The applicant proposes to construct an Integrated Gasification Combined-Cycle polygeneration project, referred to as the Hydrogen Energy California (HECA) project. HECA would use a blend of petroleum coke and coal to produce synthesis gas (syngas), which would be purified to hydrogen-rich fuel used to generate electricity. This combined cycle plant would produce from 405 to 431 gross-megawatts (MW) and provide up to 300 MW of power to the grid. The HECA site would include an integrated manufacturing complex to produce approximately 1 million tons per year of low-carbon nitrogen-based products, including urea, and urea ammonium nitrate (UAN), to be used in agricultural applications (HECA 2012e, §2.1).

---

[8] Not all flows are diverted for agricultural uses. An agreement was signed in 1999 allowing some flows to remain in the Kern River during summer months in most years for recreation purposes at the Kern River Parkway area, located in the City of Bakersfield, and for groundwater recharge (ECORP 2007).

[9] From1977 through 2006, excess flows were directed to the Aqueduct during 10 of these years. The largest volume occurred in 1983 with 750 thousand acre-feet of floodwater. In 1969, prior to construction of the Intertie, it is estimated about 227 thousand acre-feet of Kern River flow reached the Tulare Lakebed (ECORP 2007).

Other major items of HECA would include (HECA 2012e, §2.1):

- Supporting process systems – raw water treatment, wastewater treatment, air separation unit, and other plant systems; and
- Linear facilities – an electrical transmission line, a natural gas supply line, water supply pipelines (both process water and potable water), a carbon dioxide pipeline, and potentially an Industrial Railroad Spur.

Additionally, the gasification block would capture 90 percent of raw syngas carbon dioxide (3 million tons per year). Approximately 2.6 million tons per year would be transported via a 12" diameter pipeline to the Elk Hills Oil Field, approximately 3.4 miles to the south, where it would be used to facilitate carbon dioxide, enhanced oil recovery (CO_2-EOR) and resulting sequestration (storage) of the CO_2 (HECA 2012e, §2.1).

In CO_2-EOR operations, compressed CO_2 (which has the characteristics of a liquid) is injected into an oil reservoir through injection wells designed for CO_2 injection. The CO_2 flows from the injection well and dissolves in the oil. To optimize CO_2-EOR performance, a technique of alternating cycles of water injection with cycles of CO_2 injection may be used (referred to as "Water Alternating Gas" or "WAG"). The fluids produced by this process would be a mixture of hydrocarbons (oil and gas), water and CO_2, which would be processed on-site. At the surface, the recovered fluids would be transferred to a separator at the EOR Processing Facility where the oil, water, and natural gas would be separated. Separated natural gas would enter a pipeline for transport to the existing gas processing facility to combine and process with other produced gas from the field for sale to customers. The CO_2 separated from the produced natural gas would be recompressed for reinjection along with more CO_2 purchased from HECA to further optimize the CO_2-EOR process (HECA 2012e, Vol. II).

Major elements of the CO_2-EOR component are (OXY 2012f, Attach A177-2):

- CO_2 Injection and Recovery Equipment – CO_2 supply system, 13 satellite gathering stations, infield gathering and injection distribution pipelines
- Recovered CO_2 Purification and Compression – central tank battery (CTB), reinjection compression facility (RCF), CO_2 recovery plant (CRP), water treating and injection plant
- Backup CO_2 Injection Facility
- Supporting Process Systems – hazardous material management, hazardous waste management, storm water management, fire protection, control systems, utilities, project buildings/facilities, security systems
- CO_2 sequestration, monitoring, measurement, verification and closure

Although the CO_2-EOR component of the project would occur at the Elk Hills Oil Field, which is outside Energy Commission jurisdiction[10], these proposed activities are

[10] For further discussion on jurisdictional authority over the CO_2-EOR component of the project that would occur at the Elk Hills Oil Field, refer to the **Project Description** section of this **PSA/DEIS**.

considered in the **PSA/DEIS** as part of the whole of the HECA project. Therefore, CEQA assessment of impacts to soil and water resources of both HECA and CO_2-EOR component are included in this section.

Refer to the **Project Description** section of this **PSA/DEIS** for more information on HECA major features including water use, wastewater handling, and storm water handling. Additional information relevant to the soil and water resources analysis is summarized below. For a complete detailed description of the proposed project, refer to the HECA Application for Certification ([AFC] HECA 2012e) and the applicant's related supplemental material.

Construction of the proposed HECA is anticipated take 42 months to complete. The project would have a project lifespan of 25 years, and the applicant requests that commercial operation begin in September 2017 (HECA 2012e, §2.1). Initial construction of the proposed CO_2-EOR component is anticipated take about 32 months to complete and would have a project lifespan of 20 to 40 years (OXY 2012f, Attach A177-2).

Soil Disturbance and Grading

HECA Site and Laydown Areas

The existing project site topography is generally flat, but some grading would be required to provide a level area for project construction. Earthwork associated with HECA would include site grading for drainage as well as excavation for foundations and underground systems. Excavated material suitable for compaction would be stockpiled in designated onsite locations. Soil unsuitable for supporting facility foundations or pavement would be excavated and used to level open areas and to construct the earthen berms located at the north and east fence lines (HECA 2012e, §2.7.1).

Preliminary grading plans indicate approximately 850,000 cubic yards of excavated soil and 500,000 cubic yards of imported fill. Syndex Ready Mix, a commercial aggregate company located within five miles of the site in Buttonwillow, is expected to provide the imported fill material (HECA 2012r, §26). No onsite or offsite fill disposal is expected (HECA 2012e, §5.9.2.1).

Gravel and road base material would be used to help stabilize soil for temporary construction roads, laydown, parking, and work areas (HECA 2012e, §2.7). Other erosion control measures would include (HECA 2012bb, §A116):

- tracking weather conditions and maintaining soil stabilization of disturbed areas prior to and during rain events.
- arranging the construction schedule as much as practicable to leave existing vegetation undisturbed until immediately prior to grading; and
- placing temporary soil stabilization and sediment control measures as soon as possible after grading, and permanent erosion control as soon as possible after construction is complete.

At the end of construction, temporary disturbance areas would be cleaned up and restored to their pre-construction conditions (HECA 2012bb, §A116).

Linear Facilities

Construction of proposed linear facilities would include installation of approximately 32 miles total of underground pipelines, as well as construction of a transmission line and potentially an industrial railroad spur (see **Soil & Surface Water Figure 5**). Construction of the underground pipelines would consist primarily of crews performing the following typical pipeline construction activities: hauling and stringing of the pipe along the route; welding; radiographic inspection; coating of the pipe welds; trenching; lowering of the pipe into the trench; backfill of the trench; hydrostatic testing of the pipeline; purging the pipeline; and cleanup and restoration of construction areas. Grade cuts would be restored to their original contours and affected areas would be restored to their original state to minimize erosion (HECA 2012bb, §A116).

At areas where pipes would cross certain watercourses and roadways, the applicant proposes to use horizontal directional drilling (HDD) to avoid direct disturbances at these locations. HDD involves drilling from the ground surface adjacent to the area of concern, such as a stream, using a technique that guides the direction of the drill to pass under the stream and emerge on the ground surface on the opposite side without disturbing the streambed. Staging areas are required at the entry and exit points of the drill, with each “entry pit” requiring a temporary disturbance area of approximately 120 feet by 100 feet and each “exit pit” requiring an area of approximately 75 feet by 100 feet (HECA 2012bb, §A116).

Construction and installation of the electrical transmission line would follow a sequence similar to that of underground facilities, with trench excavation being replaced by augering of holes to facilitate placement of the reinforced concrete foundations for the tubular-steel transmission structures, followed by backfilling and compaction. Grade cuts would be restored to their original contours, and affected areas would be restored to their original state to minimize the potential for erosion. To the extent possible, the material excavated from trenches and auger holes would be used to backfill around the foundations and in the trenches. Additional excess material that cannot be reused along the easement corridor would be transported to another reuse area or disposed of at an offsite landfill facility (HECA 2012bb, §A116).

Construction and installation of the industrial railroad spur would follow a typical method used on similar rail projects. Work would consist of clearing and grubbing, rough grading, tract embankment fill, drainage ditches, drainage culverts, road crossings, ballast placement, track placement, and crossing signals/signs. Some existing utility relocation work is anticipated which would be performed during rough grading. BMPs would be implemented to minimize construction-related impacts on soils and agricultural lands (HECA 2012bb, §A116).

CO_2-EOR Component

Currently at the proposed site of the CO_2-EOR component, over 200 water injection wells are used as secondary phase oil recovery to inject produced water[11] from the Elk Hills oil field, “sweep” or displace oil from the reservoir, and push the oil towards a production well. The proposed CO_2-EOR component would convert many of the existing water injector wells to CO_2 injector wells for WAG. CO2 from HECA would be transported via a pipeline to the CO_2-EOR facility, at which point the CO_2 would be distributed to CO_2 injection wells placed in a well pattern designed to optimize the recovery of oil from the reservoir. For each injection well there may be three or more nearby production wells where produced fluids are pumped to the surface and then transported by pipeline in a closed loop system to a centralized collection and processing facility. The recovered fluids would be transferred to a separator at the CO_2-EOR facility where the oil and natural gas are separated. The natural gas would be combined with other produced gas from the field for sale to customers. The CO_2 would be recompressed for reinjection along with additional purchased CO_2 from HECA to further optimize the CO_2-EOR process (HECA 2012e, Vol. II).

Disturbed Areas

Construction of HECA and associated linear facilities would affect the areas listed in **Soil & Surface Water Table 2**. Soil disturbance would occur as a result of grubbing, grading, and/or excavation activities. After construction, some of these areas would be covered with impervious material (i.e. concrete foundations, asphalt pavement) and temporary construction areas would be restored to natural existing conditions.

Soil & Surface Water Table 2
Disturbed Acreage (HECA and Linear Facilities)

Project Component	Temporary Disturbance[1] (acres)	Permanent Disturbance[2] (acres)
HECA Site (453 acres) Construction time: approximately 42 months	453	453
Temporary Construction Laydown Areas (in the Controlled Area) Construction time: approximately 42 months	91	None

[11] Produced water is a term used in the oil industry to describe water that is produced when oil and gas are extracted from the ground.

Project Component	Temporary Disturbance[1] (acres)	Permanent Disturbance[2] (acres)
Electrical transmission line (approx. 2.1 miles) Temporary: 25-foot wide road, plus up to 25-foot-diameter structural base for each of 15 poles. Permanent: Up to 25-foot diameter structural base for each of 15 poles. Construction time: approximately 3 months	7.35	0.15
Natural gas pipeline (approx. 13 miles) Temporary: 50 feet wide, plus 100-foot by 100-foot metering station at the inlet. Disturbance area shared with railroad spur. Permanent: Metering station at the inlet. Construction time: approximately 6 months	47.43[3]	0.23
BVWSD well field and process water pipeline (approx. 15 miles) Temporary: 50 feet wide, plus 150-foot by 100-foot area around each of 5 wells. Permanent: areas around each of 5 wells (100 feet by 100 feet). Construction time: approximately 6 months	90.25	1.15
Potable water pipeline (approx. 1 mile) Temporary: 10 feet wide and within transmission line corridor. Permanent: None. Construction time: approximately 3 months	Included with transmission line[4]	None
Railroad spur (Single track railroad approx. 5.3 miles) Temporary: 75 feet wide, plus 3 acres of laydown area. Permanent: 60 feet wide. Construction time: approximately 5 months	51	38.4

Project Component	Temporary Disturbance[1] (acres)	Permanent Disturbance[2] (acres)
PG&E Switching Station (4 acres) Construction time: “a few months”	4	4
OEHI Carbon dioxide pipeline[5] (approx. 3.4 miles) Temporary: 80 feet wide, plus 2 entry pits (120-foot by 100-foot each) and 2 exit pits (75-foot by 100-foot each) for HDD, plus two 50-foot by 50-foot valve box areas. Permanent: two 50-foot by 50-foot valve box areas. Construction time: approximately 6 months	29	0.11
Total	773	497

Sources: HECA 2013u, §A211; HECA 2012e, §5.14

Notes:

1. Temporary disturbance area is the total area disturbed during construction.
2. Permanent disturbance area is the disturbed/developed area that remains after construction.
3. The temporary disturbance area along the portion of the natural gas linear that follows the railroad spur from the project site to the interconnection of the railroad with the existing San Joaquin Valley Railroad line is included in the temporary disturbance area for the railroad spur.
4. The potable water pipeline temporary disturbance area is included in the temporary disturbance area for the electrical transmission line.
5. Sources: HECA 2012e, App A-2; HECA 2012s, §A59

The location of the proposed CO_2-EOR component is heavily industrial with large areas of significant disturbance. Proposed facilities include: CO_2-EOR Processing Facility, 13 Satellite Stations, new injection and production wells, new water distribution lines, and pipelines for producing and injection lines (see **Soil & Surface Water Figure 6**). A substantial portion of the CO_2-EOR component would utilize these existing disturbed acreages, well sites and pipeline alignments, however additional pipelines, satellites, and well sites would be required (HECA 2012e, Vol. II, OXY 2012f, Attach A177-2).

- Four new buildings for the CO_2-EOR component: administration/control building, maintenance/warehouse building, and two compressor shelters
- The estimated total length of all new pipelines is 652 miles, much of which will be located in existing pipeline corridors that are sited on disturbed acreage. Disturbances would be minimized due to multiple pipelines being bundled when practical and some types of pipelines being installed using pipe-rack support located above ground.
- The current estimated number of producing and injection wells is approximately 720 (309 injection and 411 production wells). Existing wells would be used for 570 of the wells. The remaining 150 wells would be new installations.
- **Soil & Surface Water Table 3** shows the total estimated disturbances from the various project components.

Soil & Surface Water Table 3
Disturbed Acreage (CO_2-EOR Component)

Project Component	Temporary Disturbance (acres)	Permanent Disturbance (acres)
CO_2-EOR Processing Facility and Central Tank Battery	-	101.8
CO_2-EOR Satellite Stations (2.6 acres for each of 13 stations)	-	33.8
New Well Installations (0.84 acres for each of 150 new wells)	-	126
Buried Pipelines (approx. 260.5 miles)	1448	None

Source: HECA 2012e, Vol. II

Different areas within the CO_2-EOR component site would be disturbed at different times during the 20 year construction phase of the proposed project. The CTB, which is the primary oil/water separation system for the CO_2-EOR process, would be designed based on two units operating at a maximum design capacity of 50 percent. One unit would be installed initially. The second unit will be installed when liquid production increases above 50 percent of maximum design capacity for the first unit (OXY 2012f, Attach A177-2).

In the initial years of CO_2-EOR operations, the average CO_2 content in the produced gas is relatively low. As a result, only the RCF equipment would be required to process the lower quantities of CO_2 for approximately the first 4 years of production. When CO_2 injected in the reservoir reaches the production wells in larger quantities, “breakthrough” has occurred. At this point, the CRP will be constructed to recover the larger quantities of CO_2. Both RCF and CRP operate at partial load until peak gas rate is reached approximately 6 years later (OXY 2012f, Attach A177-2).

Three of the proposed 13 Satellite Gathering Stations would be constructed initially, which would be sufficient to accommodate CO_2 volumes provided by HECA. Installation of systems would start in the eastern portion of the CO_2-EOR site, then the other ten systems would be added over time and progress westerly as reservoir development evolves. Approximately 10 to 12 years after startup, injection systems will be installed in the northwest area (OXY 2012f, Attach A177-2).

Storm Water and Drainage

HECA Site and Laydown Areas

The proposed HECA site is within agricultural fields with relatively flat topography and roughly 1-percent grade. During rain events, storm water that does not soak into the ground runs generally from east to west across the project site. Surface water runoff in the area is intersected directly along various paved roads, levees, and irrigation ditches located within and surrounding the site (HECA 2012bb, §A116).

The HECA site would require earthwork movement to form level building pads for the various HECA process areas and associated facilities. All existing irrigation ditches within the project site would be abandoned and filled in to meet design elevations. **Soil & Surface Water Figure 7** shows the project's major components. They would be placed on concrete pads and grouped into different areas as follows:

- the main plant area that includes the power and gasification blocks, acid gas removal (AGR), fertilizer complex, water treatment, and associated cooling towers;
- the ammonia and methanol storage area;
- the air separation unit (ASU) and associated cooling tower;
- the remote solids handling area; and
- the administration complex.

The completed HECA facility would increase the site's impervious area from the current three percent to a total of 29 percent of the entire 453 acres, consequently increasing the amount of storm water runoff during rain events (HECA 2012bb, §A116).

Storm water runoff would be directed to one of the onsite retention basins or sumps designed to prevent onsite storm water from leaving the site. Additionally, the potentially polluted contact[12] storm water would be completely separated from non-contact storm water runoff. Runoff would be managed as follows (HECA 2012bb, §A116):

- Potentially contaminated storm water runoff from the ASU and main plant areas would be collected and routed to retention basins with an impermeable liner. Water would be tested to determine an appropriate destination for reuse. Depending on the water quality, it may be used for cooling tower makeup, used for gasifier slurry water makeup, or disposed in one of the zero liquid discharge (ZLD) systems. (Further description of ZLD is found in the "Wastewater" subheading below.)
- Storm water that may be contaminated with oil would be separately collected then routed to an oil/water separator, and the separated water would be either reused in the facility or processed in a ZLD system.

[12] Contact runoff refers to storm water in contact with exposed polluted or hazardous materials and/or surfaces that can potentially result in contaminated runoff (containing trace oil, chemicals, metals, toxic substances, or other materials).

- Runoff in the AGR unit would be collected in a separate lined retention basin, dedicated for AGR storm water runoff. This isolated basin would also contain any potentially contaminated water that could result in the event of a methanol spill.
- Storm water runoff from chemical and oil storage areas would be held within the associated secondary containment. The captured water would be tested later then, based on the results, routed to an oil/water separator or to a retention basin.
- Storm water within the process plant area where solids are present (e.g., coal, petcoke, or gasification solids) would be collected and conveyed to the solids handling water collection facility. The collection facility would be constructed of concrete and would provide for mobile equipment access to remove accumulated solids. Water that accumulates within the collection facility would be processed in the ZLD system at the wastewater treatment plant.
- Storm water from remote solids handling areas, such as the feedstock unloading and the crusher station, would be collected in solids drain sumps for settlement, testing, reuse, and/or treatment as appropriate.
- Non-contact storm water runoff from administration complex and areas outside the main plant areas would be routed to storm water retention basins to allow sediment to settle. The water would be filtered and reused as cooling tower makeup water. If this collected storm water is determined unsuitable for cooling tower use, then it would be reused in the slurry preparation area or disposed of in one of the ZLD systems.
- Existing drainage patterns of storm water outside the site boundary would remain undisturbed. Offsite runoff would follow existing drainage patterns to convey flow around the project site. No runoff from outside the site boundary would flow onto the site.

Prior to construction, the applicant would prepare a Storm Water Pollution Prevention Plan (SWPPP) to control storm water and soil erosion during the facility's construction using best management practices (BMPs)[13]. Similarly for the facility's operation, a Storm Water Management Plan with a corresponding SWPPP would be developed to manage storm water and prevent soil erosion through the life of the project (HECA 2012bb, §A116).

Linear Facilities

During construction of linear facilities, measures to avoid or reduce storm water impacts include (HECA 2012bb, §A116):

- Avoiding sensitive habitats by developing construction exclusion zones and silt fencing in sensitive areas;

[13] Storm water and soil erosion BMPs are methods that have been determined to be the most effective, practical means of preventing or reducing pollution from nonpoint sources. BMPs can be classified as "structural" (i.e., devices installed or constructed on a site) or "non-structural" (procedures, such as modified landscaping practices). There are a variety of BMPs available, depending on pollutant removal capabilities.

- Avoiding wetlands and water courses where possible by establishing a distance of at least 10 feet between construction activities and these areas; and
- Preventing flows from work areas into surrounding water systems by installing physical barriers and other BMPs during construction.

At the end of construction, temporary disturbance areas would be cleaned up and restored to their pre-construction conditions (HECA 2012bb, §A116).

CO_2-EOR Component

During construction activities, clean storm water runoff from the site would be routed to an onsite storm water retention basin. A project-specific construction storm water pollution prevention plan (SWPPP) would be developed prior to construction. Storm water runoff at the CO_2-EOR component would be managed using BMPs, Rainfall Erosivity Waiver, or Notice of Intent (NOI) coverage under California Stormwater Construction General Permit, as appropriate. Construction project site storm water runoff in non-process areas but within the main plant area would be routed to a retention basin. Retention basins and storm water collection/conveyance systems would be designed in accordance with the Kern County Development Standards (OXY 2012f, Attach A177-2).

Initial plant construction would include the RCF, one unit of the CTB, supporting buildings/structures, and three Satellite Stations (with corresponding wells and piping).

After initial plant construction is complete, construction activities would continue to expand the CO_2-EOR processing facility and oil field with additional Satellite Stations.

All construction activities would continue to be subject to the project-specific construction SWPPP. Storm water from non-process areas outside the main plant area but within the CO_2-EOR component site is expected to reflect natural drainage conditions. Runoff from these areas follows natural drainage patterns of the Elk Hills Oil Field (OXY 2012f, Attach A177-2).

Project Water Use

For a detailed water use discussion of HECA and the CO_2-EOR component, refer to the **Water Supply** section of this **PSA/DEIS**.

Wastewater Management

HECA: Industrial

The primary sources of the project's wastewater would be from cooling tower blowdown, raw water treatment, process condensate wastewater from the gasifier, the sour water stripper, the AGR unit, and the Urea Plant. Process wastewater would be treated on-site and recycled to the cooling towers as make-up water. Cooling tower blowdown would also be treated on-site to produce demineralized and utility water. The reject from the cooling tower blowdown treatment plant would be sent to a zero liquid discharge (ZLD) system. The ZLD unit produces both high purity water that gets treated and recovered for further use within the plant and a solid salt cake. The ZLD solids would be disposed of at an approved off-site facility (HECA 2012bb, §A116). See the **Waste Management** section of this **PSA/DEIS** of this document for further analysis of the ZLD waste and disposal mitigation.

HECA: Sanitary Waste

No municipal sanitary sewer system is available in the vicinity of the project site. Sanitary wastewater from restrooms, showers, and kitchens would be disposed to a private onsite sewage disposal system consisting of a conventional septic tank and leach field (HECA 2012bb, §A116).

CO_2-EOR Component

All water to be injected would be produced water from the Elk Hills Oil Field, which would be treated in-field to remove trace oil and reinjected (OXY 2012e). The Satellite Gathering Stations would provide primary separation of the oil/water and gas from the production well stream. After separation, the gas and oil/water would flow separately via the infield gathering lines to the main process units for further processing. The liquid would flow to the CTB where the oil and water would be separated. The oil would be pumped to the existing oil shipment facility for export and sale. Produced water would then be treated at the water treatment portion of the CTB to remove oil, solids and other contaminants. It would then be pressurized in the injection pumps and sent to the Satellites Gathering Stations for reinjection. All produced water would be reused in the reinjection process (OXY 2012f, Attach A177-2).

Because no municipal sanitary sewer system is available in the vicinity of the project site, sanitary wastewater during construction would use portable chemical toilets. A sanitary waste contractor would pump and dispose the sanitary waste offsite (OXY 2012f, Attach A177-2). After permanent onsite facilities are constructed, sanitary waste would be disposed to an onsite sewage disposal system consisting of a conventional septic tank (OXY 2012f, Attach A177-4).

Contaminated Soil and Groundwater

HECA

The applicant conducted a Phase I Environmental Site Investigation for the proposed HECA site in 2009. Two Recognized Environmental Concerns (RECs) were identified on site. A standpipe, which may be associated with an underground storage tank (UST), was observed at the northwest corner of the site. Records also indicate that other USTs may be present either on or adjacent to the project site (HECA 2012e, App. L).

The Port Organic Products, LTD (PO) fertilizer manufacturing plant is located in the northwest corner of Section 10, Township 30 South, Range 24 East, directly adjacent to the propped project site. Approximately 0.8 acres of the PO facility lies within the HECA property boundary. The PO facility contains no solid waste storage; historically PO hired a contractor to transport solid waste offsite (HECA 2012e, App. L).

The PO facility historically discharged 500 to 750 gallons per day of manufacturing liquid to an onsite drainage ditch, located at the east side of the facility. The Phase I investigation recommends that this discharge be investigated to evaluate its impact to the environment (HECA 2012e, App. L).

The PO facility contained USTs in the past and may still contain USTs, as indicated in the Phase I assessment. The site has a long history of violations related to hazardous materials storage. The Kern County Environmental Health Services Department (KCEHSD) issued multiple Notices of Violation (NOVs) to PO within the last ten years. On January 31, 2009, PO's lease of the property expired. The status of site cleanup and the extent of soil contamination are still under investigation.

CO_2-EOR Component

After the sale of the Elk Hills Oil Field to OEHI, the California Department of Toxic Substances Control (DTSC) completed a Resource Conservation and Recovery Act (RCRA) Facility Assessment of the oil field in 1998. The Department of Energy (DOE) agreed to head up an environmental and human health risk assessment of the entire site with remediation to address the effects of past practices at the site. DOE and DTSC signed a Corrective Action Consent Agreement to complete the work for the assessment of 131 Areas of Concern (AOCs), which consists of both small and large areas of contamination. The work was stalled for seven years. In December 2011 and early 2012, DOE representatives submitted numerous Pre-Decisional Project Approach documents. The documents include an "overview of the planned approach to achieve site closure" for each of the 131 AOCs (HECA 2012s, §A121). For further discussion of potentially contaminated soil at the CO_2-EOR component, refer to the **Waste Management** section of this **PSA/DEIS**.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

This section provides an evaluation of the expected direct, indirect, and cumulative impacts to soil and water resources that could be caused by construction, operation, and maintenance of HECA. Staff's analysis consists of a description of the potentially significant impact, gathering data related to construction and operation of the project, then reaching a conclusion to determine whether or not the project presents a potentially significant impact. If staff determines there is a significant impact, then staff evaluates the applicants' proposed mitigation for sufficiency and staff may or may not recommend additional or entirely different mitigation measures that are potentially more effective than those proposed by the applicant. Mitigation is designed to reduce the effects of potentially significant HECA impacts to a level that is less than significant. The determination of significance for potential impacts to soil and water resources is discussed below.

METHOD FOR DETERMINING SIGNIFICANCE OF IMPACTS

This document analyzes the project's impacts pursuant to both the National Environmental Policy Act (NEPA) and CEQA. The two statutes are similar in their requirements concerning analysis of a project's impacts. Therefore, unless otherwise noted, staff's use of, and reference to, CEQA criteria and guidelines also encompasses and satisfies NEPA requirements for this environmental document.

This section provides an evaluation of the expected direct, indirect, and cumulative impacts to soil and water resources that would be caused by construction, operation, and maintenance of the project. Staff's analysis consists of a description of the potentially significant impact, gathering data related to construction and operation of the project, then reaching a conclusion to determine whether or not the project presents a potentially significant impact. If mitigation is warranted, staff provides a summary of the applicant's proposed mitigation and a discussion of the adequacy of the proposed mitigation. If necessary, staff presents additional or alternative mitigation measures and refers to specific conditions of certification related to a potential impact and the required mitigation. Mitigation is designed to reduce the effects of potential significant project impacts to a level that is less than significant.

Impacts leading to soil erosion or depletion or degradation of water resources, including beneficial uses, are among those staff believes could be most potentially significant soil and water resource issues associated with the proposed project. The determination of significance for these issues is discussed below.

SOIL RESOURCES

Staff evaluated the potential impacts to soil resources including the effects of construction and operation activities that could result in erosion and downstream transportation of soils and the potential contamination of soil and water resources. There are extensive regulatory programs in effect designed to prevent or minimize these types of impacts. These programs are effective, and absent unusual circumstances, an applicant's ability to identify and implement Best Management Practices (BMPs) to prevent erosion or contamination is sufficient to ensure that these impacts would be less than significant. The LORS and policies presented in **Soil & Surface Water Table 1** were used to determine the significance of project impacts with respect to CEQA.

WATER RESOURCES

Staff evaluated the potential of the project's proposed water use to cause a substantial depletion or degradation of groundwater resources, including beneficial uses. Staff considered compliance with the LORS and policies presented in **Soil & Surface Water Table 1** and whether there would be a significant impact under CEQA.

To evaluate if significant CEQA impacts to soil or water resources would occur, the following questions were addressed. Where a potentially significant impact was identified, staff or the applicant proposed mitigation to ensure the impacts would be less than significant.

a. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner which would result in flooding or substantial erosion or siltation on or offsite?

b. Would the project create or contribute runoff water that would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of polluted runoff?

c. Would the project place housing within a 100-year flood hazard area as mapped on the federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map?

d. Would the project place within a 100-year flood hazard area structures that would impede or redirect flood flows?

e. Would the project expose people or structures to a significant risk or loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam?

f. Would the project result in substantial soil erosion or the loss of topsoil?

g. Would the project violate any water quality standards or waste discharge requirements?

h. Would the project cause substantial degradation to surface water or groundwater quality?

