Angeles, Riverside, Orange, and Ventura counties and one record from Kern County (south of SR 119 and east of I-5 in mixed annual grassland/chenopod scrub habitat during 1995, CCH 2010). As a CNPS List 3.2 plant species, this species is considered fairly endangered in California and staff considers this species locally rare since it is not commonly known from Kern County. Therefore, project impacts to this species would be significant.

No other special-status plant species have been observed within any other project linear alignment; however, sufficient focused botanical surveys have not been conducted due to lack of site access or insufficient rainfall years. Plant surveys were conducted on March 27 through 30th, 2012 in portions of the project area that are not currently farmed although these surveys were performed in conjunction with wetland delineation surveys and not following the standard plant survey protocol (CDFG 2009). Sites 1, 2, 3 and 5 located along the natural gas pipeline route were not surveyed due to property access restrictions and only portions of Site 4 and non-farmed areas along the railroad spur were surveyed in March 2012 (URS 2012a). This incidental observation of CNPS List 3.2 plant species, vernal barley, near Site 1 of the natural gas pipeline indicates that these sites and other linear facilities have the potential to support additional rare plant species and focused botanical surveys following protocol (CDFG 2009) are warranted.

Construction and Operation Impacts to Special-status Plants

Individual plants could be crushed or damaged by vehicle traffic, equipment or destroyed by grading, pipeline trenching, or other site preparation work. Seedbanks of these plants could also be destroyed or buried. Indirect effects include population fragmentation and disruption of gene flow; potential impacts to pollinators; increased risk of fire; herbicide drift; and disruption of photosynthesis and other metabolic processes from fugitive dust during construction and operation of the project. These special-status plant species could also be directly and indirectly affected by changes in hydrology due to re-contouring or redirecting of natural drainage flow or direct removal of irrigation channels or drainages. This is primarily a concern along the carbon dioxide pipeline route located south of the California Aqueduct where ephemeral drainages may occur. Since the applicant has not provided a Streambed Alteration Agreement application or provided information on the occurrence of drainages in the area of the proposed carbon dioxide pipeline alignment, staff cannot determine if these types of indirect effects to rare plants would occur. Additionally, wildfires (caused by construction or downed transmission lines) are rare but do occur and exotic species often frequent burned areas following a wildfire. Other impacts that occur from the project during construction and operation could occur to surrounding vegetation communities from grading activities creating air-borne, fugitive dust, sedimentation, and erosion, which can lead to compaction and decline of surrounding vegetation.

Hoover's Eriastrum

Hoover's eriastrum was federally listed as threatened in 1990 and has subsequently been removed from the Federal Endangered Species Act threatened species list as a result of many new occurrences between 1986 and 1997. Prior to 1986, this species was known from only 19 sites in four counties primarily from low-elevation, hillier intermixed annual grassland and saltbush scrub regions of the western San Joaquin Valley floor. Hoover's eriastrum has since been discovered in San Benito and Kings counties and in numerous additional locations of the four original counties. Presently, most of the occurrences are from four metapopulations including: 1) Kettleman Hills in Fresno and Kings counties; 2) Carrizo Plain-Temblor Range region of Santa Barbara and San Luis Obispo counties; 3) Lokern-Elk Hills-Coles Levee – Lost Hills region of western Kern County; and 4) Antelope Plain-Semitropic area in Kern County (USFWS 1998). Presently, Hoover's eriastrum is a CNPS List 4.2 plant species indicating it is of limited distribution and on a CNPS's Watch-list. This species continues to be threatened primarily by urban development and agricultural conversion. Hoover's eriastrum was observed during a single survey performed along the proposed carbon dioxide pipeline alignment on April 14, 2011 but a map showing the locations or population size estimate was not provided.

The Recovery Plan (USFWS 1998) indicates that since Hoover's eriastrum occurs on hillier slopes many of which are oil fields, that petroleum production does not pose a threat in most cases but could be detrimental if larger areas of occupied habitat were disturbed. Recovery strategies for this species includes protecting existing populations of a minimum size of 40 acres from incompatible uses assuming habitat conversion on the Kern Valley floor will continue, protecting unoccupied suitable habitat with buffers to allow for annual population fluctuations between years, and long-term monitoring, habitat management, and reporting.

Oil Nest Straw

Oil nest straw is a CNPS List 1B.1 species indicating it is seriously threatened in California with a high degree of threat (CNPS 2013). In addition, it is globally ranked as G2 indicating it is imperiled (6 to 20 element occurrences or 1,000 to 3,000 individuals in existence). In petroleum-producing areas, this species occurs on flatlands and hillier slopes generally from 200 to 1,000 feet elevation. Historically, there were five known populations of oil nest straw, four of which were in Kern County in the vicinity of

Bakersfield, McKittrick, and Taft (USFWS 1998). Oil neststraw is currently only known from Elk Hills and Coles Levee Preserve; the status of other oil-producing areas in western Kern County are unknown and undocumented. On Elk Hills, this species has been on 61 sections since floristic surveys began in 1995 (Quad Knopf 2001) and was found to be most prevalent in the northwestern and southeastern portions of the EHOF. The Elk Hill's oil neststraw population represents a single metapopulation (USFWS 1998). There are ten records of this species in the Consortium of California Herbaria, eight of which are from Kern County and two of which are records from the Naval Petroleum Reserve in Elk Hills (CCH 2010). Given this species' high degree of threat in California and known occurrences in the Elk Hills region, staff considers this species to be regionally rare and restricted in its geographic range, a portion of which occurs in the project area on the EHOF. Therefore, a substantial loss or impact to an oil nest straw population from construction and operation of the HECA project could be a significant impact to this species since its geographic range is restricted in California and threats to existence are high. The conservation strategy identified in the Recovery Plan (USFWS 1998) for this species includes protecting at least five distinct populations of the five extant occurrences presently known of this species. The metapopulation of oil neststraw at Elk Hills represents one of the required five populations for protection and to prevent extinction or extirpation of the species.

Staff needs additional botanical survey data for the carbon dioxide pipeline alignment in order to determine the level of impact of the project on this locally rare plant species that occurs on Elk Hills. Because the Elk Hills metapopulation is one of five known remaining populations, the plants identified during April 2012 surveys along the carbon dioxide route must be avoided during grading and construction of the pipeline route. Without further information of this occurrence and others along the pipeline route as well as special-status plant species occurrences along the natural gas pipeline route (Sites 1 through 5), staff cannot determine the project's impacts or compliance with LORS for this biological resource.

Special-status Plant Mitigation

The applicant has proposed several impact avoidance and minimization measures for special-status plant species (HECA 2012b). Staff believes that the successful implementation of the applicant's proposal to avoid impacts to special-status plants would depend on the applicant's incorporation of CDFW's rare plant survey protocols (CDFG 2009) and the applicant's ability to identify all locations for special-status plant species prior to project disturbance.

Staff's proposed Condition of Certification **BIO-17** requires the applicant to prepare a Revegetation Plan which would include a discussion of revegetation methods and goals taking into consideration a phased construction schedule of linear routes; performance standards and timeline for meeting success criteria; methods for salvaging the seed bank of annual species, storing topsoil, and preserving germplasm for use in revegetation areas; methods for controlling invasive weeds and weed management measures in revegetation areas; contingency parameters if success criteria are not met; and a long-term monitoring and reporting schedule during construction and operation. Establishing the goals in the Revegetation Plan is of utmost importance since shrub cover and percent ground cover can influence the presence of wildlife prey and predator abundance. Since dense shrub areas can attract kit fox predators such as coyotes, it is preferred that areas subject to revegetation be planted with low-growing herbaceous grassland species which is suitable habitat for kangaroo rat, ground squirrels, and other small mammals, a good prey base and essential habitat element for San Joaquin kit fox, burrowing owl, and other wildlife. A habitat reclamation study for endangered species performed at the EHOF evaluated revegetation success on disturbed sites for the purpose of reducing erosion and restoring carrying capacity of habitat for endangered species and their prey (Hinshaw et al 1999). In this study, revegetation was considered successful when a site's vegetative cover at the end of a growing season was greater than 70 percent of the average cover observed at reference sites and after five years, 47 percent of revegetation sites met this criterion. After the first two years of monitoring, annual grasses comprised most of the cover and after four years, shrubs comprised most of the plant cover. Lagomorphs and small rodent populations stabilized by the second year and use of the reclaimed sites by kit fox, coyotes, and bobcats slightly increase three to four years following treatment. Since reclaimed sites appeared to favor kit fox predators (such as coyotes and bobcats) once more shrubs became established and given the high costs of revegetation and monitoring of the study, the effectiveness of habitat reclamation for endangered species at EHOF was poor. In summary, if disturbed areas are going to be subject to revegetation for the HECA project, staff believes shrub density must be monitored and maintained at low enough levels as to not favor kit fox predators in revegteation areas.

The applicant has indicated temporary disturbance areas along Highway 58 associated with the natural gas pipeline including Site 1 and Sites 2 through 5 pending landowner approval would be subject to post-construction revegetation and monitoring activities (Biological Resources Figure 2, URS 2012c). Depending on the level of maintenance (vehicle traffic) required along linear facility maintenance roads and existing habitat disturbance levels, staff believes the following areas should also be considered for revegetation activities:

- Any entry and exit pits used for HDD that would not revert back to active farmland;
- Any portion of the buried pipelines (carbon dioxide, natural gas, processed water, potable water) that would not be used as a permanent maintenance road; and
- the carbon dioxide pipeline alignment since this facility would impact disturbed, natural allscale scrub lands.

In order to determine species-specific impacts of the project on special-status plants, additional focused botanical surveys, data, and mapped occurrences are needed along the carbon dioxide pipeline route and Sites 1 through 5 of the natural gas pipeline following CDFW's 2009 protocol (CDFG 2009) in order to identify the locations and number of plants that would be directly or indirectly impacted by the project. Staff's proposed Condition of Certification **BIO-17** (Special-status Plant Species Impact Avoidance Measures) requires the applicant to perform preconstruction focused botanical surveys prior to beginning work in suitable habitat areas that are previously undisturbed, identifying any populations in construction zones and on construction drawings as Environmentally Sensitive Area, and other site design modifications.

Implementation of staff's above listed conditions of certification would benefit all special-status plant species and sensitive vegetation communities by minimizing disturbance areas. Given the status of Hoover's eriastrum as a CNPS List 4.2 Watch-list, increasing but fluctuating trends on EHOF, and other known localities of this species on Coles Levee Preserve and Buttonwillow, staff believes the potential for impacts to Hoover's eriastrum would be reduced to less than significant levels with the incorporation of **BIO-4**, **BIO-5**, **BIO-6**, and **BIO-17**. Staff believes that with the incorporation of the above conditions of certification, impacts to most common and special-status plants would be reduced and minimized where possible; however, staff cannot determine if the project's impacts to oil neststraw, vernal barley, and potentially other special-status plants would be reduced to less than significant levels due to insufficient botanical baseline data on the occurrence of special-status plants in the project areas. Other special-status herbaceous annuals with a moderate to high likelihood to occur along project linear routes that could have been missed due to the lack of focused botanical surveys following agency protocol (CDFG 2009) include but are not limited to cottony buckwheat, Tejon poppy, and San Joaquin bluecurls.

PROJECT IMPACTS TO SENSITIVE VEGETATION COMMUNITIES

Staff believes that one CNDDB record for valley sink scrub occurs in the vicinity of the processed water pipeline and proposed well field. This record is described as roughly 325 acres in size and occurs northwest of Highway 58 near the KRFCC. The mapped area is characterized by *Atriplex spinifera*, *A. polycarpa*, *Suaeda moquini*i with non-native herbaceous grasses and forbs (CDFG 2012). In addition, small patchy sections of riparian habitat occur west of the proposed well field and processed water pipeline. Several Swainson's hawk, other hawk nests, and common raven nests that could be utilized by nesting raptors occur in these trees along the KRFCC and West Side Canal. If these patchy riparian and valley sink scrub habitats are supported by shallow groundwater or other sub-surface water flows through adjacent irrigation canals, continuous pumping for the project could cause a gradual decline of these nest trees and more analysis is required. Staff considers the potential long-term, indirect impacts to these vegetation communities a potentially significant CEQA impact due to a dramatic decrease in occurrence and range of these communities in the southern San Joaquin Valley.

Although water supply to the root system of nest trees and valley sink scrub in the project area are believed to be sourced by irrigation runoff in agricultural canals, more data and analysis is needed on the baseline groundwater levels and water use of these sensitive vegetation communities that occur in the project area. If water drawdown is consistent enough over the course of several years, staff believes the decrease in water supply to these vegetation communities could result in gradual decline, an alteration in biotic community structure or composition, or failure. In preparation of the FSA/FEIS, staff needs additional information on the baseline water supply and water use of sensitive vegetation communities in this area in order to determine the level of significance of project impacts to sensitive vegetation communities.

Impacts to Waters of the State and Waters of the United States

HECA conducted pre-survey investigations and field surveys, including a significant nexus determination for potential Waters of the United States. The estimated boundaries and areas of jurisdictional features within the project area were based on current regulations, written policies, and guidance from the Corps. The applicant delineated a total of 187.91 acres of water features in the project area, of which a total of 92.51 acres were delineated as waters of the U.S. including portions of the West Side Canal/Outlet Canal; Kern River Flood Control Channel; East Side Canal; California Aqueduct; several agricultural ditches, canals, and stock ponds that connect to these features; and depressional wetland areas (URS 2012a, URS 2013c). Since the Corps has not issued a Jurisdictional Determination for the project to date, the Corps' regulation of these delineated features under Clean Water Act Section 404 is unknown at this time. A 250-foot buffer from all project areas was used to define the potentially impacted areas. The KRFCC was identified as Waters of the U.S.- 54, of which approximately 87.88 acres could potentially be affected by the project. The estimated acreage reflects the portion of the KRFCC that is within the 250-foot buffer area of the project areas associated with the processed water pipeline and carbon dioxide pipeline. These features may also be subject to CDFW Fish and Game Code Section 1600 jurisdiction. The applicant has submitted a request for a Jurisdictional Determination to the Corps and a Section 1600 Notification of a Lake or Streambed Alteration Agreement application to CDFW (URS 2013c, 2013d); however, the extent of Corps and CDFW jurisdiction over the project is unknown at this time.

A depressional area that ponded water long enough to support western spadefoot toad tadpoles was identified between the Outlet Canal and California Aqueduct, which indicates depressional wetlands that support sufficient wetland hydrology occur in the project area. Sufficient wetland hydrology in a depressional area may also indicate that hydric soils and hydrophytic vegetation have become established over time in these depressional areas; however only the Corps can determine the occurrence of jurisdictional wetland or other Waters of the U.S. in the project area. Direct impacts that could occur to potential jurisdictional waters include inadvertent fill or grading during construction activities. Indirect impacts could occur during construction and operation of the project including contamination of nearby irrigation ditches, drainages, and other waterways from stormwater runoff, impacts to water quality from changes to hydrology or inadvertent release of drilling fluids during HDD activities, increased rates of erosion, and changes in vegetation community due to hydrological alterations, among others.

The applicant has proposed to avoid all potentially state and federally jurisdictional waters by using HDD underneath these features including the point where the carbon dioxide pipeline would cross under the California Aqueduct, Westside/Outlet Canal, and KRFCC (HECA 2012b). All entry and exit pits for HDD would be located outside of the identified potential waters of the U.S. HDD is a surface launched, guided, and steerable drilling system used for the trenchless installation of pipelines and avoids direct impacts to the water courses and other sensitive features such as highways, railroads, airport runways, and pipeline corridors by drilling underneath these features. The HDD process includes a drilling rig that would bore a horizontal hole under the water crossings. The depth of drilling and depth of cover varies depending on the physical and geotechnical parameter of the feature being drilled under; however, the minimum separation between the bottom of a canal channel and the top of the drilling pipe is 25 feet and the maximum depth for linear installations at proposed HDD crossings is 100 feet. Each entry pit for HDD would temporarily impact approximately 120 feet by 100 feet and HDD exit pits would be approximately 75 by 100 feet in size (URS 2012b). The applicant has indicated that depending on the canal specific hydrologic conditions at the time of the work, an assessment will consider whether HDD or conventional open cut methods would be used. When possible, crossings of canals would be performed when the canal is dry and not holding water (URS 2012b). CDFW has indicated that HDD activities under water conveyance features would require a California Fish and Game Code Section 1600 Streambed Alteration Agreement and preparation of a frac-out plan. During May 2013, the applicant submitted a draft HDD Plan (including a frac-out plan) for the proposed HDD activities in conjuction with the notification package to CDFW for a Lake or Streambed Alteration (URS 2013d). The applicant submitted a Jurisdictional Delineation report for the HECA project and a Nationwide Permit 33 Preconstruction Notification during March 2012 (URS 2013c) which staff has preliminarily reviewed and will completely review upon preparation of the FSA/FEIS. The applicant has requested authorization for the temporary fill of 0.20 acre of non-wetland Waters of the U.S.from the Corps under Nationwide Permit 33 (Temporary Construction Access, (HECA 2012b). For a complete discussion of the existing setting and project impacts to surface waters, see the **Soil & Surface Water** section of this PSA.

In order to minimize or avoid the potential for impacts to potentially jurisdictional waters during construction, staff has proposed Condition of Certification **BIO-19** which includes standard streambed impact avoidance measures that are typical of Lake or Streambed Alteration Agreements issued by CDFW and a requirement to update and finalize the draft HDD Plan that was previously submitted. The applicant has delineated potential state waters that occur within the project area (URS 2013d). Several braided ephemeral drainages are apparent upon review of aerial photography and the carbon dioxide pipeline route transverses these drainages. Staff believes these drainages may fall under California Fish and Game Code Section 1600 jurisdiction. OEHI has indicated they hold a 12-year site-wide streambed alteration maintenance agreement with CDFW as required by 1601 and 1603 of California Fish and Game Codes (OEHI 2013a); however, the applicant and OEHI have been unable to provide a copy of the maintenance agreement. Therefore, implementation of **BIO-19** would assist in minimizing impacts to state waters; however, staff needs additional information on the occurrence of potential waters of the state occurring along the proposed carbon dioxide pipeline route in order to determine the level of significance of project impacts to state waters. Implementation of **BIO-19** would minimize the impacts of the project to potential state waters as well as potential Waters of the U.S. However, until the Corps issues a Jurisdictional Determination for the project and CDFW determines the extent of 1600 jurisdiction over the project, staff cannot determine if project impacts to Waters of the U.S. and state waters would be reduced to less than significant levels.

Other Construction Impacts

Noise

Animals rely on hearing to avoid predators, obtain food, and communicate. Excessive construction noise could disrupt the behaviors of several special-status species by interfering with normal communication, potentially interfering with maintenance of contact between mated birds, obscuring warning and distress calls that signify predators and other threats, and affecting feeding behavior and protection of the young. Behavioral and physiological responses to noise and vibration have the potential to cause injury, energy loss (from movement away from noise source), a decrease in food intake, habitat avoidance and abandonment, and reproductive losses (Hunsaker 2001; National Park Service 1994). Alert distance refers to the distance between an animal and an activity when the animal becomes visibly alert. Flush initiation distance, also called flight distance, refers to the distance between the animal and an activity when the animal takes flight (Taylor and Knight 2003). The species-specific alert and flush initiation distances are unknown for the species most likely to be found nesting within the project area and likely vary considerably among species based on flock size, time of year, time of day, distance to refuge, and other unknown factors (Blumstein et. al 2002).

As discussed previously, a fenced tule elk herd occurs at the Tule Elk State Reserve located less than one mile east of the project site. The project would not result in any direct impacts to tule elk or habitat; however, potential indirect impacts could occur to this elk herd and all wildlife species during project construction, specifically unsilenced steam blows and pile driving, and operation; for elk, the potential for indirect noise impacts could occur more prominently during two sensitive time periods for tule elk, during the rut season (roughly June through November) and calving season (roughly March through July) which could result in a disruption of breeding behaviors (Pers. comm. California State Parks). The increased energy costs of movement, escape, and stress caused by frequent and unpredictable disturbance may be detrimental to elk calf growth (Kuck et al 1985). North American elk have also been known to become habituated to human activities and disturbance as evidenced in more urbanized area in the Rocky Mountains in parts of Montana. Avoidance and attraction are responses to negative stimuli or positive rewards. Habituation occurs when animals stop responding to repeated activities that are not accompanied by positive or negative reinforcement (Thompson and Henderson 1998). Likewise, if the human activity is predictable and harmless to elk and does not prove detrimental to their daily activities, elk can be readily domesticated and can habituate to human activity (Thompson and Henderson 1998).

Project construction activities would generally begin at 6:00 AM on a five- day week basis and would result in a short-term, temporary although relatively long-term (approximately 42 months) increase in the ambient noise level (HECA 2012b). Equipment used during the construction process will differ from phase to phase. In general, heavy equipment (bulldozers, dump trucks, and concrete mixers) will be used during excavation and concrete-pouring activities. Most other phases involve the delivery and erection of the equipment and building components. Studies have shown that noise levels over 60 A-weighted decibels (dBA) can affect the behavior of certain bird species (Dooling and Popper 2007).

For construction of the linear facilities, the loudest construction activities are associated with pile driving. Kangaroo rats are especially sensitive to loud construction noise and vibrations and OHV activity has been known to rupture the auditory bullae of kangaroo rats (pers comm., Julie Vance). Construction noise levels at 50 feet from the project site boundary to the nearest sensitive receptor are predicted to range from 60 dBA (pickup trucks) to 101 dBA (pile driving). Due to sound propagating, construction noise levels are expected to attenuate to a range of 40 to 81 at approximately 480 feet from the site boundary (HECA 2012b, Table 5.5-18, Individual Equipment Noise Levels Generated by Project Construction). Several sensitive receptors were evaluated for the noise analysis and staff is focusing on sites LT-2/ST-2 and ST-4, since these sites are located on the west and north side of the Tule Elk State Reserve, respectively. Baseline noise levels at LT-2/ST-2 and ST-4 are estimated to be 48 and 45 dBA, respectively. The highest site-average sound levels (89 to 91 dBA) are associated with foundation and site clearing phases of the construction (HECA 2012b). For the two sensitive receptor locations along the Tule Elk State Reserve listed above, construction of each linear facility was estimated to generate a range of 45 to 60 dBA of noise.

Construction of the transmission line would consist of installing footings, poles, insulators and hardware, and pulling conductors and shield wires. Construction of the transmission line may require pile driving although it is expected that any piles required for transmission line construction would be augured; however, if pile driving is needed to install power line poles, pile driving activity noise levels could range from 45 to 72 dBA along the transmission line route (HECA 2012b, Tables 5.5-22 through 5.5-25). Construction of the potable water/transmission line facility is the facility most likely to cause indirect impacts to tule elk and other wildlife since this facility would be located immediately north of the Tule Elk State Reserve. For a complete analysis of operational noise impacts, refer to the **Noise and Vibration** section of this PSA.

During the final construction phase, a method used to clean piping and testing called “steam blows” creates substantial noise. The intent of the steam blows is to heat and sweep the piping systems to remove any debris or fine particles that could damage the steam turbine generator or other equipment. Each steam blow is followed by a cool-down period. The heating and cooling cycles are expected to last 2 or 3 hours each, and will be performed several times daily over a period of 2 or 3 weeks. The applicant proposes to employ temporary silencing systems to minimize these short-term, temporary noise impacts during steam blows since typical steam blow silencing should be able to reduce noise levels by 20 dBA to 30 dBA at each receptor location (HECA 2012b); as a result, estimated silenced steam blow noise levels at LT-2/ST-2 would range from 62 to 72 dBA and would range from 58 to 68 dBA at ST-4 (HECA 2012b, Estimated Silenced Steam Blow Noise Levels). Staff concludes the potential for impacts to wildlife present at the Tule Elk State Reserve due to loud construction noise would be significant and mitigation is required. To minimize the impact of steam blows, pile driving, and other loud construction activities over 60 dBA, staff has incorporated into Condition of Certification **BIO-6** (Impact Avoidance and Minimization Measures) a requirement that if these activities are required, they must occur outside of the peak calving season (February 15th to June 15th) which also incorporates the peak nesting bird season.

Conducting focused wildlife surveys prior to the start of ground-disturbing activities per staff's proposed conditions of certification **BIO-7, BIO-8, BIO-9**, **BIO-10**, **BIO-11**, **BIO-12**, **BIO-13**, **BIO-14, BIO-15,** and **BIO-16** would ensure that no nesting birds, San Joaquin kit fox, American badger, blunt-nosed leopard lizard, listed small mammals, western spadefoot toad, giant garter snake or other special-status or common wildlife are present or in the immediate vicinity of the site during construction. Specifically, songbird nests will be identified within 200 feet of the project boundaries and a minimum construction avoidance buffer of 0.50 mile from active Swainson's hawk nests would be implemented per Conditions of Certification **BIO-9** and **BIO-10**. Staff believes that with the incorporation of these measures as well as **BIO-6**, the potential for indirect effects to the tule elk herd, nesting birds and other wildlife would be reduced to less than significant levels.

Noxious Weed Spread and Fugitive Dust

Construction activities and soil disturbance could introduce new noxious weeds to lands adjacent to the power plant site and linear facilities and could further spread exotic plant species already present in the vicinity. The spread of invasive plants is a major threat to biological resources because non-native plants can displace native plant communities, increase the threat of wildfire, and supplant wildlife foods that are important to herbivorous species. Bermuda grass (*Cynodon dactylon*), erodium, Mediterranean barley (*Hordeum marinum*), fescue (*Vulpia* spp.), Mediterranean grass, Russian thistle (*Salsola tragus*), red brome and many more exotic plant species are already present in the project area and are expected to increase as a result of construction- and operation-related disturbance. Following construction, exotic plant species are characteristically opportunistic and could occupy disturbed soils within areas that have recently been disturbed and spread into adjacent vegetation communities, primarily along linear transmission line and pipeline routes.