DIRECT IMPACTS

Soil Erosion Due to Water and Wind

Erosion during Construction

Soil losses would be created by construction and grading activities that would expose and disturb the soil and leave soil particles vulnerable to detachment by wind and water. Soil erosion results in the loss of topsoil and increases in sediment loading to nearby water resources. In the absence of proper BMPs, earthwork could cause significant fugitive dust and erosion.

The magnitude, extent, and duration of those impacts would depend on several factors, including weather patterns in the vicinity of the HECA site, the types of soil that could be affected, and the method, duration, and time of year of construction activities. Prolonged periods of precipitation, or high intensity and short duration runoff events coupled with earth disturbance activities could result in accelerated onsite erosion. In addition, high winds during grading and excavation activities could cause wind borne erosion leading to increased particulate emissions that adversely impact air quality. The implementation of appropriate erosion control measures would help conserve soil resources, maintain water quality, prevent accelerated soil loss, and protect air quality.

HECA Site and Laydown Areas

Construction of HECA is scheduled to last 42 months (HECA 2012e, §2.7.1). The potential for erosion by water during construction is expected to increase as a result of loss of vegetative cover and increased local sediment transport through creation of localized gullies and rills on newly graded areas. The applicant submitted a Draft Drainage, Erosion, and Sedimentation Control Plan ([DESCP] HECA 2012bb, §A116) that lists standard BMPs applicable to HECA construction activities along with a Conceptual Erosion Control Plan that show locations of specific BMPs at the proposed project site and the adjacent temporary construction laydown area. In addition, the DESCP identifies specific measures to reduce erosion including:

- tracking weather conditions and maintaining soil stabilization of disturbed areas prior to and during rain events.
- arranging the construction schedule as much as practicable to leave existing vegetation undisturbed until immediately prior to grading; and
- placing temporary soil stabilization and sediment control measures as soon as possible after grading, and permanent erosion control as soon as possible after construction is complete.

At the end of construction, temporary disturbance areas would be cleaned up and restored to their pre-construction conditions (HECA 2012bb, §A116).

Staff concurs with the applicant that soil types at the proposed HECA site fall under Hydrologic Soil Group C, having low infiltration with moderate to high runoff, and Wind Erodibility Group 7, having a low potential for wind erosion. Staff reviewed the Draft DESCP and agrees that BMPs during construction would reduce or avoid impacts to soil from erosion. To protect surface waters, standardized storm water and soil erosion Best Management Practices (BMPs)[14] have been determined by the SWRCB and RWQCBs to be the most effective, practical means of preventing or reducing pollution from nonpoint sources. The conceptual plans for erosion control during construction appear reasonable, but as project plans approach final design stages any additional elements should be incorporated into the final DESCP as required in Condition of Certification **SOILS-1**.

Staff believes that compliance with an approved DESCP in accordance with Condition of Certification **SOILS-1** would reduce the impacts of soil erosion during construction. Staff believes the applicant should be required to comply with Condition of Certification **SOILS-1** which would require the applicant to identify the specific BMPs that would be used in the Final DESCP for staff's approval. In addition, the project activities require that it be covered under the federal General Construction Permit (SWRCB Order No. 2009-0009-DWQ), which would be issued by the State Water Resources Control Board (SWRCB) prior to construction. To ensure compliance with this order, staff proposes Condition of Certification **SOILS-2** which requires the applicant to implement a construction Storm Water Pollution Prevention Plan (SWPPP). The SWPPP would specify BMPs that would prevent all construction pollutants including erosion products from contacting storm water, eliminate or reduce non-storm water discharges to waters

[14] BMPs can be classified as "structural" (i.e., devices installed or constructed on a site) or "non-structural" (procedures, such as modified landscaping practices). There are a variety of BMPs available, depending on pollutant removal capabilities.

of the United States, and provide for inspection and monitoring of BMPs. Also, Conditions of Certification in the **Air Quality** section of this **PSA/DEIS** require a construction mitigation plan to prevent significant impacts from fugitive dust and wind erosion during construction. With implementation of BMPs and associated monitoring activities included in the approved DESCP and SWPPP, impacts on soil erosion would be expected to be less than significant during construction of the proposed HECA site.

Linear Facilities

Construction of proposed linear facilities would include installation of approximately 32 miles total of underground pipelines, as well as construction of a transmission line and an industrial railroad spur. Soil disturbance required for linear facilities would account for about 35 percent of total soil disturbance during construction, spanning across a number of different soil types (see **Soil & Surface Water Figure 8**). The runoff potential, water erosion hazard, and wind erosion hazard are shown below in **Soil & Surface Water Table 4**.

Soil & Surface Water Table 4
Soils Characteristics at Linear Facilities

Linear Facility	Temporary Disturbance (acres)	Runoff Potential	Water Erosion	Wind Erosion
Electrical transmission line	7.35	high	moderate	low
Natural gas pipeline	47.43	very high to very low	low to high	low to high
BVWSD well field and process water pipeline	90.25	high	moderate	low
Potable water pipeline	Included with transmission line	high	moderate	low
Railroad spur (single track railroad approx. 5.3 miles)	51	high	moderate	low
PG&E switching station	4	high	moderate	low
OEHI carbon dioxide pipeline	29	negligible to high	moderate	low to high
OEHI EOR Processing Facility	63.79	medium	moderate	somewhat low

Sources: HECA 2013u, §A211; U.S. Dept of Agriculture: http://websoilsurvey.nrcs.usda.gov

Activities such as clearing vegetation, excavation, and vehicle travel would present the highest potential for erosion. The proposed route of the railroad spur crosses one existing irrigation canal (East Side Canal) managed by BVWSD. The applicant states that they would work with BVWSD to engineer an appropriate canal crossing and secure the appropriate approvals. For pipeline construction, the applicant proposes a number of construction BMPs to reduce impacts to soil erosion such as:

- avoid sensitive habitats and species during construction by developing construction exclusion zones and silt fencing in sensitive areas
- provide worker environmental awareness training for all construction personnel
- general avoidance of wetland/stream impacts
- revegetation and restoration of disturbed areas
- implement specific BMPs for construction activities near sensitive areas, as described below.

Horizontal Directional Drilling Activities

Horizontal Directional Drilling (HDD) is used to avoid disturbance of sensitive areas such as water courses and wetlands. However, potential water quality impacts are associated with HDD. Those potential impacts include occasional unintended fracturing (frac-outs) of the ground above the drill resulting in a pathway through which drilling mud discharges onto the ground surface or streambed. Although generally not toxic, the drilling mud can cause turbidity impacts or coat streambed surfaces to the detriment of aquatic life. Frac-outs can sometimes be difficult to detect, particularly in streams with flowing water (See the **Biological Resources** section of this **PSA/DEIS** for further discussion on frac-outs in relation to biological resources).

The Draft DESCP states that when a proposed linear facility route crosses Interstate 5, Highway 58 and the adjacent RailAmerica railroad line, the East Side Canal, California Aqueduct, Kern River Flood Control Channel, or the West Side Canal, the pipeline may be installed under these features using HDD. The applicant has to date identified that HDD would be used to pass the CO_2 pipeline under the Outlet Canal, the Kern River Flood Control Channel (KRFCC), and the California Aqueduct (Aqueduct), as shown on **Soil & Surface Water Figure 9**. In addition, an assessment of the crossing methods to use (conventional open trenching or HDD) would be made for all water bodies, such as other irrigation canals along the pipeline route.

The Draft DESCP includes precautions that would be implemented to prevent or reduce potential damage caused by HDD activities to nearby features and the environment. Proposed BMPs include:

- conducting tunneling activities outside of wetland and riparian areas
- performing work during dry months
- preparing and implementing a Frac-Out Contingency Plan
- maintaining an on-call vacuum truck in case a spill, seep, or frac-out occurs

The depth of HDD under the water bodies would comply with all applicable federal and state regulations. Specific requirements imposed by DWR regarding the use of HDD within the right-of-way of the Aqueduct would be implemented to help protect the Aqueduct from potential damage. These requirements include: an encroachment permit from DWR, a site-specific geotechnical report, and detailed drawings to show that materials and activities meet DWR regulations and standards. The Draft DESCP lists proposed BMPs for HDD activities including:

- silt fencing around drill sites at the entry/exit pits
- energy dissipation devices for discharging water from hydrostatic testing of the pipeline
- selecting drilling fluids for environmental compatibility
- removing spent fluids from the areas immediately adjacent to water bodies
- erosion control measures to prevent runoff

Trenching Across Watercourses

Water course crossings where HDD would not be used would instead be crossed by traditional open trench methods. Potential construction-related impacts of an open trench crossing a watercourse include:

- increased sediment delivery to the water flow through disturbance of the channel bed and banks during construction;
- destabilization of the channel bed and banks resulting in long-term erosion; and
- introduction of foreign contaminants through the use of heavy machinery in the channel.

The applicant proposes in the Draft DESCP to implement practices to reduce impact when crossing watercourses including:

- when feasible, crossing canals using dry-ditch techniques when the canal is dry
- if water is present at the time of crossing a canal, evaluating individual sites to determine if conventional opencut, flume variation of open-cut, or dam and pump variation of open-cut would be used
- limiting the amount of vegetation cleared between the waterbody and the work area and minimize the amount of extra work space near canal crossings to the greatest extent possible
- restoring canals and banks to preconstruction contours or to a stable angle of repose

Staff reviewed the Draft DESCP and agrees that proposed measures would reduce impacts to soil from erosion. However, staff recommends compliance with Condition of Certification **SOILS-1** that requires the applicant to show all locations of HDD activities in the final DESCP, rather than only stating possible locations. This way, staff can verify the proximity of potential resources at and in the vicinity of HDD activities. Staff asks the applicant to provide additional information, as specified in the "Outstanding Information" under the **Staff Conclusions** heading below.

Also, Condition of Certification **BIO-16** requires an approved HDD Plan, including proposed BMPs around entrance/exit pits and a frac-out contingency plan to ensure HDD activities would not significantly impact biological resources. With implementation of these Conditions of Certification, impacts on soil would be expected to be less than significant during construction of linear facilities of HECA. Condition of Certification **SOILS-3** would ensure that the applicant meets encroachment requirements where linear facilities cross features owned by the other agencies, such as Department of Water Resources, the Central Valley Flood Protection Board, Buena Vista Water Storage District, Caltrans, and Kern County.

CO_2-EOR Component

Initial construction of the CO_2-EOR component is expected to take about two years, which includes Phase 1 of the CO_2-EOR processing facility and three Satellite Gathering Stations (OXY 2012f, Attach A177-2). These activities are subject to federal, state, and local requirements that would work together to reduce the amount of potential soil erosion during construction activities:

- Federal Clean Water Act (enforced by the State Water Resources Control Board) through a Construction General Permit
- San Joaquin Valley Air Pollution Control District's Rule 8021 to reduce fugitive dust emissions
- Kern County grading and drainage ordinances

Mitigation measures proposed by OEHI include (HECA 2012e, Vol. II):

- All disturbed areas, including storage piles, which are not being actively utilized for construction purposes, shall be effectively stabilized of dust emissions using water, chemical stabilizer/suppressant, covered with a tarp or other suitable cover or vegetative ground cover.
- All on-site unpaved roads shall be effectively stabilized of dust emissions using water or chemical stabilizer/suppressant.
- All land clearing, grubbing, scraping, excavation, land leveling, grading, cut and fill, and demolition activities shall be effectively controlled of fugitive dust emissions utilizing application of water or by presoaking.
- Suspend excavation and grading activity when winds exceed 20 mph
- Storm Water Compliance Plan would be implemented to reduce erosion.
- The project would be designed to minimize the footprint of new disturbed area by attempting to use as many existing wells and pipelines in previously disturbed acreage as much as possible.

With implementation of these applicable LORS, impacts on soil would be expected to be less than significant during the initial construction phases of the proposed CO_2-EOR component.

Erosion during Operations

Soil losses could be ongoing after the construction of the project. Areas disturbed during the construction phase are subject to potential erosion during the operational life of the proposed project. HECA would be designed for an operating life of 25 years, and the CO_2-EOR component is expected to have an operating lifespan of 20 to 40 years.

HECA: Onsite Erosion

The estimated total area of land grading and excavation during construction of the HECA site and laydown area would be about 544 acres, as shown in **Soil & Surface Water Table 2**. After project completion, the temporary parking and construction laydown areas outside of the process areas would be restored to preconstruction conditions and about 131 acres would become impervious due to the addition of concrete foundations and asphalt paving (HECA 2012bb, §A116). The balance of the previously disturbed area, roughly 413 acres, would be susceptible to potential erosion during the operational life of HECA.

The Draft DESCP states that a combination of landscaped and hydroseeding areas would be implemented as permanent erosion control measures to reduce potential soil related impacts. Landscaped areas would be irrigated and consist of a variety of vegetation and density that would comply with the Kern County ordinance. Hydroseeding would be used in open areas outside of the process and building areas where no landscaped areas are planned. These drought-resistant plants would consist of perennial/annual native plants that would protect the open areas and berm from wind or surface runoff erosion. These plants would be low maintenance after establishment.

Staff agrees that implementation and maintenance of permanent BMPs after project completion would prevent or reduce impacts to onsite soil from erosion. Staff believes compliance with the Condition of Certification **SOILS-1** which would require the applicant to develop and implement an approved DESCP would reduce the impacts of soil erosion during operation of the proposed project.

HECA: Offsite Erosion

The project’s increase of impervious area to the site could potentially increase velocities of storm water runoff leaving its boundaries, possibly increasing the potential to erode offsite areas downstream of the project. To prevent an increase in storm water flows discharged offsite, the applicant proposes to retain all storm water onsite with nine retention basins located throughout the project site. Staff agrees with the applicant that the project’s impacts to offsite soil erosion during operations would be less than significant.

CO_2-EOR Component

Different areas within the CO_2-EOR site would be disturbed at different times during the 20 year construction phase of the proposed project (HECA 2012e, Vol. II). Installation of systems would start in the eastern portion of the CO_2-EOR site, then the other ten systems would be added over time and progress westerly as reservoir development evolves. Approximately 10 to 12 years after startup, injection systems will be installed in the northwest area (OXY 2012f, Attach A177-2).

As construction activities continue after the initial phases of the CO_2-EOR component begins operations, the potential for soil erosion impacts would also continue. Because these activities are still subject to requirements as discussed above (see "Erosion during Construction"), mitigation measures would be implemented. Therefore, impacts on soil would be less than significant during continued construction and expansion of the proposed CO_2-EOR component.

Water Quality of Surface Waters

HECA and CO_2-EOR component could have an adverse effect on water quality if discharges create pollution, contamination, or nuisance. Construction and operation of an industrial facility can impact the quality of surface waters by any of the following activities:

- Sediment Increase - Grading or clearing of land so that sediment is discharged into a water resource. Sediment is considered a pollutant with potential to cause or contribute to the degradation of a water resource's beneficial uses.
- Impervious Area Increase - Increasing impervious surface areas resulting in increased amount of storm water runoff volume and rate. This can cause substantial flooding, erosion, and/or siltation, which could impact water resources.
- Aquatic Resources Impacts - Placing development in, or discharging sediment into, a river, stream, lake, wetland or water of the US and/or water of the state[15], or into a buffer area for one of these water bodies. Impacts or losses to these special aquatic resources may require specific mitigation measures.
- Polluted Runoff - Storing equipment, raw materials, finished products, or waste products in a manner that exposes them to precipitation and/or storm water runoff. Contact runoff could concentrate various pollutants that would then discharge to a water resource.
- Operation Wastewater - Discharging wastewater from an industrial or commercial process. Because of the high concentrations of total dissolved solids and the further concentration through evaporation, the liquids could be considered "designated wastes" with regulated disposal requirements.

The following discussion analyzes project information to determine whether HECA would sufficiently avoid or reduce the potential impacts listed above. Where appropriate,

[15] Refer to the **Biological Resources** section of this **PSA/DEIS** for further discussion on jurisdictional determination of wetlands or watercourses as a Water of the US or a Water of the State.

staff recommends conditions of certification to ensure that any impacts are less than significant and the project complies with applicable LORS.

Sediment Increase

To prevent the discharge of sediment, HECA would implement temporary BMPs during construction and permanent BMPs during operation to prevent or reduce soil erosion, as discussed in "Soil Erosion Due to Water and Wind" above. The SWRCB and RWQCBs have determined that standardized storm water and soil erosion BMPs are the most effective, practical means to protect surface waters by preventing or reducing pollution from nonpoint sources. Staff agrees that carefully chosen BMPs for both construction and operation activities could effectively prevent or reduce sediment discharge into water resources. Staff believes compliance with the conditions of certification relating to soil erosion (identified in the "Soil Erosion Due to Water and Wind" discussion above) would ensure that the impact of sediment to surface water quality would be less than significant.

Similarly, the CO_2-EOR component would implement mitigation measures required by federal, state, and county LORS, as discussed in "Soil Erosion Due to Water and Wind" above. The project would be designed to minimize the footprint of new disturbed areas by attempting to use as many existing wells and pipelines in previously disturbed acreage as much as possible. The short-term increases in erosion as a result of continued ground disturbance would be minimized through implementation of the project-specific Storm Water Compliance Plan. In addition, the project would comply with Kern County grading and drainage ordinances (HECA 2012e, Vol. II). Therefore, impact of increased sediment to surface water quality would be less than significant.

Impervious Area

Construction of the proposed HECA site would increase the project site's impervious area, from three percent prior to construction to 29 percent after construction. As a result, the post-construction runoff would greatly exceed pre-construction runoff due to the increase of impervious areas. To prevent an increase in storm water flows discharged offsite, the applicant proposes to retain all storm water onsite with nine retention basins located throughout the project site.

The applicant submitted a Preliminary Hydrology Study (HECA 2012bb, §A116) which conducted an onsite investigation of the HECA area's hydrology and performed computer modeling of both pre-construction and post-construction storm flows. Drainage features would be designed in accordance with Kern County's Development Standards and the Kern County Hydrology Manual. Because the applicant's storm water system of retention basins would prevent flows from leaving the site boundaries, staff does not identify any significant impacts to water quality as a result of added impervious surfaces.

Descriptions of the CO_2-EOR component state that the main processing facility would result in 101.8 acres of permanent disturbance (HECA 2012e, Vol. II). Because a site layout or other information was not provided, staff could not determine the amount of this area that would become impervious[16]. However, the proposed project must comply with Kern County grading and drainage ordinances, which would reduce impacts from increased impervious areas. Considering the relatively low annual rainfall to Elk Hills and the absence of tributary streams connecting to offsite water resources, in addition to compliance with Kern County LORS, staff expects impacts to water quality as a result of added impervious surfaces would be reduced to less than significant.

Aquatic Resources

To avoid impacts or losses to special aquatic resources, HECA proposes to implement a Biological Resources Mitigation Implementation and Monitoring Plan during construction activities (refer to the **Biological Resources** section of this **PSA/DEIS**) in addition to implementing standardized storm water and soil erosion BMPs. Plan details are still unknown pending the identification of specific mitigation and monitoring requirements.

USACOE has not yet finalized their analysis of HECA. If federal jurisdictional waters are found to be impacted, then Central Valley RWQCB would also review the project for compliance with state water quality standards. If USACOE and Central Valley RWQCB determine that additional mitigation measures would be necessary under CWA Sections 404 and/or 401, staff anticipates that compliance with those measures would address impacts to special aquatic resources and water quality. In the **Biological Resources** section , staff recommends the applicant be required to provide a copy of the 404 and/or 401 Certifications, in accordance with Condition of Certification **BIO-5** (Biological Resources Mitigation Implementation & Monitoring Plan). See the **Biological Resources** section of the **PSA/DEIS** for a discussion of potential impacts and mitigation.

Potential impacts of the CO_2-EOR component to the natural drainage ways, associated riparian vegetation, and the wildlife that depend on them could occur from increased sediment from storm water runoff. As discussed above, potential increases in erosion from ground disturbance would be minimized through implementation of the project-specific OEHI Storm Water Compliance Plan. The project would be designed to minimize the footprint of new disturbed areas by attempting to use as many existing wells and pipelines in previously disturbed acreage as much as possible (HECA 2012e, Vol. II). The project must also comply with Kern County grading and drainage ordinances.

For these reasons, staff expects impacts to aquatic resources as a result of increased sediments would be reduced to less than significant.

In addition, OEHI presently implements mitigation measures to protect biological resources through existing biological permits (for more details, see the **Biological**

[16] The submitted Biological Assessment states that the size of the EOR processing facility would be 60.61 acres (HECA 2013u, Attch A56-1). Permanent disturbed areas could include gravel surfaces, unpaved compacted soil, revegetated areas, and other surfaces that allow rainfall to infiltrate into the soil. However, no specific information was given to the percentage of the area that would be impervious.

Resources section of the **PSA/DEIS**). Staff recommends that OEHI continue to implement these measures for the proposed CO_2-EOR component or as permits are amended as required by the wildlife agencies.

Polluted Runoff

To prevent contact runoff from discharging offsite during HECA construction activities, the applicant has identified a combination of standard BMPs within the Draft Drainage, Erosion, and Sedimentation Control Plan (DESCP) for pollution control measures to be implemented during construction. The BMPs would limit or reduce potential pollutants at their source before they come into contact with storm water. These BMPs also involve daily activities of the construction site, are under the control of the construction contractor, and are additional “good housekeeping practices,” which involve maintaining a clean and orderly construction site. In addition, site drainage during construction activities would be designed to prevent runoff from leaving the site.

Staff agrees that implementation and maintenance of the identified BMPs during construction of HECA would reduce or avoid impacts of contact runoff. To ensure that an updated plan would be implemented to the final project design, staff recommends Conditions of Certification **SOILS-1** and **SOILS-2** requiring an approved DESCP and Construction SWPPP. With these conditions of certification, impacts from polluted runoff would be avoided or reduced to less than significant during construction of HECA.

To prevent contact runoff from polluting offsite resources during operations, HECA would completely separate potentially polluted contact storm water from non-contact storm water (see the “Operation Wastewater” discussion below), the project would route the collected water from potentially contaminated areas into retention basins with an impermeable liner. Water not suitable for reuse would be sent to a ZLD system with resultant solids disposed of at an approved offsite facility.

Staff agrees that implementation and maintenance of these measures would prevent contact runoff from polluting offsite resources during operations. Condition of Certification **SOILS-1** requires that the final DESCP address appropriate methods and actions for the protection of water quality and soil resources for both the construction and operation phases of the project.

Furthermore, Condition of Certification **WORKER SAFETY-2** would require a Hazardous Materials Management Program, and Condition of Certification **WASTE-8** would require an Operation Waste Management Plan. Both documents would be developed by the applicant to address handling, transportation, tracking, usage, storage, emergency response, spill control and prevention, training, record keeping, and reporting of hazardous wastes on the site. Other conditions of certification in the **Waste Management** and **Hazardous Materials Management** sections of this **PSA/DEIS** address spill prevention, cleanup of all spills of hazardous substances, and emergency response. With implementation of these conditions of certification, impacts from polluted runoff would be avoided or reduced to less than significant during operation of HECA.

Similarly, the CO_2-EOR component would implement site-specific plans to control handling, transportation, tracking, usage, storage, emergency response, training, spill control and prevention, record keeping, and reporting of hazardous wastes on the site. The safe handling of these materials is addressed through existing OEHI hazardous materials handling practices that comply with applicable regulatory requirements (HECA 2012e, Vol. II). With these practices to reduce risks of exposing contaminants to storm water runoff, in addition to the relative remoteness of the CO_2-EOR site to surface water resources, impacts from polluted runoff would be avoided or reduced to less than significant.

Operation Wastewater

To prevent the discharge of untreated industrial wastewater or untreated sanitary wastewater from entering nearby water resources, HECA would keep the potentially polluted waste water (contact runoff, general facility drainage, process wastewater, and sanitary waste) completely separate from non-contact storm water runoff. Industrial wastewater would be treated onsite to produce demineralized and utility water. Reject water not suitable for reuse would be processed through the ZLD (see “Industrial Wastewater” discussion below). Sanitary waste would remain contained within the septic system (see “Sanitary Wastewater” discussion below). Hazardous liquids would be meticulously handled to prevent spills and accidental release (see **Hazardous Materials Management** and **Worker Safety** sections of this **PSA/DEIS**). All BMPs and conditions of certification would strive to prevent any chemical or hazardous pollutants from mixing with the "clean" storm water. With implementation of these measures, impacts from sanitary or industrial wastewater would be avoided or reduced to less than significant during operation of the proposed project.

Similarly, the CO_2-EOR component would prevent discharge of untreated industrial wastewater or untreated sanitary wastewater from entering surface water resources. All produced water would be reused in the reinjection process (see “Industrial Wastewater” discussion below). Sanitary waste would remain contained within the septic system (see “Sanitary Wastewater” discussion below). Chemical or hazardous pollutants would be meticulously handled to prevent spills, accidental release, or mixing with the "clean" storm water. With implementation of these measures, impacts from sanitary or industrial wastewater would be avoided or reduced to less than significant during operation of the proposed project.

Flooding

HECA: Onsite Area Flooding

The post-construction runoff from the proposed HECA project site would exceed pre-construction runoff due to the increase of impervious areas. The applicant proposes to retain all storm water onsite, designing drainage features in accordance with Kern County’s Development Standards and the Kern County Hydrology Manual. The applicant submitted a Draft DESCP which includes a Preliminary Hydrology Study (HECA 2012bb, §A116). The study conducted an onsite investigation of the project area's hydrology and performed computer modeling of both pre-construction and post-construction storm flows.

Staff has reviewed the applicant's conceptual plans for managing storm water and believes the proposed design is sufficient to manage onsite drainage. Three of the unlined basins are expected to overflow excess runoff onto the site, but this excess water appears to pond onsite without leaving project boundaries. Because these particular basins would contain non-contact storm water, the overflow can infiltrate to open, revegetated areas of the site. Staff also noted that some of the lined onsite retention basins are calculated to have drawdown times that exceeds Kern County maximum of seven days[17]. The applicant states that outflow rate from the lined basins is based on the available capacity of the treatment plant or clarifier. Staff understands that the basin lining is the cause for the low drawdown times, but Kern County's limit is exceeded by weeks in one of the basin, as shown in **Soil & Surface Water Table 5**.

Soil & Surface Water Table 5:
HECA Drawdown Times for Select Basins

Storm Event	**Basin ID**	**Storage** (acre-feet)	**Drawdown[1]** (days)
10-year Storm	Basin #3	1.7	5.1
	Basin #7	3.2	9.7
	Basin #9	9.5	28.7
50-year Storm	Basin #3	2.7	8.2
	Basin #7	3.2	9.7
	Basin #9	14.9	45.0
100-year Storm	Basin #3	3.2	9.7
	Basin #7	3.8	11.5
	Basin #9	17.4	52.5

Source: HECA 2012bb, §A116
Notes:
1. Drawdown time equals the interval between the beginning of the rainfall to the time the retention basin or sump is empty.

The preliminary site drainage patterns of the proposed project (see see **Soil & Surface Water Figure 7**) appear to maintain separation of the non-contact runoff from the potentially contaminated runoff. In addition, staff believes the DESCP is reasonable and the sequence of implementing BMPs will avoid significant adverse impacts caused by onsite storm water drainage. However, staff recommends that HECA adjust the basin design and/or operations to comply with Kern County basin standards. This adjustment and new calculation would be required in the approved final DESCP and hydrology

[17] Kern County Hydrology Manual – Section 408.08.01 states that the basin must completely drain the design volume within seven days.

report. Condition of Certification **SOILS-1** requires an approved DESCP that ensures protection of water quality and soil resources of the proposed project. Staff asks the applicant to provide additional information, as specified in the "Outstanding Information" under the **Staff Conclusions** heading below.

HECA: Offsite Area Flooding

The topography in the vicinity of the proposed HECA site is relatively flat, with a very gentle slope from the southeast to the northwest. In general, the roads in the vicinity of the site are slightly raised above the agricultural fields. Tupman Road, along the eastern boundary of the site, and the levee associated with the irrigation canal south of the site create barriers that limit runoff from upstream (i.e., from the east and south) areas flowing onto the site. Similarly, the roads at the downstream edges of the site (e.g., Dairy Road along the western boundary and Adohr Road along the northern boundary) limit the amount of runoff that leaves the project site (HECA 2012e, §5.14.1.8).

The proposed project site would be graded and drained so that all runoff would be retained on-site. The increase in runoff caused by the additional impermeable surfaces would be mitigated by retention basins strategically located around the site to retain surface runoff from process and open areas. All temporary laydown areas would be restored to preconstruction conditions after construction (HECA 2012bb, §A116).

Based on a review of historical aerial photographs[18] and site reconnaissance, the applicant determined that the existing irrigation/drainage ditch crossing the project site formerly conveyed water north of the project area through an irrigation canal north of Adohr Road. The aerial photos illustrate clearly that by 1967 the portion of the canal north of Adohr Road was filled and abandoned. The canal no longer connects to the property north of the Project Site and is used only for irrigation and drainage within the Controlled Area of HECA. Therefore, filling in the canal and the on-site ditches would not impact any offsite drainage paths of adjacent properties (HECA 2012bb, §A116).

Staff reviewed the Draft DESCP and believes the proposed design adequately manages storm water from flowing offsite during both construction and operation. Because no increased flows would discharge offsite and existing drainage patterns would not be substantially altered, staff agrees that HECA would avoid significant adverse impacts which would result in offsite flooding.

Linear Facilities

Construction of proposed linear facilities would include installation of approximately 32 miles total of underground pipelines, as well as construction of a transmission line and an industrial railroad spur. Temporary soil disturbance during construction would be restored to natural existing conditions and, as a result, would not substantially increase the flooding potential to adjacent areas. Permanent disturbance for most of the proposed linear facilities would have relatively small footprints (footings for transmission

---

[18] Photographs from Appendix B of the Phase I Environmental Site Assessment (HECA 2012e, App. L).

line poles, meter station, wells, valve boxes, etc.) which are not expected to substantially increase the flooding potential. However, construction of the proposed rail spur could potentially alter existing storm water drainage patterns and possibly result in increased flooding of adjacent areas.

As shown in **Soil & Surface Water Figure 5**, the proposed rail spur would be adjacent to roads, agricultural properties, and the East Side Canal. The applicant also provided information indicating proposed locations of at-grade crossing at road intersections and figures showing typical earthwork (grading, tract embankment fill, drainage ditches, etc.) for portions of the track not constructed at-grade (HECA 2013g, Attach A155-2). Although the terrain in the vicinity is generally very flat, and water is conveyed primarily through a network of irrigation ditches, staff does not have enough information to determine whether the proposed rail spur would significantly increase flooding of adjacent areas. Staff asks the applicant to provide additional information, as specified in the “Outstanding Information” under the **Staff Conclusions** heading below.

CO_2-EOR Component

The Elk Hills Oil Field contains a large number of ephemeral/intermittent streams draining the hills, but construction and operation of the proposed CO2-EOR component would not require permanently altering the course of any of the drainages (HECA 2012e, Vol. II). Because of the relatively low annual rainfall to Elk Hills and existing drainage patterns would not be substantially altered, staff agrees that proposed CO2-EOR component would avoid significant adverse impacts which would result in offsite flooding.

Vicinity Flood Hazards

Flood hazards include direct flooding due to overtopping of nearby rivers or streams resulting from severe rainstorms, or secondary flooding due to seismic activity creating tsunamis (tidal waves) or seiches (waves in inland bodies of water).

To identify the different types of flood risks for a given location, flood hazard maps were developed by the Federal Emergency Management Agency (FEMA) to identify areas prone to flooding[19]. Although the nearby Kern River Flood Control Channel (KRFCC) is within the 100-year floodplain as defined by FEMA, HECA is not. FEMA classifies the proposed HECA site location as Zone X, an area determined to be outside the 500-year flood and protected by levee from the 100-year flood. Therefore, construction of the proposed project would not impede or redirect flows from the 100-year flood. Likewise, floods resulting from most major rain events would not likely affect the site. To prevent high water levels from over topping the banks of the Kern River, flow is directed to the Aqueduct through the Intertie and any excess flows are diverted into the KRFCC.

Isabella Lake, which was formed by the construction of Isabella Dam in 1954, is located on the Kern River approximately 56 miles northeast of the proposed HECA site. A

[19] For further discussion of FEMA and potential flooding, see Flood Management under the “Setting and Existing Conditions” heading above.

seepage study conducted in 2005-2006 by the USACOE found that a section of the dam was being subjected to higher foundation pressures than originally believed from earlier studies. It concluded that the pressures in the foundation had reached levels that could lead to potential dam safety concerns. Therefore, an emergency deviation from the water control plan was implemented in 2006 to reduce the foundation pressures and provide an acceptable factor of safety. The deviation consisted of reducing the previous lake capacity during the flood-control off-season, from April through September of each year, until a more permanent solution could be implemented. This reduced the maximum storage capacity of the lake by 37 percent (ACOE 2012).

In the unlikely event a dam should fail at Lake Isabella, the HECA site is expected to experience flooding. In 2008, the USACOE completed the initial preparation of an updated map which shows the areas around metropolitan Bakersfield that would likely be flooded. Maps show that the HECA site could be inundated with approximately 2 feet of water[20], but staff is unclear if this assumes that Isabella Lake is at 100 percent maximum storage capacity (rather than the current 37 percent capacity). Onsite retention basins at the proposed site would have a negligible effect on flood depth, but the proposed power block, storage, and process areas would be constructed on foundations with elevations at approximately 2.5 feet above existing ground elevation[21]. Assuming that the inundation maps reflect Isabella Lake at 100 percent maximum storage capacity, staff believes HECA would not expose people or structures to a significant risk as a result of dam failure.

Staff agrees with the applicant that HECA would not have significant impacts pertaining to these identified flood hazards areas. In addition, the proposed CO_2-EOR component would not have significant impacts pertaining to these identified hazards because of its location in the Elk Hills. (For discussion on tsunamis, seiches, and additional potential hazards that could be caused by soil failure such as mudflow, landslide and liquefaction, see the **Geology and Paleontology** section of this **PSA/DEIS**.)

Water Supply

Refer to the **Water Supply** section of this **PSA/DEIS** for a detailed analysis of the potential effects on water supplies and groundwater quality.

Wastewater

Construction Wastewater

HECA and Linear Facilities

Improper handling or containment of construction wastewater could cause a broad dispersion of contaminants to soil, surface waters, or groundwater. For example,

---

[20] Lake Isabella Flood Area. Kern County Engineering, Surveying and Permit Services. (http://esps.kerndsa.com/floodplain-management/lake-isabella-flood-area)

[21] The existing elevation of the proposed HECA site is approximately 286 feet amsl. Preliminary Plot Plan of the proposed project show that the elevations of foundation surfaces at 288.5 feet amsl (HEI 2009c).

hydrostatic testing[22] of a new pipeline can result in discharge of super-chlorinated water often used for the initial disinfection. Other constituents of concern include total dissolved solids (TDS) and total suspended solids (TSS). Discharge of any non-hazardous construction-generated wastewater would require compliance with discharge regulations.

Anticipated sources of wastewater, also referred to as non-storm water discharges, would be sanitary wastes, wash water, concrete washout water, paint wash water, and piping hydrostatic test water. Clean water used for dust control and soil compaction would not be considered wastewater because flows would not discharge offsite. The applicant submitted a Draft DESCP identifying a combination of standard BMPs for non-storm water management measures to be implemented during construction. Sanitary waste during construction activities would be contained in portable facilities and routinely disposed of at an offsite treatment/disposal facility by a licensed sanitary service. Concrete washout slurries would be discharged to a temporary washout facility and allowed to dry prior to disposal offsite. The Draft DESCP states that non-storm water discharges would be eliminated, controlled, or treated to minimize or eliminate the release of pollutants in storm water.

The applicant stated in the AFC that hydrostatic test water of the process equipment and piping would average 11,800 gallons per day over the HECA construction period and 2,000 gallons per day over the linear construction period. The hydrotesting of the process equipment and other piping is normally done toward the end of project construction after the mechanical construction is complete. The hydrotest water would be sampled and tested and disposed of in compliance with permit(s). Clean water with suitable chemistry would be routed to the storm water retention basin. Water that is not suitable for routing to the retention basin would be transported by truck to an appropriately licensed off-site treatment or disposal facility (HECA 2012e, §2.7.1.5).

Discharge of hydrostatic test water to land is regulated under SWRCB Order No. 2003-003-DWQ which specifically prohibits the discharge of hydrostatic test water unless all residual pollutant concentrations comply with groundwater quality objectives. Discharge of hydrostatic test water to surface waters would be subject to provisions of Central Valley Regional Board Order No. R5-2008-0081 (Waste Discharge Requirements for Dewatering and Other Low Threat Discharges to Surface Waters), which allows discharge of clean or relatively pollutant-free wastewaters that pose little or no threat to surface waters[23]. To ensure HECA would meet these requirements, staff recommends Condition of Certification **SOILS-4** (Construction Wastewater Discharge) requiring the project owner to obtain the appropriate permit(s) from Central Valley RWQCB and/or the SWRCB for proper wastewater disposal, in accordance with waste discharge requirements of the Clean Water Act (CWA). Adoption of Condition of Certification

[22] A hydrostatic test is a way in which leaks can be found in pressure vessels such as pipelines and plumbing. The test involves placing water, which is often dyed for visibility, in the pipe or vessel at the required pressure to ensure that it will not leak or be damaged.

[23] Discharges covered by the Order are either four months or less in duration or have an average dry weather flow of less than 0.25 million gallons per day.

SOILS-4, in addition to a complete and approved DESCP and Construction SWPPP as required in Conditions of Certification **SOILS-1** and **-2**, would reduce potential impacts from proposed management and disposal of wastewater during construction to a less than significant level.

CO_2-EOR Component

Hydrostatic test water would be produced during construction of the CO_2-EOR component, but project documents did not indicate the amount expected. The hydrostatic test water would be reused as practical, then sampled, tested, and disposed of in compliance with permit(s). Clean water with suitable chemistry would be collected in an onsite storm water basin. Water that is not suitable for routing to a storm water basin would be transported to an appropriately licensed off-site treatment or disposal facility (OXY 2012f, Attach A177-2). By complying with appropriate permit(s) from Central Valley RWQCB and/or the SWRCB for proper wastewater disposal, potential impacts from proposed management and disposal of wastewater during construction would be reduced to a less than significant level.

Industrial Wastewater

HECA

HECA has been designed to minimize wastewater. Water losses from the Plant Wastewater Treatment Unit are very small due to the incorporation of zero liquid discharge (ZLD) technology. Plant wastewater (including cooling tower blowdown, water treatment reject, evaporative cooler blowdown, and other miscellaneous drains) is evaporated and concentrated using a conventional mechanical vapor recompression brine concentrator followed by a brine crystallizer.

In some cases the ZLD sludge/solids could contain concentrations of chemicals that could be hazardous depending on water quality and cooling system operation. To ensure proper disposal of the ZLD solids, staff proposes Condition of Certification **WASTE-10** which requires that the project owner perform the appropriate tests to classify the waste and determine the appropriate method of disposal. Waste would be recycled to the greatest extent possible and non-recyclable wastes would be removed on a regular basis for disposal in a Class II landfill. With implementation of this condition of certification, impacts from industrial wastewater would be avoided or reduced to less than significant.

CO_2-EOR Component

Produced water would be treated at the water treatment portion of the CTB to remove oil, solids and other contaminants. It would then be pressurized in the injection pumps and sent to the Satellites Gathering Stations for reinjection. All produced water would be reused in the reinjection process (OXY 2012f, Attach A177-2). As a result, no produced water (industrial wastewater from the CO_2-EOR component) would discharge to any offsite surface water resources. Although the reinjection of produced water is essential to the WAG process for the CO_2-EOR component, the injection well is categorized as a "Class II" injection well and regulated under the United States Environmental Protection

Agency's (USEPA) Underground Injection Control (UIC) program. With compliance with UIC requirements for all injection wells and prohibition of direct discharges of produced water to nearby waterways, impacts from industrial wastewater would be reduced to less than significant.

Sanitary Wastewater

HECA

Because no municipal sanitary sewer system is available in the vicinity of the project site, HECA would require a septic system and leach field during operations. The use of septic tanks and leach fields for onsite treatment and disposal of domestic wastes is an established practice. However, improper construction and operation of these systems may adversely impact nearby surface and ground waters. The septic system planned for the project will contribute nitrogen to the subsurface. The amount of the contribution depends on the nitrogen concentration in the sewage effluent, volume of effluent, and subsurface processes. Key factors influencing the extent of groundwater nitrate contamination due to septic systems are 1) the nitrogen concentration in the effluent, 2) effluent volume, and 3) denitrification in the unsaturated and saturated zones.

To ensure protection of human health and the environment from improper disposal of sewage, California Plumbing Code and Central Valley RWQCB establishes specific requirements for the discharge of sewage. Included in the requirements are soil percolation standards; minimum separation/set back distances to prevent impacts to groundwater and nearby water wells; and septic tank and leach field design, sizing and construction standards to ensure adequate capacity and proper treatment and disposal of the wastewaters. Absent the Energy Commission's jurisdiction, Kern County would be responsible for permitting the construction and operation of the proposed septic system and has established requirements for such systems.

Consistent with the Energy Commission's in-lieu permit provisions, staff proposes adoption of Condition of Certification **SOILS-6** (Septic System and Leach Field Requirements) requiring compliance with the requirements of the Kern County Ordinance 14.20.050, Kern County Engineering: Division Six - Environmental Health Standards Rules and Regulations, the California Plumbing Code (CCR Title 24, Part 5), and the Central Valley RWQCB Basin Plan for all project sanitary waste disposal facilities, such as septic systems and leach fields. Adoption of Condition of Certification **SOILS-6** would both ensure compliance with LORS and, through the protectiveness provided by the County regulatory standards, reduce potential impacts from project septic systems to a less than significant level.

CO_2-EOR Component

Because no municipal sanitary sewer system is available in the vicinity of the project site, sanitary wastewater during construction would use portable chemical toilets. A sanitary waste contractor would pump and dispose the sanitary waste offsite (OXY 2012f, Attach A177-2). After permanent onsite facilities are constructed, sanitary waste would be disposed to an onsite sewage disposal system consisting of a conventional septic tank (OXY 2012f, Attach A177-4). Compliance with LORS and, through the protectiveness provided by the County regulatory standards, potential impacts from project septic systems would be reduced to a less than significant level.

Contaminated Soil and Groundwater

HECA

The Port Organics facility contained underground storage tanks (USTs) in the past and may still contain USTs, as indicated in the Phase I assessment. The site has a long history of violations related to hazardous materials storage. The Kern County Environmental Health Services Department (KCEHSD) issued multiple Notices of Violation (NOVs) to PO within the last ten years. On January 31, 2009, PO's lease of the property expired. The status of site cleanup and the extent of soil contamination is still under investigation.

In the event that construction excavation, grading, or trenching activities for the proposed project encounter potentially contaminated soils, specific waste handling, disposal, or other precautions may be necessary pursuant to hazardous waste management LORS. Staff also believes that proposed Conditions of Certification **WASTE-2** and **WASTE-3** would be adequate to address any soil or groundwater contamination contingency that may be encountered during construction of the project and would further support compliance with LORS.

CO_2-EOR Component

To ensure that contamination is not spread at the Elk Hills Oil Field and that construction workers are not exposed to hazardous materials as a result of project related activities, safety procedures should be developed and implemented for the construction of the project. All federal, state and local statutes and regulations must be complied with, and DTSC, DOE, and OEHI employees and contractors must be made aware of areas of concern/contamination. Staff recommends mitigation measures that would require OEHI to keep DOE and DTSC informed of construction areas and implement all appropriate and applicable safety measures to limit exposure to hazardous materials (See **MITIGATION MEASURE WASTE-1** in the **Waste Management** section of this **PSA/DEIS**).

Project Closure and Decommissioning

HECA

HECA is designed for an operating life of 25 years (HECA 2012e, §2.1). Facility closure can be either temporary or permanent, and closure options range from "unplanned temporary closure," with the intent of a restart at some time, to the removal of all equipment and facilities. Closure can result from two circumstances: (1) the facility is closed suddenly and/or unexpectedly because of unplanned events, such as a natural disaster or economic forces or (2) the facility is closed in a planned, orderly manner, such as at the end of its useful economic or mechanical life or due to gradual obsolescence.

In the event of a temporary or unplanned closure, HECA would be required to comply with all applicable conditions of certification, including an emergency Risk Management Plan to manage the possible release of hazardous substances present onsite (see the **Hazardous Materials** section of this **PSA/DEIS**). Depending on the expected duration of the shutdown, other appropriate measures would be taken such as removing chemicals from storage tanks or equipment.

Permanent closure (decommissioning) requires a Facility Closure Plan, as discussed in the **Facility Design** and **Compliance Conditions** sections of this **PSA/DEIS**, which would be submitted to the Energy Commission for approval prior to decommissioning. Future conditions that could affect decommissioning are largely unknown at this time; however compliance with all applicable LORS, and any local and/or regional plans would be required. The plan would address all concerns in regard to potential erosion and impacts on water quality. Refer to the **Facility Design** section of this **PSA/DEIS** for further discussion on temporary and permanent facility closure.

CO_2-EOR Component

The OEHI CO_2-EOR operations would close after all economic production of hydrocarbons has been exhausted, which is expected to be about 40 years. The closure phase consists of site decommissioning, well plugging and abandonment, and appropriate post-injection care and monitoring. In addition to those measures generally required for closure of UIC Class II wells, OEHI would conduct closure activities that demonstrate that the injected CO_2 is properly contained within the confinement zone and is not endangering human health or the environment. Closure will be conducted pursuant to a post-injection closure plan that will be performance-based and specifically tailored for the CO_2-EOR Project (OXY 2012f, Attach A177-2).

Existing water injection wells that are used for EOR purposes are categorized as “Class II” injection wells under the USEPA’s UIC program. The USEPA’s well permitting process and regulations under the UIC are designed to protect underground sources of drinking water under the Safe Drinking Water Act. In California, EOR well regulation is delegated to the Department of Conservation, Division of Oil, Gas, and Geothermal Resources (DOGGR), the state agency that regulates statewide oil and gas activities. However, Class II well requirements are not intended for injecting CO_2 for sequestration purposes. The USEPA promulgated Class VI injection well regulations specifically tailored for wells intended for sequestering the injected CO_2. The Class VI regulations include specific requirements for the construction of new wells and retrofitting of existing wells, and also for the operation and monitoring of the wells during and after termination of the injection activities (see the **Carbon Sequestration and Greenhouse Gas Emissions** section of this **PSA/DEIS**).

Because DOGGR regulates plugging and abandonment of EOR wells, the CO_2-EOR component must comply with DOGGR requirements for temporary or permanent closure of EOR activities. To address issues pertaining to CO_2 sequestration, Energy Commission staff has developed proposed Conditions of Certification, as discussed in the **Carbon Sequestration and Greenhouse Gas Emissions** section of this

PSA/DEIS, to ensure effective CO_2 sequestration and ensure that impacts from the injection of the carbon dioxide would have no significant impacts on underground sources of drinking water.

INDIRECT IMPACTS

Indirect impacts are effects caused by the project and occurring later in time or farther removed in distance, but still reasonably foreseeable. Indirect impacts usually result from a chain of events caused by the project, intended or not.

Soil Erosion and Surface Water Quality

With any new project, possible indirect impacts affecting soil and water resources would be in response to additional construction activities. For example, additional housing could be needed to accommodate workers for construction and operation of a proposed project, or additional industrial facilities may be attracted to an area containing an established industrial facility. These in turn can further result in additional roads or other infrastructure. Potential impacts of these various resultant activities would be similar to the potential direct impacts of the project itself such as: potential erosion due to construction activities, potential flooding impacts due to structures within a 100-year flood zone or increase of impervious surfaces, potential contamination from industrial activities, and potential impacts from wastewater.

The **Socioeconomics** section of this **PSA/DEIS** discusses growth-inducing impacts, and concludes that no significant socioeconomic impacts to infrastructure is anticipated for either HECA or the OEHI CO_2-EOR component. The construction and operation workforces would not induce a substantial population growth or displacement of population, or induce substantial increases in demand for housing. The **Land Use** section of this **PSA/DEIS** did not identify growth-inducing impacts associated with any of the new proposed linear facilities or the proposed OEHI CO_2-EOR component. Based on this information, staff believes HECA and the OEHI CO_2-EOR component would not indirectly result in significant impacts to soil resources or surface water quality.

Water Supply and Groundwater Quality

Refer to the **Water Supply** section of this **PSA/DEIS** for a detailed analysis of the potential effects on groundwater supplies and groundwater quality.

CUMULATIVE IMPACT ANALYSIS

A project may result in a significant adverse cumulative impact where its effects are cumulatively considerable. "Cumulatively considerable" means that the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of reasonably foreseeable future projects (CCR, Title 14, section 15130). The construction and operation activities of the various projects could potentially overlap and result in cumulative impacts to the same resource(s).

SOIL EROSION AND SURFACE WATER QUALITY

Staff identified 42 projects in the vicinity of HECA and the CO_2-EOR component have been approved or are under review for construction. Because these projects are located in the same watershed and upstream of the Tulare dry lakebed, they have the potential to increase local soil erosion and storm water runoff. Without the use of storm water BMPs and erosion control BMPs, these changes could incrementally increase local soil erosion and storm water runoff leading to significant impacts to the quality of receiving water bodies. By complying with all applicable erosion and storm water management LORS, including the Basin Plan, HECA and the CO_2-EOR component would avoid or substantially lessen the cumulative problem[24]. The proposed project's contribution would not be "cumulatively considerable" and, thus, not significant.

WATER SUPPLY AND GROUNDWATER QUALITY

Refer to the **Water Supply** section of this **PSA/DEIS** for a detailed analysis of the potential cumulative effects on groundwater supplies and groundwater quality.

COMPLIANCE WITH LORS AND STATE POLICY

CLEAN WATER ACT, ANTIDEGRADATION POLICY, PORTER-COLOGNE WATER QUALITY CONTROL ACT, AND SWRCB ORDERS 2009-0009-DWQ, 2003-003-DWQ, AND 97-03-DWQ

The Clean Water Act (CWA) (33 USC, section 1257 et seq.) requires states to set standards to protect water quality, which include regulations of storm water and wastewater discharge during construction and operation of a facility. California established its regulations to comply with the CWA under the Porter-Cologne Water Quality Control Act. The SWRCB regulates storm water discharges associated with construction of projects affecting areas greater than or equal to 1 acre. Under Order 2009-0009-DWQ, the SWRCB has issued a National Pollutant Discharge Elimination System (NPDES) General Permit for storm water discharges associated with construction activity, Order 2003-03-DWQ is for water discharges to land that has a low threat to water quality (includes water from hydrostatic testing of pipes), and Order 97-03-DWQ is for storm water discharges associated with industrial activity. Projects qualify under these permits if specific criteria are met and an acceptable Storm Water Pollution Prevention Plan (SWPPP) is prepared and implemented after notifying the SWRCB with a Notice of Intent.

HECA would satisfy these requirements of the SWRCB and Central Valley RWQCB with the development of a DESCP in accordance with Condition of Certification **SOILS-1**, the development of construction SWPPPs in accordance with Condition of

[24] CEQA also allows the lead agency to determine that a project's contribution to a cumulative impact is not significant "if the project will comply with the requirements in a previously approved plan or mitigation program which provides specific requirements that will avoid or substantially lessen the cumulative problem … within the geographic area in which the project is located." (California Code of Regulations, Title 14, section 15064(h)(3).)

Certification **SOILS-2**, compliance with requirements for hydrostatic test water discharge in accordance with Condition of Certification **SOILS-4**.

Staff also recommends Condition of Certification **SOILS-5** requiring that HECA comply with all requirements of the General NPDES Permit for Discharges of Storm Water Associated with Industrial Activity, including the development of an Industrial SWPPP. This federal permit is not required if the facility does not discharge to Waters of the U.S. Although HECA is designed to prevent storm water discharge offsite, this may not be the case for extremely heavy rain events larger than the 100-year storm event. Documentation from the SWRCB or the RWQCB indicating that there is no requirement for a general NPDES permit for discharges of storm water associated with industrial activity would satisfy Condition of Certification **SOILS-5**.

NOTEWORTHY PUBLIC BENEFITS

Staff has not identified any noteworthy public benefits of the proposed project that are associated with soil and surface water resources.

DOE FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, Department of Energy (DOE) would not provide financial assistance to the Applicant for the HECA Project. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

RESPONSE TO AGENCY AND PUBLIC COMMENTS

The table below contains staff's responses to comments received pertinent to topics addressed in this section. The comments were submitted by:

- Agency – Central Valley Regional Water Quality Control Board (CVRWQCB)
- Agency – U.S. Environmental Protection Agency (USEPA)
- Intervenor – Association of Irritated Residents (AIR)
- Intervenor – HECA Neighbors
- Members of the public

Submitted by:	*COMMENT and RESPONSE*
AGENCY: Central Valley Regional Water Quality Control Board (CVRWQCB)	
Agency – CVRWQCB	Comment: (summarized) The Applicant needs to clarify how the daily volume of gasification solids from the combustion of coal and petcoke would be generated, contained,

Submitted by:	COMMENT and RESPONSE
(TN-65731) Docketed June 12, 2012	conveyed, and treated/disposed. The Applicant needs to provide additional details about the location and design of the solids handling collection facility; the solids drain sumps, and the operational procedures to remove the solids and fluid that collect in the sumps. The design of the sumps and storage area pads containing wastes may be such that submittal of a Report of Waste Discharge may be required. <u>Response</u>: The Applicant provided additional information in Data Responses A108 through A114 submitted August 2012 (HECA 2012q).
AGENCY: U.S. Environmental Protection Agency (USEPA)	
Agency – USEPA (TN-66381) Docketed July 30, 2012	<u>Comment</u>: (summarized) The environmental review process should document the project's consistency with applicable storm water permitting requirements under the Federal Clean Water Act, and should discuss specific mitigation measures that may be necessary or beneficial in reducing adverse impacts to water quality and aquatic resources. <u>Response</u>: The proposed project's consistency with applicable storm water permitting requirements under the Federal Clean Water Act is described in "Compliance with LORS and State Policy". Specific mitigation measures are discussed in "Direct Impacts" and "Proposed Conditions of Certification".
Agency – USEPA (TN-66381)	<u>Comment</u>: (summarized) The environmental review document should describe the original (natural) drainage patterns in the project locale, as well as the drainage patterns of the area during project operations. Identify and quantify all wetlands and waters of the U.S. within the study area. Identify whether any components of the proposed project are within a 50 or 100-year floodplain. <u>Response</u>: The original (natural) drainage patterns are described in "Setting and Existing Conditions". Discussion of wetlands and waters of the U.S. are included in the BIOLOGICAL RESOURCES section of this PSA/DEIS. The HECA site is located outside the 100-year floodplain (as shown on **Soil & Surface Water Figure 3**), which is also outside the 50-year floodplain.
INTERVENOR: Association of Irritated Residents (AIR)	
Intervenor – AIR (TN-66342) Docketed July 27, 2012	<u>Comment:</u> Area proposed for HECA is a floodplain with above average danger of flooding. The area has been flooded many times in the past. The rich top soil is direct evidence of many flooding episodes. One local resident commented at the DOE scoping meeting June 12 in Tupman that there were old treaties or binding agreements that say no flood waters may be diverted from the site. A careful examination of these claims must be

Submitted by:	COMMENT and RESPONSE
	made and analyzed as to their possible effect on the HECA project for the next 100 years. Rapid snow melt due to climate change gives an even greater possibility of flooding compared to recent history. Response: The proposed HECA site is located in a portion of the San Joaquin Valley that once contained the largest single block of permanent and seasonal wetlands in California. Today, these areas are heavily farmed, with all the region's streams diverted for irrigation or other purposes, except in the wettest years (DWR 2009). Because canals divert water from the Kern River upstream of Bakersfield, there is no river flow downstream of Bakersfield except during very wet years. Only when flows in the Kern River exceed the capacity of these diversion canals, water continues southwest past Bakersfield to the Buena Vista (dry) Lakebed near Tupman (KJC 2011). From there, excess flows would either be directed north to the Tulare (dry) Lake via the Kern River Flood Control Channel or in the California Aqueduct via the Kern River-California Aqueduct Intertie (Intertie) located near the Tupman. Both the Kern River Flood Control Channel and the Intertie were constructed to protect surrounding farmland and residences from flood damage. Staff researched and found no information regarding the existence of old treaties or binding agreements that say no flood water may be diverted from the proposed HECA site. In fact, the main purpose of both the Kern River Flood Control Channel and the Intertie is to divert flood water.
INTERVENOR: HECA Neighbors	
Intervenor – HECA Neighbors (TN-66249 and TN-66382) Docketed July 16, 2012 and July 30, 2012	Comment: What if the unforeseen happens… a problem with their pipes, an earthquake, an accident, or an unknown that has not been regulated yet, or something else (a spill, an explosion). Our ground water will be contaminated. Contaminated water is impossible to correct. Wells supply homes very near HECA. What is the protection? Response: Several different Conditions of Certification have been developed to require the project to address spill prevention, cleanup of all spills of hazardous substances, and emergency response. As an additional level of protection, potential spills from the power block, facilities, and processing areas would drain into sumps or lined retention basins to prevent the contaminated material from leaching into the soil.
PUBLIC COMMENTS	
Public – Antongiovanni (TN-66397)	Comment: According to multiple ground contour and elevation maps, the footprint for the HECA project sits lower in elevation than land deemed "Swamp" and "Overflowed Land"… All forms of nitrogen stored at the facility add to the damage caused by a flooding event. A flood would disperse the nitrogen

Submitted by:	COMMENT and RESPONSE
Docketed July 30, 2012	(a known ground water pollutant in the southern San Joaquin Valley) throughout the lakebed and contaminate our ground water supply. <u>Response:</u> The proposed HECA site is located in Zone X, as designated by the Federal Emergency Management Agency (FEMA). Zone X is defined as an area determined to be outside the 0.2% annual chance flood also known as the 500-year flood (the flood that has a 0.2% chance of being equaled or exceeded in any given year). In addition, the HECA site drainage is designed to retain all storm water onsite for rain events up to the 100-year storm. Project facilities and processing areas would drain into sumps or lined retention basins to prevent the contaminated material from leaching into the soil.
Public – Douglas (TN-66389) Docketed July 30, 2012	<u>Comment:</u> [The HECA project] is also on the floodplain of the Kern River. Water from our crumbling Isabella Dam would cover the site if we were to get an earthquake and/or dam failure. Last, the site backs up to the California Aqueduct; can you take a chance on endangering Southern California's water supply? <u>Response:</u> Isabella Dam is discussed in the "Vicinity Flood Hazards" under Direct Impacts. Impacts relating to earthquakes are included in the **GEOLOGY and PALEONTOLOGY** section of this **PSA/DEIS.** Although the proposed HECA site is within half-a-mile from the California Aqueduct, a system of irrigation canals (including the West Side Canal and the Outlet Canal) and the Kern River Flood Control Channel are located between them (see **Soil & Surface Water Figure 3**). Under current conditions, no water directly flows from the site to the Aqueduct. In addition, the Aqueduct was designed and constructed to prevent surrounding surface waters from flowing into the channel. Furthermore, the HECA site would be graded to drain runoff away from the Aqueduct (see **Soil & Surface Water Figure 7**) and onsite retention basins would prevent storm water runoff from leaving the site.