Disturbance of the soil's surface caused by construction equipment and other activities would result in increased wind erosion of the soil. Dust can have deleterious physiological effects on plants and may affect their productivity and nutritional qualities. The destruction of plants and soil crusts by dust exacerbates the erosion of the soil and accelerates the loss of nutrients (Okin et al. 2001). Soil erosion from construction activities and vehicle activity, which affects vegetation and soil properties, could have an adverse effect on many special-status plant and wildlife species that are known to occur in the project area.

Staff considers these impacts to be significant and require mitigation. Measures to implement during construction of the power plant site and linear facilities to control the spread of noxious weeds have also been incorporated into staff's proposed Condition of Certification **BIO-6** (Impact Avoidance and Minimization Measures) such as requiring that all construction vehicles and equipment be cleaned at truck wash facilities and inspected by a Biological Monitor before entering the project site or construction area, use of certified noxious weed-free straw or hay bales for erosion control, and use of manual, mechanical, and use of herbicides to control the spread of exotic weeds. Measures to control dust and soil erosion have also been incorporated into **BIO-6** such as applying non-toxic soil binders and establishing initial stabilized ground surfaces within 21 days following construction disturbance. It is important to note that any herbicide use for the project would need to conform to current USFWS policy at the time of use and would be determined during Section 7 consultation for the project; no use of any pesticide or herbicide would be permitted without prior consultation and approval from the USFWS. Moreover, staff has required that the project's WEAP (**BIO-4**) and BRMIMP (**BIO-5**) specifically include parameters to prevent the spread of noxious weeds during construction of the project. With the incorporation of these conditions of certification, the project's impacts to the spread of noxious weeds and fugitive dust and the effects on habitat alteration would be reduced to less than significant levels.

Other Operational Impacts

Potential operation-related impacts include impacts to birds due to collision with and/or electrocution by the transmission line and disturbance to wildlife due to increased noise and lighting.

Operational Noise

The project site would be located in a relatively open, non-habituated agricultural area. The western boundary of the Tule Elk State Reserve is approximately one mile east of the project site which staff considers a sensitive noise receptor. Excessive noise during operation of the project could disrupt breeding and calving behaviors of the tule elk herd. Also, loud operational noise could disrupt breeding and mating behaviors of nesting birds and other wildlife. The sum of the project's operational noise contribution and existing ambient noise at LT-2/ST-2 and ST-4 is expected to range from 30 to 37 dBA (HECA 2012b, Table 5.5-30 Summary of Project Contributions with Noise Control Features). These levels are below the typical studied threshold of 60dBA for indirect impacts to nesting birds and other wildlife. Therefore, staff concludes there will be no significant impacts to biological resources by increased operational noise and no additional biological resource mitigation is proposed. For a complete analysis of operational noise impacts, refer to the **Noise and Vibration** section of this PSA.

Avian Collision and Electrocution

The tallest structures and features associated with the construction of the power plant would include the following (measured as feet above grade): the gasification structure (305 feet), air separation column can (200 feet), AGR methanol wash column (235 feet), and the feedstock barn(160 feet) (HECA 2012b, Figure 2-6 Project Elevations). A proposed 2-mile electrical transmission line will interconnect the project site to a future PG&E switching station and the power generated by the project would be connected to the PG&E system by a new single-tower, 230-kV transmission line. This single-circuit line would connect to a new switchyard at the project site.

Birds are known to collide with transmission lines, exhaust stacks, and other structures, causing mortality to the birds. Bird collisions with power lines and structures generally occur when a power line or other structure transects a daily flight path used by a concentration of birds and these birds are traveling at reduced altitudes and encounter tall structures in their path (Brown 1993). Collision rates generally increase in low light conditions, during inclement weather, during strong winds, and during panic flushes when birds are startled by a disturbance or are fleeing danger. Collisions are more probable near wetlands, within valleys that are bisected by power lines, and within narrow passes where power lines run perpendicular to flight paths (APLIC 1996).

Raptors, and other large aerial perching birds, are susceptible to transmission line electrocution if they simultaneously contact two energized phase conductors or an energized conductor and grounded hardware. This happens most frequently when a bird attempts to perch on a transmission tower or pole with insufficient clearance between these energized elements. The majority of bird electrocutions are caused by lines that are energized at voltage levels between 1-kV and 60-kV, and “the likelihood of electrocutions occurring at voltages greater than 60-kV is low” because phase-to-phase and phase-to-ground clearances for lines greater than 60-kV are typically sufficient to prevent bird electrocution (APLIC 2006). The proposed HECA transmission line would be 230-kV; therefore, phase-to-phase and phase-to-ground clearances are expected to be sufficient to minimize bird electrocutions.

To avoid potential electrocution and collision from transmission lines, staff requires in Condition of Certification **BIO-6** (Impact Avoidance and Minimization Measures) that the transmission lines are constructed in accordance with Avian Powerline Interaction Committee (APLIC) guidelines specifically designed to reduce the risk of bird electrocution. Specifically, the phase conductors shall be separated by a minimum of 60 inches and bird perch diverters and/or specifically designed avian protection materials should be used to cover electrical equipment where adequate separation is not feasible (APLIC 2006). With implementation of this condition of certification, the potential for electrocution and collision impacts to birds would be reduced to less than significant levels.

Operation Lighting

Lighting plays a substantial role in collision risk because lights can attract nocturnal migrant songbirds and major bird kill events have been reported at lighted communications towers (Manville 2001) with most kills from towers higher than 300 to 500 feet (Kerlinger 2004). Many of the avian fatalities at communications towers and other tall structures have been associated with steady-burning, red incandescent L-810 lights used at communications towers that seem to attract birds (Gehring et al. 2009). Longcore et al. (2008) concluded that use of strobe or flashing lights on towers resulted in less bird aggregation, and, by extension, lower bird mortality, than use of steady-burning lights. Night lighting can also alter foraging and breeding behaviors of nocturnal mammals, reptiles, amphibians, and other wildlife. Existing night lighting in the area is scattered and generally limited to the few residences that occur in the project area. The few major sources of night lighting in the region include oil extraction operations in the Elk Hills and an existing fertilizer facility. Overall, the region is primarily dark with numerous light sources that while visible, do not tend to light the night sky significantly (HECA 2012b).

Lighting that is not required continuously during nighttime hours will be controlled with sensors or switches such that lighting will be on only when needed. In addition, structures and transmission towers will be treated to reduce sun reflectivity and reduce potential glint/glare and high-pressure sodium vapor fixtures will be used which produce low-intensity amber light during nighttime hours (HECA 2012b). The project's lighting system would provide power plant personnel with illumination in both normal and emergency conditions; the system would primarily consist of alternating current (AC) lighting and direct current (DC) lighting for activities or emergency egress required during an outage of the project's electrical system. The project's lighting would be designed to directionally orient, shield, and hood lighting to minimize off-site migration of light (HECA 2012b). While the project may slightly add to existing lighting, the project will not significantly contribute to ambient night lighting in the project area due to the design features discussed above. With the incorporation of these design measures into the project's lighting plan and implementation of staff's Condition of Certification **BIO-6** to minimize lighting impacts which would be monitored and reported on during construction, staff concludes there will be no significant impacts to wildlife from the night lighting associated with operation of the new facility.

Retention Ponds

To allow for stormwater drainage and reclaimed water testing, nine retention ponds are proposed within the project site; the ponds range in size from 0.26 acre to 3.07 acres and four would be lined (URS 2012b). The length of time the ponds would hold water varies, but for a 10-year stormwater flow scenario, basin water drawdown ranges from 1.8 to 28.7 days; however, the Kern County Engineering, Surveying, and Permit Services department has retention basin design standards which require that retention basins fully drain within 7 days (Kern County Development Standards, Division 4 Standards for Drainage, Chapter 8); therefore, the applicant would need to consult with Kern County on retention basin design if the basin would hold water beyond the 7 day requirement. For a complete discussion on retention pond design and county design requirements, see the **Soil & Surface Water** section of this PSA/DEIS.

Stormwater that is separated to collect for testing for contaminants and potential re-use, poses a threat to wildlife in the project area, particularly migrating or wintering waterfowl. A report for the San Joaquin Valley Drainage Implementation Program indicates that a variety of waterfowl and shorebirds can seasonally inhabit or utilize ponds for resting, foraging during migration, and nesting resulting in indirect impacts from high selenium or hyper-saline conditions and high total-dissolved-solids concentrations (EPTC 1999). Potential impacts to wildlife exposed to high concentrations of selenium from operation of evaporation ponds bioaccumulation of selenium by waterbirds from ingestion of a variety of organisms used as food resources such as macroinvertebrates, egg shells, and tissue; increased mortality; reduced reproductive success growth or condition, and exposure to elevated concentrations of water quality constituents including, but not limited to salts. Wildlife species inhabiting areas adjacent to the evaporation basins are susceptible to potential indirect adverse effects since several large mammals, raptors, and other predators may forage on wildlife that utilizes ponds providing a trophic pathway for exposure of these wildlife species to evaporation basin constituents (EPTC 1999). This report goes on to say that management of evaporation basins were regulated by waste discharge requirements in the past, until studies by USFWS revealed adverse impacts to wildlife occurring at evaporation basins in the Tulare Lake Basin which prompted CDFW to develop measures to reduce the impacts to wildlife consisting of the following measures:

minimum water depth of 2 feet, levee slopes as steep as practicable, vegetation control, no construction of exposed windbreaks, disease surveillance and control program, invertebrate sampling, and hazing (EPTC 1999).

Staff believes that allowing stormwater to pond in retention basins for extended periods longer than 24 hours, especially for the larger retention ponds could act as an attractant to waterfowl or shorebirds, given the high amounts of over-wintering and migrating birds that occur in the project area primarily during winter months. In order to minimize birds and other wildlife from entering the ponds and exposure to hypersaline waters and other contaminants, staff has incorporated into Condition of Certification **BIO-10** (Mitigation for other MBTA-protected Birds) a requirement for the applicant to apply netting over the retention ponds, monitor, and report monthly on the effectiveness of the exclusion netting.

Nitrogen Deposition

Atmospheric nitrogen (N) alters the structure and function of terrestrial ecosystems because nitrogen is often the limiting nutrient in many soils and ecosystems throughout California. Nitrogen oxides (NOx) and ammonia (NH_3) can be deposited directly to the ground or undergo chemical and phase transformation in the atmosphere and be deposited from tens to thousands of kilometers from the source (CEC 2007). Nitrogen-poor soils and nitrogen-sensitive plant communities are often more susceptible to detrimental effects of nitrogen saturation including decreased plant function due to leached nutrients from the soil or a decrease in symbiotic mycorrhizal fungi (CEC 2007). Mechanisms by which nitrogen deposition can lead to impacts on sensitive species include direct toxicity, changes in species composition among native plants, and enhancement of invasive species (Fenn et al. 2003; Weiss 2006a).

The major documented impact of N-deposition on California terrestrial biodiversity is to increase growth and dominance of invasive annual grasses in low biomass ecosystems primarily coastal sage scrub, serpentine grassland, and desert scrub and to a lesser extent vernal pools and sand dune ecosystems (CEC 2007).

In a research study on the *Impacts of Nitrogen Deposition on California Ecosystems and Biodiversity* (2007) prepared for the Energy Commission, several California natural communities were mapped and modeled using Forest Research and Protection (FRAP) to assess nitrogen deposition. The east side of the San Joaquin Valley and lower Sierra Nevada foothills receive from 5 to 9 kg of N per hectare per year; the west side of the San Joaquin Valley and adjacent slopes of the Inner Coast Ranges experience 3 to 4 kg of N per hectare per year (CEC 2007).

Staff uses a 6-mile radius to evaluate the direct nitrogen plume impacts of power plants. It is staff’s experience that by the time the plume has traveled this distance, in-plume concentrations become indistinguishable from background concentrations. Staff considers the sensitive biological resources that could be impacted by the nitrogen deposition plume within 6 miles of the project site the following: Tule Elk State Reserve and portions of the Kern Water Bank, Coles Levee Ecoystem Preserve, EHOF, and the Lokern Ecological Reserve (Biological Resources Figure 1). These natural areas are considered sensitive as described under the ‘Regional Setting’ subsection of this

PSA/DEIS. Staff believes that given the sources of NOx emissions from the proposed project, the project's nitrogen deposition plume could affect these areas and potentially others along linear facilities. Nitrogen deposition modeling has not been performed to date, although modeling will be performed in preparation of the FSA/FEIS. Therefore, the potential for the project to affect sensitive biological resources from nitrogen deposition are unknown at this time.

OEHI Component of HECA

The following section provides an analysis of the environmental effects of the OEHI component of HECA to biological resources in accordance with the California Environmental Quality Act. Where significant impacts have been identified, staff has provided recommended mitigation measures to the applicable permitting authorities in order to reduce an impact to biological resources to less than significant levels.

This environmental analysis has been prepared assuming the OEHI component would consist of the following:

- Construction of 720 proposed wells (309 injection wells and 411 production wells). OEHI has designed the project to utilize existing wells to the maximum extent feasible and it is estimated that 570 of the 720 wells necessary for the CO_2 EOR project would utilize pre-existing well locations. The remaining 150 wells would be new installations;
- Construction of a new CO_2 EOR processing facility which includes a central tank battery, water treatment plant, reinjection compression facility, and carbon dioxide recovery plant (approximately 60.61 acres of impact)(URS 2013b);
- Installation of an estimated total length of 652 miles of new pipelines, much of which would be located in existing pipeline corridors that are sited on disturbed acreage. Pipeline routes would range in right-of-way size from 40 to 59 feet wide; and
- Construction of an estimated 13 new CO_2 EOR satellite gathering stations estimated to range in size from 1.1 acres to 2.6 acres each (URS 2013b). Nine of the 13 satellite gathering stations are proposed for the southeastern portion of the EHOF in disturbed, high oil production areas (referred to hereafter as the nine proposed southeastern satellites). The four remaining satellites are proposed for lands on the northwestern flank of the EHOF (referred hereafter as the four proposed northwestern satellites) in areas of lower oil production in areas immediately adjacent to various mitigation parcels of the Elk Hills Conservation Area.

Results of Biological Field Surveys

OEHI has performed various wildlife and botanical surveys along the proposed carbon dioxide pipeline route, proposed EOR processing facility, and first three satellite locations. OEHI performed protocol-level blunt-nosed leopard lizard (BNLL) hatchling surveys between August 24, 2012 and September 14, 2012 along the proposed carbon dioxide pipeline route and proposed EOR processing facility within the southeastern section of Section 27 South and no BNLL were observed during these surveys.

However, 2 burrowing owls, 5 potential owl burrows, 11 giant kangaroo rat precincts, and 6 San Joaquin antelope squirrels were observed within the survey area during those surveys. Also, several hundred observations of side-blotched lizard (*Uta stansburiana*) were identified indicating the habitat is suitable for supporting reptiles such as BNLL. OEHI performed two additional reconnaissance-level biological surveys on December 4 and December 6, 2012 within the three test satellite locations that would be constructed during the demonstration period of the OEHI component during which loggerhead shrike was the only special-status species observed (OEHI 2013b).

Staff notes that the area surveyed during biological surveys did not cover the entire Phase 1 injection pattern for the three proposed satellite locations identified in OEHI's Class II Underground Injection Control (UIC) permit application provided to the Energy Commission, which identified a much broader area being impacted by injection wells and pipelines (OEHI 2012c). On the EHOF, these field surveys of the three satellite locations covered portions of Sections 35 South and 3G whereas the UIC Class II permit identified the Phase 1 injection area including the installation of injection wells, production pipelines, and injection pipelines covering the two above referenced sections as well as Sections 33 South, 34 South, 4G and 2G which were not surveyed. Consequently, staff does not consider these biological surveys complete or conclusive; however, the results do give an understanding of sensitive biological resources that occur in the Phase 1 injection areas.

Summary of 2011 Elk Hills Conservation Area Monitoring Survey Results

During 2011 monitoring of the Elk Hills Conservation Area by Western Kern Environmental Consulting (2012), San Joaquin kit fox were rarely identified along the Skyline Road during nighttime spotlight surveys and scent stations, a method used to attract animals to a scented area in order to look for footprints to indicate animal presence or absence in an area. Since Skyline Road bisects EHOF from east to west through high oil production areas, this may indicate that San Joaquin kit fox utilize high oil production areas for night movements. However, kit fox visitation was most frequently identified along the north flank scent station lines during spring and fall survey periods. Kit fox were observed frequently along the northern but more frequently along the southern flank Buena Vista Valley route and no natal dens were identified on the entire EHOF during 2011 monitoring.

The northern flank survey route recorded the greatest number of kangaroo rat observations with 217 sightings during the spring survey period; the most burrowing owl incidental observations were along the northern flank as well. San Joaquin antelope squirrel was the listed mammal most frequently encountered in high oil production areas; however, kangaroo rat species were the most frequently captured small mammals during small mammal trapping and during 2011 trapping efforts, short-nosed kangaroo rat was the most frequently trapped mammal. During the fall, the northwestern flank route had the highest recorded kangaroo rat observations with 23 sightings. Giant kangaroo rat was the most frequently identified species during the 2011 field surveys near the proposed four northwestern satellites. The highest number of active giant kangaroo rat precincts was recorded along the northwestern portion of Elk Hills and adjacent lands in Sections 11Z, 12Z 13Z, and 14Z where a total of 1,328 precincts were identified, immediately west of the proposed four northwestern satellites.

Most of the BNLL observations were along the southern Buena Vista Valley survey route. No BNLL were identified along the north flank driving route in 2011, although five BNLL were observed along the north flank during walking surveys. Hoover's eriastrum is the only special-status plant species that is routinely monitored in Elk Hills Conservation Area. Annual monitoring results indicate that the mean density of Hoover's eriastrum increased on three of six monitoring sites since last year, including Section 7R which is located within the area of the proposed four northwestern satellites.

Construction Impacts to Habitat and Special-status Species

Staff primarily reviewed OEHI's existing USFWS Biological Opinion, California Endangered Species Act Memorandum and Take Authorization including two amendments (URS 2012d, OEHI permitting documents) and Appendix A of the HECA project's Amended AFC (HECA 2012b, Appendix A), among other sources in determining the effects of the proposed project's actions. The following discussion provides an overview of the direct and indirect impacts to biological resources that are expected to occur with the development of the proposed project.

Construction of new wells, conversion of existing wells, and trenching and installation of over 650 miles of new pipeline within existing pipeline corridors would result in direct impacts to special-status plant and wildlife species and staff considers these impacts significant. During construction activities, individual kit foxes, blunt-nosed leopard lizards, and kangaroo rats may be directly injured or killed by vehicle strikes from construction-related traffic, through inadvertent crushing or entombment in collapsed dens or burrows, or entrapment in construction area trenches. During project grading and trenching activities kangaroo rat burrow systems, namely giant kangaroo rat precincts, could be destroyed, vegetative food sources removed, and soil conditions could become more compacted making it difficult for small mammals to burrow. Because BNLL inhabit washes, this species is more vulnerable to accidental wastewater discharges and oil spills. Individual plants and plant populations could be crushed or damaged by vehicle traffic or destroyed by grading, pipeline trenching, or other disturbances. Seed banks of special-status plants may be buried or otherwise destroyed. Other impacts that may occur during construction or operations include wildfires or contact with oil spills or sumps. Operational impacts to these same species include dust and direct mortality from routine vehicle maintenance traffic among other activities. Additionally, individual wildlife may be subject to impacts from increased levels of human disturbance, including increased noise and vibration. Some wildlife may be able to escape direct mortality or injury but may be displaced to adjacent areas making these animals vulnerable to increased predation, exposure, and stress through loss of cover sites.

In general, construction of the nine southeastern satellites are proposed for disturbed, high oil production areas where staff considers the overall biological value of habitat lands to be low, simply due to higher levels of disturbance from oil production; however, this does not preclude the occurrence of special-status plants and wildlife in these locations and in fact, several special-status wildlife species are known to occupy these areas. The four northwestern satellites are proposed for lands generally in lower oil production areas along the northwestern flank of the Elk Hills and provide much higher biological values to special-status plants and wildlife given their adjacency to Elk Hills

Conservation Areas and lower level of disturbance from oil production on the northern flank of Elk Hills. Based on a large number of precincts identified in the location of the four proposed northwestern satellites during 2011 monitoring surveys, staff believes giant kangaroo rat would likely be impacted by ground disturbance from the development of satellites in this area. However, staff recognizes that small mammal populations naturally fluctuate from year to year based on rainfall levels and vegetation growth. Kangaroo rats are especially sensitive to loud construction noise and vibrations and off-highway vehicle noise activity has been known to rupture the auditory bullae of kangaroo rats. Staff believes grading and drilling for new well casings would significantly impact the large number of kangaroo rat precincts and other ground-dwelling species presently identified in this area.

The four northwestern satellites are proposed for an area where a Hoover’s eriastrum population is known to occur. Following 2011 monitoring surveys, the density of Hoover’s eriastrum was 21.17 plants per square foot, a substantial increase in this population since this population’s density was zero following 2007 monitoring surveys. The Recovery Plan *(*USFWS 1998) indicates that since Hoover’s eriastrum occurs on hillier slopes many of which are oil fields, that petroleum production does not pose a threat in most cases but could be detrimental if larger areas of occupied habitat were disturbed and identifies a recovery strategy for this species of protecting existing populations of a minimum size of 40 acres from incompatible land uses. However, staff believes it is likely unfeasible to avoid or preserve a 40-acre portion of natural lands that supports Hoover’s eriastrum, given the site plan provided for the proposed four northwestern satellites. Oil nestraw was observed during April 2011 field surveys along the proposed carbon dioxide pipeline route indicating other special-status plant populations likely occur along the north flank. The Elk Hill’s oil neststraw population represents a single metapopulation and the Recovery Plan (USFWS 1998) identifies the metapopulation of oil neststraw at Elk Hills as one of the five populations that requires protection in order to prevent extinction or extirpation of the species.

OEHI has indicated the project would result in a total of approximately 261.6 acres of permanent disturbance and 1,447 acres of temporary disturbance upon construction of the entire OEHI component including the installation of 150 new wells, construction of 13 satellite stations, and new pipeline routes. OEHI has also indicated 570 existing wells would be converted for project use, but has not described or included acreage disturbances for this work associated with the proposed project. Staff believes this construction could result in substantial additional disturbance to natural lands and loss of habitat values and these impacts have not been included in the disturbance acreages. Each satellite gathering station is estimated to have a permanent surface footprint of 230 by 200 feet (approximately 1.056 acre each) including a surrounding 500-foot survey buffer (OEHI 2013b).

OEHI has indicated that construction of the first three satellites would impact 63.79 acres of disturbed ruderal habitat on EHOF during DOE’s demonstration period (URS 2013b). These impacts include 60.61 acres of impact from the estimated 1,200 feet by 2,200-foot CO_2 EOR facility and 3.17 acres of impact for construction of the 3 satellite gathering stations. However, this acreage conflicts with a larger area that is identified as the Phase 1 demonstration period in OEHI’s Class II UIC permit application which shows a broader disturbance area being impacted for injection and production pipelines.

Therefore, it is unknown whether 3.17 acres of impact for each satellite gathering station includes impacts associated with the construction of approximately 25 injection patterns including 34 offsetting production wells as well as injection and production pipelines represented in OEHI's Class II UIC permit application (OEHI 2012c). In summary, staff believes the permanent disturbance acreage identified in **Biological Resources Table 9** below does not include impacts and ground disturbance associated with the conversion of 570 existing wells.

Biological Resources Table 9:
Project Impacts to Natural Ruderal Lands[6]

Project Component	Project Quantity	Acres Disturbed	Type of Disturbance
New Well Installations (130' x 280' = 0.84 acres/well)	150	126	Permanent
Conversion of existing wells	570	Not provided	Permanent
CO2 EOR Processing Facility	1	101.8[7]	Permanent
CO2 EOR Satellite Stations (2.6 acres each)	13	33.8	Permanent
4-Inch Diameter Buried Pipelines (40 foot wide right of way)	777,057 linear feet	714	Temporary
6-Inch Diameter Buried Pipelines (59 foot wide right of way)	63,903 linear feet	87	Temporary
12-Inch Diameter Buried Pipelines (4 foot wide ' right of way)	261,019 linear feet	282	Temporary
16-Inch Diameter Buried Pipelines (47 foot wide right of way)	19,122 linear feet	21	Temporary
18-Inch Diameter Buried Pipelines (59 foot wide right of way)	54,852 linear feet	74	Temporary
26-Inch Diameter Buried Pipelines (59 foot wide right of way)	199,656 linear feet	270	Temporary
Total Permanent Disturbance = 261.6 Acres			
Total Temporary Disturbance = 1,447 Acres			

[6] These acreages were developed from HECA Amended AFC, Volume 2, Appendix A-1 (HECA 2012b).

[7] The acreage of the CO2 EOR processing facility (101.8 acres) provided in HECA 2012b conflicts with the acreage of the CO2 EOR processing facility (60.61 acres) provided in URS 2013b, Section 7 Biological Assessment, Table 6.