STAFF CONCLUSIONS

Based on the assessment of the proposed project, California Energy Commission (Energy Commission) staff concludes:

- Compliance with an approved DESCP in accordance with Condition of Certification **SOILS-1** would reduce the impacts of soil erosion during construction and operations.

- Conditions of Certification **SOILS -1**, **-2**, and **-4** would reduce or avoid impacts of contact runoff during construction activities. Conditions of Certification **SOILS -1** and **-5** would reduce or avoid impacts of contact runoff during operations.
- The discharge of construction wastewater would be in compliance with LORS and would have no adverse environmental impact provided the requirements of Condition of Certification **SOILS-4** are met.
- Condition of Certification **SOILS-3** would ensure that the applicant meets encroachment requirements where linear facilities cross features owned by other agencies, such as Department of Water Resources, the Central Valley Flood Protection Board, Buena Vista Water Storage District, Caltrans, and Kern County.
- The discharge of sanitary waste would be in compliance with LORS and would have no adverse environmental impact provided the requirements of Condition of Certification **SOILS-6** are met.
- Through Compliance with Conditions of Certification **SOILS-2** through **-6**, HECA would conform with applicable federal, state, and local LORS and state policy related to water quality and hydrology, with the exception of the Kern County basin standard (see “Outstanding Information” below).
- Staff has not identified any significant impacts that would occur regarding water quality and hydrology caused by the proposed OEHI CO_2-EOR component.
- Staff has not identified any significant adverse direct or cumulative soils or surface water impacts resulting from the construction or operation of the proposed project, including impacts to the environment justice population. Therefore, there are no soils or surface water environmental justice issues related to this project and no environmental justice populations would be significantly, adversely, or disproportionately impacted.

OUTSTANDING INFORMATION REQUIRED FOR COMPLETION OF THE FSA/FEIS

Additional Information for the draft DESCP

- The applicant has identified that HDD would be used to pass the CO_2 pipeline under the Outlet Canal, the Kern River Flood Control Channel (KRFCC), and the California Aqueduct (Aqueduct), as shown on **Soil & Surface Water Figure 9**. In addition, the draft DESCP states that an assessment of the crossing methods (conventional open trenching or HDD) would be made for all water bodies, such as irrigation canals, along other pipeline routes. If additional HDD locations are anticipated, staff needs to analyze the proximity of potential resources at and in the vicinity of these locations. Please show all potential locations of HDD activities in the DESCP and update the disturbed soil estimates of entry/exit pits. If HDD sites are not yet finalized, please be conservative and include all potential sites.
- Staff notes that some of the lined retention basins at the HECA site are calculated to have drawdown times that exceed the Kern County maximum of seven days (Kern

County Hydrology Manual – Section 408.08.01). Please adjust the basin design and/or operations to comply with the Kern County basin standard. Also revise the DESCP and hydrology report to reflect these changes.

Proposed Rail Spur Impacts to Offsite Flooding

Construction of the proposed rail spur could potentially alter existing storm water drainage patterns and possibly result in increased flooding of adjacent areas. Please provide additional information:

- Maps and drawings that show locations where construction would cross drainages, canals, and other water bodies. Identify what local and/or permits would be required for these crossings.
- Description of typical methods proposed for accommodating flows under or around the rail bed. Include maps that show locations of drainage features and indicate what flows they would be designed to handle.
- Identify whether the rail bed would be constructed in or near a FEMA 100-year floodplain Zone A. If so, discuss the measures that would be required to ensure no upstream or downstream impacts.

PROPOSED CONDITIONS OF CERTIFICATION

DRAINAGE EROSION AND SEDIMENTATION CONTROL PLAN

SOILS-1: Prior to site mobilization, the project owner shall obtain the CPM's approval for a site specific Drainage Erosion and Sedimentation Control Plan (DESCP) that ensures protection of water quality and soil resources of the project site and all linear facilities for both the construction and operation phases of the project. This plan shall address appropriate methods and actions, both temporary and permanent, for the protection of water quality and soil resources, demonstrate no increase in offsite flooding potential, and identify all monitoring and maintenance activities. The project owner shall complete all engineering plans, reports, and documents necessary for the CPM to conduct a review of the proposed project and provide a written evaluation as to whether the proposed grading, drainage improvements, and flood management activities comply with all requirements presented herein. The plan shall be consistent with the grading and drainage plan as required by Condition of Certification **CIVIL-1** and shall contain at a minimum the following elements:

Vicinity Map: A map shall be provided indicating the location of all project elements with depictions of all major geographic features to include watercourses, washes, irrigation and drainage canals, major utilities, and sensitive areas.

Site Delineation: The site and all project elements shall be delineated showing boundary lines of all construction areas and the location of all existing and proposed structures, underground utilities, roads, and drainage facilities. With legend, indicate types and locations of storm water control measures built to permanently control storm water pollution. Distinguish between pollution prevention, treatment, and containment devices. Identify sanitary waste facilities. Adjacent property owners shall be identified on the plan maps. All maps shall be presented at a legible scale.

Drainage: The DESCP shall include the following elements:

1. Topography. Topography for offsite areas is required to define the existing upstream tributary areas to the site and downstream to provide enough definition to map the existing storm water flow and flood hazard. Spot elevations shall be required where relatively flat conditions exist.

2. Proposed Grade. Proposed grade contours shall be shown at a scale appropriate for delineation of onsite ephemeral washes, drainage ditches, and tie-ins to the existing topography.

3. Hydrology. Existing and proposed hydrologic calculations for onsite areas and offsite areas that drain to the site; include maps showing the drainage area boundaries and sizes in acres, topography and typical overland flow directions, and show all existing, interim, and proposed drainage infrastructure and their intended direction of flow.

4. Hydraulics. Provide hydraulic calculations to support the selection and sizing of the onsite drainage network, diversion facilities and BMPs.

Watercourses and Critical Areas: The DESCP shall show the location of all onsite and nearby watercourses including washes, irrigation and drainage canals, and drainage ditches, and shall indicate the proximity of those features to the construction site. Maps shall identify high hazard flood prone areas.

Clearing and Grading: The plan shall provide a delineation of all areas to be cleared of vegetation and areas to be preserved. The plan shall provide elevations, slopes, locations, and extent of all proposed grading as shown by contours, cross-sections, cut/fill depths or other means. The locations of any disposal areas, fills, or other special features such as Horizontal Directional Drilling (HDD) pits shall also be shown. Existing and proposed topography tying in proposed contours with existing topography shall be illustrated. The DESCP shall include a statement of the quantities of material excavated at the site, whether such excavations or fill is temporary or permanent, and the amount of such material to be imported or exported or a statement explaining that there would be no clearing and/or grading conducted for each element of the project. Areas of no disturbance shall be properly identified and delineated on the plan maps.

Soil Wind and Water Erosion Control: The plan shall address exposed soil treatments to be used during construction and operation of the proposed project for both road and non-road surfaces including specifically identifying all chemical based dust palliatives, soil bonding, and weighting agents appropriate for use at the proposed project site that would not cause adverse effects to vegetation; BMPs shall include measures designed to prevent wind and water erosion including application of chemical dust palliatives after rough grading to limit water use. All dust palliatives, soil binders, and weighting agents shall be approved by the CPM prior to use.

Project Schedule: The DESCP shall identify on the topographic site map the location of the site-specific BMPs to be employed during each phase of construction (initial grading, project element construction, and final grading/stabilization). BMP implementation schedules shall be provided for each project element for each phase of construction.

Best Management Practices: The DESCP shall show the location, timing, and maintenance schedule of all erosion- and sediment-control BMPs to be used prior to initial grading, during project element excavation and construction, during final grading/stabilization, and after construction. BMPs shall include measures designed to control dust and stabilize construction access roads and entrances. The maintenance schedule shall include post-construction maintenance of treatment-control BMPs applied to disturbed areas following construction.

Erosion Control Drawings: The erosion-control drawings and narrative shall be designed, stamped and sealed by a professional engineer or erosion-control specialist.

Agency Comments: The DESCP shall include copies of recommendations from the Kern County and RWQCB, if applicable.

<u>Verification</u>: The DESCP shall be consistent with the grading and drainage plan as required by Condition of Certification **CIVIL-1**. In addition, the project owner shall do all of the following:

- No later than ninety (90) days prior to start of site mobilization, the project owner shall submit a copy of the DESCP to Kern County and the RWQCB for review and comment. No later than 30 days prior to the start of site mobilization, the project owner shall submit a copy of the DESCP with Kern County and RWQCB comments attached to the CPM for review and approval.
- During construction, the project owner shall provide an analysis in the monthly compliance report on the effectiveness of the drainage, erosion, and sediment control measures and the results of monitoring and maintenance activities.

- Once operational, the project owner shall provide in the annual compliance report information on the results of storm water BMP monitoring and maintenance activities.

NPDES GENERAL PERMIT FOR CONSTRUCTION ACTIVITY

SOILS-2: The project owner shall comply with the requirements of the general National Pollutant Discharge Elimination System (NPDES) permit for discharge of storm water associated with construction activity. The project owner shall submit copies of all correspondence between the project owner and the State Water Resources Control Board (SWRCB) or the Central Valley Regional Water Quality Control Board regarding this permit to the CPM. The project owner shall also develop and implement a construction Storm Water Pollution Prevention Plan (SWPPP) for construction on the HECA main site, laydown areas, linear facilities, and transmission line.

Verification: No later than thirty (30) days prior to site mobilization, the project owner shall submit a copy of the construction SWPPP to the SWRCB for review and approval, and retain a copy of the approved SWPPP on site throughout construction. The project owner shall submit copies of all correspondence between the project owner and the SWRCB or the Central Valley Water Board regarding the NPDES permit for the discharge of storm water associated with construction activity to the CPM within 10 days of its receipt or submittal. Copies of correspondence shall include the Notice of Intent sent to the SWRCB, the confirmation letter indicating receipt and acceptance of the Notice of Intent, a copy of the construction SWPPP, any permit modifications or changes, and completion/permit Notice of Termination.

ENCROACHMENT FOR LINEAR FACILITIES

SOILS-3: The project owner shall comply with relevant jurisdiction limitations for encroachment into public rights-of-way for construction activities of linear facilities and shall obtain all necessary encroachment permits from all relevant jurisdictions including, but not limited to: Department of Water Resources (California Aqueduct), Caltrans (Interstate 5, Highway 58), RailAmerica (railroad), Central Valley Flood Protection Board (Kern River Flood Control Channel), Buena Vista Water Storage District (irrigation canals), and Kern County (county roads).

Verification: No later than thirty (30) days prior to mobilization construction work of linear facilities, the project owner shall submit to the CPM copies of all necessary encroachment permits relative to construction of linear facilities, unless the permitting agency states that a permit is not required. In addition, the project owner shall retain copies of these permits and supporting documentation in its compliance file for at least six months after the start of commercial operation.

CONSTRUCTION WASTEWATER DISCHARGE

SOILS-4: Prior to hydrostatic test water discharge to land, the project owner shall fulfill the requirements contained in State Water Resources Control Board (SWRCB) *Order No. 2003-003-DWQ Statewide General Waste Discharge*

Requirements (WDRs) for Discharges to Land with a Low Threat to Water Quality (General WDRs) and all subsequent revisions and amendments.

Prior to hydrostatic test water discharge to surface waters or designated Waters of the State, the project owner shall fulfill the requirements contained in Central Valley Regional Board *Order No. R5-2008-0081 (Waste Discharge Requirements for Dewatering and Other Low Threat Discharges to Surface Waters)* and all subsequent revisions and amendments.

Prior to transport and disposal of any facility construction-related wastewaters offsite, the project owner shall test and classify the stored wastewater to determine proper management and disposal requirements. The project owner shall provide evidence that wastewater is disposed of at an appropriately licensed facility. The project owner shall ensure that the wastewater is transported and disposed of in accordance with the wastewater's characteristics and classification and all applicable LORS (including any CCR Title 22 Hazardous Waste and Title 23 Waste Discharges to Land requirements).

<u>Verification:</u> The project owner shall submit to the CPM copies of all relevant correspondence between the project owner and the SWRCB or Central Valley RWQCB about the hydrostatic test water discharge requirements within 10 days of its receipt or submittal. This information shall include copies of the Notice of Intent and Notice of Termination for the project. A letter from the SWRCB or Central Valley RWQCB indicating that there is no requirement for the discharge of hydrostatic test water would satisfy the corresponding portion of this condition.

Prior to transport and disposal of any facility construction-related wastewaters offsite, the project owner shall test and classify the stored wastewater to determine proper management and disposal requirements. The project manager shall ensure that the wastewater is transported and disposed of in accordance with the wastewater's characteristics and classification and all applicable LORS (including any CCR Title 22 Hazardous Waste and Title 23 Waste Discharges to Land requirements). The project owner shall provide evidence to the CPM of proper wastewater disposal, via a licensed hauler to an appropriately licensed facility, in the monthly compliance report.

INDUSTRIAL - NPDES GENERAL PERMIT

SOILS-5: The project owner shall comply with the requirements of the State Water Resources Control Board's NPDES General Permit for Discharges of Storm Water Associated with Industrial Activities (Order No. 97-03-DWQ, NPDES No. CAS000001) and all subsequent revisions and amendments. The project owner shall develop and implement a Storm Water Pollution Prevention Plan (SWPPP) for project operation. The project owner may also submit a Notice of Non- Applicability (NONA) to the State Water Resources Control Board (SWRCB) to apply for an exemption to the general NPDES permit.

<u>Verification</u>: At least thirty (30) days prior to operation, the project owner shall submit copies to the CPM of the operational SWPPP and shall retain a copy on site.

Within 10 days of its mailing or receipt, the project owner shall submit to the CPM any correspondence between the project owner and the SWRCB or Central Valley RWQCB about the general NPDES permit for discharge of storm water associated with this activity. This information shall include a copy of the Notice of Intent sent by the project owner to the SWRCB and the notice of termination. A letter from the SWRCB or the RWQCB indicating that there is no requirement for a general NPDES permit for discharges of storm water associated with industrial activity would satisfy this condition.

SEPTIC SYSTEM AND LEACH FIELD REQUIREMENTS

SOILS-6: The project owner shall comply with the requirements of the Kern County Ordinance 14.20.050, Kern County Engineering: Division Six - Environmental Health Standards Rules and Regulations, and the California Plumbing Code (CCR Title 24, Part 5) regarding sanitary waste disposal facilities such as septic systems and leach fields. The septic system and leach fields shall be designed, operated, and maintained in a manner that ensures no deleterious impact to groundwater or surface water. Compliance shall include an engineering report on the septic system and leach field design, operation, maintenance, and loading impact to groundwater.

Verification: The project owner shall submit the appropriate fee and required documentation to the Kern County Environmental Health Department for review and comment to ensure that the project has complied with county sanitary waste disposal facilities requirements including: soil percolation standards; minimum separation/set back distances to prevent impacts to groundwater and nearby water wells; and septic tank and leach field design, sizing and construction standards to ensure adequate capacity and proper treatment and disposal of the wastewaters. Written assessments prepared by Kern County regarding the project’s compliance with these requirements must be submitted to the CPM for review and approval at least thirty (30) days prior to use of the septic systems.

TRAFFIC AND TRANSPORTATION

John Hope

SUMMARY OF CONCLUSIONS

Energy Commission staff has analyzed the information provided in the Application for Certification (AFC) and acquired from other sources to determine the potential for the Hydrogen Energy California (HECA) project to have significant adverse traffic and transportation-related impacts. Staff has also assessed the potential for mitigation proposed by the applicant and conditions developed by staff to reduce any potential impacts, as well as the feasibility and enforceability of those proposed mitigations and recommended conditions of certification.

As currently proposed, the HECA project could result in significant impacts to the traffic and transportation system serving the project site and surrounding community as follows:

- The HECA project could significantly degrade existing peak hour levels-of-service (LOS) at the intersections of SR 43/Stockdale Highway, SR 119/Tupman Road, Dairy Road/Adohr Road, and Dairy Road/Stockdale Highway resulting in increased delays for vehicles. However, Conditions of Certification **TRANS-1** and **TRANS-2** would reduce these impacts.
- The HECA project could substantially increase traffic on certain roadway segments resulting in potential degradation of roadway surfaces. However, Conditions of Certification **TRANS-3** and **TRANS-4** would reduce these impacts.
- High velocity thermal plumes emitted from the HECA project's exhaust stacks could present a potentially significant hazard to aircraft flying directly overhead at low altitude. However, Conditions of Certification **TRANS-7** through **TRANS-10** would reduce these potential impacts to a less than significant level.
- Although potentially significant impacts associated with implementation of the proposed HECA project can be mitigated to a less-than-significant level, staff has concerns that the project has the potential to substantially increase traffic levels on farming roads not currently intended for heavy truck traffic and heavy load capacities. This substantial increase in traffic also has the potential to impact traffic associated with existing farming activities (e.g., tractors traveling on public roadway) thereby potentially resulting in safety issues and increased accidents to the public. Based on a recent Board of Supervisor's meeting held on February 26, 2013, the Board instructed the Public Works Department to review the roadways intended for heavy truck, and worker traffic and report back at their June 2013 Board meeting as to recommendations for improvements to the local roadway system. Staff will address the concerns and/or recommendations by Kern County in the FSA.

It is noted that there are outstanding issues for the proposed project which are not able to be analyzed as part of this PSA/DEIS. These outstanding issues are discussed in the "Outstanding Information Required for Completion of the FSA/FEIS" section below. Staff is unable to reach a conclusion until outstanding information is provided.

INTRODUCTION

In compliance with California Environmental Quality Act (CEQA) and Energy Commission requirements, this analysis identifies the HECA project's potential impacts to the surrounding transportation systems and proposes mitigation measures (conditions of certification) that would avoid or lessen these impacts to a less-than-significant level. It also addresses the project's consistency with applicable federal, state, and local transportation-related laws, ordinances, regulations, and standards (LORS).

As discussed in the Introduction, this document analyzes the project's impacts pursuant to both the National Environmental Policy Act (NEPA) and CEQA. The two statutes are similar in their requirements concerning analysis of a project's impacts. Therefore, unless otherwise noted, staff's use of, and reference to, CEQA criteria and guidelines also encompasses and satisfies NEPA requirements for this environmental document.

SETTING

The 453-acre proposed HECA project site is comprised of parcels currently used for farming purposes. In addition, the applicant is also purchasing additional parcels adjacent to the project site totaling 633 acres for the purposes of public access control and future land uses. The HECA site is bounded by Adohr Road on the north, Tupman Road to the east, an irrigation canal to the south, and Dairy Road to the west. Primary access to the site would be from Station Road via Morris Road and Stockdale Highway. Stockdale Highway and Interstate 5 (I-5) are located approximately 1 mile to the north and 3 miles to the east, respectively. The Elk Hills-Buttonwillow Airport, which is a public airport primarily used for general aviation, is located approximately 5 miles northwest of the proposed project site. Elk Hills Oil Field is located approximately 1 mile south of the proposed HECA site. **Traffic and Transportation Figures 1-1** and **1-2** display the regional and local roadway system.

APPLICANT-PROPOSED IMPROVEMENTS AND TRAFFIC MEASURES

In the AFC for the HECA project, the applicant has proposed the following roadway improvements and traffic measures:

- The project owner will coordinate with Kern County to identify and construct roadway improvements, if needed, to support construction traffic to ensure that roadway impacts are less than significant.
- The project owner will coordinate with Kern County and Caltrans to identify and construct intersection improvements needed to support construction traffic so that intersection impacts are reduced to less-than-significant levels. The following intersections will require improvements:
    - Signalization of the current 4-way-stop SR 43 (Enos Lane)/Stockdale Highway intersection.
    - Signalization of the current 2-way-stop SR 119/Tupman Road intersection.

- At the Dairy Road/Stockdale Highway intersection, construct a separate left-turn lane on the westbound approach of Stockdale Highway, and construct a separate right-turn lane on the northbound approach of Dairy Road.
- At the Dairy Road/Adohr Road intersection, reconstruct the intersection to accommodate the turning radius needed by large trucks to make the turns.

- The project owner will use proper signs and traffic control measures in accordance with Caltrans and county requirements. All traffic signs, equipment, and control measures shall conform to the provisions specified in the Manual of Uniform Traffic Control Device (MUTCD), California Edition.
- The project owner will schedule potential traffic lane or road closures during off-peak hours whenever possible.
- The project owner will limit vehicular traffic to designated access roads, construction laydown and worker parking areas, and the project construction site.
- The project owner will implement Transportation Demand Management Measures (TDM) which encourage worker carpooling to minimize drive-alone worker trips. The project owner will provide incentives and develop a reward system to increase voluntary participation of various TDM measures.
- The project owner will limit vehicular traffic to designated access roads. The project owner will encourage worker carpooling to minimize drive-alone worker trips.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

Traffic and Transportation Table 1 provides a general description of adopted federal, state, and local LORS pertaining to traffic and transportation relevant to the proposed project.

TRAFFIC and TRANSPORTATION Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable Law	Description
Federal	
Aeronautics and Space Title 14 Code of Federal Regulations (CFR), part 77 Objects Affecting Navigable Airspace (14 CFR 77)	Establishes standards for determining physical obstructions to navigable airspace; sets noticing and hearing requirements; and provides for aeronautical studies to determine the effect of physical obstructions on the safe and efficient use of airspace.
49 CFR, Subtitle B	Includes procedures and regulations pertaining to interstate and intrastate transport (including hazardous materials program procedures) and provides safety measures for motor carriers and motor vehicles that operate on public highways.
State	
California Vehicle Code, div. 1; div. 2, chapter 2.5; div. 6, chap. 2 & 7; div. 13, chap. 5; div. 14; div. 14.1, chap. 1 & 2; div. 14.3; div. 14.7; div. 14.8; div. 15	Includes regulations pertaining to licensing, size, weight, and load of vehicles operated on highways; safe operation of vehicles; and the transportation of hazardous materials.
California Streets and Highway Code, division 1 & 2, chapter 3 & chapter 5.5	Includes regulations for the care and protection of state and county highways and provisions for the issuance of written permits.
California Street and Highway Code §§117, 660-711	Requires permits from California Department of Transportation (Caltrans) for any roadway encroachment during truck transportation and delivery.
California Street and Highway Code §§660-711	Requires permits for any load that exceeds Caltrans weight, length, or width standards for public roadways.
California Manual on Uniform Control Devices (MUTDC) Chapter 6C	Describes temporary traffic control (TTC) measures to be used for facilitating road users through a work zone or an incident area. TTC plans play a vital role in providing continuity of reasonably safe and efficient road user flow when a work zone, incident, or other event temporarily disrupts normal road user flow.
CPUC Code Reference §§1001, 1007, 1008, 1904(a)	Requires an Application for Certificate of Public Convenience and Necessity (CPCN) to operate a rail facility.
CPUC General Order 22-B, 26-D, 33-B, 72-B, 75-D, 88-B, 95, 108, 110, 114, 118-A, 125, 126, 135, 145, 161	Safe operation of rail lines

Local	
Kern County Airport Land Use Compatibility Plan (ALUCP)	Requires local agencies to ensure compatible land uses in the vicinity of existing or proposed airports; to coordinate planning at state, regional, and local levels; to prepare and adopt an airport land use plan; to review plans, regulations, or locations of agencies and airport operators; and to review and make recommendations regarding the land uses, building heights, and other issues relating to air navigation safety and promotion of air commerce.
Kern County (ALUCP) Section 3.3.5	Prohibits land use characteristics that may produce hazards to aircraft in flight including sources of electrical interference with aircraft communications or navigation
Kern County General Plan Circulation Element	• Chapter 2 (Circulation Element), Goal 5, specifies that all county roadways shall operate at a Level of Service D or better; • Circulation Element Subsection 2.3.3 (Highway Plan), Goal 5, specifies that all county highways shall operate at a Level of Service D or better; and • Circulation Element, Policy 4, specifies that as a condition of private development approval, developers shall build roads needed to access the existing road network. Developers shall build these roads to County standards unless improvements along state routes are necessary then roads shall be built to California Department of Transportation standards. Developers shall locate these roads (width to be determined by the Circulation Plan) along centerlines shown on the circulation diagram map unless otherwise authorized by an approved Specific Plan Line. Developers may build local roads along lines other than those on the circulation diagram map. Developers would negotiate necessary easements to allow this requirement.
Kern County Regional Transportation Plan	Chapter 4 (Strategic Investments) of the Regional Transportation Plan (RTP) includes a listing of State highways and principal arterials within Kern County designated as part of the Congestion Management System, including level of service standards (Level of Service E or better) for these designated RTP roadways.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

METHOD AND THRESHOLD FOR DETERMINING SIGNIFICANCE

Significance criteria used in this document for evaluating environmental impacts are based on the CEQA Guidelines, the CEQA Environmental Checklist for Transportation/Traffic, and applicable LORS used by other governmental agencies. These criteria also satisfy NEPA requirements for analyzing environmental impacts. Specifically, staff analyzed whether the proposed project would result in the following:

1. Cause an increase in traffic which is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume-to-capacity ratio on roads, or congestion at intersections);
2. Conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system, taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths;
3. Conflict with an applicable congestion management program, including, but not limited to, level of service standards (LOS) and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways;

4. Substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment);
5. Result in inadequate emergency access;
6. Conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities;
7. Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks;
8. Produce a thermal plume in an area where flight paths are expected to occur below 1,000 feet from the ground[1]; or
9. Have individual environmental effects which, when considered with other impacts from the same project or in conjunction with impacts from other closely related past, present, and reasonably foreseeable future projects, are considerable, compound, or increase other environmental impacts.

ASSESSMENT OF TRAFFIC IMPACTS

Setting

The following roadways are located near the proposed HECA project and may be impacted by construction and operations traffic.

Interstate 5 (I-5)

I-5, located approximately 4 miles east of the HECA site, is a major north-south regional transportation route through Kern County. Near the HECA site, I-5 provides two mainline lanes in each direction with wide shoulders and a center median, providing separate acceleration/deceleration lanes at the interchange of I-5/State Route 119, I-5/Stockdale Highway, and I-5/State Route 58. The speed limit of I-5 in the vicinity of the proposed HECA site is posted at 70 miles per hour (mph) for cars and 55 mph for trucks. The Annual Average Daily Traffic (AADT) on the segment of I-5 within the proposed project area is 31,000 vehicles per day, with truck traffic accounting for 25 percent of this volume (URS 2012a, pp. 5.10-5 - 5.10-6).

State Route 119 (SR 119)

SR 119 is an east-west state highway located approximately 7 miles south of the HECA site. SR 119 provides regional and emergency egress and workforce commute to the HECA site. SR 119 connects to State Route 99 (SR 99) on the east with State Route 33 (SR 33) on the west. Near the HECA site, SR 119 has a two-lane (one lane in each direction) cross section with an 8- to 12-foot shoulder on both sides with a posted speed limit of 55 mph. The ADT on the highway just west of I-5 southbound ramps is 10,000 vehicles per day, with truck traffic accounting for 20% of this volume. The proposed project does not plan to use SR 119 as the primary access route during construction and operation activities (URS 2012a, p. 5.10-6). The ADT on the segment of SR 119 east of Tupman Road is projected to be approximately 12,000 vehicles per day in 2016

[1] The FAA recommends that pilots avoid overflight of plume-generating industrial sites below 1,000 feet AGL (FAA 2006).

(URS 2012b, p. 159-2).

State Route 58 (SR 58)

SR 58, located approximately 4 miles north of the proposed HECA site, is an east-west state highway consisting of a two-lane conventional state highway with 4- to 8-foot shoulders and a posted speed limit of 55 mph in vicinity near the HECA site (HEI 2008c, p. 5.10-5). The I-5 southbound ramp/SR 58 interchange is currently signalized. The ADT on the segment of SR 58 west of SR 43 is 6,900 vehicles per day, with truck traffic accounting for 21% of this volume. SR 58 is designated as a state truck route (URS 2012a, p. 5.10-6).

State Route 43 (SR 43)

SR 43, located approximately 7 miles east of the proposed HECA site, is a north-south state highway. SR 43 is a two-lane road north of its intersection with Stockdale Highway. SR 43 becomes Central Valley Highway in the city of Shafter, California, and widens to a four-lane undivided highway. North of Shafter, SR 43 becomes a four-lane divided highway with a 65 mph speed limit. In Kern County, SR 43 is a designated Terminal Access Truck Route. The ADT on the segment of SR 43 north of Stockdale Highway is 9,000 vehicles per day, with truck traffic accounting for 21% of this volume (URS 2012a p. 5.10-6).

Stockdale Highway

Stockdale Highway is an east-west highway located one mile north of the HECA site. It starts near Wasco Way on the west and continues to the east through metropolitan Bakersfield, with an unsignalized freeway interchange providing connection to I-5. The segment of Stockdale Highway in the vicinity of the proposed HECA project has two through lanes (one lane in each direction) with no shoulders and a posted speed limit of 55 mph (URS 2012a, p. 5.10-6). The ADT on the segment of Stockdale Highway west of I-5 is projected to be approximately 2,000 vehicles per day in 2016 (URS 2012b, p. 159-2).

Adohr Road

Adohr Road is an east-west roadway containing two-lanes and is classified as Major (Arterial) Highway by the Kern County General Plan Circulation Element and would provide main access to the proposed HECA site (HEI 2008c, p. 5.10-7). This roadway starts at Freeborn Road on the west and ends at Tupman Road on the east and is relatively straight with flat terrain in the vicinity of the proposed HECA site (URS 2012a, p. 5.10-7). The ADT on the segment of Adohr Road east of Dairy Road is projected to be approximately 300 vehicles per day in 2016 (URS 2012b, p. 159-2).

Dairy Road

Dairy Road is a north-south local roadway containing two-lanes starting at Adohr Road on the south and ends at Stockdale Highway on the north. The intersection of Stockdale Highway and Dairy Road is controlled by a stop sign on Dairy Road. The roadway segment is relatively straight and the terrain is flat in the vicinity of the proposed HECA site (URS 2012, p. 5.10-7). The ADT on the segment of Dairy Road south of Stockdale Highway is projected to be approximately 200 vehicles per day in 2016 (URS 2012b, p.

159-2).

Morris Road

Morris Road is a north-south local roadway containing two-lanes starting at Station Road on the south and ends at Stockdale Highway on the north. The intersection of Stockdale Highway and Morris Road is controlled by a stop sign on Morris Road. The roadway segment is relatively straight and the terrain is flat in the vicinity of the HECA site (URS 2012a, p. 5.10-7). The ADT on the segment of Morris Road south of Stockdale Highway is projected to be approximately 300 vehicles per day in 2016 (URS 2012b, p. 159-2).

Station Road

Station Road is an east-west local roadway containing two-lanes starting at Tupman Road on the west and ends at Morris Road on the east. The intersection of Tupman Road and Station Road is controlled by a stop sign on Station Road. The roadway segment is relatively straight and the terrain is flat in the vicinity of the proposed HECA site (URS 2012a, p. 5.10-67). The ADT on the segment of Station Road west of Morris Road is projected to be approximately 230 vehicles per day in 2016 (URS 2012b, p. 159-2).

Wasco Way

Wasco Way is a north-south local roadway containing two-lanes starting at Stockdale Highway on the south and ends at SR 58 on the north. The intersection of SR 58 and Wasco Way is controlled by a stop sign on Wasco Way. The roadway segment is relatively straight and the terrain is flat in the vicinity of the HECA site. The ADT on the segment of Wasco Way north of Stockdale Highway is projected to be approximately 1,900 vehicles per day in 2016 (URS 2012b, p. 159-2).

Tupman Road

Tupman Road is a north-south, two-lane primary road with 2-foot shoulders on both sides, and is classified as a collector road by the Kern County General Plan Circulation Element. Tupman Road is adjacent to the eastern boundary of the HECA site. The intersection of Tupman Road and SR 119 is unsignalized, with stop signs on Tupman Road. Heading north from SR 119, terrain along Tupman Road is relatively flat to moderately rolling grade, with some segments having limited horizontal sight visibility to opposing traffic. The posted speed limit is 55 mph in the vicinity of the proposed HECA site (URS 2012a, p. 5.10-7). The ADT on the segment of Tupman Road south of Adohr Road is projected to be approximately 130 vehicles per day in 2016 (URS 2012b, p. 159-2).

9th Street

9th Street is an east-west street in Wasco, California, extending from H Street to J Street on the north side of Wasco Coal Terminal. 9th Street has two lanes and is 55 feet wide with parking allowed on both sides of the street. The roadway segment is relatively straight, and the terrain is flat with good sight distance in both directions (URS 2012a, p. 5.10-7). The ADT on the segment of 9th Street east of H Street is projected to be approximately 350 vehicles per day in 2017 (URS 2012b, p. 159-3).

H Street

H Street is a north-south street in Wasco, California, extending north from J Street on the west side of Wasco Coal Terminal. H Street has two lanes and is 55 feet wide with parking allowed on both sides of the street. The roadway segment is relatively straight, and the terrain is flat with good sight distance in both directions (URS 2012a, p. 5.10-7). The ADT on the segment of H Street south of 9th Street is projected to be approximately 1,100 vehicles per day in 2017 (URS 2012b, p. 159-3).

J Street

J Street is a north-south street in Wasco, California, extending from Poso Avenue on the east side of Wasco Coal Terminal. J Street has four lanes and is 56 feet wide with parking allowed on both sides of the street. The roadway segment is relatively straight, and the terrain is flat with good sight distance in both directions (URS 2012a, p. 5.10-7). The ADT on the segment of J Street north of Poso Avenue is projected to be approximately 2,100 vehicles per day in 2017 (URS 2012b, p. 159-3).

Wasco Avenue

Wasco Avenue is a north-south street in Wasco, California, extending from Poso Avenue to Kimberlina Road on the east side of Wasco Coal Terminal. North of Poso Avenue, Wasco Avenue turns and becomes J Street. The roadway segment is relatively straight, and the terrain is flat with good sight distance in both directions (URS 2012a, pp. 5.10-7,-8). The ADT on the segment of Wasco Avenue north of Poso Avenue is projected to be approximately 1,500 vehicles per day in 2017 (URS 2012b, p. 159-3).

Poso Avenue

Poso Avenue is an east-west street in Wasco, California. Poso Avenue intersects SR 43 at an all-way stop-controlled intersection. Between SR 43 and Wasco Avenue there is an at-grade rail crossing with gates and flashing lights. The roadway segment is relatively straight, and the terrain is flat with good sight distance in both directions (URS 2012a, p. 5.10-8). The ADT on the segment of Poso Avenue east of SR 43 is projected to be approximately 2,800 vehicles per day in 2017 (URS 2012b, p. 159-3).

Kimberlina Road

Kimberlina Road is an east-west street in Wasco, California. Kimberlina Road intersects SR 43 at a signalized intersection. The roadway segment is relatively straight, and the terrain is flat with good sight distance in both directions. The ADT on the segment of Kimberlina Road east of SR 43 is projected to be approximately 3,900 vehicles per day in 2017 (URS 2012b, p. 159-3).

Level of Service and Study Locations

Level of Service (LOS)

Level of Service (LOS) is a generally accepted measure used by traffic engineers and planners to describe and quantify the traffic congestion level on a particular roadway or intersection in terms of speed, travel time, and delay. The *Highway Capacity Manual*

2000[2], published by the Transportation Research Board Committee on Highway Capacity and Quality of Service, includes six levels of service for roadways and intersections. These levels of service range from LOS A, the best and smoothest operating conditions, to LOS F, the worst, most congested operating conditions.

The following locations on the surrounding roadway network were reviewed:

Freeways and Roadways:

- Interstate 5 (I-5) (north and south of Stockdale Highway)
- State Route 43 (SR 43) (north of Stockdale Highway, north of SR 58, south of 7th Standard, south of Lerdo Highway, south of Poso Avenue)
- State Route 119 (SR 119) (east of Tupman Road)
- Stockdale Highway (west of Dairy Road, west and east of I-5)
- Dairy Road (south of Stockdale Highway)
- Adohr Road (east of Dairy Road)
- Station Road (west of Morris Road)
- Morris Road (south of Stockdale Highway)
- Wasco Way (north of Stockdale Highway)
- Tupman Road (south of Adohr Road, north of SR 119)
- Wasco Avenue (south of Poso Avenue)
- J Street (north of Poso Avenue, south of 9th Street)
- H Street (south of 9th Street)
- Kimberlina Road (east of SR 43)
- Poso Avenue (east of SR 43)
- 9th Street (East of H Street)

Intersections:

- I-5 NB Ramp / Stockdale Highway
- I-5 SB Ramp / Stockdale Highway
- I-5 NB Ramp / SR 119
- I-5 SB Ramp / SR 119
- SR 119 / SR 43
- SR 43 / Stockdale Highway
- Stockdale Highway / Morris Road

[2] The *Highway Capacity Manual* (HCM) is the most widely used resource for traffic analysis. The Highway Capacity Manual is prepared by the Transportation Research Board, Committee on Highway Capacity and Quality of Service. The current edition was published in 2010.

- SR 119 / Tupman Road
- Tupman Road / Grace Avenue
- Tupman Road / Station Road
- Dairy Road / Stockdale Highway
- Dairy Road / Adohr Road
- SR 43 / Poso Avenue
- SR 43 / Kimberlina Road
- SR 43 / Shafter Avenue
- SR 43 / Central Avenue
- SR 43 / Lerdo Highway
- SR 43 / 7th Standard Road
- SR 43 / SR 58 (Rosedale Highway West)
- SR 43 / SR 58 (Rosedale Highway East)
- SR 58 / Wasco Way
- H Street / 9th Street
- H Street / Wasco Avenue
- Wasco Avenue / Poso Avenue
- Wasco Avenue / Kimberlina Road
- J Street / 9th Street

Level of service (LOS), volume-to-capacity (V/C), and delay standards for the various roadways and intersections in the vicinity of the HECA project are established by and under the jurisdiction of several different agencies. Staff used these standards to evaluate potential HECA-generated traffic impacts. The following is a list of the applicable standards:

- <u>Kern County - Kern County General Plan Circulation Element</u>

  The acceptable LOS standard for county roadways is LOS D or better.

- <u>California Department of Transportation (Caltrans) – Guide for the Preparation of Traffic Impact Studies (2002)</u>

  Caltrans endeavors to maintain a target LOS at the transition between LOS C and LOS D on state highway facilities. If an existing state highway facility is operating at less than the appropriate target LOS, the existing measures of effectiveness (MOE) should be maintained.

Peak Hour

Peak hour is defined as the part of a day during which traffic congestion on roads and crowding on public transport is at its highest. Typically this occurs twice per day – one time in the morning and one time in the evening – during times when the majority of people commute.

To determine the AM peak hour and PM peak hour for the proposed HECA project, traffic counts are taken for two hours between 7:00 and 9:00 AM and two hours between 4:00 and 6:00 PM. Traffic counts conducted during the 2-hour periods are then reviewed to identify the hour when the most vehicles are counted, or the hour of highest traffic (e.g., 7:15 to 8:15 AM). The number of vehicles counted during an identified peak hour is then used in the analysis of potential traffic impacts.

DIRECT/INDIRECT IMPACTS AND MITIGATION

The direct and indirect impacts of the proposed HECA project on the traffic and transportation system are discussed in this section and based on an analysis comparing pre-HECA and post-HECA conditions. Staff evaluated the HECA project's impacts for two separate future scenarios: peak construction period (when construction activity and employment would be maximized) and first year of full operation.

Traffic during the decommissioning period would likely be similar to traffic volumes experienced during construction, depending on the duration and extent of decommissioning, including dismantling of facilities and/or site remediation.

Construction Traffic

Analysis of HECA project construction impacts focuses on the peak construction period, which would generate the most vehicle trips and result in the worst-case scenario for traffic impacts.

Worker Traffic

As stated in AFC Section 2.0 (Project Description), the applicant expects that construction of the proposed HECA project would last approximately four years, starting in September/October 2013 and ending in September 2017. Peak construction trips were used to determine potential impacts as this would represent the worst-case construction traffic scenario. There would be a peak daily workforce of 2,460. The traffic analysis assumed that some workers would carpool and assumed one-third of the worker vehicles would arrive during the morning peak hour of 7:00 AM to 9:00 AM, and all would depart during the evening peak hour of 4:00 PM to 6:00 PM (URS 2012a, p. 5.10-30).

Construction equipment and material delivery projections indicate that during the peak construction month there would be 50 truck deliveries daily, a total equal to 100 daily one-way truck trips per day. These trips were subsequently converted into passenger car equivalent (PCE) trips at 3 PCE per truck (or 300 PCE trips). Even though truck deliveries would likely arrive and depart throughout the day, to represent the worst-case scenario the truck trips were conservatively assumed to occur during the morning peak hour. Additionally, the analysis assumed that there would be minimal deliveries during the evening peak hour (e.g., deliveries of time-critical equipment and materials, specialty loads).

During construction, soil fill materials would be imported to the HECA project site. The soil fill material deliveries were assumed to originate from local sources. Soil fill projections indicate that during the peak construction month there would be on average 160 truck deliveries daily, or 320 one-way daily truck trips per day. These trips were subsequently converted into PCE trips at 3 PCE per truck (or 960 trips). For purposes of this analysis, both the construction vehicle delivery and worker trips were converted to PCE trips, consistent with Caltrans *Highway Capacity Manual* guidelines. PCE is defined as the number of passenger cars that are displaced by a single heavy vehicle of a particular type under the prevailing traffic conditions. For example, a PCE of 2.0 indicates that two passenger vehicles are displaced by one heavy vehicle in the same traffic conditions. Heavy vehicles have a greater impact on traffic than passenger cars for the following reasons:

- Heavy vehicles are larger than passenger cars thereby occupying more space; and
- Heavy vehicle's performance characteristics are generally inferior to passenger cars which lead to the formation of downstream gaps in the traffic stream, especially on grades, which cannot always be effectively filled by normal passing maneuvers.

Based on the lack of elevation changes in the project vicinity and the physical size of heavy trucks anticipated to be used during construction of the proposed project, the applicant applied a PCE of 3.0 to each truck trip as part of this analysis. PCE 3.0 indicates that it is anticipated that one heavy vehicle associated with the project would displace three passenger vehicles in the same traffic conditions.

Traffic and Transportation Table 2 lists the estimate of total construction vehicle trips for the proposed HECA project in PCE, identifying which of those would be generated during both the AM and PM peak hour periods.

Traffic and Transportation Table 2
Estimated Average and Peak Hour Trip Generation – Peak Construction Period

	Actual Vehicle Round Trips	Peak Daily Trips	AM Peak Hour			PM Peak Hour		
			In	Out	Total	In	Out	Total
Construction Worker Vehicles[1]	1,230	2,460	410	0	410	0	1,230	1,230
Truck Deliveries[2]	50	300	75	75	150	0	0	0
Soil Fill Deliveries[3]	160	960	48	48	96	0	0	0

Source: URS 2012a, p.5.10-30

Notes:

1. Note that 2.0 passenger occupancy per vehicle was assumed to account for the carpooling of approximately 2,461 workers conservatively analyzed during the peak construction month, yielding 1,230 vehicles for the construction workers. It was conservatively assumed that one-third of the worker vehicles will arrive during the a.m. (peak one hour between 7:00 to 9:00 a.m.) and all will leave during p.m. (peak one hour between 4:00 to 6:00 p.m.) peak hours.
2. Trucks deliveries shown in the table were adjusted into Passenger Car Equivalent (3 PCE) vehicles. The trip generation estimate was based on the average 24-hour and maximum 1-hour truck delivery trips during Project construction. There are 50 (average 24-hour) truck deliveries @ 3 PCE/truck = 150 PCE vehicles. Peak daily trips (including both the inbound and outbound trips) = 2 × 150 PCE vehicles = 300 PCE Trips. There are 25 (maximum 1-hour) truck deliveries @ 3 PCE/truck = 75 PCE vehicles. Therefore, peak hourly trips (assuming equal number of inbound and outbound trips) = 2 × 75 PCE vehicles = 150 PCE Trips. It was further assumed that there will no Project deliveries during the p.m. peak hour.
3. Average import fill delivery truck trips (at 18-cubic-yard capacity per truck), adjusted into PCE vehicles (3 PCE per truck). The trip generation estimate was based on the average 24-hour and 1-hour trips during Project construction site preparation. There are 160 (average 24-hour) truck deliveries @ 3 PCE/truck = 480 PCE vehicles. Peak daily trips (including both the inbound and outbound trips) = 2 × 480 PCE vehicles = 960 PCE Trips. There are 16 (average 1-hour) truck deliveries @ 3 PCE/truck = 48 PCE vehicles. Therefore, peak hourly trips (assuming equal number of inbound and outbound trips) = 2 × 48 PCE vehicles = 96 PCE Trips. It must be noted that applying the maximum number of fill material truck loads is not appropriate, as these trips are anticipated to decrease and taper off on the later months of the Project construction schedule. For construction analysis purposes, using the average number of fill material truck loads is very conservative when added to the peak construction workforce as well as construction material delivery trips as these peak construction activities overlap.

Based on the construction vehicle trip calculations presented in **Traffic and Transportation Table 2**, an analysis was conducted in the AFC to determine the impacts of these construction vehicle trips on current study area intersections LOS. **Traffic and Transportation Table 3** identifies the current (2012) and future (2016) LOS anticipated with and without the proposed project construction vehicle traffic for critical intersections in the vicinity of the project. As described in **Traffic and Transportation Table 1,** Kern County does not have any LORS specifying acceptable LOS thresholds for intersections (General Plan Circulation Element LOS thresholds are specific to roadway segments). However, in maintaining consistency with the Kern County General Plan Circulation Element, staff utilized a LOS D threshold for determining intersection LOS impacts.

As shown in **Traffic and Transportation Table 3**, with the addition of the HECA project's peak construction traffic, all study area intersections will continue to operate at an acceptable LOS during the AM peak hour as compared to the future Year 2016 without project conditions. During the PM peak hour, the HECA project's peak construction traffic will temporarily impact both the SR 43/Stockdale Highway and SR 119/Tupman Road intersections, which are projected to degrade to LOS F.

It should be noted that 2016 With Project conditions, shown in **Traffic and Transportation Table 3**, include implementation of roadway improvements by the applicant (e.g., signalization of the current 4-way-stop SR 43 (Enos Lane)/Stockdale

Highway intersection; signalization of the current 2-way-stop SR 119/Tupman Road intersection; construct a separate left-turn lane on the westbound approach of Stockdale Highway and construct a separate right-turn lane on the northbound approach of Dairy Road at the Dairy Road/Stockdale Highway intersection; reconstruct the Dairy Road/Adohr Road intersection to accommodate the turning radius needed by large trucks to make the turn).

Traffic and Transportation Table 3
Current and Anticipated Year 2016 With and Without Project Intersection LOS - Construction

Intersection[1]	AM						PM					
	Current (2012)		2016 Without Project		2016 With Project		Current (2012)		2016 Without Project		2016 With Project

[1] For existing intersection control features refer to **Traffic and Transportation Table 2**
*Degradation over the existing LOS to unacceptable level.
Bold text indicates unacceptable operating conditions
OVRFL indicates calculation exceeds the limits of the software program

Based on the construction vehicle trip calculations presented in **Traffic and Transportation Table 2**, an analysis was also conducted to determine the impacts of these construction vehicle trips on current traffic volumes on roadway segments in the study area. **Traffic and Transportation Table 4** identifies the baseline (2016) and future traffic volumes anticipated with the proposed project construction vehicle traffic for roadway segments in the vicinity of the project. As described in **Traffic and Transportation Table 1,** Kern County has LORS specifying LOS D as the acceptable LOS thresholds for roadway segments.

As shown in **Traffic and Transportation Table 4**, with the addition of the HECA project's peak construction traffic, all study area roadway segments will continue to operate at an acceptable LOS as compared to future Year 2016 without project conditions. Although all study area roadways will continue to operate at an acceptable LOS, implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2016 without project conditions. Specifically, some roadway segments would experience a substantial increase in the AADT such as Dairy Road (1,262% increase), Adohr Road (438% increase), and Tupman Road (902% and 133% increases). It should be noted that trips added to Wasco Way, north of Stockton Highway, are attributed to an alternative traffic route for construction workers traveling from the HECA site during the PM peak hour (HECA, pers. comm., 2013).

Bold text indicates substantial increase in number of vehicle trips (50% increase or greater)

To minimize impacts from construction related trips, staff is proposing Condition of Certification **TRANS-1,** which would require the project owner to prepare a Construction Traffic Control Plan prior to site mobilization in order to reduce the significance of construction traffic. Even with the implementation of Condition of Certification **TRANS-1,** construction related traffic impacts would remain significant at both the SR 43/Stockdale Highway and SR 119/Tupman Road intersections due to construction related traffic temporarily reducing these intersections to LOS F conditions during the PM peak hour.

As stated previously, construction activities associated with the project would substantially increase the number of trips on certain roadways segments and would equally increase trips through specific intersections including Tupman Road/SR 119, Morris Road/Stockdale Highway, Dairy Road/Stockdale Highway, Dairy Road/Adohr Road, and Station Road/Tupman Road. These intersections are currently stop controlled in only one direction (through traffic is unimpeded while adjoining traffic is required to stop). Uncontrolled intersections are known sources of accidents because these intersections incur the majority of risk to travelers. Therefore, the increase in construction truck traffic with implementation of the proposed project would subsequently increase risk to travelers and the potential for accidents.

As indicated in the AFC and also stated earlier in this analysis, the applicant is proposing improvements to four intersections (i.e., SR 43/Stockdale Highway, SR 119/Tupman Road, Dairy Road/Adohr Road, Dairy Road/Stockdale Highway) to reduce LOS impacts (URS 2012, p. 5.10-13). Staff recommends improvements at two additional intersections (i.e., Morris Road/Stockdale Highway, Station Road/Tupman Road) to reduce the potential for accidents. To ensure these improvements are made, Condition of Certification **TRANS-2** is proposed and will require physical improvements at these intersections to reduce impacts from construction-related trips.

Linear Facilities

In addition to direct construction related trips, interconnecting the HECA project into the Pacific Gas and Electric (PG&E) system will require the construction of approximately 8 miles of transmission line. Intersections and roadway segments along the transmission line routes may be temporarily affected during construction. However, traffic impacts at roadways during utility infrastructure stringing activities would be site-specific and temporary in duration.

Project linear facilities include 8 miles of electrical transmission line, 8 miles of natural gas supply pipeline, 7 miles of potable water supply pipeline, and 4 miles of carbon dioxide pipeline. These linear facilities have the potential to result in temporary lane closures during stringing and tunneling activities. Traffic impacts from the construction of the linear facilities would be short term in nature, mitigated by cones and flagmen when necessary, and not expected to significantly impact traffic flow. Proposed Condition of Certification **TRANS-1** requires the Construction Traffic Control Plan (prepared in conjunction with Kern County and Caltrans) identify any temporary closure of travel lanes or disruptions to street segments and intersections and ensures access to residential and/or commercial property during transmission line stringing activities or any other utility tie ins. This condition will mitigate any significant adverse impact on traffic flows on the local roadway system during construction of the linear facilities.

Rail

The applicant is proposing to construct a 5-mile long rail spur as one alternative option for delivering coal to the facility. This rail spur would traverse south from SR 58 (between Brandt Road and Tracy Lane) to the East Side Canal, then parallel the East Side Canal to Dairy Road, and then parallel Dairy Road to the project site. Construction of the rail spur would generate additional construction-related trips. Intersections and roadway segments along the new rail line route may be temporarily affected during construction. However, traffic impacts at roadways during rail line construction activities would be site-specific and temporary in duration.

The rail line has the potential to result in temporary lane closures during construction activities. Traffic impacts from construction of the rail line would be short term in nature, mitigated by cones and flagmen when necessary, and not expected to significantly impact traffic flow along Stockdale Highway and Adohr Road. Proposed Condition of Certification **TRANS-1** requires that the Construction Traffic Control Plan (prepared in conjunction with Kern County and Caltrans) identifies any temporary closure of travel lanes or disruptions to street segments and intersections and requires the project owner to ensure access to residential and/or commercial property during rail line construction activities. This condition will mitigate any significant adverse impact on traffic flows on the local roadway system during construction of the rail line.

Bridge Capacities

Construction of the proposed project would involve transportation of heavy project components, such as turbines, from the Port of Stockton via heavy trucks. Dependent upon the route(s) trucks carrying heavy project components take, the trucks could require crossing a bridge. The applicant engaged a heavy haul contractor to evaluate the truck route from the Port of Stockton to the project site. The evaluation concluded that all bridges along the truck route have the capability to support the estimated heavy haul loads (HECA, pers. comm., 2013).

Enhanced Oil Recovery (EOR)

The OEHI CO_2 EOR Project (OEHI) would generate new vehicle trips during construction and operational phases that would occur over a 20-year timeframe. The majority of personnel required during construction would be employees currently involved with existing facility operations with additional personnel comprising of local contractors. The annual average vehicle trips estimated during construction are shown in **Traffic and Transportation Table 5**. As shown in **Traffic and Transportation Table 5**, the amount of construction worker vehicle trips would be higher during earlier years of construction then would decline over the remaining years.

Traffic and Transportation Table 5
Construction Annual Average Daily Trips

Year	Construction AADT (one way)	Year	Construction AADT (one way)
2014	140	2024	48
2015	241	2025	56
2016	25	2026	3
2017	149	2027	27
2018	161	2028	64
2019	243	2029	22
2020	21	2030	3
2021	27	2031	21
2022	2	2032	3
2023	6	2033	19

Source: URS 2012, Appendix A-1, pp. 4.15-17

As shown in **Traffic and Transportation Table 6**, with the addition of the OEHI project's traffic, five intersections in the project area are projected to degrade to LOS E by the year 2030.

Traffic and Transportation Table 6
Existing and Projected Year 2030 with Project Intersection LOS

Intersection	2004 or 2006		2015		2030	
	Peak Hour	LOS	Peak Hour	LOS	Peak Hour	LOS

SR 43 / SR 119	1,150	D	1,500	D	2,000	**E**

Source: URS 2012, Appendix A-1, pp. 4.15-13
Bold text indicates unacceptable operating conditions

Caltrans proposes improvements to SR 119 in the OEHI project area, including intersections potentially impacted by construction-related activities of the OEHI project. Improvements would include widening SR 119 from a two-lane highway to a four-lane expressway. These improvements to SR 119 are planned to be completed by the year 2025 (Caltrans 2006, pp. 12).

Kern County is the licensing authority for the OEHI project. Therefore, to minimize impacts from EOR construction related trips, staff recommends Kern County adopt mitigation like what is proposed in Condition of Certification **TRANS-1,** which would require implementation of a Construction Traffic Control Plan to reduce the significance of construction traffic impacts associated with the HECA project.

Operational Impacts and Mitigation

Once operational, the proposed HECA project would require a fulltime employee workforce to oversee project operations and maintenance (O&M). Anticipated HECA project operational traffic would be associated primarily with operation worker commute trips, feedstock deliveries, process materials and products truck trips, and O&M trips

(URS 2012a, p. 5.10-11).

Two alternatives are under consideration for transporting coal to the HECA project site:

1) constructing a rail spur or;

2) using trucks to deliver coal after it has been transported by rail from New Mexico.