San Jouaqin Kit Fox Presence on EHOF

The remaining San Joaquin kit fox population is fragmented and constitutes a metapopulation of three large core populations and less than ten small sub-populations. The largest extant population of San Joaquin kit fox occurs from Elk Hills and the Buena Vista Valley in western Kern County and the Carrizo Plain Natural Area in San Luis Obispo County (USFWS 1998), one of the three large core populations identified in the Recovery Plan. Therefore, movement within and around Elk Hills and connection with other sub-populations in western Kern County is essential to promoting gene flow and preventing local extirpations to the greatest extent possible. Both developed sites including the Naval Petroleum Reserves in California (NPRC including NPR-1 and NPR-2) and oil fields around McKittrick, and undeveloped sites, primarily the Lokern Natural Area, have been subject to several long-term San Joaquin kit fox population studies. In a San Joaquin kit fox population dynamics study of a 216-square mile study area on NPRC from 1980 to 1995, kit fox abundance varied widely and ranged from 46 foxes in 1991 to 363 in 1994. Kit fox population dynamics appeared to vary closely related to the availability of primary prey species, rabbits (leporids) and kangaroo rats (Cypher et al 2000). Variation in prey availability, particularly kangaroo rats, produced significant and often rapid changes in kit fox abundance. Kit fox density and population growth on NPRC was strongly related to precipitation patterns although precipitation did not directly affect kit fox, but it more directly affected primary productivity by reducing food and cover of prey populations, which is typical in arid ecosystems like the southern San Joaquin Valley. Similar results were documented at Camp Roberts and on the Carrizo Plain where kit fox population declines were attributed to declining prey availability during periods of below-average precipitation (Cypher et al 2000).

Predators, mostly coyotes but also some bobcats (*Lynx rufus*), were the most frequent cause of adult and juvenile kit fox mortality on NPRC. Cypher et al (2000) concluded that although populations of coyotes and kit foxes on NPRC appeared to be inversely related in the early 1980s, populations of both species closely tracked each other from 1985 to 1995 indicating that other factors (such as food availability) was influencing each population. Interestingly, the Cypher et al study (2000) concluded that coyotes seem to predate on San Joaquin kit fox on NPRC as exploitative competition and not predation for food which was consistent with findings of an Energy Commission study that indicated that coyotes rarely consumed the foxes they killed and coyote attacks of kit foxes were more likely the result of competitive exclusion. The 15-year study performed by Cypher et al (2000) also concluded that oilfield activities also had minimal effects on the San Joaquin kit fox population. Relatively few foxes died as a direct result of oilfield activities on NPRC; of the 712 recovered dead kit foxes, 43 died from oilfield-related causes, 35 of the 43 were hit by vehicles on NPRC roads and the others either drowned or were entombed in oil facilities during the 15-year study period. This same study concluded that individual foxes on NPRC used an average of 11.8 dens each year and over 1,000 dens were found on NPRC; therefore, the availability of denning habitat did not appear to be a limiting factor. Cypher et al (2000) also concluded kit foxes were often observed around oilfield equipment and activities and when dens were found, dens were often times in man-made structures (pipes, culverts) on NPRC. Space use and den use patterns of kit foxes did not appear to be affected by oil activities; nightly movements and home range parameters were similar in developed and undeveloped areas of NPRC (Cypher et al 2000). Spiegel et al (1991) studied developed sites (oil fields) and undeveloped sites (Lokern Natural Area) in western Kern County denning, foraging, and concluded that home ranges ranged from 1.36 to 6.66 square km (0.76 to 2.57 square mile) in undeveloped plots. Nightly movements on the Elk Hills Naval Petroleum Reserve averaged 9.6 miles during the breeding season, which are much longer than the average nightly movement of 6.3 miles during the pup-rearing season and the pup-dispersal season, 6.5 miles (USFWS 1998). In general, kit foxes are able to adapt to oilfield activities, are able to persist in areas of development, and appear to be tolerant of human activity. This same study concluded that the most significant direct effect of oilfield activities to the San Joaquin kit fox population on EHOF is habitat loss due to facility construction, which reduces carrying capacity.

Impacts to San Joaquin Kit Fox

Staff believes that with the implementation of the OEHI component of HECA, the direct and indirect effects to San Joaquin kit fox along with the loss of an estimated 261 acres and 1,447 acres of permanent and temporary impacts to San Joaquin kit fox habitat, respectively, would significantly impact this species and mitigation is required. OEHI estimates that each year the OEHI component would create 36 wells, consisting of either new well installations or conversion of existing wells, for approximately 20 years (HECA 2012b, Appendix A). Staff believes this would result in a substantial long-term construction impact over the course of 20 years. As the project is phased and the location of satellites is determined for project UIC permitting, certain habitat areas would be unavailable for use by kit fox and all wildlife during construction depending on the locations of any new well and pipeline installations and well conversions. Phasing of the project over a 20-year construction window could substantially hinder the movement of the local Elk Hills kit fox population as well as regional movement between other sub-populations. This impact would be especially significant during the breeding and dispersal seasons and may affect nighttime foraging distances and dispersal patterns of adults and young of the year. As outlined above, studies indicate that the primary predictor of kit fox population trends is the abundance of prey (kangaroo rats and rabbits primarily) which in turn is driven by precipitation and therefore prey species abundance can vary considerably from year to year. Therefore, the OEHI components's effects to the Elk Hills small mammal populations would directly influence the San Joaquin kit fox population dynamic over the course of 20 years of construction.

The Cypher et al (2000) study concludes that long-term monitoring is essential to follow kit fox population variability and land management strategies should focus on land management activities that would conserve viable populations during unfavorable environmental conditions. The current biological permits require the long-term population monitoring of the Elk Hills Conservation Area as well as setting aside additional conservation lands prior to the impacts occurring. Staff has recommended mitigation measures to minimize the potential for significant impacts to special-status species as outlined in the “Recommended Mitigation Measures” section.

Operational Impacts

Greenhouse Gas Emissions and Potential for Carbon Dioxide Leaks

The following section discusses the potential for carbon dioxide leakage during operation of the OEHI component and effects of greenhouse gas emissions on soil and vegetation. Carbon capture and storage technology includes two basic approaches: 1) carbon dioxide gas is captured directly from large and stationary source points, and then transported through pipelines (such as the HECA power plant) and injected into geologic storage sites far below the ground surface known as carbon capture and storage (CCS), and 2) atmospheric carbon gas is biologically fixed by growing vegetation (e.g. forest trees, biomass crops, etc) and stored in aboveground and belowground plant parts, referred to as carbon sequestration (CS) (Patil 2012) and the CCS and CS processes complement each other. CCS technology is being increasingly considered as a mechanism that can contribute to reducing the carbon dioxide emissions over the next 50 years. Carbon dioxide is an odor less and non-toxic gas; however, exposure to high concentrations poses danger to human beings, animals, and the surrounding environment. Since typically in CCS systems the carbon dioxide is captured from large production sites and transported through pipelines over long distances, the first point of leakage would be pipeline failure, small leaks from joints or pipeline corrosion; therefore, pipelines require continuous surveillance and monitoring. The potential for leakage from geologic storage sites may occur from failure of the sealing cap of the injection well or migration of gas through geologic media. If there were slow yet large leaks, there are chances that a continuous release from CCS sites could go unnoticed since leaking carbon dioxide gas would quickly diffuse in the atmosphere. When it comes to the long-term safety of CCS technology, there are uncertainties on the long-term fate and safety of large volume of carbon dioxide gas to be injected into geologic formations (Patil 2012); however, with OEHI's sophisticated monitoring system in place as described below, the likelihood of a carbon dioxide leak occurring and going un-noticed is low.

OEHI has indicated the likelihood of carbon dioxide leakage from sequestering activities is low for a number of reasons. On July 23, 2010, OEHI submitted a Monitoring, Reporting, and Verifying Plan (MRV Plan, OEHI 2010) which provides details on how the wells and an existing sophisticated system of monitoring equipment would be centrally monitored and controlled. This monitoring system would include monitoring for CO_2 leakage and would offer an added level of monitoring to ensure early detection and control of potential leaks. The MRV Plan included several components for monitoring leakage of injected carbon dioxide such as risk assessment of leakage and determining sequestration volumes. Staff concludes that it is feasible to inject the projected amount of carbon dioxide over 20 years into the Stevens reservoir and the potential for carbon dioxide leakage from the OEHI component is low. Given the geologic lifetime of natural carbon dioxide domes, and many long-lasting carbon dioxide injection projects, it is likely that the carbon dioxide would be stored permanently in the EHOF. OEHI would intensively monitor injection and production wells for any sub-surface and surface carbon dioxide leakage in several ways. Staff further concludes that the injection pressures required for this project are below pressures required to fracture the formation and would not induce significant seismic events. For a complete analysis of the impacts of the proposed project, see the **Carbon Sequestration And Greenhouse Gas Emissions** section of this PSA/DEIS.

Although there is minimal potential for leakage of carbon dioxide along well casings, the OEHI component would still emit significant levels of carbon dioxide during various construction and operation activities. The OEHI component's greenhouse gas (GHG) emissions include the direct onsite emissions from EOR Processing Facility processes and the indirect onsite emissions from power consumption, as well as emissions from onsite ancillary and auxiliary equipment and from material and personnel transportation. The onsite emissions sources include the following sources:

- EOR Project Power Consumption (indirect)
- CO_2 Injection Heater
- Regeneration Gas Heater
- Triethlylene Glycol (TEG) Reboiler
- Amine Unit
- Central Tank Battery (CTB)
- Reinjection Compression Facility (RCF)
- Fire Pump Engines
- Piping Fugitives

As described in the **Carbon Sequestration And Greenhouse Gas Emissions** section of this PSA/DEIS, the offsite emission sources include material and worker transportation. Over 75 percent of the onsite GHG emission total is indirectly emitted that accounts for the OEHI component's power consumption. The OEHI component requires moving of the injection and production wells periodically, corresponding new or repurposed pipeline work, and new well drilling. Therefore, construction of this project is ongoing for the twenty-year life of the project. The annual average emissions of the OEHI component over the course of 20 years of construction is 4,330 metric tonne of carbon dioxide with over 99 percent of this coming from on-road and off-road combustion sources during construction. Operation of the proposed OEHI component would cause GHG emissions from a number of onsite and offsite sources including the EOR Project Power Consumption, CO_2 Injection Heater, Regeneration Gas Heater, Triethlylene Glycol (TEG) Reboiler, Amine Unit, Central Tank Battery (CTB) Flare, Reinjection Compression Facility (RCF) Flare, Fire Pump Engines, Piping Fugitives, and materials and employee vehicle trips. The annual average emissions of the OEHI component during operation is 339,976 metric tonne of carbon dioxide.

Effects of GHG Emissions on Soils and Vegetation

Atmospheric carbon is naturally exchanged between reservoirs and sinks (known as the carbon cycle) of which the terrestrial environment, generally vegetation and soils, are known to store, absorb, or sequester and eventually exchange carbon. A recent study in the Mojave Desert found that desert soil ecosystems represent a carbon sink possibly as a result of biotic crusts, vegetation, alkaline soils, or an increase in average precipitation (Campbell et al 2009). Existing vegetation, including above ground biomass and below ground plant roots that would be cleared for the installation of solar power plants and IGCC plants, including those like the HECA project would destroy biotic crusts (photosynthetic cyanobacteria, algae, lichens, and mosses), remove alkaline soils, and release any stored carbon that was in the soil (Campbell et al 2009).

Studies have shown that high carbon dioxide levels have changed the botanical composition of the world's grasslands, farms, and urban landscapes by increasing the growth, reproduction, and survival of some plant species more than others. One study reported that high carbon dioxide levels are favoring cool-season grasses over warm-season grasses and weedy shrub over native forage grasses, which are less suitable forage types for livestock grazing (USDA Agricultural Research Service 2009). This same report also concluded that high levels of carbon dioxide increase the water-use efficiency of plants and primarily benefit the development of weedy shrubs and cool-season grasses by partially closing the leaves' stomates and conserving water. Another study concluded similar results indicating that while carbon dioxide levels are the high, plant stomates shrink which cause less water release and lower evapotransporation rates, a direct warming trend and link to global warming (Carnegie Institution 2010). Two key causes of invasions of fast-growing weedy plants were found to occur, an escape from natural enemies and an increase in plant resources, which favor non-native species that have adapted to environments rich in nitrogen, water, and carbon dioxide; when these non-native plants from Europe end up in the United States, a resource-rich environment without natural enemies, they easily outcompete fast-growing native plants. In conclusion, fast-growing weeds are the type of plant most favored by global change (USDA Agricultural Research Service 2009).

An increase in soil carbon dioxide concentrations in near surface and below- ground canopies could have significant effects on the above-ground vegetation, soil-inhabiting micro-organism and organic matter by suppressing root respiration, altering plant water/nutrient uptake capacity and soil pH, and ultimately effecting the above-ground biomass and photosynthetic capacity of vegetation. A study at the Artificial Soil Gassing and Response Detection (ASGRD), an experimental field facility, was implemented where carbon dioxide was artificially injected into soil plots to simulate build up gas concentrations and its slow release to the soil surface into experimental, individual plots of pasture grass, commercial turf, and fallow lands and an equal number of control plots of each crop type (Patil 2012). The study concluded that even low levels of carbon dioxide gas injection (one to three liters) significantly increased the soil carbon dioxide concentrations in a very short period of time by displacing soil oxygen levels and adversely affected the growth of pasture, turf grass, and establishment of winter bean crop. This study also showed that different plant species tolerated soil carbon dioxide concentration levels and grasses tended to be more tolerant compared with beans and other broad-leaved species. The study also indicated that some of the more sensitive plant species (non-grassy species) could be used to grow along the path of CCS pipelines and monitored for growth and effects as an early detection warning system of leaks. A limitation of this short-term study was overall low injection rate and shallow depths of injections in comparison to the long-term injection schemes of CCS technology. Therefore, while the ASGARD site studies increased the industry's knowledge and understanding of the effects of below ground carbon dioxide leaks on soils, long-term studies to evaluate the potential long-term consequences on ecosystems are needed (Patil 2012).

Soils are mainly affected by pollutant emissions through leaching of particulate contaminants and removal of gases by precipitation, followed by surface deposition. The adsorption rate of soils is dependent on the distance from the source, the concentration of the pollutant, soil properties, hydrological situations, and meteorological conditions (HECA 2012j). The soil types at the EHOF include the Cajon, Elk Hills, Kettleman, Kimberlina, Lokern, and Bitterwater soil series and Excelsior soil variant. Except for the Lokern series, all soil series including the Excelsior soil variant are considered deep, moderately well drained coarse, loamy soils that formed on alluvial fans and low stream terraces; the Lokern series is classified similar to the above soils but is a somewhat more poorly drained soil (USDA 1988). Staff believes these soils are expected to have lower sorption capacities for carbon dioxide and other greenhouse gases since these soils are classified as well drained with high runoff. Staff concludes that although the potential for direct leaks of carbon dioxide are low along the proposed carbon dioxide pipeline and well casings, the project’s contribution to high levels of carbon dioxide during operation could significantly affect soil and vegetation over time. Staff believes that given the existing high level of disturbance of natural habitats on the EHOF and dominance of non-native plant species, any immediate effects of the OEHI’s component greenhouse gas air emissions would be minimal although the incremental effects of implementation of the OEHI component on soil and vegetation resources could be significant.

Staff’s Recommended Mitigation Measures

Presently, there are no adopted Habitat Conservation Plans or Natural Community Conservation Plans on the EHOF; however, OEHI presently implements an Endangered Species Mitigation Program in accordance with 1995 USFWS Biological Opinion, CESA 2081 Incidental Take Permits and addendums. The EHOF has already been the subject of Federal Endangered Species Act Section 7 consultation and is currently being operated in compliance with a 1995 Biological Opinion issued by the USFWS and a related 1997 Memorandum of Understanding (MOU) for a California Endangered Species Incidental Take Permit (CESA ITP) between OEHI and CDFW which has been amended twice and remains in effect until the year 2014 (URS 2012d). The earlier Section 7 consultation was undertaken in connection with the Supplemental Environmental Impact Statement/Program Environmental Impact Report for the federal government’s sale of the Naval Petroleum Reserve (OEHI 2012d). A key component of this program is the performance of pre-activity surveys prior to any ground disturbing activity. Other impact avoidance and minimization measures include but are not limited to, the presence of biological monitors during ground disturbance, a litter control program, speed limits in construction areas, avoiding and destruction of burrows including minor relocation of project facilities, and continued long-term monitoring of the Elk Hills Conservation Area. Compliance with the 1995 USFWS Biological Opinion and the 1997 CDFW MOU has been documented in annual and semi-annual monitoring reports submitted to USFWS since 1998 (URS 2013b).

OEHI reinitiated consultations with USFWS and CDFW in 2002 to support a 50-year Section 10 Habitat Conservation Plan (HCP) for all production operations at the EHOF. However, staff is unclear whether the 50-year permit would cover all future OEHI oil and gas activities including the work associated with the OEHI component of HECA and the 13 proposed satellite injection patterns. OEHI anticipates the new HCP being approved by the end of 2013. OEHI anticipates that the Biological Opinion and MOU would be replaced by new Section 10 and Section 2081 permits supported by the HCP at some point in the future. The CDFW is presently the lead agency for the CEQA document being prepared for issuance of the Section 10 HCP.

Staff understands that DOGGR would be the permitting authority over future development phases of the OEHI component of HECA; therefore, project-specific CEQA analyses would be conducted as future phasing of the OEHI component are submitted to DOGGR for permitting. Staff recommends that DOGGR and other subsequent permitting authorities of future phased components of the OEHI component adopt the conservation strategies and conservation measures identified in either the existing biological permits (URS 2012d, OEHI biological permitting documents) or as amended in the subsequently adopted OEHI Section 10 HCP and subsequent CEQA analyses.

CUMULATIVE IMPACTS

A project may result in a significant adverse cumulative impact where its effects are cumulatively considerable. "Cumulatively considerable" means that the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects (Cal. Code Regs., tit. 14, § 15130). Cumulative impacts must be addressed if the incremental effect of a project, combined with the effects of other projects is “cumulatively considerable” (14 Cal. Code Regs, § 15130(a)). Such incremental effects are to be “viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects” (14 Cal. Code Regs., § 15164(b)(1)). This cumulative impact analysis makes a broad, regional evaluation of the impacts of past, currently proposed, and future projects that threaten plant and wildlife communities within the southern San Joaquin Valley.

The size of the San Joaquin Valley floor below 500 feet elevation covers approximately 3.44 million acres. The valley extends westward up into the foothills to approximately 3,000 feet elevation and supports natural and man-altered plant communities. Four urban areas (Stockton, Modesto, Fresno, and Bakersfield) and eight smaller urban centers (Lodi, Tracy, Manteca, Turlock, Merced, Madera, Hanford-Lemoore, and Visalia) occupy the San Joaquin Valley floor. Less than 150,000 acres or 5 percent of the valley floor remains uncultivated with most of the undeveloped lands in the foothill regions. Significant portions of land not cultivated or urbanized has been developed for petroleum extraction, strip-mined for clay, or occupied by roads, canals, oil storage facilities, pipelines, or evaporation ponds (USFWS 1998). The southern San Joaquin Valley has experienced substantial losses of habitat and reduction of species due to past urban, industrial, and agricultural development. The San Joaquin Valley floor’s original natural lands have mostly been tilled or developed, so that by 1979 only 6.7 percent of the original natural lands south of Stanislaus County remained (USFWS 1998). Of over 5.2 million acres in the southern San Joaquin Valley region that were studied by the Energy Commission (including the Carrizo Plain Natural Area and most of the Tulare Basin below the woodland belts), approximately 800 acres of degraded wetlands were found in 1989 with over 100,000 acres of seasonal wetlands occurring farther north near Modesto and Merced (USFWS 1998).

Several multispecies Habitat Conservation Plans (HCP) are in various stages of plan development including the Metropolitan Bakersfield HCP (MBHCP Steering Committee 1994), San Joaquin County HCP (SJMSCP 2000), and the draft Kern County Valley Floor HCP (Garcia and Associates 2006). The Energy Commission has conducted two large-scale natural community and species survey efforts, the Southern San Joaquin Valley Ecosystem Protection Program (largely surveyed lands in the Tulare Basin) and quarter-sections surveys that were later conducted on the Carrizo Plain Natural Area; both of these programs collectively provided more extant biotic community and habitat distribution information than all others combined (USFWS 1998). Other habitat conservation efforts in the southern San Joaquin County include the following, but are not limited to: Carrizo Plain Natural Heritage Program; the Bureau of Land Management's Lokern Area of Critical Environmental Concern, the Center for Natural Land Management's (CNLM) Lokern Ecological Preserve in the Lokern Natural Area, several Energy Commission mitigation programs; CDFW mitigation program in Allensworth Natural Area; the endangered species habitat protection programs on Occidental of Elk Hills; Kern and Pixley National Wildlife Refuge programs; and several mitigation banks including Aera Energy's Coles Levee Ecosystem Preserve, the Kern Water Bank, and Chevron Lokern HCPs, all of which are located in Kern County. The Lokern Ecological Preserve is part of the larger, Lokern Natual Area (LNA) which includes over 40,000 acres of high-quality habitat for various imperiled wildlife and plant species of the San Joaquin Valley and is located west of the HECA project.

For the purposes of determining the geographical scope of this biological cumulative impact analysis, staff considered the portion of the planning area of the Recovery Plan (USFWS 1998) that occurs in Kern County in determining the project's cumulative impacts to biological resources since the majority, if not all, special-status plant and wildlife species impacted by HECA are covered species in the Recovery Plan. Generally, the planning area addressed in the Recovery Plan includes the San Joaquin Valley, Carrizo and Elk Horn Plains, and parts of the Cuyama, Salinas, Sacramento, and other valleys. Furthermore, since HECA is proposed for the southern-most portion of the Recovery Plan area and the species potentially impacted are valley floor to lower foothill species, staff utilized the Kern County Planning and Community Development Department's list of discretionary projects in determining the scope of projects that would likely be approved and/or constructed in the foreseeable future. Staff focused on development projects proposed on the valley-floor to lower elevation plain areas roughly between the Tehachapi Mountains to the east and the Temblor Range to the west.

Kern County has identified the following 25 solar projects as approved or proposed on the Kern County valley floor which staff has assumed would directly affect the same biological resources as HECA upon development:

- Chevron Energy Solutions (18 acres, Conditional Use Permit);
- Meadows Field Solar (9 acres, Conditional Use Permit);

- Renewable Technology Development (2 acres, Conditional Use Permit);
- Lost Hills Solar Project by NextLight – an application for a General Plan Amendment, cancellation of a Williamson's Act contract, and Conditional Use Permit for a photovoltaic (PV) solar facility on 370 acres of land located near Lost Hills, Kern County, California;
- Maricopa Sun Solar Complex Project by Maricopa Sun LLC – an application for a General Plan Amendment, Conditional Use Permit, Tentative Parcel Map, and cancellation of a Williamson Act contract on 6,046 acres for PV solar facilities and 2,000 acres for future solar facilities near Taft, California;
- SKIC Development Inc (321 acres, Conditional Use Permit);
- Lerdo Detention Facility Expansion Project by Kern County General Services (14 acres, Conditional Use Permit);
- RE Distributed Solar (47 acres, Conditional Use Permit);
- Elk Hills Solar by enXco (47 acres, Conditional Use Permit);
- Goose Lake Solar by enXco (94 acres, Conditional Use Permit);
- Smyrna Solar by enXco (125 acres, Conditional Use Permit);
- Cynergy Power (29 acres, Conditional Use Permit);
- RE Old River One and Two Solar Projects (105 acres, Conditional Use Permit);
- Valley Solar Projects by EnXco – an application for a Conditional Use Permit to serve four PV solar facilities on a total of 309 acres near Taft, Elk Hills, Dustin Acres and Arvin, California;
- Pioneer Green Solar (3 sites, 480 acres, Conditional Use Permit);
- SunGen Solar by LaPaloma (398 acres, Conditional Use Permit);
- FRV Orion Solar (265 acres, Conditional Use Permit and Williamson Act cancellation);
- Wasco-Chara (72 acres, Conditional Use Permit);
- Kern Solar Ranch Project (6,100 acres, zone change and Conditional Use Permit);
- Chaparral Solar (172 acres, Conditional Use Permit);
- Browning Road Solar (28 acres, Conditional Use Permit);
- Twisselman Solar (103 acres, Conditional Use Permit);
- Axio Power (Conditional Use Permit);
- Beacon PV Project;
- Pond-Poso Solar (35 acres, Conditional Use Permit); and
- Ignite Solar (40 acres, Conditional Use Permit)

In addition, staff reviewed the Kern County Planning Department's website and there are 14 projects with Notice of Preparations that staff consider reasonably foreseeable projects being developed in Kern County; however the occurrence of these projects on the Kern Valley floor is unknown (Kern County Planning and Community Development Department 2010):

- Caliente Sand and Gravel by Caliente Sand and Mineral;
- Desert Solar Project by EnXco – an application for two conditional use permits to operate a solar PV power generation plant proposed near California City, Kern County on a 1,270-acre site;
- Fremont Valley Preservation Project by AquaHelio Resources, LLC;
- FRV Orion Solar Project;
- High Desert Solar by Element Power;
- Kingbird Solar Project;
- Lehigh Alternative Fuels Project by Lehigh Southwest Cement Company;
- Monte Vista Solar Array by First Solar Inc. – an application for a zone change and Conditional Use Permit for construction of a PV solar facility on 1,040 acres near the community of Mojave, California;
- Nautilus Solar Energy Photovoltaic Project – an application for a zone change and Conditional Use Permit for a PV solar facility on approximately 150 acres near Rosamond and Mojave, California;
- Pioneer Green Energy Solar Project;
- Rising Tree Wind Farm Project;
- Rosamond Solar Array by First Solar, Inc – an application for a Specific Plan Amendment, Conditional Use Permit, and concurrent zone change for a PV solar facility on 1,177 acres near Rosamond, California;
- Solari Sand and Gravel Project by Granite Construction;
- Willow Spring Solar Array by First Solar, Inc – an application for a Specific Plan Amendment, Conditional Use Permit, and concurrent zone change for a PV solar facility on 1,400 acres near Rosamond, California.

Lastly, Kern County has the following list of project's with CEQA environmental documents in preparation that staff is considering active, currently proposed projects in the Kern County area; however the occurrence of these projects on the Kern Valley floor is unknown:

- Alta East Wind Project;
- Alta Infill II Wind Energy Project EIR;
- Alta-Oak Creek Mojave Project EIR;

- Antelope Valley Solar EIR proposed by Renewable Resource Group - an application for a Specific Plan Amendment, cancellation of a Williamson's Act contract, concurrent zone change, and Conditional Use Permit for a PV solar facility on a 5,400-acre site located near Rosamond, Kern County California;
- Avalon Wind Energy Project;
- Beech Avenue Industrial Park Project;
- Catalina Renewable Energy;
- Clean Harbors Hazardous Waste Disposal Facility;
- Clearvista Wind;
- Frazier Park Estates Recirculated;
- Greater Tehachapi Area Specific Plan;
- Kern River Valley Specific Plan;
- Liberty Energy Center Biofuels Gasification;
- Lower West Wind Energy;
- Mojave-Rosamond Recycling and Sanitary Landfill;
- Morgan Hills Wind Energy;
- North Sky River Wind Energy Project and Jawbone Wind Energy;
- Pacific Wind Energy;
- PdV Wind Energy;
- Reina Ranch;
- Ridgecrest Recycling and Sanitary Landfill;
- Rosamond Solar Project by SGS Antelope Valley – an application for a Specific Plan Amendment, Conditional Use Permit, and concurrent zone change for a PV solar facility on 960 acres Rosamond, California;
- Rosedale & Renfro Precise Development Plan;
- Soledad Mountain;
- Taft Sanitary Landfill; and
- Tejon Mountain Village

Implementation of all of the above listed projects, which is not intended to be a comprehensive list of proposed development, along with HECA would undoubtedly contribute to a significant cumulative effect to plants, wildlife, and other sensitive resources primarily in terms of habitat loss and fragmentation. The analysis of the contribution of HECA alone to a cumulative impact is complex. If the 25 proposed solar projects on the Kern Valley floor listed above were permitted and constructed, an estimated loss of approximately 15,230 acres of land would occur. The HECA project alone would result in the loss of approximately 773 acres of lands in an agricultural setting, amounting to approximately 5 percent of the total loss due to solar projects, which does not include the proposed wind and other non-energy projects proposed on this part of the Kern Valley floor. Several of the linear facilities are proposed along and near existing agricultural canals and irrigation ditches that the San Joaquin kit fox, in particular, is known to use for dispersal and movement; therefore, construction of these facilities could disrupt wildlife movement. Additionally, almost all of the PV solar facility plants in the above list involve the cancellation of a Williamson's Act contract indicating presently farmed agricultural fields would be lost to development, an incrementally significant loss of foraging habitat for Swainson's hawk. Staff believes implementation of the above projects would exacerbate threats to survival of upland species covered under the Recovery Plan. In order to determine if the project's contribution to the combined cumulative effect would be cumulatively considerable, additional data is needed regarding the project's effects of vehicle mortality to wildlife, habitat loss, and a comprehensive mitigation strategy. With the incorporation of Conditions of Certification **BIO-1** through **BIO-20** impacts to upland species would be reduced and minimized where possible; however, staff cannot determine if the project's contribution to cumulative impacts to upland species of the southern San Joaquin Valley would be cumulatively considereable without the submittal of this data.

DOE'S FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the applicant for HECA. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

COMPLIANCE WITH LORS

The project must comply with state and federal laws, ordinances, regulations, and standards (LORS) that address the protection of state and federally listed species and other sensitive species and habitats. The project's compliance with applicable LORS is summarized in **Biological Resources Table 10**. The Energy Commission has a one-stop permitting process for all thermal power plants rated 50 MW or more under the Warren-Alquist Act (Pub. Resources Code § 25500). Under the Warren-Alquist Act, the Energy Commission's license is "in-lieu of" other state, local, and regional permits (*ibid*.). Accordingly, staff has coordinated joint environmental review with CDFW and consulted with USFWS regarding compliance with federal LORS. The project's compliance with state and federal LORS is discussed in further detail following **Biological Resources Table 10.**

Biological Resources Table 10
Summary of HECA Project Compliance with LORS

Applicable LORS	Rationale for Compliance or Non-compliance
FEDERAL	
Endangered Species Act (Title 16, United States Code, section 1531 et seq., and Title 50, Code of Federal Regulations, part 17.1 et seq.)	The project has not demonstrated compliance with ESA at this time. The Department of Energy has re-initiated Section 7 ESA consultation and a revised Section 7 Biological Assessment has been submitted to the USFWS (**Biological Resources Appendix A**). Incorporation of staff's proposed Conditions of Certification **BIO-1** through **BIO-20** which require measures to avoid or mitigate impacts to federally listed species would aid in ensuring compliance with ESA; however, additional information is needed on the project's overall listed species mitigation strategy. Staff has inserted **BIO-20** as a placeholder for federally-listed species habitat compensation.
Migratory Bird Treaty Act (Title 16, United States Code, sections 703 through 711)	The project's compliance with MBTA is unknown at this time. Staff's proposed Conditions of Certification **BIO-9**, **BIO-10**, and **BIO-11** require the applicant to perform pre-construction surveys and identify nests for Swainson's hawk, burrowing owl and all nests of bird species protected by MBTA; however additional data is needed regarding the source of water supply and effects of groundwater pumping on raptor nest trees which may constitute take under MBTA.
Clean Water Act (Title 33, United States Code, sections 1251 through 1376, and Code of Federal Regulations, part 30, section 330.5(a)(26))	It is unclear whether the project complies with CWA at this time since the Corps has not issued a Jurisdictional Determination for the project. Staff's proposed Condition of Certification **BIO-19** would minimize the project impacts to potentially jurisidcitonal waters of the U.S.
STATE	
California Endangered Species Act of 1984 (Fish and Game Code, sections 2050 through 2098)	The project'scompliance with CESA is unknown at this time. Additional data and coordination with CDFW is needed on the project's potential impact to Swainson's hawk nest trees, a state-listed species, in terms of groundwater drawdown and nest tree decline, which may constitute take under CESA. Also, blunt-nosed leopard lizard is a state-listed species and since incidental take of this species cannot legally be granted nor can avoidance of take be guaranteed for the life of the project, HECA may not comply with CESA. Incorporation of staff's proposed Conditions of Certification **BIO-1** through **BIO-20** which require measures to avoid or mitigate impacts to state listed species would aid in ensuring compliance with CESA; however, additional information is needed on the project's overall listed species mitigation strategy. Staff has inserted **BIO-20** as a placeholder for state-listed species habitat compensation.

Applicable LORS	Rationale for Compliance or Non-compliance
Fully Protected Species (Fish and Game Code, sections 3511, 4700, 5050, and 5515)	It is unclear whether the project would complywith Fish and Game Code Section 5050 relating to Fully Protected Reptile and Amphibian Species (blunt-nosed leopard lizard) at this time. Staff concludes that even with the implementation of **BIO-1** through **BIO-20** including proposed take avoidance and minimization measures in **BIO-8**, incidental take of blunt-nosed leopard lizard would like occur over the life of the project; therefore, it is unclear whether the project would comply with FGC Section 5050.
Nest or Eggs (Fish and Game Code section 3503); Birds of Prey (Fish and Game Code section 3503.5); Migratory Birds (Fish and Game Code section 3513)	The project's compliance with Fish and Game Code Section 3503, 3503.5, and 3513 is unkonwn at this time. Additional data and coordination with CDFW is needed on the project's potential impact to raptor nest trees in terms of groundwater drawdown and nest tree decline which may constitute take under Fish and Game Codes 3503, 3503.5, and 3513. Staff's proposed Conditions of Certification **BIO-9**, **BIO-10**, and **BIO-11** require the applicant perform pre-construction surveys and identify nests for Swainson's hawk, burrowing owl and all nests of bird species protected by MBTA will minimize impacts.
Designated Ecological Reserves (Fish and Game Code section 1580 et seq.)	The project would not impact the Buttonwillow or Lokern Ecological Reserves; therefore, the project is compliant.
Streambed Alteration Agreement (Fish and Game Code sections 1600 et seq.)	It is unknown whether the project would comply with Fish and Game Code Section 1600 at this time since the extent of Section 1600 jurisdiction over the project has not been determined by CDFW. The applicant has submitted a Section 1600 Lake or Streambed Alteration Agreement application which staff has preliminarily reviewed. Staff has inserted **BIO-19** impact avoidance and minimization measures for potential state waters and **BIO-20** as a placeholder for mitigating project impacts to state waters.

FEDERAL LORS

ENDANGERED SPECIES ACT

Potential take of federally-listed species (i.e., federally endangered San Joaquin kit fox, federally endangered blunt-nosed leopard lizard, federally endangered giant kangaroo rat, federally endangered Tipton kangaroo rat, federally endangered Buena Vista Lake shrew) requires compliance with the federal Endangered Species Act (ESA; 16 USC §§ 1531 et seq.). "Take" of a federally listed wildlife species is prohibited without a permit, which may be obtained through consultation with USFWS under Section 10 of ESA by a private party or initiation of formal consultation under Section 7 of ESA by a federal agency. Since USFWS cannot issue incidental take coverage for federally-listed plants species, like Kern mallow, avoidance of special-status plant species is strongly encouraged.

HECA involves a federal nexus through the receipt of DOE federal funding; therefore, DOE is the federal agency initiating formal consultation with USFWS under Section 7 of ESA. A Section 7 Biological Assessment (BA) was submitted on March 6, 2013 for HECA including the OEHI component proposed on EHOF (**Biological Resources**

Appendix A). Following the conclusion of formal consultation, the USFWS would issue a Biological Opinion (BO) for the entire project, the conservation measures of which would be incorporated into the Energy Commission Decision through Condition of Certification **BIO-5** (Biological Resources Mitigation Implementation and Monitoring Plan). Compliance of the project with the Endangered Species Act cannot be determined at this point.

CLEAN WATER ACT

Potentially jurisdictional waters of the U.S. under Section 404 of the Clean Water Act occur within the project area including the Westside Canal/Outlet Canal, Kern River Flood Control Channel (KRFCC), California Aqueduct, the Kern River farther south of the project site, and several agricultural and irrigation ditches. The applicant has submitted a formal wetland delineation to the Corps and to date, the Corps has not issued a formal Jurisdictional Determination on the occurrence of Section 404 jurisdictional waters in the project area. The applicant identified a total of 92.51 acres of waters of the U.S. in the project area although the project awaits response from the Corps on the jurisidciton of these delineated features under Section 404. Therefore, compliance of the project with the Clean Water Act cannot be determined at this point.

STATE LORS

CALIFORNIA ENDANGERED SPECIES ACT

The California Endangered Species Act prohibits the "take" (defined as "to hunt, pursue, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill") of state-listed species except as otherwise provided in state law. Staff is coordinating with the CDFW regarding the project's potential for take of state-listed species (i.e., state threatened Swainson's hawk, state threatened San Joaquin antelope ground squirrel, state threatened San Joaquin kit fox, state endangered Tipton kangaroo rat, state endangered and California Fully Protected blunt-nosed leopard lizard, and state endangered giant kangaroo rat) in order to incorporate any measures that would be required in an Incidental Take Permit under Section 2081 of the California Endangered Species Act into staff's conditions of certification, excluding blunt-nosed leopard lizard from the list above since incidental take of this species cannot be authorized. During May 2013, the applicant submitted an application for an Incidental Take Permit to CDFW and the Energy Commission (URS 2013d) although it is unknown whether the project complies with CESA at this time. Additional data and coordination with CDFW is needed on the project's potential impact to Swainson's hawk nest trees, a state-listed species, in terms of groundwater drawdown and nest tree decline, which may constitute take under CESA. Also, blunt-nosed leopard lizard is a state-listed species and since incidental take of this species cannot legally be granted nor can avoidance of take be guaranteed for the life of the project, the project may not comply with CESA.

CALIFORNIA FISH AND GAME CODE SECTION 1600

Similar to the state Incidental Take Permit, compliance with Fish and Game Code Section 1600 is achieved through the Energy Commission's in lieu authority. The applicant has submitted an application for a Lake or Streambed Alteration Agreement to staff and CDFW which staff has preliminarily reviewed. Staff believes ephemeral drainages occur along the proposed carbon dioxide pipeline route that may fall under Fish and Game Code 1600 jurisdiction. Until this information is submitted, compliance of the project with Section 1600 of the California Fish and Game Codes cannot be determined at this point.

CALIFORNIA FISH AND GAME CODE SECTION 5050

Staff concludes that even with the implementation of the identified take avoidance and minimization measures in Condition of Certification **BIO-8**, incidental take of BNLL would likely occur over the life of the project. Staff notes that any impacts to BNLL habitat loss even if mitigated as required under CEQA, the project may still violate the California Fish and Game Code Section 5050 and Section 86 which defines take due to the species' status as a California Fully Protected species since the avoidance of BNLL take cannot be guaranteed for the life of the project; therefore, it is unclear whether the project would comply with these LORS.

NOTEWORTHY PUBLIC BENEFITS

Construction and operation of the HECA Project would not result in any noteworthy public benefits with regard to biological resources.

CONCLUSIONS

Construction of the project would primarily impact agricultural lands and intermixed non-native grassland, allscale scrub habitats that provide habitat for a number of upland species covered under the U.S. Fish and Wildlife Service's *Recovery Plan for Upland Species of the San Joaquin Valley* (Recovery Plan, USFWS 1998). HECA would impact approximately 33 acres of allscale scrub habitat which would mostly occur along the carbon dioxide pipeline route. The proposed carbon dioxide pipeline route located on the lower flanks of the Elk Hills Oil Field and immediately north of the Elk Hills mitigation parcels, is the linear route that supports the most contiguous natural, non-farmland type of habitat in the project area and staff believes this linear route represents the highest quality natural habitat and poses the highest threat for construction impacts to upland species. In addition, five sites along the natural gas pipeline route also support areas of disturbed allscale scrub and some of these sites represent similar habitat values as the nearby Buttonwillow Ecological Reserve, located north of the project site. Approximately 740 acres of additional impacts would occur to various agricultural land types (alfalfa, orchards, row crops) and existing disturbed lands.

HECA is proposed for an area located in a San Joaquin kit fox Core Recovery Area known as natural lands of western Kern County, which include critical dispersal and connection points between the Elk Hills, Buena Vista Valley, and Lokern Natural Areas, and urban Bakersfield satellite populations of kit fox. The Recovery Plan states that the Carrizo Plain and western Kern County San Joaquin kit fox populations are important for kit fox recovery and preliminary population viability analyses indicate that the possibility of the extinction of this species dramatically increases if either the Carrizo

Plain or western Kern County populations are eliminated (USFWS 1998). Staff estimates the project's impacts to 773 acres of habitat represents a loss of denning and regional movement lands for San Joaquin kit fox. HECA would not result in the construction of any new roads; however, construction and operation would contribute considerable amounts of increased traffic on several local and collector roads that intersect with other irrigation canals that kit fox are known to use for movement. Staff believes increased vehicle traffic from the project, especially non-peak traffic during dawn, dusk and nighttime hours, could result in a considerable increase in direct vehicle-fox strike mortality and all wildlife that occurs on or near roadways. Staff has proposed Condition of Certification **BIO-7**, which requires that the applicant conduct focused den surveys prior to construction for San Joaquin kit fox and American badger, establish exclusion zones, and continue monitoring the activity of potential dens identified in active construction areas. Condition of Certification **BIO-7** also requires that the applicant follow the USFWS's *Standardized Recommendations for Protection of the San Joaquin Kit Fox Prior to or during Ground Disturbance* for avoiding impacts to this species (USFWS 2011). Staff's proposed Condition of Certification **BIO-12** requires that the applicant prepare an agency-approved Small Mammal Relocation Plan. In addition, staff has proposed Conditions of Certification **BIO-13** (giant kangaroo rat) and **BIO-14** (Tipton kangaroo rat and San Joaquin antelope squirrel), which require the applicant perform focused preconstruction surveys and mapping for giant kangaroo rat precincts and small mammal burrows, preconstruction trapping and relocation in order to minimize and avoid take of small burrowing mammals in active construction areas, and burrow excavation once burrows and precincts have been completely trapped and evaluated for small mammal presence.

Blunt-nosed leopard lizard is a California fully-protected species under California Fish and Game Code Section 5050 and therefore, incidental take of the species is not legally permitted as defined by Section 86 of the Fish and Game Code. This species is present at the Elk Hills Oil Field and has a high potential to occupy the proposed carbon dioxide pipeline route as well as disturbed allscale scrub areas along the natural gas pipeline. The construction of the project would impact approximately 192 acres of natural allscale scrub and disturbed lands which provide small mammal burrow habitat for blunt-nosed leopard lizard; this poses a threat to BNLL in the form of mortality from vehicles and equipment on roadways, entrapment in construction-related trenches or pipes, burial in burrows by equipment, avoidance of certain habitats, modification to breeding and/or foraging behaviors, reduced carrying capacity of natural scrub habitat and neighboring lands known to be occupied by BNLL. Staff has proposed Condition of Certification **BIO-8**, which requires that the applicant prepare a Blunt-nosed Leopard Lizard Impact Avoidance and Minimization Plan to further minimize the potential for take during construction and operation of the project; in particular, this plan would take into consideration the phasing of linear construction and how clearance surveys, exclusion fencing, and fence and burrow monitoring would also be phased in order to ensure blunt-nosed leopard lizards remain clear of active construction areas. Condition of Certification **BIO-8** also requires that various impact avoidance measures be incorporated including scheduling surface ground disturbing during the blunt-nosed leopard lizard's active season (approximately April 15 to October 15) to the greatest extent practicable, particularly in habitat areas where this species is mostly likely to be encountered, minor shifts in proposed pipeline alignments in order to avoid potentially occupied small mammal burrows, and presence of biological monitor(s) in active construction areas. Staff concludes that even with the implementation of staff's proposed take avoidance and minimization measures, incidental take of blunt-nosed leopard lizard would likely occur over the life of the project. Therefore, staff considers this impact significant and unavoidable under CEQA even with the incorporation of mitigation and the project may not comply with the California Endangered Species Act or California Fish and Game Code Section 5050 relating to Fully Protected Reptile and Amphibian Species since take avoidance cannot be guaranteed for the life of the project.

During protocol-level surveys performed for Swainson's hawk, 12 active raptor nests were found within the surveyarea, six of which were confirmed Swainson's hawk nests. All six Swainson's hawk nests appear to be within a 0.25 mile of either the project site or a proposed linear facility and therefore could be affected by construction noise or other construction disturbances during the nesting season. The majority of these nest trees occur along canal levees of the Kern River Flood Control Channel, West Side Canal and other smaller unnamed agricultural canals and ditches and are likely supplied to some extent by irrigation runoff that accumulates in irrigation canals as well as groundwater. In addition, valley sink scrub, a sensitive vegetation community identified by the California Natural Diversity Database, potentially occurs in these same areas in association with the Kern River Flood Control Channel. Staff believes that a more definitive analysis is needed on the water source of the nest trees that occur in the project area and pre- and post-project groundwater drawdown around the proposed well field. Staff also believes the loss of approximately 571 acres of agricultural lands including alfalfa, wheat, onion fields, and other low-growing crop types that provide forage value is a significant loss of foraging habitat for Swainson's hawk. More definitive analysis is needed on the baseline groundwater levels and water source of the nest trees and sensitive vegetation communities that occur in the project area. Staff's proposed Condition of Certification **BIO-9** (Swainson's Hawk Impact Avoidance Measures) requires that the applicant perform focused, preconstruction surveys within 0.50-mile of all project facilities and a minimum construction avoidance buffer of 0.50 mile must be implemented around any active Swainson's hawk nests following the recommended survey protocol for this species. Condition of Certification **BIO-9** also requires the applicant to prepare and implement a Swainson's Hawk Monitoring and Mitigation Plan which would account for a phased construction schedule and need to phase preconstruction surveys. With the incorporation of the above conditions of certification, the project's impacts to Swainson's hawk habitat would be reduced; however, until additional data is provided regarding the project's impacts and overall mitigation strategy, staff cannot determine if the project's impacts to Swainson's hawk habitat would be reduced to below a level of significance. If water drawdown from project groundwater pumping is consistent enough over the course of several years, staff believes the decrease in water supply to the tree's root system could result in gradual decline and eventually nest tree failure which may constitute take under the California Endangered Species Act, the Migratory Bird Treaty Act, and California Fish and Game Code 3503; therefore, it is unknown if HECA complies with these LORS at this time.

Staff has proposed several impact avoidance and minimization measures to reduce the potential for impacts to special-status plants and wildlife primarily during construction of the project. Specifically, staff has proposed Conditions of Certification **BIO-1** through **BIO-6** which would apply to all species that could be impacted by the project by requiring the applicant appoint a Designated Biologist and Biological Monitors for routine monitoring and reporting of the project during construction and implementation of a worker awareness training program. Conditions of Certification **BIO-7** through **BIO-17** are species-specific conditions, which in essence require the applicant perform focused, preconstruction surveys in suitable habitat areas, implement species- specific construction impact avoidance measures, and monitor for signs of disturbance during construction following wildlife agency protocols. These conditions also require the applicant to prepare species-specific mitigation and monitoring plans specifically for blunt-nosed leopard lizard, Swainson's hawk, burrowing owl, and listed small mammals (giant kangaroo rat, Tipton, San Joaquin antelope squirrel) outlining construction avoidance procedures and to take into account the phasing of the construction schedule along linear routes when implementing clearance surveys.

Energy Commssion staff, the California Department of Fish and Wildlife (CDFW), and U.S. Fish and Wildlife Service (USFWS) have determined that permanent protection and perpetual management of compensatory habitat is necessary and required in accordance with CEQA and biological laws, ordinances, regulations, and standards (LORS). This determination is based on factors including an assessment of the importance of the habitat in the project area and the extent to which project activities would impact the habitat. There remains much uncertainty regarding the applicant's overall compensatory mitigation proposal for the project. The applicant submitted a Section 7 Biological Assessment for HECA including the OEHI component of HECA on March 1, 2013 (Biological Resources Appendix A, URS 2013b). The applicant has proposed to mitigate for permanent and temporary habitat impacts to federally and state listed species at a 0.1:1 and 2.1:1 ratio, respectively, which staff believes would not suffice as adequate habitat compensation for project impacts to special-status species (HECA 2012b, URS 2013b). The applicant has also proposed to purchase habitat credits from the Kern Water Bank as mitigation for the project, which the wildlife agencies have indicated is not a feasible option for mitigating HECA's impacts to special-status wildlife species. During May 2013, the applicant submitted a Section 2081 Incidental Take Permit application which would contain a mitigation strategy for project impacts to state-listed wildlife species that staff has preliminarily reviewed. Staff has inserted Condition of Certification **BIO-20** (Compensatory Habitat Mitigation for Upland Species) as a placeholder. Staff will continue to work publicly with the applicant, CDFW, and USFWS in order to develop an appropriate mitigation strategy for HECA that is consistent with the goals and objectives of the *Recovery Plan for Upland Species of the San Joaquin Valley*. Additional conditions of certification, and modifications to currently proposed conditions of certification including Condition of Certification **BIO-20**, are likely to be necessary based on further consultation with the wildlife agencies and information provided by the applicant. With the implementation of staff's proposed Conditions of Certification **BIO-1** through **BIO-20**, impacts to special-status species would be reduced. However, without an adequate mitigation proposal, staff cannot make a determination whether the project would comply with laws, ordinances, regulations, or standards (LORS) or that project impacts to sensitive biological resources would be reduced to less than significant levels in accordance with CEQA.

OUTSTANDING INFORMATION REQUIRED FOR COMPLETION OF THE FSA/FEIS

The following is a list of information related to biological resources that the applicant must provide to staffin order to finalize preparation of the FSA/FEIS:

- Comprehensive mitigation strategy for project impacts to San Joaquin kit fox, giant kangaroo rat, Tipton kangaroo rat, San Joaquin antelope squirrel, blunt-nosed leopard lizard, Swainson's hawk, burrowing owl and HECA's incremental contribution to cumulative effects to these species that are covered in the *Recovery Plan of Upland Species of the San Joaquin Valley*. Specifically, identify which species and acreage the applicant is proposing to mitigate through purchase of mitigation credits from the Kern Water Bank and which species and acreages would be mitigated through offsite land acquisition. For offsite land acquisition, please identify the species-specific habitat critieria for offsite mitigation lands and cost estimates for determining security (eg. cost estimates for land acquisition, start-up actitivites and initial habitat improvements, funding during the three-year interim management period, and long-term management). Please also provide any preliminary discussions with land management entities for land acquisition and long-term habitat management for project impacts to listed species;
- Additional focused protocol-level botanical surveys (CDFG 2009) along all linear routes and additional baseline botanical data, primarily the proposed carbon dioxide pipeline route;
- Extent of CDFW Section 1600 jurisdiction and impacts to state waters (ephemeral drainages) in the project area, including all linear routes and ephemeral drainages that may occur along the proposed carbon dioxide pipeline route;
- Extent of U.S. Army Corps of Engineers Section 404 jurisdiction in the project area and impacts to Waters of the U.S.;
- Habitat mitigation strategy for habitat loss impacts from OEHI component of HECA at the Elk Hills Oik Field. Please identify whether species impacts including habitat loss for the OEHI component would be included under the Section 10 Habitat Conservation Plan currently under preparation or if habitat loss for the OEHI component of HECA would be mitigated under separate consultations with CDFW and USFWS;
- Western spadefoot toad habitat assessment along project linear routes including upland refugia and aquatic habitats preferably during the wet season (defined as October 15 to April 15 of any given year) and following sufficient winter or spring rains in order to identify potential depressional areas and upland refugia that may provide habitat for western spadefoot toad. All potential ponding areas should be identified and mapped with a GPS unit including the single pond where this species was identified previously. Information to be collected at each GPS'ed potential breeding area includes, but is not limited to: the specific numbering system of each potential breeding area, presence of tadpoles and species (if any), habitat community, microhabitat features, observed plant species, observed

wildlife species including invertebrates, water temperature, approximate depth and surface area, and level of disturbance;

- Vehicle-fox strike and incidental take analysis considering the project's contribution to existing traffic volumes and intersections of the proposed construction and operation routes with other linear right-of-ways that occur within and outside of San Joaquin kit fox core recovery areas. The applicant should calculate vehicle mortality rates to kit fox and other mammals over the life of the project; and
- Water supply analysis and the effects of groundwater pumping to the sensitive vegetation communities and raptor nest trees which occur in the project area. The applicant must provide an analysis of the baseline groundwater levels and water source of raptor nest trees and alkali sink scrub habitat along HECA's linear routes, primarily the natural gas pipeline, processed water pipeline, and well field.