For the rail spur option (listed as Alternative 1 in the AFC), an approximately 5-mile-long new industrial railroad spur would be constructed to connect the HECA project site to the existing San Joaquin Valley Railroad (SJVRR) Buttonwillow railroad line. This railroad spur would also be used to transport some HECA products to market. For the no rail spur option (listed as Alternative 2 in the AFC), an approximately 27-mile-long truck transport route would be used via existing roads to transport the coal from an existing coal trans-loading facility located northeast of the HECA project site. The applicant is currently requesting that both options be certified.

Traffic and Transportation Table 7 lists the estimate of total peak daily operational related vehicle trip for both alternatives of the proposed HECA project, including identifying which of those trips would be generated during both the AM and PM peak hour periods.

Traffic and Transportation Table 7
Estimated Average and Peak Hour Trip Generation – Peak Daily Operation

	Actual Vehicle Round Trips	Peak Daily Trips	AM Peak Hour			PM Peak Hour		
			In	Out	Total	In	Out	Total
Truck Operation With Rail Spur								
Operations and Maintenance Trips	154	308	110	0	110	22	132	154
Process Materials and Byproducts Trips[1]	213	426	18	18	36	18	18	36

Source: URS 2012a, p.5.10-31 and -32

Notes:

1 Total process materials and product truck trips, adjusted into Passenger Car Equivalent (PCE) vehicles (3 PCE per truck). The trip generation estimate is based on the maximum 24-hour and 1-hour trips during Project operation. There are 71 (maximum 24-hour) truck deliveries and shipments @ 3 PCE/truck = 213 PCE vehicles. Peak daily trips (including both the inbound and outbound trips) = 2 × 213 PCE vehicles = 426 PCE Trips. There are 6 (maximum 1-hr) truck deliveries and shipments @ 3 PCE/truck = 18 PCE vehicles. Therefore, peak hourly trips (assuming equal number of inbound and outbound trips) = 2 × 18 PCE vehicles = 36 PCE Trips.

2 Total feedstock material delivery truck trips (including petcoke and coal), adjusted into Passenger Car Equivalent vehicles (3 PCE per truck). The trip generation estimate is based on the maximum 24-hour and 1-hour trips during Project operation. There are 55 (maximum 24-hour) truck deliveries @ 3 PCE/truck = 165 PCE vehicles. Peak daily trips (including both the inbound and outbound trips) = 2 × 165 PCE vehicles = 330 PCE trips. There are 5 (maximum 1-hour) truck deliveries @ 3 PCE/truck = 15 PCE vehicles. Therefore, peak hourly trips (assuming equal number of inbound and outbound trips) = 2 × 15 PCE vehicles = 30 PCE trips. The feedstock trip assumption was based on the train delivery of coal and trucking of petcoke to the Project site.

3 Total process materials and products truck trips, adjusted into Passenger Car Equivalent (PCE) vehicles (3 PCE per truck). The trip generation estimate is based on the maximum 24-hour and 1-hour trips during Project operation. There are 133 (maximum 24-hour) truck deliveries and shipments @ 3 PCE/truck = 399 PCE vehicles. Peak daily trips (including both the inbound and outbound trips) = 2 × 399 PCE vehicles = 798 PCE trips. There are 12 (maximum 1-hour) truck deliveries and shipments @ 3 PCE/truck = 36 PCE vehicles. Therefore, peak hourly trips (assuming equal number of inbound and outbound trips) = 2 × 36 PCE vehicles = 72 PCE trips.

4 Total feedstock material delivery truck trips (including petcoke, and coal), adjusted into Passenger Car Equivalent vehicles (3 PCE per truck). The trip generation estimate is based on the maximum 24-hour and 1-hour trips during Project operation. There are 300 (maximum 24-hour) truck deliveries @ 3 PCE/truck = 900 PCE vehicles. Peak daily trips (including both the inbound and outbound trips) = 2 × 900 PCE vehicles = 1,800 PCE Trips. There are 20 (maximum 1-hour) truck deliveries @ 3 PCE/truck = 60 PCE vehicles. Therefore, peak hourly trips (assuming an equal number of inbound and outbound trips) = 2 × 60 PCE vehicles = 120 PCE trips. There will a break in coal trucking activities during the evening peak hour to minimize roadway conflicts with heavy vehicles; coal trucking activities will resume immediately after the peak evening traffic has dissipated.

Based on the construction vehicle trip calculations presented in **Traffic and Transportation Table 7**, an analysis was conducted in the AFC to determine the impacts of operational related vehicle trips on current and future baseline levels of service for study area intersections. **Traffic and Transportation Tables 8 and 9** identify the current and future (Year 2017) LOS anticipated with and without proposed project operational vehicle traffic added to critical intersections in the vicinity of the HECA site.

As shown in **Traffic and Transportation Tables 8 and 9**, operations-related traffic associated with the project would not impact or deteriorate any project area intersections to below an LOS D (as described above, a LOS D threshold is utilized to determine intersection impacts per the Kern County General Plan Circulation Element). As noted in **Traffic and Transportation Tables 8 and 9,** the operational related analysis assumes that intersection improvements required by Condition of Certification **TRANS-2** (required for construction impacts) would occur, and are considered a component of the existing street system in Year 2017 with project traffic conditions**.** Therefore, HECA project operations would have no additional impact on study area intersection LOS. Consequently, no operations-related mitigation measures are required.

[2] Assumed to be signalized in Year 2017 as part of Condition of Certification **TRANS-2**
Bold text indicates unacceptable operating conditions

As shown in **Traffic and Transportation Tables 10 and 11**, with the addition of the HECA project's peak operation traffic, all study area roadway segments would continue to operate at an acceptable LOS as compared to future Year 2017 without project conditions. Although all study area roadways would continue to operate at an acceptable LOS, it should noted that implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Specifically, some roadway segments would experience a substantial increase in the AADT such as Dairy Road (132% increase), Station Road (1,087% increase), and Morris Road (878% increase).

Bold text indicates substantial increase in number of vehicle trips (50% increase or greater)

Kern Council of Governments Regional Transportation Plan

California State Proposition 111, passed by voters in 1990, established a requirement that urbanized areas prepare and regularly update a Congestion Management Program (CMP). The purpose of the CMP is to monitor the performance of the countywide transportation system, develop programs to address near-term and long-term congestion, and better integrate transportation and land use planning. The Kern Council of Governments (KCOG), as the designated Congestion Management Agency for the Kern County region, must develop, adopt, and regularly update the CMP.

The 2011 KCOG Final Regional Transportation Plan (RTP) identifies the I-5, SR 119, SR 58, and SR 43 highways as CMP roadways (KCOG 2010, p. 4-107). The RTP identifies that all roadway segments on the Congestion Management network shall maintain a LOS E or better (KCOG 2010, p. 4-109). As discussed above, proposed project construction traffic would impact both the SR 43/Stockdale Highway and SR 119/Tupman Road intersections, which are projected to degrade to LOS F, thus violating designated KCOG RTP thresholds. However, Conditions of Certification **TRANS-1** and **TRANS-2** will reduce impacts from construction related trips at these intersections. As shown in **Traffic and Transportation Tables 10, 11, 12, and 13**, operations-related traffic associated with the project would not impact or deteriorate any project area intersections or roadway segments to below an LOS E. Therefore, impacts to CMP designated roadways that would occur from construction- or operational-related HECA project traffic would be reduced upon the implementation of Conditions of Certification **TRANS-1** and **TRANS-2**.

As shown in Traffic and Transportation **Tables 10 and 11**, operation activities associated with the project would substantially increase the number of trips on certain roadways segments and would equally increase trips through specific intersections near the HECA project site including Morris Road/Stockdale Highway, Dairy Road/Stockdale Highway, Dairy Road/Adohr Road, and Station Road/Tupman Road. In addition, operation of the project without the rail spur component would substantially increase the number of trips on certain roadway segments and subsequent intersections in the city of Wasco including J Street/H Street, 9th Street/H Street, and 9th Street/J Street. Each of these intersections are currently stop controlled in only one direction (through traffic is unimpeded while adjoining traffic is required to stop).

The resulting increase in truck traffic would alter the accident risks for local road users in the project vicinity. This truck traffic increase could cause traffic congestion which could, thereby, increase the number of accidents. However, congestion may actually reduce the number of injuries and fatalities associated with those accidents. A complex relationship exists between traffic congestion and vehicular accidents. While less congested roads lead to fewer accidents, in general, less congested roads also frequently reduce speeds, thereby reducing the severity of accidents that do occur (AAA, 2011). However, heavy truck loads weigh 5 to 10 times as much as passenger vehicles. It should be stated that farm equipment is considered the same as passenger vehicles for the purposes of accidents. Collisions between heavy trucks and passenger vehicles tend to increase the severity of accidents, increase the number of injuries, increase the severity of injuries, and increase the number of fatalities per accident for occupants in passenger cars by nearly a factor of 10 (Scott and O'Day, 1971; AAA, 2011).

While it is not possible to accurately quantify or estimate the net result of interaction between these relative risk factors, the applicant is proposing improvements to four intersections (i.e., SR 43/Stockdale Highway, SR 119/Tupman Road, Dairy Road/Adohr Road, Dairy Road/Stockdale Highway) to reduce LOS impacts (URS 2012, p. 5.10-13). Staff recommends improvements at five additional intersections (i.e., Morris Road/Stockdale Highway, Station Road/Tupman Road, J Street/H Street, 9th Street/H Street, 9th Street/J Street) to reduce the potential for accidents. To ensure these improvements are made, Condition of Certification **TRANS-2** is proposed and would require physical improvements at these intersections. Implementation of Condition of Certification **TRANS-2** would significantly reduce the frequency of collisions between passenger vehicles and heavy trucks in the project vicinity. With these intersection improvements, staff concludes there would not be a significant impact on vehicular injury and fatality rates associated with increased truck traffic in the project vicinity as compared to the existing truck traffic conditions without the project.

Rail

The proposed project would construct a new rail spur that connects to the Buttonwillow Subdivision rail line located north of the HECA site. The spur would be approximately 5 miles long. The SJVRR operates the Buttonwillow Subdivision which extends 33 route miles between Buttonwillow and Kern Junction. The line connects with UPRR at Kern Junction (KCOG 2012, p. 2). The spur would be dedicated solely for deliveries to and from HECA and no stops would be made between the Buttonwillow Subdivision rail line and the HECA site.

Operation of the rail spur would require public road crossings at Stockdale Highway and Adohr Road. Design and operation of the rail line, including the public road crossings, are regulated under numerous rules and regulations codified in the Public Utilities Code and in Title 20, California Code of Regulations, Division 1 to reduce roadway crossing hazards and ensure safe operation. These rules and regulations are traditionally within the California Public Utilities Commission's (CPUC) jurisdiction to implement and enforce. At the time of this Preliminary Staff Assessment (PSA), specific designs for the road crossings have not been provided to Energy Commission staff. The applicant conducted a field visit with CPUC staff at the proposed site for the rail line on February 7, 2013. During the field visit, the applicant provided design drawings of the proposed rail line for CPUC staff to look at.

Because the rail spur is dedicated to HECA (it will only be used for delivery to and from the project) and essential to its operation (it is necessary for delivery of the fuel needed to operate the project) it is by definition a related facility and, thus, subject to the Energy Commission's jurisdiction. Nevertheless, because the CPUC traditionally has jurisdiction over such facilities, staff continues to coordinate closely with the CPUC to ensure appropriate design of the rail line for safe operation. In order to ensure that CPUC staff has sufficient information in order to help analyze the proposal, the applicant must submit a formal application pursuant to Title 20, California Code of Regulations, section 3.1.

The HECA project site is designed to allow for an entire train to be located completely onsite, and remain onsite, during offloading of coal. Specifically, the HECA site incorporates two loops for the rail line, one loop inside the other, located on the eastern third of the project site. The outer loop would be nearly 15,000 feet (2.8 miles) in length and the inner loop would be approximately 14,000 feet (2.6 miles) in length. In addition, the rail line extends from the northwestern corner of the HECA site to the northeastern portion of the site for approximately 4,700 feet (0.9 mile) which would provide additional onsite parking for trains. In total, the HECA project provides approximately 33,700 feet (6.4 miles) of rail line completely onsite for parking during the process of offloading the coal.

The HECA project would require the use of 200 train cars per day during maximum operations for delivery of coal. Assuming the project would use standard hopper cars to transport coal to the HECA site, a train with 200 hopper cars would be approximately 10,000 feet (1.9 miles) in length (refer to **Traffic and Transportation Table 12** below). Based on this project site design and train dimensions, trains used during maximum project operations would be adequately accommodated on the HECA site during the process of offloading the coal.

Traffic and Transportation Table 12
Individual Train Lengths – Maximum Operations

Component	Number	Length (feet)	Total Length (feet)
Hopper car	200	45.5	9,100
Tongues	200	4	800
Engines	5	73	365
TOTAL			**10,265**

Sources: Enviromodal, 2012; Northeastern Railroad, 2012.

Enhanced Oil Recovery (EOR)

The OEHI CO_2 EOR Project (OEHI) would generate 25 new vehicle trips during the operational phase that would occur over a 20-year timeframe. Implementation of the OEHI project would account for a maximum of 8 percent of existing peak hour traffic at any one project area intersection. In addition, Caltrans proposes improvements to SR 119 in the OEHI project area, including intersections potentially used by 25 full-time positions. Therefore, vehicle trips generated by operation of the OEHI project would not substantially degrade any intersection LOS and impacts are considered to be less-than-significant.

Parking

During construction, all temporary construction equipment laydown and parking, including construction parking, offices, and construction laydown areas, would be located within the proposed project site (URS 2012a, p. 2-56). Therefore, no off-site construction worker parking would occur during construction of the proposed project. Once operational, worker parking would be located within the HECA site. Staff is proposing Condition of Certification **LAND-3** to ensure internal operational employee parking requirements are consistent with Kern County regulations (Zoning Ordinance sections 19.82.030 and 19.82.090 [Off-street Parking - Design and Development

Standards]) and are met by the proposed HECA project. Specifically, Condition of Certification **LAND-3** would require the project owner to submit a site development plan, which conforms with Kern County regulations relating to parking, to Kern County and the Energy Commission for review and approval. With the incorporation of this condition, both construction and operation of the proposed project would have no impact on parking resources serving the area.

Hazardous Materials / Waste Transportation

Quantities of hazardous materials needed onsite during construction are anticipated to be small (URS 2012a, p. 5.10-13). Over the course of construction, one or two truck deliveries of hazardous materials would be required. Hazardous materials to be used during construction may include gasoline, diesel fuel, oil, and lubricants, as well as minimal amounts of cleaners, solvents, adhesives, and paint materials. Acutely Hazardous Materials (AHMs) will not be used or stored on site during construction and storage of hazardous materials will not occur outside of the HECA project site (URS 2012a, p. 5.12-4).

Project operations would require regular transportation of two hazardous materials (methanol and caustic [sodium hydroxide]) to the HECA project site (URS 2012a, p. 5.12-19). The total number of truck deliveries, maximum of 30 truck trips per day, from the site during project operations would be low and infrequent as compared to trips generated during peak daily operation (see **Traffic and Transportation Table 7**) (URS 2012a, p. 5.12-19 and -20). Therefore, the number of hazardous materials truck deliveries would not cause a significant impact to traffic congestion or LOS.

The applicant's proposed routes for hazardous materials delivery to and from the HECA project site would be I-5 to Stockdale Highway west, then Morris Road south to Station Road, right on Station Road to the HECA project site along Tupman Road (URS 2012a, p. 5.12-19 and -20). Staff also reviewed routes to four potential customers for degassed liquid sulfur identified in the AFC. These routes would avoid sensitive receptor locations, such as schools and daycare facilities.

The proposed truck routes appear to be consistent with all relevant jurisdictions' regulations related to hazardous materials transportation routes. However, to further ensure that the truck routes used comply with limitations set by local jurisdictions and Caltrans, staff has included Condition of Certification **TRANS-5** to require the project owner to obtain any necessary permits from Caltrans and any relevant local jurisdictions, including Kern County and city of Bakersfield.

Delivery of materials, such as methanol and caustic (sodium hydroxide), to the HECA project site could be hazardous to the public if a spill were to occur. The HECA project would also produce certain hazardous materials that would primarily be used onsite to produce nitrogen-based products. However, some of the surplus materials may be sold and transported offsite on tanker trucks and/or railcars. Similarly, transportation of these materials (i.e., degassed liquid sulfur), from the HECA project site could be hazardous to the public if a spill were to occur.

The likelihood of an accident-caused spill would be lower during low traffic periods, and if a spill were to occur during these hours, fewer commuters would be exposed. Therefore, staff recommends Condition of Certification **TRANS-5** to ensure that all deliveries of hazardous materials would occur outside of normal commute hours. **TRANS-5** would also require that the project owner obtain all the proper permits and/or licenses from Caltrans, Kern County, and city of Bakersfield for transporting hazardous materials.

In addition, oversized or overweight trucks with unlicensed drivers could be hazardous to the general public and/or damage roadways. To mitigate this hazard, Condition of Certification **TRANS-6** also requires that the project owner comply with local jurisdictions' and Caltrans' limits on vehicle sizes and weights and driver licensing regulations.

For a more detailed discussion on the handling and disposal of hazardous substances, see the **Hazardous Materials Management** and **Waste Management** sections of this PSA.

Emergency Access

In the event of an emergency at the HECA project site during construction, emergency vehicles would likely use either Dairy Road or Tupman Road and existing driveways to access the project site. To maintain temporary access for emergency vehicles and allow for adequate access into the facility, proposed Condition of Certification **TRANS-1** requires the preparation of a construction traffic control plan, which includes the assurance of access and movement of emergency vehicles. Furthermore, all internal access roadways would be designed consistent with Kern County standards (Kern County General Plan Circulation Element Policy 4) to provide adequate room for emergency vehicles to navigate within the facility boundaries and internal circulation roadways. As discussed in the **Worker Safety and Fire Protection** section in this PSA, Condition of Certification **WORKER SAFETY-6** requires the project owner to identify and identify three secure access points for emergency personnel to enter the site. These access points and the method of gate operation would be required to be submitted to the Kern County Fire Department for review and comment and to the CPM for review and approval. These conditions would ensure emergency access is provided during both HECA construction and operation, resulting in less than significant impacts to emergency access.

ASSESSMENT OF IMPACTS TO OTHER TRANSPORTATION SYSTEMS

Passenger Rail

The closest passenger rail service to the HECA project site is provided by Amtrak. Amtrak operates the San Joaquin train route which has stops in the city of Bakersfield and city of Wasco. The San Joaquin route runs multiple times daily between the San Francisco Bay Area (or Sacramento) and Bakersfield (Amtrak 2013). The Amtrak station is located approximately 18 miles north of the HECA project site in the city of Wasco. The Amtrak station located in Bakersfield is approximately 21 miles to the east of the project site.

Construction and operation activities associated with the proposed HECA project would not result in any effects to the operation of passenger rail in the project area.

Bus Service

The nearest KRT bus line to the proposed HECA project site is the Buttonwillow Route located approximately 3.9 miles northwest of the project site (Kern County 2012). Therefore, no local bus stops are in immediate proximity of the HECA site.

As indicated earlier in this analysis, the HECA project would generate 2,460 daily trips during construction and could generate nearly 3,000 daily trips during operations (Alternative 2). See **Traffic and Transportation Table 2** and **Table 7**. However, these increased trips would not conflict with the operation of bus service in the project area.

Bicycle and Pedestrian Facilities

Based on the 2001 Kern County Bicycle Plan and visual inspections of the proposed HECA site, no existing or planned bicycle facilities are within the immediate vicinity of the project site (KCOG 2001, p. 10). However, operation of the proposed project could create truck trips in further reaches of Kern County, including the cities of Shafter and Wasco. According to the Kern County Bicycle Facilities Plan (2001) and confirmed by Energy Commission staff, there is no adopted bicycle plan and there are no bicycle travel facilities provided in the community of Shafter. As for the community of Wasco, the Plan identifies two existing bicycle facilities including a looped Class I bike path around Westside Park and a Class 1 bike path on the south side of Barker Park from Maple Avenue to Birch Avenue. It should be noted the Kern County Bicycle Facilities Plan identifies planned bicycle facilities in Shafter along SR 43 between Tulare Avenue and Riverside Street (KCOG 2001, p. 31).

Staff researched Bakersfield-area bike clubs to attempt to determine if any popular bike routes used roadways near the HECA project site. It was found that one organized group ride begins and ends in Buttonwillow with a route that travels along SR 58 and the McKittrick grade (Kern Wheelmen Bicycle Club 2013).

As indicated earlier in this analysis, the HECA project would generate 2,460 daily trips during construction and could generate nearly 3,000 daily trips during operations (Alternative 2). See **Traffic and Transportation Table 2** and **Table 7**. However, these increased trips would not conflict with any existing or planned bicycle or pedestrian facilities. In addition, project-generated trips would not increase hazards to bicyclists or pedestrians along any existing or planned facilities.

Airports/Aviation Activities

Aviation Background

One existing airport is currently operating in the vicinity of the HECA project site. This airport includes the Elk Hills-Buttonwillow Airport, located approximately 4.6 miles west of the HECA project site.

Elk Hills-Buttonwillow Airport

Elk Hills-Buttonwillow Airport is a general aviation airport with one runway, runway 11/29 oriented northwest/southeast. Elk Hills-Buttonwillow Airport is owned by the Kern County Department of Airports and serves agricultural and other general aviation activities. For the one-year time frame ending April 25, 2011 (most recently published statistic), the Elk Hills-Buttonwillow Airport handled an average of 23 aircraft per week, of which 100 percent was transient general aviation. Elk Hills-Buttonwillow Airport runway 11/29 observes a recommended right turn traffic pattern when departing Runway 11 (to the northwest) and a recommended left turn traffic pattern when departing Runway 29 (to the southeast), directing aircraft toward the proposed HECA project site (AirNav 2012).

Airspace

The proposed HECA project site and Elk Hills-Buttonwillow Airport lie beneath Class E airspace. A Class E surface area is designated to provide controlled airspace for terminal operations where a control tower is not in operation. Class E surface areas extend upward from the surface to a designated altitude; or to the adjacent or overlaying controlled airspace (FAA Order JO 7400.2J, *Procedures for Handling Airspace Matters*, Section 18-1-2(a)).

The HECA project site is considered to be located in a sparsely populated area. According to FAA regulations, aircraft must maintain an altitude of at least 500 feet above ground level (AGL) above any person, vessel, vehicle, or structure in sparsely populated areas (14 C.F.R., § 91.119).

Using the longitude and latitude of the HECA feedstock dryer and gasification structure (tallest structures proposed), the HECA project was run through the California Military Land Use Compatibility Analysis (CMLUCA) database to determine if the HECA site is located within 1,000 feet of a military installation, is located within military based special use airspace, or is located beneath a military designated low-level flight path. Based on the CMLUCA report, the proposed HECA project does not intersect with any military bases, special use airspaces, or low level flight paths (CMLUCA 2012).

Aviation Impacts

To assess the HECA project's aviation impacts, staff examined whether the project's construction equipment, project structures, gen-tie structures, and/or thermal plumes could obstruct airspace and findings are discussed later in this analysis.

Construction and Structure Heights

Staff has been advised by the applicant that during construction, tall equipment, such as cranes and derricks, would be in use on the project site. Title 14, Part 77.9 of the Code of Federal Regulations requires FAA notification for any proposed structure over 200 feet in height AGL, regardless of the distance from an airport. The HECA project includes several structures taller than 200 feet, with the project's tallest structures proposed including the feedstock dryer and gasification structure, each at 305 feet in height (URS 2012a, Figure 2-6). Construction associated with HECA triggers the need for the project owner to file FAA Form 7460-1, *Notice of Proposed Construction or*

Alteration, in accordance with FAA CFR Title 14 Part 77.9 because the project would use structures or equipment (e.g., cranes) that are greater than 200 feet in height.

On June 25, 2012 the HECA applicant obtained from the FAA a *Determination of No Hazard to Air Navigation*, stating that all HECA structures would pose no safety impact to aircraft operations (FAA 2012). This determination includes temporary construction equipment (e.g., cranes, derricks) which may be used during construction of the structure. Equipment which has a height greater than the studied structure requires separate notice to the FAA (FAA 2012). To ensure compliance with the FAA 7460 Determination of No Hazard to Air Navigation, Condition of Certification **TRANS-8** is required to satisfy the FAA determination of no hazard to air navigation by requiring the project owner to ensure that any temporary or permanent structure, including all appurtenances, that exceeds an overall height of 200-feet AGL be marked and/or lighted consistent with FAA Advisory Circular 70/7460-1 K Change 2, Obstruction Lighting/Marking Requirements. The incorporation of this condition would ensure less than significant impacts to Elk Hills-Buttonwillow Airport air traffic operations from project structures would occur. Therefore, the project is consistent with both FAA and Kern County ALUCP LORS.

Thermal Plumes

HECA main gas turbine/heat recovery steam generator (HRSG) operation and wet cooling tower exhaust would result in thermal air plumes during project operation. Thermal plumes have the ability to impact low flying aircraft and could cause moderate to severe turbulence to low-flying aircraft above the HECA site. The FAA formally acknowledged plume hazards by amending the Aeronautical Information Publication to establish thermal plumes as flight hazards and recommend that pilots avoid overflight below 1,000 feet and fly upwind of facilities producing thermal plumes (FAA 2011). Aircraft flying through plumes can experience significant air disturbances, such as turbulence and vertical shear.

A plume velocity analysis was conducted for the HECA project and is presented in detail as APPENDIX TT-1 of this PSA. As described in APPENDIX TT-1, worst-case analysis for plume sources was used (please refer to APPENDIX TT-1 for an explanation of these conditions). The worst-case airspace conditions used in the velocity calculations are a frequent natural occurrence and would presumably occur during the life of the power plant and potentially when small aircraft fly above HECA site.

Energy Commission staff uses a 4.3 meters per second (m/s) vertical velocity threshold[3] for determining whether a plume may pose a hazard to aircraft. This velocity generally defines the point at which general aviation aircraft would begin to experience more than light turbulence. Exhaust plumes with high vertical velocities may damage aircraft airframes or cause turbulence resulting in loss of aircraft control and maneuverability (FAA 2006). As shown in APPENDIX TT-1, the calculated worst case calm wind

[3] This is based on staff's review of a 2004 safety circular (AC 139-05(0)), prepared by the Australian Government Civil Aviation Safety Authority, that noted "aviation authorities have established that an exhaust plume with a vertical velocity in excess of 4.3 meters per second (m/s) may cause damage to an aircraft airframe or upset an aircraft when flying at low levels" (CASA 2004). In their safety study on thermal plumes, FAA regulators noted that they "do not necessarily approve/disapprove or warrant the data contained in the CASA AC 139-05." The safety team accepted "the information and data contained in AC 139-05 as a valid representation of hazardous exhaust velocities" (FAA 2006).

condition vertical plume average velocities from the HECA gas turbine/HRSG are not predicted to exceed 4.3 m/s at heights at or above 730 feet above ground level (AGL).

As described above in the environmental setting discussion of airports, Elk Hills-Buttonwillow Airport runway 11/29 observes a recommended right turn traffic pattern when departing Runway 11 (to the northwest) and a recommended left turn traffic pattern when departing Runway 29 (to the southeast), directing aircraft toward the proposed HECA project site (AirNav 2012). While recommended traffic patterns of Elk Hills-Buttonwillow Airport direct traffic toward the HECA site, the proposed HECA project site is approximately 4.6 miles southeast of the Elk Hills-Buttonwillow Airport. As indicated, the Elk Hills-Buttonwillow Airport handled an average of 23 aircraft per week, of which 100 percent were transient general aviation (AirNav 2012). As these aircraft have the potential to fly below 730 feet AGL above the HECA site, staff concludes there is the potential for thermal plumes from the HECA project to impact aircraft utilizing Elk Hills-Buttonwillow Airport. Staff is proposing Condition of Certification **TRANS-8**, which will require the project owner to work with the FAA to notify all pilots using Elk Hills-Buttonwillow Airport and to update all airspace charts that include the HECA site to announce that invisible air plume hazards could exist and pilots should avoid direct overflight below 730 feet AGL.

All land uses within one-mile of the project site are farmland or operations in support of agricultural activities (URS 2012a, p. 5.4-24). Therefore, agricultural production in the vicinity of the HECA site may use aeronautic crop dusting aircraft that fly at a low altitude (500 feet and below) near and over the project site. Based on the findings in APPENDIX TT-1, HECA thermal plume sources could significantly impact crop dusting aircraft operations over the HECA site. To reduce this potential impact, staff is proposing Condition of Certification **TRANS-9**, which will require the project owner to advise the Kern County Agricultural Commissioner that crop-dusting aircraft should avoid direct overflight of the project site. To further reduce potential impacts related to crop dusting aircraft operations, staff is proposing Condition of Certification **TRANS-10**, which will require the project owner to include marker balls on the proposed 230 kV transmission line interconnect between the HECA site and PG&E Midway Substation. The incorporation of these conditions into the proposed project will reduce potential impacts to low flying crop dusting aircraft to a less-than-significant level.

Aircraft Communications

Walkie-talkies and other communications equipment planned for use during construction would not interfere with frequencies used for aviation communication. HECA communications equipment (e.g., walkie-talkies) would typically operate in the 27 or 400 to 500 megahertz ranges, which do not coincide with the communication frequencies used by aircraft in the vicinity, which are 122.9, 121.125, 115.40, 117.50, and 117.10, megahertz (AirNav 2012). Therefore, the proposed HECA project is consistent with Policies 3.3.5(c) and 3.5.5(a)(4) of the *County of Kern Airport Land Use Compatibility Plan (March 29, 2011)*, which prohibits land use characteristics that may produce hazards to aircraft in flight including sources of electrical interference with aircraft communications or navigation.

Hazards and Public Safety

Increased vehicle activity during construction has the potential to create impacts to motorist and public safety. Although heavy trucks serve agricultural operations in the project area, existing heavy truck operations are infrequent. Implementation of the HECA project under the no rail spur option would substantially increase the frequency of heavy truck operations on local roadways (e.g., Morris Road, Station Road). Potential construction vehicle impacts would be minimized to the maximum extent feasible by proposed Condition of Certification **TRANS-1** which requires preparation of a construction traffic control plan that includes use of flagging and covering open trenches, would minimize hazards due to possible traffic stacking as construction workers enter and exit the project site when their shifts begin and end, and would divert construction-related traffic to the maximum extent feasible away from residential areas.

The Kern County Roads Department has indicated that Dairy Road and Adohr Road are not currently of adequate design or capability to accommodate heavy truck traffic that would be generated by the proposed project without the rail spur under Alternative 2 (Kern County 2010). There would be a potential for unexpected damage to roads by vehicles and equipment within the project area that could result in a roadway hazard to the public. Therefore, staff proposes Conditions of Certification **TRANS-3** and **TRANS-4**. Implementation of Condition of Certification **TRANS-3** would require a pavement test be conducted along with redesigning and repaving of all public roads, easements, and rights-of-way that would be utilized by the project to a standard that accommodates heavy trucks. Implementation of Condition of Certification **TRANS-4** would require any road damaged by project construction and operation be repaired to its original condition. This would ensure that any damage to local roadways would not be a safety hazard to motorists.

The use of oversize vehicles during construction could create a hazard to the public by limiting motorist views on roadways and by the obstruction of space. As described above in **Traffic and Transportation Table 1**, California Vehicle Code sections 35550-35559 establish guidelines for oversize vehicle loads. To ensure consistency with these applicable ordinances, staff proposes Condition of Certification **TRANS-6**, which would require that all oversize vehicles used on public roadways during construction comply with Caltrans, Kern County, and other relevant jurisdictions' limitations on vehicle sizes and weights, as well as use oversize vehicle routes and any other applicable limitations or other relevant jurisdictional policies.

The implementation of Conditions of Certification **TRANS-1**, **TRANS-3**, **TRANS-5**, and **TRANS-6** would ensure that the proposed project results in less than significant hazard and safety impacts to motorists and ensures project compliance to LORS pertaining to such.

School Traffic

The HECA site is located in the Elk Hills School District (EHSD) and Taft Union High School District (TUHSD). However, operation of the proposed project under Alternative 2 (truck transportation) would place an increased volume of heavy trucks on roadways between the HECA site and Wasco. This route would traverse the Richland School District (RSD), which serves the community of Shafter, and Wasco Union High School

District (WUHSD) and Wasco Union Elementary School District (WUESD). Staff reviewed the bus routes for each school district and determined that project-related truck trips would not increase hazards to school traffic because truck trips would be spread throughout the day (not conglomerated into morning or afternoon hours) and there are not any bus stops located along the truck routes (EHSD, TUHSD, RSD, WUHSD, WUESD; 2012).

Farm Machinery Traffic

The HECA project site is located in a predominantly agricultural area. All land uses within one-mile of the project site are farmland or operations in support of agricultural activities (URS 2012a, p. 5.4-24). Therefore, agricultural production in the vicinity of the HECA site will likely lead to farm machinery being driven on roadways near the project site. However, traffic associated with construction and operation of the proposed project would be limited to specific roadways outside of a highway including Morris Road, Station Road, and Dairy Road. There is the potential for farm machinery and project-related heavy trucks to utilize these roadways at the same time. Although there are numerous adjacent roads (e.g., private dirt roads) that can be used by farm equipment to reduce the need for using a public roadway, the proposed project has the potential to disrupt farming activities and create a traffic hazard resulting from heavy trucks and farm machinery using certain public roadways at the same time. Therefore, staff proposes Condition of Certification **TRANS-1** which would require the applicant to prepare traffic control plan that addresses the safe operation of heavy trucks and farm machinery on the same public roadway. The incorporation of this condition into the proposed project will reduce potential impacts to farm machinery traffic.

In addition, the HECA project could disrupt local farming activities with a proposed rail spur which would block access along private roads. As shown in **Traffic and Transportation Figure 1-3**, the proposed rail spur would cross multiple private roads and potentially cut east-west access along these private roads. Blocking these private roads could prevent the movement of farm equipment between adjacent fields.

As shown in **Traffic and Transportation Figure 1-3**, the applicant is proposing construction of rail safety devices at six private at-grade crossings including warning devices (i.e., CPUC standard No. 1-X private crossing sign) and concrete roadway surfaces at six locations along the rail spur. It should be noted the CPUC does not issue permits for private crossings (though they may intercede if complaints over a private crossing are filed). An agreement to construct a private crossing would occur exclusively between the rail spur property holder (i.e., HECA project owner) and those seeking to build the private crossing. The builder of the private crossing would be required to ensure it is not publicly used. With construction of these private at-grade rail crossings, east-west access along private roads would continue to be allowed and disruption to farming activities would not occur. However, each rail crossing would create a point of risk associated with the potential for conflict between motor vehicles (e.g., farm machinery) and trains. Therefore, the CPUC generally recommends that rail crossings be minimized to the extent feasible. Staff currently has no information concerning the analysis the applicant conducted in determining that private at-grade crossings were needed at each of the identified locations. Therefore, staff requests the applicant provide such an analysis and attempt to further reduce the number of crossings proposed. This analysis should also discuss potential impacts to the movement of farm machinery and equipment due to reduced crossings, and should identify to what extent lands on either side of the proposed spur are owned and maintained by the same person or entity, and, thus, could possibly be impacted by reduced connectivity. Additionally, staff requests that the applicant submit to the CPUC and Energy Commission staff all the information that would otherwise be required for an application for authority to construct a new public rail crossing at the two locations proposed.

Tule Fog and Ground Fogging

The HECA project site is located in a geographic area prone to Tule fog. Ground fog is created when weather conditions in the Central Valley are stable, when air remains moist and still, and when the ground cools through the night and chills the air. Over time the moist air condenses and forms a ground-hugging cloud, or Tule fog. Tule fog is a seasonal phenomenon that occurs primarily in the Sacramento and San Joaquin valleys during the late fall and winter months because the low angle of the sun does not create enough heat for the fog to evaporate, therefore, the fog never dissipates.

Visibility in Tule fog is usually less than an eighth of a mile (approximately 600 feet) but can be as little as one foot. Variability in visibility can be a cause of chain-reaction accidents on roads and freeways. The Highway Patrol does not provide regional accident statistics; however, statewide highway fatalities mirror the Central Valley fog patterns (Los Angeles Times 1989).

According to the applicant’s estimate of monthly construction labor power (URS 2012a, Table 2-25), periods of heavy construction activities would occur over a minimum of one year. Therefore, it can be assumed that heavy construction truck traffic could occur during the late fall and winter months when Tule fog has the greatest potential to form.

Although construction and operation of the project could place trucks on roadways during events of Tule fog, truck speeds would be reduced depending on conditions (e.g., fog, rain) affecting the roadway surface and visibility. Safe operation of vehicles and trucks is regulated by the California Vehicle Code. Specifically, sections 24400 through 24411 require the equipping and use of lights during inclement weather. Section 22350 of the vehicle code requires a person to not drive a vehicle at a speed greater than is reasonable or prudent for weather and visibility. Compliance of truck drivers with regulations of the California Vehicle Code would ensure safe operation of trucks and would not create a traffic hazard associated with Tule fog.

In addition to natural occurring Tule fog, operation of the HECA project has the potential to create ground fog from the air separation unit (ASU) cooling tower. The Seasonal/Annual Cooling Tower Impacts (SACTI) model was used to determine frequency and direction of potential plume ground fogging events that could impact traffic safety along Adohr Road, Dairy Road, and Tupman Road adjacent to the project site. The center of ASU cooling tower is located approximately 3,445 feet south of the intersection of Dairy Road and Adohr Road and approximately 4,990 feet west of Tupman Road.

Staff modeled different project operating conditions to determine the worst case ground fogging plume for the ASU cooling tower which would occur at colder ambient conditions and when 3 of the 4 cells would be in operation. Based on the model, a ground fogging plume could occur up to a distance of 1,000 feet from the ASU. The ground fogging plume is predicted to occur for only a few hours during the four years of meteorological data modeled (see **Appendix VR-2, Visual Plume Modeling Analysis** within the **Visual Resources** section). Therefore, the ground fogging plume would not impact traffic safety along roadways in the project area.

COMPLIANCE WITH LORS

Traffic and Transportation Table 13 provides a general description of applicable laws, ordinances, and regulations (LORS) applicable to the proposed HECA project and pertaining to traffic and transportation.

Additionally, staff has reviewed **Socioeconomics Figure 1**, which shows the environmental justice population (see the **Socioeconomics** and **Executive Summary** sections of this PSA for further discussion of environmental justice) is greater than fifty percent within a six-mile buffer of the proposed HECA project. As discussed in the **Socioeconomics** section, the minority population in the six-mile buffer of the project site constitutes an environmental justice population as defined by *Environmental Justice: Guidance Under the National Environmental Policy Act*.

Staff has proposed Conditions of Certification **TRANS-1 through TRANS-6** that would reduce impacts associated with traffic and transportation; therefore, staff concludes that there would be no significant impact from construction or operation of the HECA project on minority populations. Therefore, there would not be a disproportionate Traffic and Transportation impact resulting from construction and operation of the proposed project to an environmental justice population.

Traffic and Transportation Table 13
Project Compliance with Adopted Traffic and Transportation Laws, Ordinances Regulations, and Standards

Applicable Law	LORS Description and Project Compliance Assessment
Federal	
Title 14, CFR, section 77 (14 CFR 77)	Includes standards for determining physical obstructions to navigable airspace. Sets forth requirements for notice to the Federal Aviation Administration of certain proposed construction or alterations. Also provides for aeronautical studies of obstructions to air navigation to determine their effect on the safe and efficient use of airspace (including temporary flight restrictions).
	On June 25, 2012 the FAA filed a Determination of No Hazard to Air Navigation stating that all HECA structures would pose no safety impact to aircraft operations. To ensure compliance with the FAA 7460 Determination of No Hazard to Air Navigation, Condition of Certification **TRANS-8** is required to ensure that any temporary or permanent structure, including all appurtenances, that exceeds an overall height of 200-feet above ground level (AGL) would be marked and/or lighted consistent with FAA Advisory Circular 70/7460-1 K Change 2, Obstruction Lighting/Marking Requirements.
CFR, Title 49, Subtitle B	Includes procedures and regulations pertaining to interstate and intrastate transport (includes hazardous materials program procedures) and specifies safety measures for motor carriers and motor vehicles that operate on public highways.
	Enforcement is conducted by state and local law enforcement agencies and through state agency licensing and ministerial permitting (e.g., California Department of Motor Vehicles licensing, Caltrans permits), and/or local agency permitting (e.g., Kern County Department of Public Works permits). For a discussion of the potential impacts related to the transport of hazardous materials, please see the **Hazardous Materials Management** section in this PSA.
State	
California Vehicle Code, div. 1; div. 2, chapter 2.5; div. 6, chap. 2 & 7; div. 13, chap. 5; div. 14; div. 14.1, chap. 1 & 2; div. 14.3; div. 14.7; div. 14.8; div. 15	Includes regulations pertaining to licensing, size, weight, and load of vehicles operated on highways; safe operation of vehicles; and the transportation of hazardous materials.
	Enforcement is provided by state and local law enforcement agencies and through ministerial state agency licensing and permitting and/or local agency permitting. The use of oversize vehicles during construction can create a hazard to the public by limiting motorist views on roadways and by the obstruction of space by the oversize vehicle. Therefore, staff proposes Condition of Certification **TRANS-9**, which would require that all oversize vehicles used on public roadways during construction comply with Caltrans, Kern County, and other relevant jurisdictions limitations on vehicle sizes and weights.
California Streets and Highway Code, division 1 & 2, chapter 3 & chapter 5.5	Includes regulations for the care and protection of state and county highways and provisions for the issuance of written permits.
	Enforcement is provided by state and local law enforcement and through ministerial state agency licensing and permitting and/or local agency permitting. There is also a potential for unexpected damage to roads by vehicles and equipment within the project area. Therefore, staff proposes Condition of Certification **TRANS-8**, which would require that any road damaged by project construction be repaired to its original condition.
California Manual on Uniform Control Devices (MUTDC) Chapter 6C	Includes regulations for a temporary traffic control plan to be provided for "continuity of function (movement of traffic, pedestrians, bicyclists, transit operations) and access to property/utilities" during any time the normal function of a roadway is suspended.
	Enforcement is provided by state and local law enforcement and through ministerial state agency licensing and permitting and/or local agency permitting. Construction traffic would impact both the SR 43/Stockdale Highway and SR 119/Tupman Road intersections, which are projected to degrade to LOS F

	without mitigation, during the PM peak hour. Therefore, staff proposes Condition of Certification **TRANS-1**, which would require the project owner to prepare and implement a Traffic Control Plan (TCP) prior to construction in order to reduce construction-related traffic impacts. The TCP would require the project owner to address specific construction-related traffic issues such as redirecting traffic, temporary closure of travel lanes, and ensuring access for emergency vehicles.
CPUC General Order 22-B, 26-D, 33-B, 72-B, 75-D, 88-B, 95, 108, 110, 114, 118-A, 125, 126, 135, 145, 161	Includes regulations related to safe operation of railroads.
	Enforcement is provided by state and local law enforcement and through ministerial state agency licensing and permitting and/or local agency permitting. One option for delivery of coal proposed includes construction of a 5-mile long rail spur, which would affect traffic operations and safety on local roadways. Staff is coordinating with the CPUC to analyze the project's conformance with these requirements.
Local	
Kern County Airport Land Use Compatibility Plan (ALUCP) Section 3.3.5	Prohibits land use characteristics that may produce hazards to aircraft in flight including sources of electrical interference with aircraft communications or navigation.
	Walkie-talkies and other communications equipment planned for use during construction would not interfere with frequencies used for aviation communication. HECA communications equipment (e.g., walkie-talkies) would typically operate in the 27 or 400 to 500 megahertz ranges, which do not coincide with the communication frequencies used by aircraft in the vicinity, which are 122.9, 121.125, 115.40, 117.50, and 117.10, megahertz.
Kern County General Plan Transportation Element	• Chapter 2 (Circulation Element), Goal 5, specifies that all county roadways shall operate at a Level of Service (LOS) D or better; • Circulation Element Subsection 2.3.3 (Highway Plan), Goal 5, specifies that all county highways shall operate at a Level of Service (LOS) D or better; and • Circulation Element, Policy 4, specifies that as a condition of private development approval, developers shall build roads needed to access the existing road network. Developers shall build these roads to County standards unless improvements along state routes are necessary then roads shall be built to California Department of Transportation standards. Developers shall locate these roads (width to be determined by the Circulation Plan) along centerlines shown on the circulation diagram map unless otherwise authorized by an approved Specific Plan Line. Developers may build local roads along lines other than those on the circulation diagram map. Developers would negotiate necessary easements to allow this requirement.
	Construction traffic would impact both the SR 43/Stockdale Highway and SR 119/Tupman Road intersections, which are projected to degrade to LOS F without mitigation, during the PM peak hour. Therefore, staff is proposing Conditions of Certification **TRANS-1** and **TRANS-2,** which would require the project owner to prepare and implement a TCP and intersection improvements prior to construction in order to reduce the impact of a decreased LOS at these intersections. Specifically, the TCP would require the project owner to address specific construction-related traffic issues such as redirecting traffic, temporary closure of travel lanes, and ensuring access for emergency vehicles. Intersection improvements would include • Signalization of the SR 43 (Enos Lane)/Stockdale Highway intersection, • Signalization of the SR 119/Tupman Road intersection, • Construction of a separate left-turn lane on the westbound approach of

	Stockdale Highway and a separate right-turn lane on the northbound approach of Dairy Road at the Dairy Road/Stockdale Highway intersection, and • Reconstruction of at the Dairy Road/Adohr Road intersection to accommodate the turning radius needed by large trucks. In a letter to staff dated April 13, 2010, Kern County has indicated that Adohr Road and Tupman Road alignments require a dedication of 45 feet and 55 feet from the centerline of the roads. No facilities or structures can be constructed in this area. If a portion of the proposed facility needs to encroach into those dedications, then a General Plan Amendment would be required to delete or downgrade the alignment. This process requires a hearing before the Board of Supervisors and can only be heard once every 3 months at the scheduled General Plan Amendment window dates. Based on design of facilities at the HECA project site, it would be feasible for the project owner to provide the required dedications. To accommodate these restrictions, Condition of Certification **TRANS-2** requires project owner and/or construction contractor coordination with Kern County prior to making the intersection improvements specified in **TRANS-2**. Furthermore, all internal access roadways would be designed consistent with Kern County standards. As discussed in the **Worker Safety and Fire Protection** section in this PSA, Condition of Certification **WORKER SAFETY-6** requires the project owner to identify and provide a second access point for emergency personnel to enter the site. This access point and the method of gate operation shall be submitted to the Kern County Fire Department for review and comment and to the CPM for review and approval. These conditions would ensure HECA compliance with these Kern County General Plan Goals and Policies.
Kern County Regional Transportation Plan	Chapter 4 (Strategic Investments) of the Regional Transportation Plan (RTP) includes a listing of state highways and principal arterials within Kern County designated as part of the Congestion Management System, including level of service standards (LOS E or greater) for these designated CMP roadways.
	Both SR 43 and SR 119 are classified as CMP roadways by the Kern County RTP. Project construction traffic would impact both the SR 43/Stockdale Highway and SR 119/Tupman Road intersections, which are projected to degrade to LOS F without mitigation during the PM peak hour, thus violating designated KCOG RTP thresholds. However, Conditions of Certification **TRANS-1** and **TRANS-2,** which would require the project owner to prepare a Traffic Control Plan and intersection improvements prior to construction, would reduce impacts from construction related trips on these intersections.

CUMULATIVE IMPACTS AND MITIGATION

A project may result in a significant adverse cumulative impact when its effects are cumulatively considerable. *Cumulatively considerable* means that the incremental effects of an individual project are significant when viewed in connection with the effects of (1) past projects; (2) other current projects; and (3) probable future projects (Cal. Code Regs., tit. 14, § 15130). In this section, staff discusses whether the HECA project could combine with other projects to create cumulatively considerable adverse impacts to traffic and transportation.

Traffic Impacts

To complete this Cumulative Impacts analysis, staff reviewed known past, current, and probable future projects within 6 miles of the proposed HECA project site or located within the cities of Wasco or Shafter. A distance of 6 miles from the HECA project site was chosen after review of pending projects in Kern County, including their location, and the potential for resulting in a cumulative impact. Under the no rail spur option (Alternative 2), the HECA project would involve routine transportation of coal by truck from the city of Wasco. Therefore, pending projects located along the truck route were also reviewed, including those located in Kern County but primarily focused on the cities of Shafter and Wasco.

Continued development of the Kern County area has contributed to congestion on area roadways that would be used by HECA related traffic, including within the communities of Shafter and Wasco. Staff identified no cumulative projects within 6 miles of the HECA site area that could potentially contribute cumulative added trips. Similarly, staff's review of projects in the cities of Shafter and Wasco identified no cumulative projects that would contribute traffic to roadways that would be used by HECA truck traffic as part of Alternative 2.

Consistent with the Kern County Roads Department requirements (URS 2012a, p. 5.10-12), an annual ambient traffic growth of 2 percent was used to establish No Project baselines for Year 2016 construction and Year 2017 operations analysis scenarios, as shown in **Traffic and Transportation Tables 3, 8,** and **9**. Therefore, temporary and permanent roadway congestion resulting from the proposed HECA project that could combine with other projects and growth within the area was considered in the proposed project analysis.

Condition of Certification **TRANS-1,** which would require the project owner to prepare a Construction Traffic Control Plan prior to construction, would reduce the overall potential for temporary project construction traffic to contribute cumulatively to local area traffic delays. However, as discussed earlier, construction-related traffic associated with the proposed project could have the potential to contribute cumulatively to an increase in traffic that could be substantial in relation to the existing traffic load and capacity of two intersections: SR 43/Stockdale Highway and SR 119/Tupman Road. Condition of Certification **TRANS-2** would require physical improvements at the SR 43/Stockdale Highway, SR 119/Tupman Road, Dairy Road/Stockdale Highway, and Dairy Road/Adohr Road intersections to reduce impacts from construction related trips at both the SR 43/Stockdale Highway and SR 119/Tupman Road intersections. These improvements would not only reduce the proposed project potential to contribute to cumulative delays at these intersections, but expand capacity of these intersections for traffic associated with cumulative development that could overlap with the HECA construction schedule. Furthermore, with the intersection improvements required by Condition of Certification **TRANS-2**, construction related traffic associated with the proposed project is not considered by staff to have the potential to contribute to significant cumulative traffic impacts.

Conditions of Certification **TRANS-3** through **TRANS-10** are proposed to reduce the proposed project's potential to contribute cumulatively to aviation, roadway hazards, physical damage to local transportation facilities, and alternative transportation impacts. These conditions would ensure the proposed project's cumulative contribution to these impacts remains less than significant. Furthermore, as the proposed project would not result in impacts to public parking facilities, it would not contribute cumulatively to any parking impacts.

Furthermore, it is assumed that all cumulative project development occurring within Kern County would include environmental review and mitigation similar to that for the proposed project (e.g., development of a construction traffic control plan, necessary roadway improvements) and would require approval from all affected jurisdictions and agencies. Mitigation associated with approval of individual projects would reduce cumulative transportation and traffic impacts as well. As agency approval of projects is gained, jurisdictional staggering of project construction and timing may occur to further reduce any potential cumulative transportation and traffic impacts. Therefore, the proposed project would not have a considerable cumulative contribution to transportation and traffic impacts within the HECA project area.

HECA construction workforce traffic, construction truck traffic, and operational truck traffic would not exclusively travel through areas with an identified high percentage of minority or low-income population. Therefore, the proposed project would not introduce traffic and transportation-related environmental justice issues.

Decommissioning

Decommissioning would not likely occur for at least 20 years and is not expected to result in adverse cumulative traffic and transportation impacts. Generated trips would likely be similar to the trips generated by construction, depending on the duration and extent of decommissioning, including dismantling of facilities and/or site remediation. Any cumulative impacts could be mitigated by staggering construction employees' work schedules or scheduling commute trips for off-peak hours to ensure acceptable LOS levels. Decommissioning would not cause any cumulative impacts to aviation.

NOTEWORTHY PUBLIC BENEFITS

Neither the applicant nor staff has identified any traffic-related benefits associated with the proposed HECA project. While the proposed project would include several improvements to existing intersections and roadways as a result of Conditions of Certification **TRANS-2** through **TRANS-4**, these improvements are necessary to mitigate potential construction and operation traffic impacts and are not considered to be public benefits.

DOE'S FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the Applicant for the HECA Project. The Applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with traffic and transportation.

RESPONSE TO AGENCY AND PUBLIC COMMENTS

Staff received the following comments on aspects of the proposed HECA project related to traffic and transportation:

TOM FRANTZ, ASSOCIATION OF IRRITATED RESIDENTS (TN 66072)

June 29, 2012

Comment: Tom Frantz asks whether the project would receive approval with an option to use either a railroad spur or trucks for delivery of coal from the depot in Wasco.

> **Response:** The proposed HECA project is being analyzed for its potential environmental impacts associated with operating a rail spur under Alternative 1 and operating without a rail spur under Alternative 2.

CHRIS ROMANINI (TN 66249)

July 12, 2012

Comment: Chris Romanini asks where the rail spur will be located.

> **Response:** The proposed HECA project is being analyzed for its potential environmental impacts associated with operating a rail spur under Alternative 1 and operating without a rail spur under Alternative 2.

Comment: Chris Romanini expresses concern with increased volume of vehicles competing with farm equipment, flocks of walking sheep, school buses, and Tule fog.

> **Response:** Project-related haul routes for construction- and project-related traffic are currently utilized by school buses and farm equipment. Please refer to the "Hazards and Public Safety" subsection above. Analysis determined that project-related truck trips would not increase hazards to school traffic because truck trips would be spread throughout the day and there are not any bus stops located along the truck routes. In addition, the analysis concluded there is the potential for the project to create a traffic hazard resulting from heavy trucks and farm machinery using certain roadways at the same time. Condition of Certification **TRANS-1** is being recommended which would require the applicant to prepare traffic control plan that addresses the safe operation of heavy trucks and farm machinery on the same roadway.
>
> Drivers on project-related haul routes for construction- and project-related traffic have the potential to experience Tule fog. Please refer to the "Hazards and Public Safety" subsection above. Analysis determined that safe operation of vehicles and trucks is regulated by the California Vehicle Code (sections 24400 through 24411 and 22350). Compliance of drivers with regulations of the California Vehicle Code would ensure safe operation and would not create a traffic hazard associated with Tule fog.

Regarding project-related vehicles competing with flocks of walking sheep, vehicles associated with implementation of the proposed project would be required to comply with all California vehicle code regulations. In addition, the California vehicle code provides for warning lights on vehicles herding livestock (Section 25270.5). The livestock owner would have responsibility to provide adequate warning to travelers on a public roadway.

Comment: Chris Romanini states if rail brings in coal then roads will continue to be clogged with vehicles related to employees, coke trucks, waste removal, and fertilizer business.

Response: The proposed HECA project is being analyzed for its potential environmental impacts associated with operating a rail spur under Alternative 1. Recommended conditions of certification would continue to apply to whichever project alternative is implemented by the applicant. Condition of Certification **TRANS-1** is being recommended which would require the applicant to prepare traffic control plan that addresses the safe operation of heavy trucks and farm machinery on the same roadway. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

Comment: Chris Romanini asks who will enforce the project owner to using a specific transportation route.

Response: The proposed HECA project acknowledges the need for roadway improvements (i.e., signalization of the current 4-way-stop SR 43 /Stockdale Highway intersection; signalization of the current 2-way-stop SR 119/Tupman Road intersection; construct a separate left-turn lane on the westbound approach of Stockdale Highway and construct a separate right-turn lane on the northbound approach of Dairy Road at the Dairy Road/Stockdale Highway intersection; reconstruct the Dairy Road/Adohr Road intersection to accommodate the turning radius needed by large trucks). The project applicant also states as part of the AFC (page 5.10-20) that the project owner will limit vehicular traffic to designated access roads.

BENJAMIN MCFARLAND, KERN COUNTY FARM BUREAU (TN 66242)

July 12, 2012

Comment: Benjamin McFarland states the project would impact agriculture through bifurcation of local farming activities as a result of new rail lines and disruption of neighboring farming activities.

Response: The HECA project could disrupt local farming activities with a proposed rail spur which would block access along private roads. As shown in **Traffic and Transportation Figure 1-3**, the HECA project would involve construction of rail safety devices at private at-grade crossings including warning devices and concrete roadway surfaces at six locations along the rail spur.

Construction of these private at-grade rail crossings would allow for east-west access along private roads and allow farming activities to continue undisrupted. However, staff is concerned that the number of crossings proposed could result in increased risks from the rail spur and has requested additional information from the applicant to evaluate this issue.

TOM FRANTZ, ASSOCIATION OF IRRITATED RESIDENTS (TN 66342)

July 27, 2012

Comment: Tom Frantz states the project must choose which option to use either a railroad spur or trucks for delivery of coal from the depot in Wasco.

> **Response:** The proposed HECA project is being analyzed for its potential environmental impacts associated with operating a rail spur under Alternative 1 and operating without a rail spur under Alternative 2.