PROPOSED CONDITIONS OF CERTIFICATION

For the purposes of staff's proposed conditions of certification, staff defines project disturbance areas encompassing all areas to be temporarily and permanently disturbed by the project, including the plant site, linear facilities, and areas disturbed by temporary access roads, fence installation, construction work lay-down and staging areas, parking, storage, or any other area resulting in disturbance to soil or vegetation. Since the Energy Commission's license is in-lieu of all state permits normally required, incidental take per the California Endangered Species Act (CESA) and California Fish and Game Codes could be granted for the following covered species in accordance with the conditions of certification in the Energy Commission's license: San Joaquin kit fox, giant kangaroo rat, San Joaquin antelope squirrel, Tipton's kangaroo rat, and Swainson's hawk. Blunt-nosed leopard lizard is a California Fully Protected species and incidental take, including capture, is prohibited under California Fish and Game Code Section 5050. Therefore this species is not a covered species and incidental take of this species will not be authorized or granted through the Energy Commission's license. No state listed plants are covered species nor could incidental take be authorized.

Staff has inserted Condition of Certification **BIO-20** (Compensatory Habitat Mitigation) as a placeholder, which would require the applicant to permanently protect and perpetually manage compensatory habitat. However, the estimate of the acreage required to provide for adequate compensation is unknown at this time and will be finalized upon preparation of the FSA/FEIS upon submittal of the data requested and further public consultation between the applicant, staff, CDFW, and USFWS. The need for compensatory mitigation is based on factors including an assessment of the importance of the habitat in the project area and the extent to which the project would impact the habitat.

DESIGNATED BIOLOGIST SELECTION AND DUTIES

BIO-1 The project owner shall assign at least one Designated Biologist to the project. The project owner shall submit the resume of the proposed

Designated Biologist, with at least three references and contact information, to the Energy Commission compliance project manager (CPM) for approval, in consultation with California Department of Fish and Wildlife (CDFW) and U.S. Fish and Wildlife (USFWS).

The Designated Biologist shall meet the following minimum qualifications:

1. Bachelor's degree in biological sciences, zoology, botany, ecology, or a closely related field;
2. Three years of experience in field biology or current certification of a nationally recognized biological society, such as The Ecological Society of America or The Wildlife Society;
3. Have at least one year of field experience with biological resources and demonstrate an understanding of field survey protocols for sensitive plant and wildlife species found in or near the project area; and
4. Meet all surveyor requirements specified in agency qualifications for performing protocol-level surveys as a Level II blunt-nosed leopard lizard researcher (CDFG 2004) and San Joaquin kit fox (USFWS 1999) qualified surveyor.

The project owner shall ensure that the Designated Biologist performs the following duties during any project mobilization activities, construction-related ground disturbance, site vegetation clearing, grading, boring or trenching activities. The Designated Biologist may be assisted by an approved Biological Monitor(s) but the Designated Biologist remains the main point of contact for the project owner and CPM. The Designated Biologist duties include the following, but are not limited to:

1. Advise the project owner's construction and operation managers on the implementation of the biological resources conditions of certification;
2. Consult on the preparation of the Biological Resources Mitigation Implementation and Monitoring Plan (BRMIMP) to be submitted by the project owner;
3. Be available to supervise, conduct, and coordinate mitigation, monitoring, and other biological resources compliance efforts, particularly in areas requiring avoidance or containing sensitive biological resources, such as special-status species or their habitat;
4. Ensure that the onsite blunt-nosed leopard lizard preconstruction surveying and monitoring crews at all times consist of no more than three Level I surveyors for every single Level II surveyor;
5. Clearly mark sensitive biological resource areas and inspect these areas at appropriate intervals for compliance with regulatory terms and conditions;
6. Inspect active construction areas including all open trenches where animals may have become trapped prior to construction commencing each day. At the end of the day, inspect for the installation of structures

that prevent entrapment or allow escape during periods of construction inactivity. Periodically inspect areas with high vehicle activity (e.g., parking lots) for animals in harm's way and relocated wildlife where appropriate;

7. Notify the project owner and the CPM of any non-compliance with any biological resources condition of certification;
8. Respond directly to inquiries of the CPM and Energy Commission Biological Resources staff regarding biological resource issues;
9. Maintain written records of the tasks specified above and those included in the BRMIMP. Summaries of these records shall be submitted in Monthly Compliance Reports and the Annual Compliance Report;
10. Train the Biological Monitors as appropriate, and ensure their familiarity with the BRMIMP, Worker Environmental Awareness Program (WEAP) training, and permits;
11. Maintain the ability to be in regular, direct communication with representatives of CDFW and USFWS as well as the CPM, including notifying these agencies of dead or injured listed species within 24 hours; and
12. Be onsite and available to perform or manage Biological Monitor survey crews during all pre-construction surveying and monitoring duties related to San Joaquin kit fox, giant kangaroo rat, San Joaquin antelope squirrel, Tipton's kangaroo rat, Swainson's hawk (collectively, Covered Species) in which incidental take in accordance with the California Endangered Species Act (CESA) and California Fish and Games Codes is authorized. Other non-covered species must be included in pre-construction surveys and monitored in accordance with applicable agency protocols, including blunt-nosed leopard lizard, burrowing owl, and special-status plants.

<u>Verification:</u> The project owner shall submit a resume including the specified information at least 60 days prior to the start of any project-related ground disturbance activities for review and approval to the CPM with copies to USFWS and CDFW. No ground-disturbing activities shall commence at the project site or along liner facilities until an approved Designated Biologist is available to be onsite. At least one approved, alternate Designated Biologist shall be identified and available to monitor if the primary Designated Biologist is unavailable.

If a Designated Biologist needs to be replaced, the specified information of the proposed replacement shall be submitted to the CPM with copies to USFWS and CDFW at least 10 working days prior to the termination or release of the preceding Designated Biologist. In an emergency, the project owner shall immediately notify the CPM to discuss the qualifications and approval of a short-term replacement while a permanent Designated Biologist is proposed to the CPM for consideration.

The Designated Biologist shall submit in the Monthly Compliance Report to the CPM copies of all written reports and summaries that document biological resources compliance activities. If actions may affect biological resources during operation a

Designated Biologist shall be available for monitoring and reporting. During project operation, the Designated Biologist shall submit record summaries in the Annual Compliance Report unless his/her duties cease, as approved by the CPM.

If a listed species is killed by project-related activities during construction, or if a listed species is otherwise found dead, the Designated Biologist shall immediately notify the CPM, USFWS Sacramento Field Office, and CDFW Central Region Office and provide information on the location, species and number of animals injured or killed. Following the initial notification, the project owner shall send the CPM, CDFW, and USFWS a written report within three (3) calendar days of the finding. The report shall include the date, time, location of the finding or incident, location of the carcass, and if possible provide a photograph, cause of death, and any other pertinent information.

BIOLOGICAL MONITOR QUALIFICATIONS AND DUTIES

BIO-2 The project owner's approved Designated Biologist shall submit the resume, at least three references, and contact information of the proposed Biological Monitors to the CPM for approval, based on consultation with CDFW and USFWS. The resume shall demonstrate to the satisfaction of the CPM the appropriate education and experience to accomplish the assigned biological resource tasks. The Biological Monitors shall assist the Designated Biologist in conducting surveys and in monitoring of mobilization, ground disturbance, grading, construction, operation, and closure activities; however, the Designated Biologist shall remain the contact for the project owner and the CPM.

Biological Monitor(s) training by the Designated Biologist shall include familiarity with these conditions of certification, the Biological Resources Mitigation Implementation and Monitoring Plan (BRMIMP), Worker Environmental Awareness Program (WEAP), and all permits.

Biological Monitors shall meet the following minimum qualifications:

1. Demonstrated field experience in the identification and life history of the San Joaquin kit fox. In addition, biologist(s) must be able to identify coyote, red fox, gray fox, and kit fox tracks and scat, and to have seen a kit fox in the wild, at a zoo, or as a museum mount;
2. Demonstrated field experience identifying burrowing owl burrows and other sign;
3. Demonstrated field experience in identifying San Joaquin antelope squirrel, giant kangaroo rat, Buena Vista Lake shrew, and Tipton kangaroo rat and sign;
4. Demonstrated field experience in identifying special-status plant species known to occur in the project area; and

4\. All approved Biological Monitors must at least meet the requirements to be a CDFW-approved Level I blunt-nosed leopard lizard (BNLL) surveyor (i.e. demonstrated the ability to distinguish BNLL from other common lizard species that may inhabit the area).

Verification: The project owner shall submit resumes including the specified information for review and approval by the CPM with copies to USFWS and CDFW at least 60 days prior to the start of any project-related site ground disturbing aactivities. The Designated Biologist shall submit a written statement to the CPM confirming that individual Biological Monitor(s) has been trained including the date when training was completed. If additional Biological Monitors are needed during construction the specified information shall be submitted to the CPM for approval at least 10 days prior to their first day of monitoring activities.

DESIGNATED BIOLOGIST AND BIOLOGICAL MONITOR AUTHORITY

BIO-3 The project owner's construction and operation manager(s) shall act on the advice of the Designated Biologist and Biological Monitors to ensure conformance with the biological resources conditions of certification.

The approved Designated Biologist and Biological Monitors shall have the authority to immediately stop any activity that is not in compliance with these conditions and/or order any reasonable measure to avoid take of an individual of a listed species. If required by the Designated Biologist and Biological Monitors the project owner's construction/operation manager shall halt all site mobilization, ground disturbance, grading, construction, and operation activities in areas specified by the Designated Biologist or Biological Monitor. The Designated Biologist or Biological Monitor shall:

1. Require a halt to all activities in any area when determined that there would be an unauthorized adverse impact to biological resources if the activities continued;
2. Inform the project owner and the construction/operation manager when to resume activities; and
3. Notify the CPM if there is a halt of any activities and advise the CPM of any corrective actions that have been taken or will be instituted as a result of the work stoppage.

If the Designated Biologist is unavailable for direct consultation, the Biological Monitor shall act on behalf of the Designated Biologist.

Verification: The project owner shall ensure that the Designated Biologist or Biological Monitor notifies via phone or email the CPM immediately (i.e. no later than the morning following the incident, or Monday morning in the case of a weekend) of any non-compliance or a halt of any site mobilization, ground disturbance, grading, construction, and operation activities. The project owner shall notify via phone or email the CPM of the circumstances and actions being taken to resolve the problem.

Whenever corrective action is taken by the project owner, a determination of success or failure will be made by the CPM after receipt of notice that corrective action is completed, or the project owner will be notified by the CPM that coordination with other agencies will require additional time before a determination can be made.

WORKER ENVIRONMENTAL AWARENESS PROGRAM

BIO-4 The project owner shall develop and implement a Worker Environmental Awareness Program (WEAP) in which each of its employees, as well as employees of contractors and subcontractors who work on the project site and all related linear facilities during site mobilization, ground disturbance, grading, construction, operation, and closure are informed about sensitive biological resources associated with the project prior to their working on-site.

The WEAP shall:

1. Be developed by or in consultation with the Designated Biologist, based on input from the CPM, CDFW, and USFWS and consist of an onsite or training center presentation in which supporting written material and electronic media is made available to all participants, including photographs of protected species. Interpretation shall be provided for non-English speaking workers and the same instructions shall be provided for any new workers prior to their working on-site;

2. Discuss the locations and types of sensitive biological resources on the project site and adjacent areas including Environmentally Sensitive Areas and their designation on construction drawings and present the reasons for protecting these resources and protective measures that are being implemented;

3. Discuss the biology and general behavior of special-status species, information about the distribution and habitat needs of special-status species, sensitivity of these species to human activities, impact avoidance and minimization measures to follow during construction, and legal protection and recovery efforts. Specifically, the WEAP shall include the requirement to inspect all areas underneath parked vehicles for blunt-nosed leopard lizard (BNLL) prior to vehicle operation during the active season for BNLL (April 15 to October 15) and reporting measures to implement if a BNLL is found in a construction area.
4. Place special emphasis on covered species as well as burrowing owl, blunt-nosed leopard lizard, and special-status plants including information on physical characteristics, distribution, behavior, ecology, sensitivity to human activities, legal protection, penalties for violations, reporting requirements, and protection measures. Specifically, the WEAP shall discuss that any contractor or employee who is responsible for inadvertently killing or injuring a kit fox shall immediately report the incident to the Designated Biologist and subsequent agency notification and reporting requirements;

5. Provide pictures of covered species as well as blunt-nosed leopard lizard, American badger, burrowing owl, Buena Vista Lake shrew, and rare plants (Hoover’s eriastrum, gypsum-loving larkspur, Lost Hills crownscale, oil nest straw, San Joaquin bluecurls, cottony buckwheat, Tejon poppy, Kern mallow) and provide information on sensitivity to human activities, legal

protection, reporting requirements, and how to identify construction avoidance zones (including Environmentally Sensitive Areas) for these species as marked by flagging, staking, or other means;

6. Include a discussion of fire prevention measures to be implemented by workers during project activities and request workers to: a) use designated smoking areas and dispose of cigarettes and cigars appropriately and not leave them on the ground or buried, b) keep vehicles on graveled or well-maintained roads at all times, unless performing prescribed construction activities, to prevent vehicle exhaust systems from coming in contact with roadside weeds, c) use and maintain approved spark arresters on all power equipment, and d) keep a fire extinguisher on hand at all times;

7. Present the meaning of various temporary and permanent habitat protection measures as necessary;

8. Discuss penalties for violation of applicable federal and state laws, ordinances, regulations, and standards (LORS); and

9. Identify whom to contact if there are further comments and questions about the material discussed in the program.

The WEAP shall include a training acknowledgment form to be signed by each worker indicating that they received training and shall abide by the guidelines. This file shall indicate the name and contact information for each worker that has attended the WEAP. This list must be available to the CPM, USFWS, and CDFW upon request. Upon completion of the program, the project owner shall provide all workers who have completed the WEAP a hardhat sticker that must be displayed on their hardhat.

The specific program can be administered by a competent individual(s) acceptable to the Designated Biologist and copies of the WEAP shall be maintained at the work site. The WEAP may also contain wallet-sized cards or a fact sheet handout containing this information for workers to carry on-site. Throughout the life of the project, the WEAP shall be repeated annually for permanent employees, and shall be routinely administered within one week of arrival to any new construction personnel, foremen, contractors, subcontractors, and other personnel potentially working within the project area. Upon completion of the orientation, employees shall sign a form stating that they attended the program and understand all protection measures. These forms shall be maintained by the project owner and shall be made available to the CPM, USFWS, and CDFW upon request.

<u>Verification:</u> At least 60 days prior to construction-related ground disturbance, the project owner shall provide the draft WEAP and all supporting written materials and electronic media prepared or reviewed by the Designated Biologist to the CPM for review and approval with a copy to CDFW and USFWS. At least 10 days prior to site and related facilities mobilization, the project owner shall submit two copies of the final approved WEAP and video to the CPM with copies to the CDFW and USFWS.

In the Monthly Compliance Report, the project owner shall provide the number of persons who have completed the training in the prior month and a running total of all persons who have completed the training to date. Training acknowledgement forms signed during construction shall be kept on file by the project owner for a period of at least six months after the start of commercial operation. During project operation, signed statements for operational personnel shall be kept on file for six months following the termination of an individual's employment.

BIOLOGICAL RESOURCES MITIGATION IMPLEMENTATION AND MONITORING PLAN

BIO-5 The project owner shall develop and implement a Biological Resources Mitigation Implementation and Monitoring Plan (BRMIMP) for HECA. The BRMIMP shall incorporate all impact avoidance and minimization measures outlined in any applicable species mitigation plans subsequently prepared in accordance with these biological conditions of certification.

The BRMIMP shall be prepared in consultation with the Designated Biologist and shall include the following:

1. All biological resources mitigation, monitoring, and compliance measures specified in the conditions of certification;
2. All biological resource mitigation, monitoring and compliance measures required in federal agency terms and conditions, including the USFWS Biological Opinion for the project;
3. All sensitive biological resources to be impacted, avoided, or mitigated by project construction, operation, and closure;
4. A detailed description of measures that shall be taken to avoid or mitigate temporary disturbances from construction activities;
5. All locations on a map, at an approved scale, of sensitive biological resource areas subject to disturbance and areas requiring temporary protection and avoidance during construction;
6. GIS analysis utilizing aerial photographs, at an approved scale, of all areas to be disturbed during project construction activities; include one set prior to any site or related facilities mobilization disturbance and one set subsequent to completion of project construction, each set showing the project site plan boundaries and facilities. Provide planned timing of aerial photography and a description of why times were chosen. Provide a final accounting of the before/after acreages and a determination of whether additional habitat compensation is necessary in the Construction Termination Report;
7. Duration for each type of monitoring and a description of monitoring methodologies and frequency;
8. All performance standards to be used to help decide if/when proposed mitigation is or is not successful;

9. A discussion of biological resources-related facility closure measures including a description of funding mechanism(s); and
10. A process for proposing plan modifications to the CPM (in consultation with appropriate agencies) for review and approval.

Verification: The project owner shall provide a draft of the BRMIMP at least 60 days prior to start of any project mobilization or ground disturbance associated with the power plant site or linear facilities. The CPM, in consultation with other appropriate agencies, will review and approve the draft BRMIMP. If the Biological Opinion has not yet been received when the BRMIMP is first submitted, the Biological Opinion shall be submitted to the CPM within five (5) days of its receipt, and the BRMIMP shall be revised or supplemented to reflect the permit condition within 10 days of its receipt by the project owner. Thirty days prior to any ground disturbing project activities, the final BRMIMP shall be submitted to the CPM with copies to USFWS and CDFW. No ground disturbance may occur prior to approval of the final BRMIMP by the CPM.

The project owner shall notify the CPM no less than five working days before implementing any modifications to the approved BRMIMP to obtain CPM approval. Any changes to the approved BRMIMP must also be approved by the CPM in consultation with CDFW and USFWS to ensure that no conflicts occur with other permit requirements.

Implementation of BRMIMP measures will be reported in the Monthly Compliance Reports by the Designated Biologist and written reports documenting monthly biological compliance measures will be included (i.e., survey results, construction activities that were monitored, species observed, etc). Within thirty (30) days after completion of project construction, the project owner shall provide to the CPM, for review and approval, a written construction termination report identifying which items of the BRMIMP have been completed, a summary of all modifications to mitigation measures made during project site mobilization, ground disturbance, grading, and construction phases, and which mitigation and monitoring items are still outstanding.

IMPACT AVOIDANCE AND MINIMIZATION MEASURES

BIO-6 The project owner shall undertake the following measures to manage the construction site and related facilities in a manner to avoid or minimize impacts to biological resources:

1. Limit Disturbance Area. The boundaries of all areas to be disturbed (including staging areas, access roads, and sites for temporary placement of spoils) shall be delineated with stakes and flagging prior to construction activities in consultation with the Designated Biologist. Spoils shall be stockpiled in disturbed areas lacking native vegetation and which do not provide habitat for special-status species. Parking areas, staging and disposal site locations shall similarly be located in areas without native vegetation or special-status species habitat. All disturbances, vehicles, and equipment shall be confined to the flagged areas.

2. Minimize Road Impacts. New and existing roads that are planned for construction, widening, or other improvements shall not extend beyond the flagged impact area as described above. All vehicles passing or turning around will do so within the planned impact area or in previously disturbed areas. Where new access is required outside of existing roads or the construction zone, the route will be clearly marked (i.e., flagged and/or staked) prior to the onset of construction.

3. Minimize Traffic Impacts. Vehicular traffic during project construction and operation shall be confined to existing routes of travel to and from the project site, and cross country vehicle and equipment use outside designated work areas shall be prohibited. The speed limit shall not exceed 20 miles per hour on paved roads within the project area (10-mph on dirt roads), on non-public maintenance roads along linear routes (pipelines, transmission line, etc).

4. Monitor During Construction. Following all species-specific pre-construction clearance surveys following the applicable agency-approved survey protocol, the Designated Biologist or Biological Monitor shall be present at the construction site during all project construction activities and in work areas (including the project site and linear facilities) that have potential to disturb soil, vegetation, and wildlife. The Designated Biologist or Biological Monitor shall follow the survey and monitoring protocol that exists for the individual listed species or if a formal survey protocol does not exist, a comparable agency-approved survey and monitoring protocol.

5. Minimize Impacts of Transmission Lines/Pipeline Alignments, Roads, and Staging Areas. Transmission lines, access roads, pulling sites, storage and parking areas, and construction staging areas (at power plant site and rail yard) shall be designed, installed, and maintained with the goal of minimizing impacts to native plant communities and sensitive biological resources. Transmission lines and all electrical components shall be designed, installed, and maintained in accordance with the Avian Power Line Interaction Committee's (APLIC's) *Suggested Practices for Avian Protection on Power Lines* (APLIC 2006) and *Mitigating Bird Collisions with Power Lines* (APLIC 2004) to reduce the likelihood of large bird electrocutions and collisions.

6. Vegetation Clearing. All vegetation clearing shall be performed outside of the bird nesting season (September 1 through January 31), to the maximum extent practicable, in order to clear vegetation prior to the active bird nesting season.

7. Avoid Use of Toxic Substances. Road surfacing and sealants as well as soil bonding and weighting agents used on unpaved surfaces shall be non-toxic to wildlife and plants. Pre-emergents and other herbicides with documented residual toxicity shall not be used. Herbicides shall be applied in conformance with federal, state, and local laws and according to the guidelines for wildlife-safe use of herbicides. Use of rodenticides

and herbicides in project areas should be restricted as outlined in further detail in **BIO-7**.

8. Minimize Lighting Impacts. Facility lighting shall be designed, installed, and maintained to prevent side casting of light towards wildlife habitat. Lighting shall be shielded, directional, and at the lowest intensity required for safety. Lighting shall be directed away from biologically sensitive areas.

9. Minimize Noise Impacts. A continuous low-pressure technique shall be used for steam blows, to the extent possible, in order to reduce noise levels in sensitive habitat proximate to the power plant site. To the extent feasible, loud construction activities (e.g. unsilenced high pressure steam blowing and pile driving associated with all project facilities or other noise greater than 60 dBA) shall be avoided during the peak elk calving and nesting bird season (February 15th to June15th when construction noise levels would be greater than 60 dBA (excluding noise from passing vehicles) in nesting bird habitat and within immediate proximity of the Tule Elk State Reserve including construction of the transmission line.

10. Avoid Wildlife Pitfalls and Prevent Inadvertent Entrapment of Wildlife. To prevent inadvertent entrapment of kit foxes or other animals, the Designated Biologist or Biological Monitor shall monitor for wildlife pitfalls. At the end of each work day, the Designated Biologist or Biological Monitor(s) shall ensure that all excavated, steep-walled holes or trenches more than two feet deep shall be covered by plywood or similar materials. If trenches cannot be closed, one or more escape ramps shall be installed of either earthen fill or wooden planks at a 3:1 slope ratio at the ends or installed every 200 feet along the trench, whichever distance is shorter. Before such holes or trenches are filled, they should be thoroughly inspected for trapped animals. In addition, all construction pipes, culverts, or similar structures with a diameter of 4 inches or greater that are stored at a construction site for one or more overnight periods shall be thoroughly inspected for kit fox before the pipe is subsequently buried, capped, or moved. If a kit fox is discovered inside a pipe, that section of pipe shall not be moved. However, if necessary and approved by the CPM in consultation with USFWS and CDFW, the pipe may be moved once to remove it from the path of construction activity, until the kit fox has escaped and under the direct supervision of the Designated Biologist or Biological Monitor.

11. Minimize Standing Water. Water applied to dirt roads and construction areas (trenches or spoil piles) for dust abatement shall use the minimal amount needed to meet safety and air quality standards. A Biological Monitor shall patrol these areas to ensure water does not puddle, flood small mammal burrows, and attract wildlife to the site and shall take appropriate action to reduce water application where necessary.

12. Minimize Spills of Hazardous Materials. All vehicles and equipment shall be maintained in proper working condition to minimize the potential for fugitive emissions of motor oil, antifreeze, hydraulic fluid, grease, or other

hazardous materials. The Designated Biologist shall be informed of any hazardous spills immediately. Hazardous spills shall be immediately cleaned up and the contaminated soil properly disposed of at a licensed facility. Servicing of construction equipment shall take place only at a designated area. Service/maintenance vehicles shall carry a bucket and pads to contain leaks or spills.

13. Dispose of Road-killed Animals. Road-killed animals or other carcasses detected on project maintenance roads along linear routes and within one mile of the project site shall be picked up immediately and delivered to the Biological Monitor or Designated Biologist. For listed species road kill, the Designated Biologist or Biological Monitor shall contact USFWS and CDFW within 24 hours of receipt of the carcass for guidance on disposal or storage and need for necropsy of the carcass. The Biological Monitor or Designated Biologist shall report the special-status species record as described in these biological conditions of certification.

14. Worker Guidelines. During construction, all trash and food-related waste shall be placed in self-closing containers and removed daily from the site. Workers shall not feed wildlife or bring pets to the project site. Except for law enforcement personnel, no workers or visitors to the site shall bring firearms or weapons.

15. Avoid Spread of Noxious Weeds. The project owner shall implement the following Best Management Practices during construction and operation to prevent the spread and propagation of noxious weeds into new habitats as a result of the project:

    a. Limit the size of any vegetation and/or ground disturbance to the absolute minimum and limit ingress and egress to defined routes;

    b. Prevent spread of non-native plants via vehicular sources by implementing Trackclean™ or other methods of vehicle cleaning for vehicles coming and going from construction sites;

    c. Construction equipment shall be cleaned prior to transport to the construction site. Prior to equipment entering the work area, the contractor will notify the Designated Biologist so that a Biological Monitor or environmental inspector can inspect the equipment to ensure they are free of any dirt or mud that could contain weed seeds, roots, or rhizomes. The tracks, feet, tires, and undercarriage will be carefully inspected, and special attention will be paid to axles, frame, cross members, motor mounts, underneath steps, running boards, and front bumper/brush guard assemblies. All equipment will be washed off-site in truck wash facilities located in Bakersfield or truck stop facilities off of I-5 or other local highways. An on-site cleaning station will only be set up to clean equipment before they enter the work area if absolutely necessary. The on-site station would be large, well-graveled, and access to additional traffic restricted. Cleaning stations would use either high pressure water or air to remove dirt and mud from equipment and vehicles and would be located away from any sensitive biological resources;

d. Implement Pesticide Use Best Management Practices. During construction and operation the project owner shall conduct pesticide management in accordance with standard Best Management Practices (BMPs). The BMPs shall include non-point source pollution control measures. The project owner shall use a licensed herbicide applicator and obtain recommendations for herbicide use from a licensed Pest Control Advisor. Use of rodenticides and herbicides in project areas shall be restricted and any herbicide use must be reviewed and authorized foruse by the CPM in consultation with the USFWS and CDFW prior to application. All uses of such compounds shall observe label and other restrictions mandated by the U.S. Environmental Protection Agency, California Department of Food and Agriculture, and other state and federal legislation. If rodent control must be conducted, only zinc phosphide shall be used and application is only allowed in the power plant buildings. Use of rodenticides and herbicides in the project area will not use chemicals and pesticides known to cause harm to non-target plants and wildlife;

e. Use only certified noxious weed-free straw, hay bales, straw waddles, and seed for erosion control and sediment barrier installations;

f. Avoid using invasive non-native species in landscaping plans and erosion control;

g. Cleared vegetation and salvaged topsoil will be stockpiled adjacent to the area from which they are stripped to eliminate the transport of soil borne noxious weed seeds, roots, or rhizomes;

h. Employing manual, mechanical, and chemical control methods as appropriate to target invasive plant species; and

i. Include information on the prevention of spreading weeds in the WEAP.

16. <u>Implement Erosion Control Measures</u>. Standard erosion control measures shall be implemented for all phases of construction and operation where sediment run-off from exposed slopes threatens to enter any identified waters of the U.S. or waters of the state. Sediment and other flow-restricting materials shall be moved to a location where they shall not be washed back into the stream. All disturbed soils and roads within the project site shall be stabilized to reduce erosion potential, both during and following construction. Areas of disturbed soils (access and staging areas) with slopes toward a drainage shall be stabilized to reduce erosion potential. These measures shall be incorporated into the final Drainage, Erosion, and Sedimentation Control Plan (DESCP) required

based on the draft DESCP (URS 2012b Attachment A116-1) under **SOILS-1**.

17. Monitor Ground Disturbing Activities Prior to Site Mobilization. If ground-disturbing activities are required prior to site mobilization, such as for geotechnical borings, grubbing or vegetation removal, ground water pump testing, or hazardous waste evaluations, the Designated Biologist or a Biological Monitor shall be present to monitor any actions that could disturb soil, vegetation, or wildlife.
18. Minimize Turbidity in Waterways. The Designated Biologist or Biological Monitor shall be present to monitor for indication of frac-outs and water turbidity during HDD activities beneath canals, or as otherwise required in the project's HDD Plan.
19. Control and Regulate Fugitive Dust. To reduce the potential for the transmission of fugitive dust the owner shall implement dust control measures **AQ-SC3, AQ-SC4, and AQ-SC2** the latter of which requires the preparation of an Air Quality Construction Mitigation Plan.

Verification: All mitigation measures and their implementation methods shall be included in the BRMIMP as described in **BIO-5** and implemented. Implementation of the measures shall be reported in the Monthly Compliance Reports by the Designated Biologist or Biological Monitor.

SAN JOAQUIN KIT FOX AND AMERICAN BADGER SURVEYS AND IMPACT AVOIDANCE MEASURES

BIO-7 Following USFWS's *Standardized Recommendations for Protection of the San Joaquin Kit Fox Prior to or During Ground Disturbance* (USFWS 2011), the project owner shall implement the following impact avoidance measures for San Joaquin kit fox and American badger:

1. Pre-construction Clearance Surveys. Each construction year or start of construction in a previously undisturbed area, the Designated Biologist shall perform a pre-construction survey for San Joaquin kit fox and American badger within all suitable habitat areas (i.e. saltbush scrub habitat, fallow agriculture lands, ruderal or barren lands, disturbed areas along canals, and all other areas not actively farmed) along linear facilities and the power plant site including a 200-foot buffer area or other CPM-approved survey buffer size based upon consultation with USFWS and CDFW . These surveys shall be conducted no less than 14 days and no more than 30 days prior to the beginning of ground disturbance and following federal survey protocol. The Designated Biologist or Biological Monitor shall systematically walk transects spaced 25 feet apart through all suitable habitat areas searching for kit fox/badger dens and sign. The status of dens (known, atypical, potential, natal/pupping) shall be determined and mapped with a GPS unit during the pre-construction surveys. All identified dens will be classified in accordance with USFWS's *Standardized Recommendations for Protection of the San Joaquin Kit Fox*

Prior to or during Ground Disturbance (USFWS 2011). The project owner shall submit a letter report summarizing the results of focused surveys including a figure showing any current den locations.

2. Den Exclusion Zones. Per USFWS 2011 impact avoidance guidelines, the project owner shall avoid dens identified during preconstruction surveys; the construction exclusion zone implemented around each kit fox den or badger den measured outward from the general cluster of den entrances. No disturbance to dens shall occur within the exclusion zone and Biological Monitors shall be present to monitor construction work closely around all potential dens and buffers. The minimum exclusion radius from construction activities is:

    - Potential and atypical den: exclusion zone of 50 feet or other CPM-approved exclusion zone based on consultation with CDFW and USFWS. Placement of 4 to 5 flagged stakes approximately 50 feet from the den entrances to identify the den location; fencing is not required.
    - Known den: exclusion zone of 100 feet with flagging or other CPM-approved exclusion zone based on consultation with CDFW and USFWS.
    - Natal/pupping den: the CDFW, USFWS to be consulted on appropriate exclusion zone distance or per the project's Biological Opinion.

3. Den Monitoring and Destruction of Unoccupied Dens. The Designated Biologist shall monitor all potential dens sites for evidence of kit fox activity. If potential kit fox dens of adequate size (generally 5 to 8 inches diameter) are found within the construction zone or within 200 feet of proposed work areas, the following den monitoring protocol shall be followed:

    a. Each potential den shall be assigned a number, marked with flagging in the field, and mapped with a GPS unit.

    b. All potential dens will be monitored for at least five consecutive days from the time of the observation to allow any resident animal to move to another den during its normal activity. Dens shall be monitored using a tracking medium and infrared camers. Tracking medium (usually gypsum powder) shall be evenly spread at the entrance to each potential den. The powder shall be inspected each morning between the hours of 0500 and 1000 for five consecutive days for tracks that might indicate kit fox or badger activity. Fresh gypsum powder shall be spread at the entrances during the monitoring phase to maintain a suitable tracking surface. In addition to tracking medium, each potential den shall be outfitted and monitored with an infrared camera station. Infrared cameras shall be checked and photos shall be downloaded daily.

After five consecutive days of negative findings of sign (tracks, scat, prey remains or matter vegetation in vicinity of den) and no kit fox or badger activity has been found on camera, the den shall be determined unoccupied and may then be excavated manually under the direction of the Designated Biologist. If the unoccupied den occurs within the 200-foot survey buffer area and not within the construction footprint, the den entrance shall be temporarily blocked with vegetation or loosely packed soil and not excavated or collapsed.

If kit fox or badger activity is observed at any point during the five-day monitoring period, the den-monitoring period shall re-start again for an additional five days. Once the Designated Biologist has determined that the potential den is not occupied by either a kit fox, badger, or other listed or special-status mammal, dens shall be fully excavated by hand, backfilled with soil, and compacted to prevent animals from entering it or using it, under the direction of the Designated Biologist. Natal or pupping dens shall not be destroyed, excavated, or disturbed until it has been determined that kit fox pups are independently foraging, are no longer dependent on the adults or family group, and all adults and pups have vacated the den. If at any point during excavation a kit fox or badger are discovered inside the den, the excavation activity shall cease immediately, USFWS, CDFW, and the CPM shall be notified, and monitoring of the den as described above shall resume.

4. <u>Other avoidance and minimization measures to be implemented during construction and operation</u> (per USFWS 2011 or more current agency San Joaquin kit fox guidance).

   a. Project-related vehicles shall observe a 20-mph speed limit on all paved roads in all non-public project areas (10-mph on dirt roads), except on county roads and state and federal highways. Off-road traffic outside of designated project areas shall be prohibited. Nighttime construction and truck deliveries shall be minimized to the extent possible and is prohibited along the carbon dioxide pipeline route; however, when it does occur, speed limits shall be reduced to 10 mph on project roadways.

   b. Any contractor or employee who is responsible for inadvertently killing or injuring a kit fox shall immediately report the incident to the Designated Biologist. If at any time an accidental death, injury, or entrapment of kit fox is discovered, the USFWS Sacramento Fish and Wildlife Office and CDFW Central Regional Office shall be notified in writing within three working days at the following location:

      Sacramento Fish and Wildlife Office

Endangered Species Division
2800 Cottage Way, Suite W2605
Sacramento, California 95825-1846
(916) 414-6620

California Department of Fish and Wildlife
Central Region
1234 East Shaw Ave.
Fresno CA 93710
(559) 243-4005

c. As described in **BIO-16**, all areas subject to temporary ground disturbances, including storage and staging areas, temporary roads, pipeline corridors, etc. shall be revegetated to promote restoration of the area to pre-project conditions. Appropriate methods and plant species used to revegetate such areas shall conform with the Revegetation Plan per **BIO-16**.

d.The Designated Biologist shall be the main point of contact source for any employee or contractor who might inadvertently kill or injure a kit fox or who finds a dead, injured or entrapped individual; the Designated Biologist and approved Biological Monitors shall be identified during the WEAP training and the Designated Biologist and list of approved Biological Monitors names and contact information shall be provided to USFWS.

e.The Designated Biologist(s) shall submit all observations of San Joaquin kit fox to CDFW's California Natural Diversity Database CNDDB within 60 calendar days of the observation and the Designated Biologist(s) shall include copies of the submitted forms with the next Monthly Compliance Report h.Reasonable effort shall be made to avoid damage and destruction of potential dens or burrows occupied by kit fox or other wildlife such as minimizing grading and disturbance to the minimal area required and minor re-location of project facility and pipeline routes.

5. <u>Compensatory Mitigation for San Joaquin Kit Fox.</u> Compensatory habitat shall be acquired for San Joaquin kit fox that meets selection criteria as mitigation for this species. Compensation lands shall be acquired as specified in **BIO-20** including requirements for the acquisition, initial habitat improvement, protection, and funding for long-term maintenance and management.

<u>Verification</u>: All San Joaquin kit fox and badger impact avoidance and minimization measures shall be incorporated into the BRMIMP as required under Condition of Certification **BIO-5.**

All kit fox/badger sign and den monitoring activities shall be reported in Monthly Compliance Reports including any copies of CNDDB reports that were submitted to CDFW within 60 days of the new sighting summarizing the results of any pre-construction clearance surveys for San Joaquin kit fox and American badger and the results of den monitoring activities. The Monthly Compliance Report shall include a map showing the location of all identified dens and exclusion zones.

Within 30 days of completing initial ground-disturbing preconstruction surveys or start of construction in a previously undisturbed area along a linear route, the project owner shall submit a letter report summarizing the results of the surveys to the CPM, CDFW, and USFWS, including a figure of potential dens and all den monitoring locations and buffers.

If a natal/pupping kit fox den is found in the construction area or within 200 feet of the proposed work areas, the Designated Biologist shall provide written notification to USFWS, CDFW, and CPM (within 24 hours of the finding).

If at any time a trapped injured, or deceased San Joaquin kit fox is discovered in the project area, the project owner shall notify the USFWS Sacramento Fish and Wildlife Office and CDFW Central Region office in writing within three working days with a notification copy to the CPM.

BLUNT-NOSED LEOPARD LIZARD TAKE AVOIDANCE AND MINIMIZATION MEASURES

BIO-8: The project owner shall implement the following as take and impact avoidance measures to blunt-nosed leopard lizard (BNLL) during construction and operation of the project.

1. Prepare a BNLL Impact Avoidance and Minimization Plan. The project owner shall prepare a BNLL Impact Avoidance and Minimization Plan outlining measures to implement during construction and operation of the project in order to avoid incidental take of this species as defined by Section 86 of the Fish and Game Code. Any modifications to the approved plan shall only take place after approval from the CPM, based on consultation with USFWS and CDFW. The plan shall discuss construction schedule details such as phasing preconstruction clearance and monitoring while taking into consideration that the power plant and linear facilities would likely be constructed in stages. In addition the plan shall include: plan purpose and goals; all construction impact avoidance measures (e.g. exclusion fencing and burrow monitoring) to ensure BNLL remain outside of the construction work areas; and long-term take avoidance measures and monitoring and reporting requirements to implement during project operation.
2. Pre-construction Surveys and Reporting. For each construction year or start of construction in a previously undisturbed area, the project owner shall conduct focused surveys for BNLL during the active period for this species following CDFW's *Approved Survey Methodology for the Blunt-nosed Leopard Lizard* (CDFG 2004). Suitable BNLL habitat areas are defined as all saltbush scrub and grassland habitat and disturbed, ruderal grassland areas that

contain the required habitat elements such as small mammal burrows, including streambeds, washes, and roads along all linear facility routes where BNLL has previously been observed. The project owner shall submit a letter report summarizing the results of focused surveys (CDFG 2004) including a figure showing any current BNLL observations.

The Designated Biologist(s) shall submit all observations of BNLL to CDFW's CNDDB within 60 calendar days of the observation and the Designated Biologist(s) shall include copies of the submitted forms with the next Monthly Compliance Report.

3. Qualifications of Surveyors. An acceptable BNLL survey crew shall consist of no more than three Level I researchers for every Level II researcher as defined in the *Approved Survey Methodology for the Blunt-nosed Leopard Lizard* (CDFG 2004). The names and affiliations of all researchers shall be recorded for each survey day.

   Level I: Researcher has demonstrated the ability to distinguish BNLL from other common lizard species that may inhabit the area;

   OR

   Level II: Researcher has demonstrated the ability to distinguish BNLL from other common lizard species that may inhabit the area and has participated in at least 50 survey days for BNLL (or 25 survey days and a BNLL identification course recognized by/acceptable to CDFW). Researcher has also made at least one confirmed field sighting of a BNLL.

4. Take Avoidance Measures. The Designated Biologist shall oversee implementation of all construction take avoidance measures outlined in the approved BNLL Impact Avoidance and Minimization Plan. The following shall be implemented during construction and incorporated into the Plan:

   a. The project owner shall conduct an initial BNLL burrow survey. Burrows that may be used by BNLL shall be avoided to the maximum extent feasible including minor re-location of project facilities including pipeline alignments.

   b. To the extent practicable and feasible, initial surface disturbance within suitable habitat and locations where BNLL have been observed before (i.e. Sites 1 through 5 along natural gas pipeline route, carbon dioxide pipeline, among others, **BIOLOGICAL RESOURCES Figure 2**), shall be scheduled during the active BNLL season (April 15 to October 15) to allow BNLL to escape.

   c. Initial surface disturbance activities that occur during the active BNLL season shall be monitored by the Designated Biologist. Subsequent to initial surface disturbance activities during the BNLL active season, Biological Monitors will not be required to be present during activities. If a BNLL is observed, it will be left alone and allowed to leave on its own and shall not be relocated.

d. In areas where BNLL have been observed or where burrows have been identified, temporary exclusion fencing shall be installed in a linear manner and shall not encircle any burrows. Fencings shall be a minimum 32-guage, 610mm aluminum sheeting, flashing, or other solid, rigid, non-climbing material and shall be staked at 2.5-meter intervals, with stakes facing the construction area. The fencing shall be buried at least 150mm (0.50 foot) below ground and extend at least 460 mm (1.5 feet) above ground. Any variance from these fence specifications requires approval from the CPM based on consultation with CDFW and USFWS. Vegetation will be trimmed as needed to prevent BNLL from climbing the exclusion fence. Once construction has completed in an area with exclusion fencing, the fencing shall be removed.

e. During the active season, areas underneath parked vehicles shall be inspected for BNLL prior to vehicle operation and if BNLL are observed under vehicles, the vehicle cannot be moved until BNLL has moved on its own.

5. <u>Compensatory Mitigation for Blunt-Nosed Leopard Lizard.</u> Compensatory habitat shall be acquired for BNLL that meets selection criteria as mitigation for this species. Compensation lands shall be acquired as specified in **BIO-20** including requirements for the acquisition, initial habitat improvement, protection, and funding for long-term maintenance and management.

<u>Verification</u>: At least 60 calendar days prior to the start of any project ground-disturbing activities, the project owner shall submit a draft BNLL Impact Avoidance and Minimization Plan to the CPM, USFWS, and CDFW for review and comments. At least 30 calendar days prior to the start of construction, the project owner shall submit a final BNLL Impact Avoidance and Minimization Plan that incorporates agency comments and input. The final plan shall be reviewed and approved by the CPM based on consultation with CDFW and USFWS. Any modifications to the final plan shall be made only after review and approval by the CPM, in consultation with USFWS and CDFW.

These blunt-nosed leopard lizard impact avoidance and minimization measures shall be incorporated into the BRMIMP as required under Condition of Certification **BIO-5**. A summary of all ongoing impact avoidance measures and results of all monitoring activities during construction and operation shall be included in the Monthly Compliance Reports along with a figure showing the location of any BNLL observations.

All BNLL observations shall be reported to the CNDDB within 60 days of the sightings with copies of the CNNDB submittal forms included in Monthly Compliance Reports.

For each construction year and/or start of construction in a previously undisturbed area along a linear facility route, the project owner shall submit a technical report to the CPM, USFWS, and CDFW, within 30 days following the completion of surveys summarizing the results of the focused BNLL survey.

SWAINSON'S HAWK IMPACT AVOIDANCE MEASURES

BIO-9 The project owner shall implement the following measures to minimize the potential for incidental take and impacts to Swainson's hawk during construction and operation of the project.

1. Prepare a Swainson's Hawk Monitoring and Mitigation Plan. The project owner shall prepare a Swainson's Hawk Monitoring and Mitigation Plan outlining measures to implement during construction and operation of the project in order to avoid incidental take of this species. Any modifications to the approved plan shall only take place after approval from the CPM, based on consultation with USFWS and CDFW. The approved plan shall discuss construction schedule details such as phasing preconstruction clearance and monitoring while taking into consideration that the power plant and linear facilities would likely be constructed in stages. In addition the plan shall include: plan purpose and goals; pre-construction surveys and construction impact avoidance and minimization measures including nest buffers; nest monitoring methods to employ in order to gauge disturbance levels to nests and occupants during construction; long-term take avoidance measures to implement during project operation; and long-term monitoring and reporting of Swainson's hawk impact avoidance measures during commercial operation.

2. Preconstruction Surveys. Prior to the start of any project-related ground disturbance activities, the project owner shall conduct focused, preconstruction surveys for Swainson's hawk nests. The goal of the nesting surveys shall be to identify the location of nest sites and to establish an adequate protective buffer zone around the nest tree. If any ground-disturbing activities are scheduled to begin during the nesting bird season (February 1 to August 31), the surveyors shall perform surveys in accordance with the following guidelines:

    a. Surveys shall cover all potential nesting within the project site and along all linear facilities including a 0.50-mile survey radius (Swainson's Hawk Technical Advisory Committee 2000) or other survey boundary approved by the CPM based on consultation with CDFW. Surveys shall be conducted from one hour before sunrise to two hours after sunrise and shall conclude by 1030 at the latest. All nest trees identified in Figure A45-2, Swainson's Hawk Observations Near the Project Area (URS 2012a) shall be subject to preconstruction surveys and any other suitable nest trees located within a 0.50-mile radius around the project site and along linear routes.

b. At least two pre-construction surveys shall be conducted, separated by a minimum 10-day interval. One of the surveys shall be conducted within a 14-day period preceding the initiation of any project-related ground disturbing activity. If more than 30 days lapses between the second nesting bird survey and the start of construction, additional survey(s) shall be performed.

3. <u>Nest Buffers from Construction Activities</u>. In accordance with CDFW's *Staff Report Regarding Mitigation for Impacts to Swainson's Hawks (Buteo swainsoni) in the Central Valley of California* (CDFG 1994), no new intensive disturbances or project-related activities which may cause nest abandonment or forced fledging shall be initiated within 0.50 mile of an active nest or other CPM-approved nest avoidance buffer size based on consultation with CDFW between March 1 to September 15 of any construction year. If construction or other project–related activities, which may cause nest abandonment or forced fledgling are necessary within the 0.50-mile buffer zone, the Designated Biologist or Biological Monitor shall monitor the nest site in accordance with the approved Swainson's Hawk Impact Avoidance and Minimization Plan.

4. <u>Compensatory Mitigation for Loss of Swainson's Hawk Foraging Habitat.</u> Compensatory habitat shall be acquired for Swainson's hawk that meets selection criteria as mitigation for this species. Compensation lands shall be acquired as specified in **BIO-20** including requirements for the acquisition, initial habitat improvement, protection, and funding for long-term maintenance and management. Lands under an existing Williamson Act contract shall not be considered suitable mitigation lands for Swainson's hawks.

<u>Verification</u>: At least 60 calendar days prior to the start of any project ground-disturbing activities, the project owner shall submit a draft Swainson's Hawk Monitoring and Mitigation Plan to the CPM and CDFW for review and comments. At least 30 calendar days prior to the start of construction, the project owner shall submit a final Swainson's Hawk Monitoring and Mitigation Plan that incorporates agency comments and input. The final plan shall be reviewed and approved by the CPM based on consultation with CDFW. Any modifications to the final plan shall be made only after review and approval by the CPM, in consultation with CDFW.

These impact avoidance and minimization measures shall be incorporated into the BRMIMP as required under Condition of Certification **BIO-5**. A summary of all ongoing impact avoidance and results of all monitoring activities during construction and operation shall be included in the Monthly Compliance Reports, including a figure showing all nests and nest monitoring locations. All Swainson's hawk observations shall be reported to the CNDDB within 60 days of the sightings with copies of the CNNDB submittal forms included in Monthly Compliance Reports.

Within 30 days following the completion of preconstruction nest surveys for Swainson's hawk, the project owner shall submit a technical report summarizing the results of the preconstruction surveys to the CPM with a copy to CDFW. If an active Swainson's hawk nest is found within the approved survey area of the project site, the Designated Biologist shall notify the CPM and CDFW in writing within two business days.

MITIGATION FOR MIGRATORY BIRD TREATY ACT AND CALIFORNIA FISH AND GAME CODE PROTECTED AVIAN SPECIES

BIO-10 The project owner shall implement the following measures in order to minimize the potential for impacts to nesting birds protected by the Migratory Bird Treaty Act and California Fish and Game Code Sections 3503 (regarding unlawful "take," possession or needless destruction of the nest or eggs of any bird), 3503.5 (regarding the "take," possession or destruction of any birds-of-prey or their nests or eggs), and 3513 (regarding unlawful "take" of any migratory nongame bird):

1. Preconstruction Nest Surveys and Construction Avoidance Buffers. For each construction year or prior to the start of construction in a new project area, the Designated Biologist and/or Biological Monitor(s) shall perform pre-construction nest surveys if any construction activities would occur anytime during the nesting season (February 1 through August 31). The Designated Biologist or Biological Monitor conducting the surveys shall be experienced bird surveyors familiar with standard nest-locating techniques such as those described in Martin and Geupel (1993). The goal of the nesting surveys shall be to identify the general location of the nest sites in order to establish a protective buffer zone around nest sites.

a. Surveys shall be conducted prior to construction and shall cover all potential nesting habitat in the project site and linear facilities, including the construction footprint and a minimum 200-foot survey buffer. Songbird nest surveys shall be conducted no earlier than one hour before sunrise and within two hours following sunrise and shall conclude by 10:30 a.m.

b. At least two pre-construction surveys shall be conducted, separated by a minimum 10-day interval. One of the surveys shall be conducted within a 14-day period preceding initiation of construction activity. Additional follow-up surveys shall be required if periods of construction inactivity exceed 30 days.