ANTON GARABETIAN, CALIFONRIA PUBLIC UTILITIES COMMISSION (TN 68923)

December 13, 2012

Comment: Anton Garabetian acknowledges previous information provided by Energy Commission staff related to the proposed rail spur as part of the HECA project. Anton identifies the CPUC's role and process for reviewing and approving rail crossings.

> **Response:** Energy Commission staff desires to coordinate with the CPUC regarding their assistance with permit issuance and compliance review for the proposed rail spur.

SIERRA CLUB (TN 66429, 67239)

August 2, 2012 and September 21, 2012

Comment: Sierra Club requests more information on the practical and theoretical capacity of the existing rail corridors that would be used for transportation of the project's raw materials and products.

> **Response:** As identified by the applicant, implementation of the project with the rail spur under Alternative 1, the project would generate two trains in both directions per week on average (URS 2012c). Staff reviewed a study related to train operations of the SJVR in Fresno County. This study identified that as of January 2011 approximately 4,550 train trips per year occur on the SJVR in Fresno County exclusively. In addition, the same study identified a future potential of 9,649 train trips per year on the SJVR (FCOG 2011). Assuming the number of train trips would be similar in Kern County, project-related train trips would account for less than 5 percent of the total current train trips and less than 3 percent of the future potential train trips occurring on the SJVR.

Comment: Sierra Club requested more information regarding whether the additional train cars would result in constraints to the passenger rail system or adversely affect the transportation of freight in California and/or New Mexico.

> **Response:** One Amtrak passenger train currently operates per day in both directions on the Burlington Santa Fe (BNSF) route between Los Angeles and

Chicago (Amtrak 2013, URS 2012c). Train traffic generated by the HECA project would use a portion of the same route west of New Mexico. In most sections of this rail line, the route is double-tracked and train dispatching is conducted through centralized traffic control. Although the number of trains operating along this route is unknown, this route is considered a main artery and the project's low volume of trains would not affect the overall train operations on this route.

Comment: Sierra Club requested more information regarding whether the rail system would require improvements to the existing rail corridors.

Response: As identified by the applicant, the project would upgrade an existing 7-mile length of SJVR track between Bakersfield and the proposed rail spur (URS 2012c).

RICHARD AND JAN WOLFE (TN 66386)

July 30, 2012

Comment: Richard and Jan Wolfe identify themselves as living very close to the proposed coal plant and express concern with excessive traffic (additional 300+ trucks daily, 24 hours per day) and road damage. The commenter asks who will be responsible for repairing the roads from the increased heavy traffic caused by trucks.

Response: Daily truck volumes would increase with the implementation of the proposed HECA project under the no rail spur option. Analysis of the increased truck volumes concluded that with the addition of the HECA project's peak operation traffic, all study area roadway segments would continue to operate at an acceptable level of service. The analysis also concluded implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Please refer to the "Operational Impacts and Mitigation" subsection above. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

Comment: The commenter states 300+ trucks per day hauling material to and from the plant will drastically change their way of life and states they do not need more traffic driving on front of their home.

Response: Daily truck volumes would increase with the implementation of the proposed HECA project under the rail spur option. Analysis of the increased truck volumes concluded that with the addition of the HECA project's peak operation traffic, all study area roadway segments would continue to operate at an acceptable level of service. The analysis also concluded implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Please refer to the "Operational Impacts and Mitigation" subsection above. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

TRUDY DOUGLASS (TN 66389)

July 30, 2012

Comment: Judy Douglass identifies the local roads carry school buses and slow farm machinery.

Response: Project-related haul routes for construction- and project-related traffic are currently utilized by school buses and farm equipment. Please refer to the “Hazards and Public Safety” subsection above. Analysis determined that project-related truck trips would not increase hazards to school traffic because truck trips would be spread throughout the day and there are not any bus stops located along the truck routes. In addition, the analysis concluded there is the potential for the project to create a traffic hazard resulting from heavy trucks and farm machinery using certain roadways at the same time. Condition of Certification **TRANS-1** is being recommended which would require the applicant to prepare traffic control plan that addresses the safe operation of heavy trucks and farm machinery on the same roadway.

Comment: The commenter states the proposed project would result in 1,100 vehicles per day which would result in broken and demolished roadways. The commenter states the applicant should pay for building new roads.

Response: Daily truck volumes would increase with the implementation of the proposed HECA project. Analysis of the increased truck volumes concluded that with the addition of the HECA project’s peak operation traffic, all study area roadway segments would continue to operate at an acceptable level of service. The analysis also concluded implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Please refer to the “Operational Impacts and Mitigation” subsection above. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

Comment: The commenter identifies the potential for Tule fog in the project area.

Response: Drivers on project-related haul routes for construction- and project-related traffic have the potential to experience Tule fog. Please refer to the “Hazards and Public Safety” subsection above. Analysis determined that safe operation of vehicles and trucks is regulated by the California Vehicle Code (sections 24400 through 24411 and 22350). Compliance of drivers with regulations of the California Vehicle Code would ensure safe operation and would not create a traffic hazard associated with Tule fog.

SAM ACKERMAN (TN 66543)

August 10, 2012

Comment: Sam Ackerman identifies concern by people with additional traffic from the proposed project causing wear and tear on roads. The commenter identifies local roadways are highly used by agricultural and oil operations. The commenter identifies the applicant plans to fund improvements to local roadways.

> **Response:** Daily truck volumes would increase with the implementation of the proposed HECA project. Analysis of the increased truck volumes concluded that with the addition of the HECA project's peak operation traffic, all study area roadway segments would continue to operate at an acceptable level of service. The analysis also concluded implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Please refer to the "Operational Impacts and Mitigation" subsection above. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

EMAIL (TN 66497)

August 3, 2012

Comment: The commenter states the proposed project will have more truck traffic on narrow county roads.

> **Response:** Daily truck volumes would increase with the implementation of the proposed HECA project. Analysis of the increased truck volumes concluded that with the addition of the HECA project's peak operation traffic, all study area roadway segments would continue to operate at an acceptable level of service. The analysis also concluded implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Please refer to the "Operational Impacts and Mitigation" subsection above. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

Kendell Hech (TN 66496)

August 3, 2012

Comment: The commenter expresses a general fear of potential traffic impacts from the project.

> **Response:** Daily truck volumes would increase with the implementation of the proposed HECA project. Analysis of the increased truck volumes concluded that with the addition of the HECA project's peak operation traffic, all study area

roadway segments would continue to operate at an acceptable level of service. The analysis also concluded implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Please refer to the "Operational Impacts and Mitigation" subsection above. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

Letter (TN 66382)

July 30, 2012

Comment: The commenter identifies a huge increase in heavy-duty trucks on small country roads. The commenter asks who will manage the road surface.

Response: Daily truck volumes would increase with the implementation of the proposed HECA project. Analysis of the increased truck volumes concluded that with the addition of the HECA project's peak operation traffic, all study area roadway segments would continue to operate at an acceptable level of service. The analysis also concluded implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Please refer to the "Operational Impacts and Mitigation" subsection above. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

Comment: The commenter asks what background checks will be conducted on truck drivers.

Response: The California Vehicle Code regulates the safe operation of vehicles, including heavy trucks. Please refer to "Compliance with Laws, Ordinances, Regulations, and Standards" subsection earlier in this document for more information. Although the project would not conduct specific background checks of truck drivers, law enforcement would be responsible for ensuring truck drivers are licensed and operating vehicles safely in accordance with the California Vehicle Code (Division 6, Chapter 7, Article 5, Section 15250).

Comment: The commenter asks how closely truck drivers will be monitored.

Response: As discussed above, the California Vehicle Code regulates the safe operation of vehicles, including heavy trucks. Please refer to "Compliance with Laws, Ordinances, Regulations, and Standards" subsection earlier in this document for more information. Although the project would not specifically monitor truck drivers, law enforcement would be responsible for ensuring truck drivers are operating vehicles safely in accordance with the California Vehicle Code.

Comment: The commenter expresses concern with trains potentially blocking Stockdale Highway or cutting through pistachio fields and other crops. The commenter requests that the public comment period be kept open for a reasonable amount of time after the rail route is announced.

Response: The project site is designed to allow for an entire train to be located completely onsite, and remain onsite, during offloading of coal and, thereby, prevent blocking nearby roadways. Specifically, the HECA site incorporates two loops for the rail line, one loop inside the other, located on the eastern third of the project site. In total, the HECA project site provides approximately 33,700 feet (6.4 miles) of rail line completely onsite for parking during the process of offloading the coal.

SIERRA CLUB (TN 66370)

July 27, 2012

Comment: Sierra Club states the Energy Commission must consider impacts from the flow of large trucks hauling supplies and materials during construction and operation.

Response: Daily truck volumes would increase with the implementation of the proposed HECA project. Analysis of the increased truck volumes concluded that with the addition of the HECA project's peak operation traffic, all study area roadway segments would continue to operate at an acceptable level of service. The analysis also concluded implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Please refer to the "Direct/Indirect Impacts and Mitigation" subsection above. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

Comment: Sierra Club states the Energy Commission should consider impacts to emergency response vehicles and school buses that share the roads with large trucks.

Response: Project-related haul routes for construction- and project-related traffic are currently utilized by school buses and emergency response vehicles. Analysis determined that project-related truck trips would not increase hazards to school traffic because truck trips would be spread throughout the day and there are not any bus stops located along the truck routes.

In addition, the analysis identified in the event of an emergency at the HECA project site during construction, emergency vehicles would likely use either Dairy Road or Tupman Road and existing driveways to access the project site. Condition of Certification **TRANS-1** is being recommended which would require the applicant to prepare traffic control plan that addresses the assurance of access and movement of emergency vehicles.

BRAD BITTLESTON (TN 66348)

July 26, 2012

Comment: Brad Bittleston states the busy trucks would affect the enjoyment provided in their paradise since the 1960s. The commenter states that 1,000 trucks passing in front of his home every day should not be labeled as clean.

> **Response:** Daily truck volumes would increase with the implementation of the proposed HECA project. Analysis of the increased truck volumes concluded that with the addition of the HECA project's peak operation traffic, all study area roadway segments would continue to operate at an acceptable level of service. The analysis also concluded implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Please refer to the "Direct/Indirect Impacts and Mitigation" subsection above. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

LORELEI OVIATT, KERN COUNTY PLANNING AND COMMUNITY DEVELOPMENT DEPARTMENT (TN 66243)

July 16, 2012

Comment: Lorelei Oviatt states Kern County wants to have further discussions regarding the structural capacity of specific haul routes that would be used by trucks, regarding the operational capacity of haul routes with respect to preliminary recommendations in the AFC for intersection signalization and other road improvements, regarding temporary impacts to existing roads resulting from construction traffic, and regarding the rail spur alignment and type of roadway crossings that would be implemented.

> **Response:** The Energy Commission desires to coordinate with Kern County regarding road design capacities for proposed truck haul routes, regarding needed road improvements, regarding potential impacts to roads, and regarding the proposed rail spur.

JERRY EZELL, SHAFTER-WASCO IRRIGATION DISTRICT (TN 69925)

March 14, 2013

Comment: Jerry Ezell expresses interest in receiving information regarding the transportation route for moving coal from off load to the project site.

> **Response:** Without the rail spur under Alternative 2, coal would be hauled by truck from Wasco to the project site via State Route 43 south to Stockdale Highway west, then to Morris Road south, and lastly to Station Road west. Maps depicting the route were also provided by the applicant in Figures A63-1 and A63-2 of the *Responses to CEC Data Requests – Nos. A1 through A123* (TN 66876).

HECA NEIGHBIORS AND FARMERS (TN 69773)

March 1, 2013

Comment: HECA neighbors and farmers express concern with dust smothering and retarding plant production.

> **Response:** Truck traffic generated by the project without the rail spur under Alternative 2 would transport coal in trailers. The California vehicle code requires vehicles to be driven such as to prevent any contents or load from dropping, sifting, leaking, spilling, or otherwise escaping from the vehicle (Section 23114(a)). In addition, the vehicle code requires vehicles transporting aggregate material upon a highway (e.g., SR 43) to cover the material (Section 23114(e)(1)). The project's compliance with state regulations would prevent coal dust from escaping truck trailers and, thereby, prevent the potential for coal dust smothering and retarding plant production.

JACQUELYN KITCHEN, KERN COUNTY PLANNING AND COMMUNITY DEVELOPMENT DEPARTMENT (TN 69831)

March 6, 2013

Comment: The Kern County Roads Department states there is not sufficient information available to make specific, detailed recommendations regarding traffic impacts. In addition, the Kern County Roads Department states the AFC does not address impacts to roadway segments related to the capacity of the road to accommodate heavy vehicles. The Kern County Roads Department has preliminarily concluded that Dairy Road, Adohr Road, Station Road, and Morris Road will not be able to withstand impacts thereby requiring reconstruction of those roadways.

> **Response:** Daily truck volumes would increase with the implementation of the proposed HECA project. Analysis of the increased truck volumes concluded that with the addition of the HECA project's peak operation traffic, all study area roadway segments would continue to operate at an acceptable level of service. The analysis also concluded implementation of the proposed project would substantially increase traffic on certain roadway segments as compared to future Year 2017 without project conditions. Please refer to the "Direct/Indirect Impacts and Mitigation" subsection above. Condition of Certification **TRANS-3** is being recommended to reduce impacts which would require the project owner to conduct a pavement test and based on test results to redesign and repave roadways used by project-related traffic. In addition, Condition of Certification **TRANS-4** is being recommended which would require the project owner to provide ongoing road repairs as needed.

CONCLUSIONS AND RECOMMENDATIONS

Staff has analyzed the proposed HECA project's impacts to the nearby traffic and transportation system. Staff recommends implementation of the proposed conditions of certification (**TRANS-1** through **TRANS-10)** to reduce potentially significant impacts associated with the proposed HECA project and for the proposed project to comply with all applicable LORS related to traffic and transportation. However, there are outstanding issues for the proposed project which are not able to be analyzed as part of this

PSA/DEIS. These outstanding issues are discussed below. Staff is unable to reach a conclusion until outstanding information is provided.

OUTSTANDING INFORMATION REQUIRED FOR COMPLETION OF THE FSA/FEIS

The applicant recently identified in their proposal to add storage of limestone and ammonium nitrate at the project site. These revisions would change the number of truck trips to and from the project site. Staff needs additional information from the applicant regarding how this revision in the number of truck trips could also change the potential impacts related to traffic and transportation. Specifically, staff requests the applicant provide revised truck trip numbers for both with the rail spur and without the rail spur and identify changes to the LOS at intersections and roadway segments that would occur with the revised truck trips. This issue will be addressed in the Final Staff Assessment (FSA).

Along with the revision to the on- site storage of limestone and ammonia nitrate used for the HECA project, staff has raised a question regarding the need to expand the Wasco coal servicing facility to serve the project's demand. Potential components of the coal servicing facility initially considered by staff include the possible need for additional storage silos and/or receiving lane for trains and/or haul trucks. Staff requests the applicant identify specific components that would need to be expanded at the coal servicing facility in Wasco. The project's potential demand for expanding the Wasco coal servicing facility will be addressed in the FSA.

Under a proposed alternative, HECA would construct and operate a rail spur for delivery of fuel and products to and from the project site. Because the CPUC traditionally has jurisdiction over such facilities, staff will continue to coordinate closely with the CPUC to ensure appropriate design of the rail line for safe operation. In order to ensure that CPUC staff has sufficient information in order to assist in analyzing the proposal, the applicant must submit all the information otherwise required for a formal application pursuant to Title 20, California Code of Regulations, section 3.1 for all public at-grade rail crossings needed for the proposed rail spur. This information is outlined in the CPUC Rules of Practice and Procedure 3.7 to 3.11 under Section 1001 of the Public Utilities Code and should be submitted, to both the CPUC and Energy Commission staff. Additionally, the applicant must provide an analysis discussing the need for each of the private at-grade crossings proposed, the potential risks involved in proposing this many private crossings in such a small area, and whether, upon further examination, any crossings can be eliminated. This analysis should also discuss potential impacts to the movement of farm machinery and equipment due to reducing the crossings, and should identify to what extent lands on either side of the proposed spur are owned and maintained by the same person or entity, and, thus, could possibly be impacted by reduced connectivity.

Although potentially significant impacts associated with implementation of the proposed HECA project can be mitigated to a less-than-significant level, staff has concerns that the project has the potential to substantially increase traffic levels on farming roads not currently intended for heavy truck traffic and heavy load capacities. This substantial increase in traffic also has the potential to impact traffic associated with existing farming activities (e.g., tractors traveling on public roadway) thereby potentially resulting in safety issues and increased accidents to the public. Based on a recent Board of Supervisor's meeting held on February 26, 2013, the Board instructed the Public Works Department to review the roadways intended for heavy truck, and worker traffic and report back at their June 2013 Board meeting as to recommendations for improvements to the local roadway system. Staff will address the concerns and/or recommendations by Kern County in the FSA.

PROPOSED CONDITIONS OF CERTIFICATION

TRANS-1 The project owner shall consult with the Kern County Roads Department and prepare and submit to the Energy Commission Compliance Project Manager (CPM) for approval a construction traffic control plan (TCP) and implementation program. The project owner shall submit the proposed TCP to the Caltrans District 6 office and to the affected local jurisdictions in sufficient time for review and comment, and to the CPM for review and approval prior to the proposed start of construction and implementation of the plan. The traffic control plan must address the following:

- Provisions for redirection of construction traffic with a flag person as necessary to ensure traffic safety and minimize interruptions to non-construction related traffic flow;
- Placement of necessary signage, lighting, and traffic control devices at the project construction site and lay-down areas;
- A heavy-haul plan addressing the transport and delivery of heavy and oversized loads requiring permits from the California Department of Transportation (Caltrans), other state or federal agencies, and/or the affected local jurisdictions;
- Location and details of construction along affected roadways at night, where permitted;
- Temporary closure of travel lanes or disruptions to street segments and intersections during construction activities;
- Traffic diversion plans (in coordination with Kern County, Caltrans) to ensure access during temporary lane/road closures;
- Access to residential and/or commercial property located near construction work and truck traffic routes;
- Ensure access for emergency vehicles to the project site;
- Advance notification to residents, businesses, emergency providers, hospitals, and school districts that would be affected when roads may be partially or completely closed;
- Provisions that allow for the safe operation of heavy trucks and farm machinery on the same roadway;
- Identification of safety procedures for exiting and entering the site access

gate; and

- Obtain all required and necessary encroachment permits from the Kern County Roads Department.

Verification: At least 60 calendar days prior to the start of construction, the project owner shall submit the TCP to the applicable agencies for review and comment and to the CPM for review and approval. The project owner shall also provide the CPM with a copy of the transmittal letter to the agencies requesting review and comment and a copy of the encroachment permit issued by the affected agency for any activities on a public road.

At least 30 calendar days prior to the start of construction, the project owner shall provide copies of any comment letters received from the agencies, along with any changes to the proposed development plan, to the CPM for review and approval.

TRANS-2 The project owner shall construct intersection improvements needed to support construction and operational traffic so that intersections will operate at an acceptable LOS and/or will operate with reduced risk for accidents, including:

- Intersection of SR 43 and Stockdale Highway: signalization of the current 4-way-stop intersection.
- Intersection of SR 119 and Tupman Road: signalization of the current 2-way-stop intersection.
- Intersection of Dairy Road and Stockdale Highway: construct a separate left-turn lane on the westbound approach of Stockdale Highway, and a separate right-turn lane on the northbound approach of Dairy Road. Reconstruct to a three-way-stop intersection with flashing lights.
- Intersection of Dairy Road and Adohr Road: reconstruct the intersection to accommodate the turning radius needed by large trucks to make required turns. Reconstruct to a four-way-stop intersection with flashing lights.
- Intersection of Morris Road and Stockdale Highway: construct a separate left-turn lane on the westbound approach of Stockdale Highway, and a separate right-turn lane on the northbound approach of Morris Road. Reconstruct to a three-way-stop intersection with flashing lights.
- Intersection of Station Road and Tupman Road: reconstruct to a three-way-stop intersection with flashing lights.

The project owner shall construct intersection improvements needed to support operational traffic, with no rail spur, so that intersections will operate with reduced risk for accidents, including:

- Intersection of J Street/H Street (in City of Wasco): reconstruct to a three-way-stop intersection.
- Intersection of 9th Street/H Street (in City of Wasco): reconstruct to a three-way-stop intersection.
- Intersection of 9th Street/J Street (in City of Wasco): reconstruct to a three-way-stop intersection.

Verification: At least 30 days prior to site mobilization, the project owner shall provide to the CPM photographic evidence and coordination documents with Kern County Roads Department (e.g., approved drawings, encroachment permits) that these intersection improvements have been completed and are fully functional.

TRANS-3 The project owner shall conduct a pavement test of Adohr Road, Dairy Road, Morris Road, Station Road, J Street (in City of Wasco), H Street (in City of Wasco), and 9th Street (in City of Wasco) that would be utilized for project-related construction and operation activities.

Based on results of the pavement test, prior to the start of construction, the project owner shall redesign and repave Adohr Road, Dairy Road, Morris Road, Station Road, J Street, H Street, and/or 9th Street as reasonably necessary to accommodate project-related construction activities that meet the minimum Caltrans standard for a roadway that accommodates heavy trucks.

If Adohr Road, Dairy Road, Morris Road, Station Road, J Street, H Street, and/or 9th Street are identified by the project owner or the affected jurisdiction as needing redesign and/or pavement replacement, the project owner shall notify the CPM and the affected jurisdiction(s) to identify the section of the public right-of-way to be redesigned and/or repaved to Caltrans standards. At that time, the project owner shall establish a schedule for completion and approval of the redesigning and/or repaving.

Verification: Prior to the start of site mobilization, the project owner shall provide a copy of the pavement test to the CPM for review. Sixty (60) days prior to the start of the construction, the project owner shall establish a schedule for completion and approval of the redesigning and/or repaving. Following completion of any public right-of-way redesigning and/or pavement replacement, the project owner shall provide documentation of any public right-of-way redesigning and/or pavement replacement to Kern County for review and comment, and to the CPM for review and approval.

TRANS-4 The project owner shall coordinate with Kern County to restore all public roads, easements, and rights-of-way that have been damaged due to project-related construction and operation activities. Restoration of significant damage which could cause hazards (such as potholes or deterioration of the pavement edges, damaged signage) must take place within two days after the damage has occurred. The restoration shall be completed to the road's original condition in compliance with the applicable jurisdiction's specifications.

If damage to public roads, easements, or rights-of-way is identified by the project owner or the affected jurisdiction, the project owner shall notify the CPM within five days and the affected jurisdiction(s) to identify the section of the public right-of-way to be repaired. At that time, the project owner shall establish a schedule for completion and approval of the repairs. Following completion of any public right-of-way repairs, the project owner shall provide the CPM letters signed by the person authorized to accept the repairs in the affected jurisdiction(s) stating their satisfaction with the repairs.

Verification: Prior to the start of site mobilization, the project owner shall photograph or videotape all of the affected public roads, easements, right-of-way segment(s), and/or intersections. The project owner shall notify affected jurisdictions that the project intends to start construction activities. The project owner shall provide the photograph or videotape to the CPM and the affected jurisdictions (California Department of Transportation (Caltrans) and Kern County). The purpose of this notification is to request that these jurisdictions consider postponement of any planned public right-of-way repair or improvement activities in areas affected by project construction until construction is completed, and to coordinate any concurrent construction-related activities that cannot be postponed.

TRANS-5 The project owner shall obtain the necessary permits and/or licenses from theCalifornia Highway Patrol, Caltrans District 6, and any relevant local jurisdictions for the transportation of hazardous materials. The project owner shall ensure compliance with all applicable regulations and implementation of the proper procedures. In addition, the owner shall ensure that hazardous materials deliveries occur outside of normal commute hours.

Verification: In the Monthly Compliance Reports (MCRs), the owner shall provide copies of all permits/licenses obtained for the transportation of hazardous substances.

At least 30 calendar days prior to the start of construction, the project owner shall provide copies of any comment letters received from the agencies, along with any changes to the proposed development plan, to the CPM for review and approval.

TRANS-6 The project owner shall comply with Caltrans, Kern County Roads Department, and other relevant jurisdictions' limitations on vehicle sizes, weights, and travel routes. In addition, the project owner shall obtain all necessary transportation permits from Caltrans, Kern County, and other relevant jurisdictions for roadway use.

Verification: In the Monthly Compliance Reports, the project owner shall submit copies of any permits received during that reporting period. In addition, the project owner shall retain copies of these permits and supporting documentation in its compliance file for at least six months after the start of commercial operation.

TRANS-7 The project owner shall ensure that all temporary and permanent HECA project components over 200-feet in height shall have lighting and marking consistent with FAA Advisory circular 70/7460-1 K Change 2, Obstruction Marking and Lighting, red lights - Chapters 4, 5(Red), & 12 so as not to create a hazard to air navigation.

Verification: The project owner shall submit FAA Form 7460-2, Notice of Actual Construction or Alteration, to the FAA at least 10 days prior to start of construction (7460-2, Part I) and again within 5 days after the construction reaches its greatest height (7460-2, Part II). A copy of these completed forms shall also be provided to the CPM. Furthermore, at least 30 days prior to start of project operation, the Project Owner shall provide to the CPM pictures of any HECA project components over 200-feet in height with all FAA required lighting and marking installed.

TRANS-8 Prior to start-up and testing activities of the plant and all related facilities, the project owner shall through the FAA notify all pilots using the Elk Hills-Buttonwillow Airport and airspace above HECA site of potential air hazards. These activities would include, but not be limited to, the project owner through the FAA issuing a notice to airmen (NOTAM) of the identified air hazard and updating the Terminal Area Chart and all other FAA-approved airspace charts used by pilots that include the HECA site to indicate that pilots should avoid overflight below 730 feet AGL. The project owner shall work with Elk Hills-Buttonwillow Airport to modify the Airport Facility Directory (AFD) to show the location of the HECA site on a map or figure and put in a remark about thermal plumes could cause moderate to severe turbulence, and therefore, pilots should avoid direct overflight below 730 feet.

Verification: At least 60 days prior to start of project operation, the project owner shall submit to the CPM for review copies of requests to the FAA and Elk Hills-Buttonwillow Airport requesting the incorporation of the project into the NOTAM, Terminal Area Chart, and Airport Facility Directory and any subsequent correspondence with these organizations.

TRANS-9 Prior to start-up and testing activities, the project owner shall notify the Kern County Agricultural Commissioners that due to the potential presence of project thermal plumes with significant size and velocities, crop dusting aircraft should avoid direct overflight of the HECA site.

Verification: At least 60 days prior to start-up and testing activities, the project owner shall provide the CPM with a copy of letters advising the Kern County Agricultural Commissioners that crop dusting aircraft should avoid direct overflight of the HECA site.

TRANS-10 The project owner shall include power line marking balls on the 230 kV transmission line interconnect between the HECA site and PG&E Midway

Substation along any segments adjacent to agricultural land uses utilizing crop dusting aircraft activities.

Verification: Prior to start of commercial operation, the project owner shall provide to the CPM pictures of HECA project transmission line demonstrating that installation of marking balls has been completed.

RECOMMENDED MITIGATION MEASURES

To minimize impacts from EOR construction related trips, staff recommends Kern County adopt the following mitigation to ensure that construction traffic impacts from the OEHI CO_2 EOR facility are less than significant:

OEHI TRANS-1 The project owner shall consult with the Kern County Roads Department and prepare and a construction traffic control plan (TCP) and implementation program. The project owner shall submit the proposed TCP to the Caltrans District 6 office and to the affected local jurisdictions in sufficient time for review and comment, and to the Kern County CPM for review and approval prior to the proposed start of construction and implementation of the plan. The traffic control plan must address the following:

- Provisions for redirection of construction traffic with a flag person as necessary to ensure traffic safety and minimize interruptions to non-construction related traffic flow;
- Placement of necessary signage, lighting, and traffic control devices at the project construction site and lay-down areas;
- A heavy-haul plan addressing the transport and delivery of heavy and oversized loads requiring permits from the California Department of Transportation (Caltrans), other state or federal agencies, and/or the affected local jurisdictions;
- Location and details of construction along affected roadways at night, where permitted;
- Temporary closure of travel lanes or disruptions to street segments and intersections during construction activities;
- Traffic diversion plans (in coordination with Kern County, Caltrans) to ensure access during temporary lane/road closures;
- Access to residential and/or commercial property located near construction work and truck traffic routes;
- Ensure access for emergency vehicles to the project site;
- Advance notification to residents, businesses, emergency providers, hospitals, and school districts that would be affected when roads may be partially or completely closed;
- Provisions that allow for the safe operation of heavy trucks and farm machinery on the same roadway;
- Identification of safety procedures for exiting and entering the site access gate; and
- Obtain all required and necessary encroachment permits from the Kern County Roads Department.

APPENDIX TT-1: PLUME VELOCITY ANALYSIS

Joseph Hughes and William