No additional measures shall be implemented if active nests are more than the following distances from the nearest work site: (a) 500 feet for raptors, or (b) 250 feet for passerine birds. The specified buffer size may be reduced on a case-by-case basis if, based on compelling biological or ecological reasoning (e.g. the biology of the bird species, concealment of the nest site by topography, land use type, vegetation, and level of project activity) and as determined by the Designated Biologist, that implementation of a specified smaller buffer distance shall still avoid project-related “take” (as defined by Fish and Game Code Section 86) of adults, juveniles, chicks, or eggs associated with a particular nest. The nests shall be continually monitored for the duration of the nesting season by the Designated Biologist or Biological Monitor unless it has been determined that the young have fledged, are no longer dependent upon parental care, or construction ends (whichever occurs first). If the nesting birds show signs of distress with a reduced buffer size during project activities, the Designated Biologist shall I contact the CPM (in consultation with CDFW and USFWS) and reinstate the recommended buffers. Buffers shall not apply to construction related traffic using existing roads that is not limited to project-specific use (i.e., county roads, highways, farm roads, etc.). Non-listed species found building nests within the standard buffer zone after specific project activities begin shall be assumed tolerant of that specific project activity and the nest will be protected by the maximum buffer practicable. However, these nests should be regularly monitored for the duration of the nesting season until the Designated Biologist or Biological Monitor has determined that the young have fledged, are no longer dependent upon parental care, or construction ends (whichever occurs first). If the nesting birds show signs of distress with a reduced buffer size during project activities, the qualified wildlife biologist shall contact the CPM (in consultation with CDFW and USFWS) and reinstate the recommended buffers.

2. Retention Pond Netting. The project owner shall cover the retention ponds, prior to any ponds becoming operational, with 1.5-inch mesh netting designed to exclude birds and other wildlife from drinking or landing on the water of the ponds. Netting with mesh sizes other than 1.5-inches may be installed if approved by the CPM in consultation with CDFW and USFWS. The netted ponds shall be monitored regularly to verify that the netting remains intact, is fulfilling its function in excluding birds and other wildlife from the ponds, and does not pose an entanglement threat to birds and other wildlife. The ponds shall include a visual deterrent in addition to the netting, and the pond shall be designed such that the netting shall never contact the water.

a. Monthly Monitoring. The Designated Biologist or Biological Monitor shall regularly survey the ponds at least once per month starting with the first month of operation of the evaporation ponds. The purpose of the surveys shall be to determine if the netted ponds are effective in excluding birds, if the nets pose an entrapment hazard to birds and wildlife, and to assess the structural integrity of the nets. The monthly survey shall be conducted in one day for a minimum of two hours following sunrise (i.e., dawn), a minimum of one hour mid-day (i.e., 1100 to 1300), and a minimum of two hours preceding sunset (i.e., dusk) in order to provide an accurate assessment of bird and wildlife use of the ponds during all seasons. Surveyors shall be experienced with bird identification and survey techniques. Operations staff at the project site shall also report finding any dead birds or other wildlife at the evaporation ponds to the Designated Biologist within one day of the detection of the carcass. The Designated Biologists shall report any bird or other wildlife deaths or entanglements within two days of the discovery to the CPM, CDFW, and USFWS.

b. Dead or Entangled Birds. If dead or entangled birds are detected, the Designated Biologist shall take immediate action to correct the source of mortality or entanglement. The Designated Biologist shall make immediate efforts to contact and consult the CPM, CDFW, and USFWS by phone and electronic communications prior to taking remedial action upon detection of the problem, but the inability to reach these parties shall not delay taking action that would, in the judgment of the Designated Biologist, prevent further mortality of birds or other wildlife at the evaporation ponds.

c. Quarterly Monitoring. If after 12 consecutive monthly site visits no bird or wildlife deaths or entanglements are detected at the evaporation ponds by or reported to the Designated Biologist, monitoring, as described in paragraph 1, can be conducted on a quarterly basis.

d. Biannual Monitoring. If after 12 consecutive quarterly site visits no bird or wildlife deaths or entanglements are detected by or reported to the Designated Biologist and with approval from the CPM, USFWS and CDFW, future surveys may be reduced to two surveys per years, during the spring nesting season and during fall migration. If approved by the CPM, USFWS and CDFW, monitoring outside the nesting season may be conducted by the Environmental Compliance Manager.

e. Modification of Monitoring Program. CDFW or USFWS may submit a request for modifications to the evaporation pond monitoring program based on information acquired during monitoring, and may also suggest adaptive management measures to remedy any problems that are detected during monitoring or modifications if bird impacts are not observed. Modifications to the evaporation pond monitoring described above and implementation of adaptive management measures shall be made only after approval from the CPM, in consultation with USFWS and CDFG.

Verification: All mitigation measures and their implementation methods shall be included in the BRMIMP as required under Condition of Certification **BIO-5**. Implementation of the measures will be reported in the Monthly Compliance Reports by the Designated Biologist.

At the end of each nesting season during each construction year, the project owner shall submit a written report documenting any variance from the standard buffers to the CPM, USFWS, and CDFW that includes the species, location, reason for the buffer reduction, the name and contact information of the Designated Biologist who authorized the buffer reduction and conducted subsequent monitoring, the reduced avoidance buffer size, duration of buffer reduction, and outcome to the nest, egg, young, and adults. The report shall also summarize the results of the pre-construction nesting bird surveyand include the time, date, and duration of the survey; identity and qualifications of the surveyor (s); and a list of species observed. If active or suspected active nests are detected during the survey, the report shall include a map or aerial photo identifying the location of the nest or suspected nest location and implemented buffer.

No less than 30 days prior to operation of the retention ponds the project owner shall provide to the CPM as-built drawings and photographs of the ponds indicating that the bird exclusion netting has been installed. For the first year of operation the Designated Biologist shall submit quarterly reports to the CPM, CDFW, and USFWS describing the dates, durations and results of site visits conducted at the evaporation ponds. Thereafter the Designated Biologist shall submit annual monitoring reports with this information. The quarterly and annual reports shall fully describe any bird or wildlife death or entanglements detected during the site visits or at any other time, and shall describe actions taken to remedy these problems. The annual report shall be submitted to the CPM, CDFW, and USFWS no later than January 31st of every year for the life of the project.

BURROWING OWL IMPACT AVOIDANCE AND MINIMIZATION MEASURES

BIO-11 The project owner shall implement the following measures to avoid and minimize impacts to burrowing owls:

1. <u>Prepare a Burrowing Owl Monitoring and Mitigation Plan</u>. The project owner shall prepare and implement a Burrowing Owl Monitoring and Mitigation Plan that incorporates the most recent mitigation guidance on this species (CDFG 2012b). Any modifications to the approved plan shall only take place after approval from the CPM based on consultation with CDFW.

   At a minimum the plan shall include the following: plan purpose and goals; a discussion of take avoidance measures including preconstruction survey methods; burrow monitoring methods; a discussion of all impact avoidance and minimization measures to employ prior to implementing passive relocation and burrow eviction as a last option; a discussion of scenarios in which passive relocation would be necessary; identify and describe suitable relocation sites; potential use of artificial burrows if passive relocation is necessary; monitoring and management of relocation sites and any installed artificial burrows; and long-term monitoring and reporting requirements during operation.

2. <u>Pre-Construction Surveys</u>. For each construction year or prior to the start of ground disturbing activities in a previously undisturbed area, the Designated Biologist or Biological Monitor(s) shall conduct focused surveys for burrowing owls no more than 30 days prior to initiation of construction activities. Surveys shall be focused exclusively on detecting burrowing owls, and shall be conducted

from two hours before sunset to one hour after or from one hour before to two hours after sunrise. The survey area shall include the proposed construction areas and a surrounding 500-foot survey buffer.

3. Implement Impact Avoidance Measures. To the extent feasible, impacts to occupied burrows will be minimized during the nesting season, from February 1 through August 31 of any given year. If an active burrowing owl burrow is detected within the construction work zones or a 500-foot survey buffer, the following avoidance and minimization measures shall be implemented:

   a. Establish Non-Disturbance Buffer. If construction commences during the burrowing owl nesting season (February 1 through August 31), either buffer zones, visual screens, or other approved measures shall be implemented and based on site-specific conditions, the results of preconstruction owl surveys, and any follow up monitoring surveys of occupied burrows. Buffer sizes shall be determined based on the time of year and level of disturbance identified in the *Staff Report on Burrowing Owl Mitigation* (CDFG 2012b). Buffer sizes shall be installed in accordance with the approved Burrowing Owl Monitoring and Mitigation Plan with a minimum buffer size of 200 meters, or other CPM-approved buffer size, during the peak nesting season. Materials used to identify non-disturbance buffers shall not preclude access or disturb access of the burrow by owls. The non-disturbance buffer shall be identified as an “Environmentally Sensitive Area” in the construction area. Signs shall be posted in English and Spanish at the fence line indicating no entry or disturbance is permitted within the fenced buffer.

   b. Monitoring: If construction activities would occur within 500 feet of any identified occupied burrows during the nesting season (February 1 – August 31) the Designated Biologist or Biological Monitor shall monitor the occupied burrow in accordance with the approved Burrowing Owl Monitoring and Mitigation Plan to determine if these activities are adversely affecting burrowing owl nesting behaviors.

4. Compensatory Mitigation for Burrowing Owl. Compensatory habitat shall be acquired for burrowing owl that meets selection criteria as mitigation for this species. Compensation lands shall be acquired as specified in **BIO-20** including requirements for the acquisition, initial habitat improvement, protection, and funding for long-term maintenance and management.

Verification: At least 60 calendar days prior to the start of any project ground-disturbing activities, the project owner shall submit a draft Burrowing Owl Monitoring and Mitigation Plan to the CPM and CDFW for review and comment. At least 30 calendar days prior to the start of construction, the project owner shall submit a final Burrowing Owl Monitoring and Mitigation Plan that incorporates agency comments and input. The final plan shall be reviewed and approved by the CPM based on consultation with CDFW. Any modifications to the final plan shall be made only after review and approval by the CPM, in consultation with CDFW.

All mitigation measures and their implementation methods shall be included in the BRMIMP as required under Condition of Certification **BIO-5**. Implementation of the measures shall be reported in the Monthly Compliance Reports by the Designated Biologist.
These impact avoidance and minimization measures shall be incorporated into the BRMIMP as required under Condition of Certification **BIO-5**. A summary of all ongoing impact avoidance and results of all monitoring activities during construction shall be included in the Monthly Compliance Reports, including a figure showing all burrows and burrow monitoring locations. All burrowing owl observations shall be reported to the CNDDB within 60 days of the sightings with copies of the CNNDB submittal forms included in Monthly Compliance Reports.

Within 30 days following the completion of preconstruction nest surveys for burrowing owl in a new construction area, the project owner shall submit a letter report summarizing the results of the preconstruction surveys to the CPM with a copy to CDFW. If an active burrowing owl occupied burrow is found within the approved survey area of the project site, the Designated Biologist shall notify the CPM and CDFW in writing within two business days.

SMALL MAMMAL RELOCATION PLAN

BIO-12 The project owner shall prepare and implement a Small Mammal Relocation Plan for listed small mammals that will outline measures to avoid mortality of Tipton kangaroo rat, San Joaquin antelope squirrel, giant kangaroo rat, and other small mammals during construction and operation of the project. Relocation activities shall not proceed until the Small Mammal Relocation Plan has been approved in writing by the CPM, in consultation with USFWS and CDFW. Once the relocation plan is approved by the CPM, it may be used for all San Joaquin antelope squirrel, Tipton kangaroo rat, and giant kangaroo rat relocation activities for the duration of the project.

The approved plan shall discuss construction schedule details such as phasing pre-activity burrow surveys and trapping efforts while taking into consideration that the power plant and linear facilities would likely be constructed in stages. In addition the plan shall include: plan purpose and goals; measures to avoid take during construction including preconstruction surveys and trapping and relocation protocols; permitting requirements for those approved to handle listed small mammals; identification of potential release sites and minimum qualifications for such sites; monitoring and reporting of small mammals at release sites; and long-term take avoidance measures during commercial operation for listed small mammals.

Verification: At least 60 calendar days prior to the start of any project ground-disturbing activities, the project owner shall submit a draft Small Mammal Relocation Plan to the CPM, CDFW, and USFWS for review and comment. At least 30 calendar days prior to the start of construction, the project owner shall submit a final Small Mammal Relocation Plan that incorporates agency comments and input. The final plan shall be reviewed and approved by the CPM based on consultation with CDFW and USFWS. Any modifications to the final plan shall be made only after review and approval by the CPM, in consultation with CDFW and USFWS.

GIANT KANGAROO RAT IMPACT AVOIDANCE MEASURES

BIO-13 The project owner shall implement the following measures prior to ground disturbing activities to avoid and minimize impacts to burrowing mammals specifically giant kangaroo rat:

1. Giant Kangaroo Rat (GKR) Precinct Avoidance. GKR precincts shall be avoided to the maximum extent practicable. If earthwork (e.g., clearing, grubbing, blading, scraping, excavating, filling) must occur within GKR precincts, these areas shall be live trapped by the Designated Biologist prior to the initiation of ground-disturbing activities to minimize direct mortality. The Biological Monitors conducting the giant kangaroo rat precinct survey must have demonstrated experience in identifying sign of this species and specifically be approved by the CPM in consultation with CDFW and USFWS prior to conducting precinct surveys in suitable habitat areas.

   Daytime transects shall be conducted at 30 to 100 foot intervals and transect width will be adjusted based on vegetation height (USFWS 2007). The purpose of this survey is to identify precinct, giant kangaroo rat presence, and small mammal burrows that will be used to aid in defining the small mammal trapping area.

2. GKR Trapping and Burrow Excavation. Following the giant kangaroo rat precinct survey and prior to construction activities beginning in a previously undisturbed suitable habitat area, the Designated Biologist shall oversee small mammal trapping and relocation in accordance with the approved Small Mammal Relocation Plan. GKR shall be trapped and relocated to the CPM-approved release site identified in the approved Small Mammal Relocation Plan. Following live-trapping activities, any potential GKR burrows present within the portion of the project site to be disturbed by earthwork (e.g., clearing, grubbing, blading, scraping, excavating, filling) shall be fully excavated by hand by the Designated Biologist to allow any remaining GKR an opportunity to escape or be captured by hand as necessary (this condition does not apply to precincts that would be disturbed only by foot traffic or rubber-tired vehicle traffic). Any GKR encountered in the excavated burrows shall be relocated to the CPM-approved release site described in the approved Small Mammal Relocation Plan. Dormant or torpid GKR encountered shall also be collected and

moved to an artificial burrow installed at the approved release site. “Soft-release” methods in cages with artificially constructed burrows shall be used at receiver sites. GKR neighbor relationships (location and distance of individual burrows relative to one another) shall be maintained when moving all or some GKR from a given precinct.

Haystacks, seed caches, and seed stores found with live-trapped GKR, or in excavated burrows, shall be relocated with the associated individual GKR, and shall be placed within the release cages and artificial burrows.

Protection of GKR Food Stores. Where temporary impacts occur that do not warrant salvage of GKR, as directed by the Small Mammal Relocation Plan, any haystacks, seed caches, or other forage stockpiled by GKR on the ground surface shall be left undisturbed to the greatest extent practicable. If avoidance is not possible, the approved GKR monitor or Designated Biologist shall implement measures to keep the food stores intact, including temporary relocation of the food stores (only in the daytime; seeds must be returned to original location for the night), cover the seeds with plywood to allow temporary vehicle or foot-traffic access, or implement other measures developed CPM in consultation with CDFW.

3. Data Collection. The Designated Biologist shall maintain a record of all giant kangaroo rats and any other common or special-status small mammals captured. The information collected for each animal includes: a) the locations (Global Positioning System [GPS] coordinates and maps) and time of capture and/or observation as well as release; b) sex; c) approximate age (adult/juvenile); d) weight; e) general condition and health, noting all visible conditions including gait and behavior, diarrhea, emaciation, salivation, hair loss, ectoparasites, and injuries; and f) ambient temperature when handled and released. A relocation summary shall be prepared and included in the Monthly Compliance Reports and shall at a minimum include an analysis of data collected, conclusions, and recommendations.

4. Notification. If a giant kangaroo rat is injured as a result of project-related activities, it shall be immediately taken to a CDFW and USFWS-approved wildlife rehabilitation or veterinary facility. The project owner shall identify the facility prior to the start of ground- or vegetation-disturbing activities in the Small Mammal Relocation Plan. The project owner shall bear any costs associated with the care or treatment of such injured giant kangaroo rat.

5. <u>Compensatory Mitigation for Giant Kangaroo Rat</u>. Compensatory habitat shall be acquired for giant kangaroo rat that meets selection criteria as mitigation for this species. Compensation lands shall be acquired as specified in **BIO-20** including requirements for the acquisition, initial habitat improvement, protection, and funding for long-term maintenance and management.

<u>Verification</u>: The project owner shall submit the resume, field experience, and qualifications of the GKR precinct surveyor at least 60 days prior to the start of any project-related ground disturbance activities occurring in GKR suitable habitat for review and approval to the CPM with copies to USFWS and CDFW.

These impact avoidance and minimization measures shall be incorporated into the BRMIMP as required under Condition of Certification **BIO-5**. A summary of all ongoing impact avoidance and results of all monitoring activities during construction shall be included in the Monthly Compliance Reports including a figure showing all small mammal burrows and trapping areas. All observations of GKR and any other special-status mammal shall be reported to the CNDDB within 60 days of the sightings with copies of the CNNDB submittal forms included in Monthly Compliance Reports.

For each construction year and/or construction phase, the project owner shall submit a final report to the CPM, CDFW, and USFWS at least 10 days prior to the start of any ground disturbing activities or construction equipment staging summarizing the results of the small mammal survey, trapping, and relocation activities. The report shall include a relocation summary including data collected during surveys and trapping for giant kangaroo rat.

If a giant kangaroo rat is injured during project-related activities, the project owner shall notify the CPM, CDFW, and USFWS immediately unless the incident occurs outside of normal business hours. In that event, CDFW, USFWS, and CPM shall be notified no later than noon on the next business day. Notification to CDFW, USFWS, and CPM shall be via telephone or email, followed by a written incident report. Notification shall include the date, time, location and circumstances of the incident and the name of the facility where the animal was taken.

TIPTON KANGAROO RAT AND SAN JOAQUIN ANTELOPE GROUND SQUIRREL IMPACT AVOIDANCE MEASURES

BIO-14 The project owner shall implement the following measures prior to ground disturbing activities to avoid and minimize impacts to burrowing mammals specifically Tipton kangaroo rat and San Joaquin antelope squirrel:

1. <u>Focused Burrow Survey</u>. In accordance with the approved Small Mammal Relocation Plan per **BIO-12** and prior to the start of ground disturbing activities within previously undisturbed suitable habitat areas (i.e. saltbush scrub habitat, non-native grassland, fallow agriculture lands, ruderal or barren lands, disturbed areas along canals, and all other areas not actively farmed) the

Designated Biologist or approved Biological Monitors shall conduct walking surveys to identify small mammal burrows that occur in the construction work zones. Daytime transects shall be conducted at 30 to 100 foot intervals and transect width will be adjusted based on vegetation height (USFWS 2007). The purpose of this survey is to identify small mammal burrows to aid in defining the small mammal trapping area.

2. Small Mammal Trapping and Relocation. Within 30 days prior to the estimated start of construction activities, the Designated Biologist and Biological Monitors shall conduct live trapping in the areas identified with small mammal burrows. The trapping protocol, trapping conditions, and relocation activities shall be performed in accordance with the approved Small Mammal Relocation Plan per **BIO-12**. San Joaquin antelope squirrels, Tipton kangaroo rats and other special-status mammals shall be trapped and relocated to the agency-approved release site only after young of the year are observed above ground and during the main activity period for San Joaquin antelope squirrel (April 1 to September 30) and the main activity period for Tipton kangaroo rat (April 1 to June 30).

   Following live trapping activities, any potential San Joaquin antelope squirrel and Tipton kangaroo rat burrows present within the portion of the project site or along project linear facilities shall be fully excavated by hand by the Designated Biologist. Any San Joaquin antelope squirrels, Tipton kangaroo rat, or other small mammals encountered in the excavated burrows during their active period shall be allowed to escape to the adjacent natural habitat or if captured shall be relocated to the CPM-approved release site. Any dormant San Joaquin antelope squirrels, Tipton kangaroo rats, or other special-status mammals encountered shall be collected and moved to an artificial burrow installed at the agency-approved release site.

3. Data Collection. The Designated Biologist shall maintain a record of all San Joaquin antelope squirrels, Tipton kangaroo rats and any other common or special-status small mammals captured. The information collected for each animal includes: a) the locations (Global Positioning System [GPS] coordinates and maps) and time of capture and/or observation as well as release; b) sex; c) approximate age (adult/juvenile); d) weight; e) general condition and health, noting all visible conditions including gait and behavior, diarrhea, emaciation, salivation, hair loss, ectoparasites, and injuries; and f) ambient temperature when handled and released. A relocation summary shall be prepared and included in the Monthly Compliance Report and shall at a minimum include an analysis of data collected, conclusions, and recommendations.

4. <u>Notification.</u> If a San Joaquin antelope squirrel or Tipton kangaroo rat is injured as a result of project-related activities, it shall be immediately taken to a CDFW and/or USFWS-approved wildlife rehabilitation or veterinary facility. The project owner shall identify the facility prior to the start of ground- or vegetation-disturbing activities in the Small Mammal Relocation Plan. The project owner shall bear any costs associated with the care or treatment of such injured San Joaquin antelope squirrel or Tipton kangaroo rat.

5. <u>Compensatory Mitigation for Tipton Kangaroo Rat and San Joaquin Antelope Ground Squirrel</u>. Compensatory habitat shall be acquired for Tipton kangaroo rat and San Joaquin antelope squirrel that meets selection criteria as mitigation for these species. Compensation lands shall be acquired as specified in **BIO-20** including requirements for the acquisition, initial habitat improvement, protection, and funding for long-term maintenance and management.

<u>Verification</u>: These impact avoidance and minimization measures shall be incorporated into the BRMIMP as required under Condition of Certification **BIO-5**. A summary of all ongoing impact avoidance and results of all monitoring activities during construction shall be included in the Monthly Compliance Reports including a figure showing all small mammal burrows and trapping areas. All observations of Tipton kangaroo rat, San Joaquin antelope squirrel and any other special-status mammal shall be reported to the CNDDB within 60 days of the sightings with copies of the CNNDB submittal forms included in Monthly Compliance Reports.

For each construction year and/or construction phase, the project owner shall submit a final pre-activity report to the CPM, CDFW, and USFWS at least 10 days prior to the start of any ground disturbing activities or construction equipment staging summarizing the results of the small mammal survey, trapping, and relocation activities. The report shall include a relocation summary including data collected during surveys and trapping for San Joaquin antelope squirrel and Tipton kangaroo rat.

If a San Joaquin antelope squirrel or Tipton kangaroo rat is injured during project-related activities, the project owner shall notify the CPM, CDFW, and USFWS immediately unless the incident occurs outside of normal business hours. In that event, CDFW, USFWS, and CPM shall be notified no later than noon on the next business day. Notification to CDFW, USFWS, and CPM shall be via telephone or email, followed by a written incident report. Notification shall include the date, time, location and circumstances of the incident and the name of the facility where the animal was taken.

GIANT GARTER SNAKE IMPACT AVOIDANCE MEASURES

BIO-15 The project owner shall implement the following measures during construction to avoid and minimize the potential for impacts to giant garter snake (GGS) that may occur in the project area.

1. Preconstruction Surveys for GGS. No more than 24 hours prior to ground disturbing activities, the Designated Biologist shall survey the work areas within potential giant garter snake habitat for giant garter snakes. Surveys of work areas shall be repeated if a lapse in construction activity of 48 hours or greater has occurred. The results of this preconstruction survey shall be reported to the CPM, USFWS, and CDFW, even if no snakes are observed (USFWS 1997, Appendix C). Suitable habitat areas to be surveyed include all linear construction rights-of-way along irrigation canal banks (i.e. processed water pipeline along West Side Canal and portion of railroad spur and natural gas pipeline along East Side Canal).
2. Biological Monitor Presence During Construction. Following completion of preconstruction survey(s), an approved Biological Monitor shall be present and monitoring during all construction activities within 200 feet of aquatic irrigation canal habitat. Prior to the start of construction along irrigation canals, the immediate construction areas shall be surveyed and cleared each construction day. The Designated Biologist will ensure that all measures related to GGS are followed and have the authority to stop construction if they are not. Any open trenches along linear facility construction routes will be inspected daily for trapped snakes

<u>Verification</u>: All mitigation measures and their implementation methods shall be included in the BRMIMP as required under Condition of Certification **BIO-5**. A summary of all ongoing impact avoidance and results of all monitoring activities during construction and operation shall be reported in the Monthly Compliance Reports.

Within 10 days following the completion of a preconstruction clearance surveys for giant garter snake or start of construction in previously undisturbed habitat, the project owner shall submit a letter report summarizing the results of the preconstruction surveys to the CPM, CDFW, and USFWS.

MITIGATION FOR WESTERN SPADEFOOT TOAD

BIO-16 The project owner shall implement the following measures to avoid and minimize impacts to western spadefoot toad.

<u>Fencing and Avoidance of Potential Breeding Areas</u>: Prior to the start of any project-related ground disturbance along a linear route in a previously undisturbed area, the Designated Biologist shall establish Environmentally Sensitive Areas (ESAs) around all identified potential spadefoot toad breeding areas that occurwithin 100 feet of project construction areas, including the single wetland depression where spadefoot toad tadpoles were found during previous biological field surveys between the West Side Canal and California Aqueduct (HEI 2009a). The locations of ESAs shall be clearly depicted on construction drawings, which shall also include a list of impact avoidance and minimization measures on the construction plans. The boundaries of the

ESAs shall be placed a minimum of 20 feet from the uphill side of the occurrence and 10 feet from the downhill side or as otherwise approved by the CPM and shall be clearly delineated in the field with temporary construction fencing and signs prohibiting movement of the fence. ESAs shall also be permanently marked (with signage or other markers) to ensure that avoided habitat areas are not inadvertently harmed during construction and operation.

<u>Verification</u>: All mitigation measures and their implementation methods shall be included in the BRMIMP as required under Condition of Certification **BIO-5**. Implementation of the above impact avoidance and minimization measures will be reported in the Monthly Compliance Reports by the Designated Biologist.

Any observations of western spadefoot toad shall be reported in Monthly Compliance Reports including any copies of CNDDB reports that were submitted to CDFW within 60 days of the new sighting.

No less than 30 days prior to the start of ground-disturbing activities and following the habitat assessment, the Designated Biologist shall establish Environmentally Sensitive Areas (ESAs) around all identified potential spadefoot toad breeding areas that occur outside and within 100 feet of project construction areas. No less than 10 days prior to the start of any project-related ground disturbing activities, the project owner shall submit grading plans and/or construction drawings to the CPM with the locations of all spadefoot toad potential breeding areas and fenced Environmentally Sensitive Areas areas.

SPECIAL-STATUS PLANT SPECIES IMPACT AVOIDANCE MEASURES

BIO-17 The project owner shall perform the following measures to avoid impacts to special-status plants during construction and operation of the project:

1. <u>Focused Botanical Surveys.</u> Prior to the start of any project-related ground disturbance in a previously undisturbed area along a linear route, the Designated Biologist and/or Biological Monitors shall conduct focused botanical surveys according to CDFW's *Protocols for Surveying and Evaluating Impacts to Special-Status Native Plant Populations and Natural Communities* (CDFG 2009). All suitable habitat areas to be directly or indirectly impacted by the project shall be surveyed prior to disturbance and at a minimum will include the entire carbon dioxide pipeline route and Sites 1 through 5 shown on **Biological Resources Figure 2** along the natural gas pipeline route including a minimum 200-foot survey buffer or other CPM-approved survey buffer. Survey results shall be submitted to the CPM, USFWS, and CDFW and will include all information contained under 'Botanical Survey Reports' identified in CDFW's field survey protocol for floristic surveys (CDFG 2009).

2. <u>Implement Construction Impact Avoidance, Minimization Measures, and Site Design Modifications</u>:

    a. Incorporate site design modifications to minimize impacts to special-status plants along the project linear routes. All identified occurrences (populations and individual plants) of CNPS List 1B and List 4 plants species shall be avoided by project construction and grading to the maximum extent feasible. The project owner shall limit the width of the work area by: adjusting the location of staging areas, lay down areas, spur roads, and transmission poles or towers; and minor adjustments to the alignment of the roads and pipelines within the constraints of linear facilities rights-of-way.

b. Establish Environmentally Sensitive Areas. The Designated Biologist shall establish Environmentally Sensitive Areas (ESAs) to protect avoided special-status plants that occur outside but within 200 feet of construction work zones. ESAs shall be clearly delineated in the field with temporary construction fencing and signage indicating construction activities are not permitted inside the ESA fencing. The locations of ESAs shall be clearly depicted on construction drawings. Areas for spoils, equipment, vehicle parking, maintenance and washing, and material storage shall be placed at least 100 feet from any ESAs.

c. The Designated Biologist shall oversee compliance with all special-status plant impact avoidance, minimization, and compensation measures described in this condition throughout construction and shall monitor for the protection of special-status plant occurrences within 200 feet of the project boundaries that will be identified and fenced as ESAs.

d. Erosion and Sediment Control Measures. Erosion and sediment control measures shall not inadvertently impact special-status plants (e.g., by using invasive or non-native plants in seed mixes, introducing pest plants through contaminated seed or straw, etc.). These measures shall be incorporated in the Drainage, Erosion, and Sedimentation Control Plan required in **SOILS-1**.

e. The Designated Biologist shall oversee and train all other Biological Monitors tasked with monitoring around plant ESAs.

<u>**Verification**</u>**:** These special-status plant impact avoidance and minimization measures shall be incorporated into the BRMIMP as required under Condition of Certification **BIO-5** and reported in Monthly Compliance Reports.

For each construction year and/or construction phase, if Kern mallow or other federally or state-listed plant species is identified during botanical surveys, the project owner shall immediately notify the CPM, USFWS's Sacramento Fish and Wildlife Office, and CDFW's Central Regional Office.

At least 60 days prior to the start of any project-related ground disturbing activities or start of construction in a previously undisturbed area along a linear route, the project owner shall submit a letter report summarizing the results of focused botanical surveys, including GPS'ed locations of all identified occupied rare plant areas. The report shall include a GPS mapping of all occupied rare plant areas, ESA locations, and installed protective fencing. The report shall include the time, date, and duration of the survey;

identity and qualifications of the surveyor (s); and a list of plant and wildlife species observed and any other information included in CDFW's botanical field survey protocol (CDFG 2009).

No less than 30 days prior to the start of any ground-disturbing activities or start of construction in a previously undisturbed area along a linear route, the Designated Biologist shall establish Environmentally Sensitive Areas (ESAs) around all identified rare plant locations that occur outside but within 200 feet of project construction areas. No less than 10 days prior to the start of any project-related ground disturbing activities, the project owner shall submit grading plans and/or construction drawings to the CPM showing the locations of all special-status plant Environmentally Sensitive Areas and fenced areas.

REVEGETATION PLAN

BIO-18 The project owner shall prepare and implement a Revegetation Plan to restore construction areas that were subject to temporary disturbance, including equipment staging areas, buried pipeline routes primarily along the carbon dioxide pipeline, and other non-farmed areas along project linear routes. The objectives of the Revegetation Plan shall be to identify areas appropriate for revegetation activities, restore wildlife habitat values, stabilize disturbed soils, minimize erosion and sedimentation impacts to soil and water resources, prevent colonization by noxious weeds and other non-native plants, and salvage native plantings and seed from project construction areas for use in revegetation.

At a minimum, the Revegetation Plan shall include: a description of the project area habitat types to be temporarily impacted; discussion of revegetation methods and goals for revegetation which takes into consideration a phased construction schedule of linear routes; performance standards and timeline for meeting success criteria; methods for salvaging seeds of annual species, storing topsoil, and preserving germplasm for use in revegetation areas and/or use of locally collected seed; methods for controlling invasive weeds and weed management measures in revegetation areas; contingency parameters if success criteria are not met; and a long-term monitoring and reporting schedule during construction and operation.

Target performance standards at the end of each annual monitoring period shall be as follows:

a. total absolute cover of all plants shall equal at least 30 percent;

b. at least 60 percent of the perennial species observed within the restored areas (relative cover) shall be locally native species that naturally occur in allscale scrub habitat; and

c. Relative cover of non-native plants within the temporarily disturbed areas shall equal or not exceed the relative cover of non-native plants in the adjacent habitats.

Verification: These measures shall be incorporated into the BRMIMP as required under Condition of Certification **BIO-5** and reported in Monthly Compliance Reports.

At least 60 calendar days prior to the start of any project ground-disturbing activities, the project owner shall submit a draft Revegetation Plan to the CPM, CDFW, and USFWS for review and comment. At least 30 calendar days prior to the start of construction, the project owner shall submit a final Revegetation Plan that incorporates agency comments and input. The final plan shall be reviewed and approved by the CPM based on consultation with CDFW and USFWS. Any modifications to the final plan shall be made only after review and approval by the CPM, in consultation with CDFW and USFWS.

As part of the Annual Compliance Report to the CPM, each year following operationand in accordance with the monitoring and reporting schedule specified in the CPM-approved Revegetation Plan, the Designated Biologist shall provide a summary of the revegetation activities for the year, a discussion of whether revegetation performance standards were met for the year, and recommendations for remedial action for the upcoming year until performance standards are met.

MITIGATION FOR STATE WATERS

BIO-19 The project owner shall finalize and implement the following measures prior to the start of any project-related ground disturbance activities in order to avoid and minimize impacts to state jurisdictional waters:

1. Finalize and implement a Horizontal Directional Drilling (HDD) Plan inclusive of a frac-out plan following the Department of Water Resources (DWR) Encroachment Permit Guidelines and application and construction drawing requirements including, but not limited to details of each crossing location; type and dimensions of pipes, joints and sleeve casings; a description of drilling mud control measures; methods to control pipeline expansion and contraction; location of shutoff valves; and location of buried aqueduct communication control cables (URS 2012b, URS 2013d).

2. Implement Streambed Impact Avoidance and Minimization Measures. The following Best Management Practices (BMPs) shall be implemented during project construction and operation to minimize indirect impacts to ephemeral drainages and irrigation canals from HDD activities in the project area:

    a. Work Period. For any work proposed in ephemeral drainages along the carbon dioxide pipeline route, the time period for completing the work within the stream zone shall be restricted to periods of low stream flow and dry weather and shall be confined to the period of May 1 to October 1. Construction activities shall be timed with awareness of precipitation forecasts and likely increases in stream flow.

Construction activities within the stream zone shall cease until all reasonable erosion control measures, inside and outside of the stream zone, have been implemented prior to all storm events. Revegetation, restoration and erosion control work is not confined to this time period.

b. No equipment shall work in the water.

c. Spoil Placement. To prevent burying, trapping, or crushing of wildlife, spoil from project construction activities shall not be placed on or near the canal banks to avoid covering rodent burrows or bank-top soil crevices

d. Heavy Equipment Confined to Existing Roads. Construction activities that occur within upland wildlife habitat will be minimized. When possible, movement of heavy equipment shall be confined to existing roadways to minimize disturbance.

e. Cover Spoil Piles. The contractor shall have readily available plastic sheeting or visquine and will cover exposed spoil piles and exposed areas to prevent these areas from losing loose soil into the stream. These covering materials shall be applied when it is evident rainy conditions threaten to erode loose soils into the stream.

f. Equipment Over Drip Pans. Stationary equipment such as motors, pumps, generators, and welders, located within or adjacent to the stream/lake shall be positioned over drip pans.

g. Check Vehicles/Equipment Daily. Any equipment or vehicles driven and/or operated within or adjacent to the ephemeral drainage shall be checked and maintained daily to prevent leaks of materials that if introduced to water could be deleterious to aquatic habitat or wildlife.

h. Control Drilling Mud. In accordance with the CPM-approved Horizontal Directional Drilling (HDD) Plan for the project, at no time shall drill cuttings, drilling mud, and/or materials or water contaminated with bentonite or any other substance deemed deleterious to fish or wildlife be allowed to enter the stream or be placed where they may be washed into the stream. Any contaminated water/materials from the drilling and/or project activities shall be pumped or placed into a holding facility and removed for proper disposal.

i. Vegetation Removal. Disturbance or removal of vegetation shall not exceed the minimum necessary to complete operations. No native trees shall be removed or damaged without prior consultation and approval of the CPM. Using hand tools (clippers, chain saw, etc.), trees may be trimmed to the extent necessary to gain access to the work sites. All cleared material/vegetation shall be removed out of the riparian/stream zone.

j. Sediment Control. Precautions to minimize turbidity/siltation shall be taken into account during project planning and implementation. This may require the placement of silt fencing, coir logs, coir rolls, straw bale dikes, or other siltation barriers so that silt and/or other deleterious materials are not allowed to pass to downstream reaches. Passage of sediment beyond the sediment barrier(s) is prohibited. If any sediment barrier fails to retain sediment, corrective measures shall be taken. The sediment barrier(s) shall be maintained in good operating condition throughout the construction period and the following rainy season. Maintenance includes, but is not limited to, removal of accumulated silt and/or replacement of damaged silt fencing, coir logs, coir rolls, and/or straw bale dikes. Products with plastic monofilament or jute netting (such as found in straw wattles/fiber rolls and some erosion control blankets) shall not be allowed. Wildlife-friendly erosion control and sediment control products that will not entangle wildlife shall be used instead. The project owner is responsible for the removal of non-biodegradable silt barriers after the disturbed areas have been stabilized with erosion control vegetation (usually after the first growing season). Upon the Designated Biologist's determination that turbidity/siltation levels resulting from project-related activities constitute a threat to aquatic life, activities associated with the turbidity/siltation shall be halted until effective CPM-approved control devices are installed or abatement procedures are initiated.

Verification: These measures shall be incorporated into the BRMIMP as required under Condition of Certification **BIO-5** and reported in each Monthly Compliance Report during project construction.

The project owner shall notify the CPM and CDFW, in writing, at least five days prior to the initiation of any project-related HDD activities under any irrigation canals in the project areas or work in jurisdictional state waters.

COMPENSATORY HABITAT MITIGATION FOR UPLAND SPECIES

BIO-20 To compensate for project impacts to covered species (San Joaquin kit fox, giant kangaroo rat, San Joaquin antelope squirrel, Tipton's kangaroo rat, and Swainson's hawk), non-covered species (blunt-nosed leopard lizard, western burrowing owl) and their habitat as indicated in the above conditions of certification (**BIO-7**, **BIO-8**, **BIO-9**, **BIO-11**, **BIO-13, and BIO-14**), the project owner shall permanently protect and perpetually manage compensatory habitat for these species.

To meet this requirement, the project owner shall provide for both the permanent protection and management of CPM-approved Habitat Management (HM) lands that meet species habitat criteria for project impacts to 773 acres of habitat for San Joaquin kit fox; 192 acres of habitat each for giant kangaroo rat, San Joaquin antelope squirrel, Tipton's kangaroo rat, burrowing owl, and blunt-nosed leopard lizard; and 571 acres of impact for Swainson's hawk foraging habitat as described below. If all or a portion of the proposed HM lands meet habitat criteria for more than one covered or non-covered species listed above and meets the approval of the CPM, these habitat mitigation acreages may be nested.

1. Cost Estimates. The CPM, afterconsultation with CDFW and USFWS, will estimate the cost of acquisition, protection, and perpetual management of the HM lands as follows and as described in Section 2 below; these estimates are used to calculate the amount of security required under this Condition of Certification:

a. Land acquisition costs estimated using local fair market current value for lands with habitat values meeting mitigation requirements;

b. Start-up costs for HM lands, including initial site protection and enhancement costs;

c. Interim management period funding; and

d. Long-term management funding estimated initially for the purpose of providing Security to ensure implementation of HM lands management.

2. Habitat Acquisition and Protection. To provide for the acquisition and perpetual protection and management of the HM lands, the project owner shall:

a. Fee Title/Conservation Easement. Acquire and transfer fee title to the HM lands or a conservation easement to the HM lands to CDFW pursuant to terms approved in writing by the CPM. Alternatively, the CPM in consultation with CDFW and USFWS may authorize a governmental entity, special district, non-profit organization, for-profit entity, person, or another entity to hold title to and manage the property provided that the entity or person is eligible to hold the lands under California law, including but not limited toGovernment Code section 65967 and Civil Code section 815.3. If CDFW does not take fee title to the HM lands, the project owner shall convey a conservation easement in a form approved by the CPM to an entity approved by the CPM. If CDFW does not hold the conservation easement, the Energy Commission shall be expressly named in the conservation easement as a third-party beneficiary. The project owner shall obtain written approval from the CPM of the grantee and the terms of any conservation easement before its execution or recordation. Any instrument conveying interest in the HM lands shall include a provision consistent with Government Code section 65967, subdivision (e) that provides for reversion of the land to the State of California or another entity designated by the CPM if it is determined the land is not being held, monitored, or managed for conservation purposes;

b. HM Lands Approval. Obtain CPM written approval of the HM lands before any acquisition or transfer of the land by submitting, at least three months before any acquisition or transfer, a formal Lands for Acquisition Proposal identifying the land to be purchased or property interest conveyed to an approved entity as mitigation for the project's impacts on covered species and non-covered species;

c. HM Lands Documentation. Provide a recent preliminary title report, initial hazardous materials survey report, and other documents required by the CPM and other agencies for review of the proposed conveyance. All documents conveying the HM lands and all conditions of title are subject to the written approval of the CPM, and, if applicable, the Wildlife Conservation Board and the Department of General Services;

d. Land Manager. Designate both an interim and long-term land manager approved by the CPM. The interim and long-term land managers may, but need not, be the same. The interim and/or long-term land managers may be the landowner or another party. Documents related to land management shall identify both the interim and long-term land managers. Any replacement of the lands manager requires CPM approval prior to the change in land owner. The project owner shall provide written notification to the CPM, CDFW, and USFWS of any subsequent changes in the land manager. If CDFW will hold fee title to the mitigation land, CDFW will also act as both the interim and long-term land manager unless otherwise specified by the CPM.

e. Start-up Activities. Provide for the implementation of start-up activities, including the initial site protection and enhancement of HM lands, once the HM lands have been approved by the CPM. Start-up activities include, at a minimum: (1) preparing a final management plan for CPM approval following consultation with CDFW and USFWS approval (see http://www.wildlife.ca.gov/habcon/conplan/mitbank/); (2) conducting a baseline biological assessment and land survey report within three months of easement recording or transfer; (3) developing and transferring geographic information systems (GIS) data if applicable; (4) establishing initial fencing; (5) conducting litter removal; (6) conducting initial habitat restoration or enhancement, if applicable; and (7) installing signage;

f. Interim Management (Initial and Capital). Provide for the interim management of the HM lands. The project owner shall ensure that the interim land manager implements the interim management of the HM lands as described in the final management plan and conservation easement approved by the CPM. The interim management period shall be a minimum of three years from the date of HM land acquisition and protection and full funding of the endowment and shall include expected management following start-up activities. Interim management period activities described in the final management plan shall include fence repair, continuing trash removal, site monitoring, and vegetation and invasive species management, among other activities determined necessary following initial assessment and approval of the HM lands by the CPM. The project owner shall include a cost estimate for interim land management activities in the security amount, which will be maintained for the three-year interim period. Upon completion of the three-year interim period, the project owner shall promptly fund the land manager's performance of the interim land management tasks outlined in the approved land management plan.

g. Reimburse State Agencies. The project owner shall reimburse CDFW or the Energy Commission for all reasonable expenses incurred by CDFW or the Energy Commission such as transaction fees, account set-up fees, administrative fees, title and documentation review and related title transactions, expenses incurred from other state agency reviews, and overhead related to transfer of HM lands to CDFW.

3. Endowment Fund. The project owner shall ensure that the HM lands are perpetually managed, maintained, and monitored by the long-term land manager in accordance with the conservation easement and the final management plan approved by the CPM by establishing a long-term management fund (endowment). The endowment must be in an amount sufficient to fund the perpetual management, maintenance, monitoring, and other activities on the HM lands consistent with the final management plan. The endowment includes the money initially deposited by the project owner and all interest, dividends, other earnings, additions and appreciation to the account. The endowment shall be held and managed pursuant to Government Code sections 65965-65968, other applicable provisions of California law, and the requirements in this Condition of Certification.

   After the interim management period, the project owner shall ensure that the designated long-term land manager implements the management and monitoring of the HM lands in perpetuity to preserve the lands' conservation values consistent with the conservation easement and in accordance with the final management plan. Such activities shall be funded through the endowment.

a. Identify an Endowment Manager. The endowment shall be held by the endowment manager, which shall be an entity eligible to hold the endowment pursuant to Government Code sections 65965-65968 and approved in writing by the CPM. The project owner shall submit to the CPM, USFWS, and CDFW a written proposal for an endowment manager along with a copy of the proposed endowment manager's certification pursuant to Government Code section 65968(e). The CPM will notify the project owner in writing of its approval or disapproval of the proposed endowment manager;

b. Calculate the Endowment Funds Deposit. After obtaining CPM written approval of the HM lands, final long-term management plan, and endowment manager, the project owner shall prepare a property analysis record (PAR) [or PAR-equivalent analysis (hereinafter "PAR")] to calculate the amount of funding necessary to ensure the long-term management of the HM lands (endowment deposit amount). The project owner shall submit to the CPM for review and approval the results of the PAR before transferring funds to the endowment manager. The CPM will consult with USFWS and CDFW during its review of the PAR.

b.1. Capitalization Rate and Fees. The project owner shall obtain the capitalization rate from the selected endowment manager for use in calculating the PAR and adjust for any additional administrative, periodic, or annual fees.

b.2.Endowment Buffers/Assumptions. The project owner shall include in PAR assumptions the following buffers for endowment establishment and use that will substantially ensure long-term viability and security of the endowment:

b.2.1. Ten Percent Contingency. A 10 percent contingency shall be added to each endowment calculation to hedge against underestimation of the fund, unanticipated expenditures, inflation, or catastrophic events.

b.2.2. Three Years Delayed Spending. The endowment shall be established assuming spending will not occur for the first three years after full funding.

b. 2.3. Non-annualized Expenses. For all large capital expenses to occur periodically but not annually such as fence replacement or well replacement, payments shall be withheld from the annual disbursement until the year of anticipated need or upon request to endowment manager and the CPM.

c. Transfer Long-term Endowment Funds. The project owner shall transfer the long-term endowment funds to the endowment manager upon CPM approval of the endowment deposit amount identified above. The approved endowment manager may pool the endowment with other endowments for the operation, management, and protection of HM lands for local populations of the covered species and non-covered species for HECA but shall maintain separate accounting for each endowment. The endowment manager shall, at all times, hold and manage the endowment in compliance with Government Code sections 65965-65968 and other applicable laws.

4. Performance Security. The project owner may proceed with project activities only after the owner has ensured funding (security) to complete any activity that has not been completed before project activities begin is available. The project owner shall provide security as follows:

   a. Security Amount. The amount of the security shall be determined based on the cost estimates identified in Section 1.0 above.

   b. Security Form. The security shall be in the form of an irrevocable letter of credit approved in advance in writing by the CMP, or another form of security approved in advance in writing by the CPM.

   c. Security Holder. The security shall be held by the Energy Commission or in a manner approved in advance in writing by the CPM after consultation with USFWS and CDFW.

   d. Security Timeline. Written verification that the security has been established shall be provided to the CPM, USFWS, and CDFW at least 30 days prior to the start of any project-related ground disturbing activities.

   e. Security Drawing. The security shall allow the CPM to draw on the principal sum if the CPM, afterconsultation with CDFW, determines that the project owner has failed to comply with the secured obligations in this Condition of Certification within the time period provided in this condition.

   f. Security Release. The security (or any portion of the security then remaining) shall be released to the project owner after the CPM has conducted an on-site inspection and received confirmation that all secured requirements have been satisfied. Confirmation shall include appropriate documentation including, but not limited to:

   - Written documentation of the acquisition of the HM lands;
   - Copies of all executed and recorded conservation easements;
   - Written confirmation from the approved endowment manager of its receipt of the full endowment deposit amount;
   - Timely submission of all required reports due prior to the release of security; and
   - Completion of start-up activities and interim management activities.

To the extent the security provided by the project owner allows partial release of the security, the CPM may authorize proportional reduction in security after completion of significant milestones, such as acquisition of approved HM lands. This condition of certification has been developed based on the listed species impact acreages specified in this condition. If following construction and the final accounting of the acreages of vegetation communities/cover types disturbed, it is determined that the project-related ground disturbance to listed species habitat exceeds these amounts, the project owner shall petition the Energy Commission for an amendment.

<u>Verification:</u> If the acquisition of HM lands required under this condition and all other activites listed in Item 1 of this Condition of Certification will not be completed prior to the start of ground-disturbing activities, the project owner shall provide written verification to the CPM, CDFW, and USFWS that the security has been established at least 30 days prior to the start of any project-related ground disturbing activities. Even if security is provided, the project owner or an approved third party must complete the required acquisition, protection, transfer of all HM lands, record any required deeds, and fund the endowment no later than 18 months from the start of project-related ground disturbing activities.

At least three months before easement recording and title transfer of the HM lands, the project owner shall submit a Formal Lands for Acquisition Proposal describing the parcels intended for purchase, including a conservation easement, baseline biological assessment, preliminary title report, land survey report and other required documents for review and approval by the CPM after consultation with CDFW and USFWS. HM lands must be approved by the CPM in writing prior to acquisition, easement recording, or title transfer.

No later than two months after the project owner transfers fee title on HM land and records the conservation easement, as determined by the date on the title, the project owner, or an approved third party, shall provide a copy of the HM land management plan for the compensation lands to the CPM for review and approval after consultation with CDFW and USFWS. The land management plan shall identify but is not limited to discussing the following: start-up habitat improvement activities, interim, and long-term management activites of the compensation lands. The land management plan shall also identify the land manager. In the case of a change in land manager of the HM lands, the project owner shall submit the change request to the CPM for approval at least 30 days prior.

The project owner shall complete and submit to the CPM, CDFW, and USFWS a PAR or PAR-like analysis no later than two months after the CPM approves the HM land management plan. The project owner must obtain approval of the PAR analysis from the CPM, after consultations with CDFW and USFWS. As determined by the approved PAR, the project owner shall fully fund the required amount for long-term maintenance and management of the HM lands by establishing a long-term management fund (endowment), no later than 30 days after the CPM approves the PAR or PAR-like analysis. Written verification shall be provided to the CPM, USFWS, and CDFW to confirm payment of the long-term maintenance and management funds.

No later than two months after the approved land management plan identifies what activities are required to provide for initial protection and habitat improvement on the compensation lands, the project owner shall pay land manager's invoices for those approved activities and provide written verification to the CPM, CDFW, and USFWS of what funds are available and how costs will be paid.

Wtihin 90 days after completion of project construction and to verify that the extent of construction disturbance does not exceed that described in this analysis, the project owner shall submit a GIS analysis using aerial photographs, at an approved scale, taken before and after construction to the CPM. The first set of aerial photographs shall reflect site conditions <u>prior</u> to any preconstruction site mobilization and construction-related ground disturbance, grading, boring, and trenching, and shall be submitted prior to initiation of such activities. The second set of aerial photographs shall be taken <u>subsequent</u> to completion of construction, and shall be submitted to the CPM no later than 90 days after completion of construction. The project owner shall also provide a final accounting of the acreages of vegetation communities/cover types present before and after construction in the construction termination report.
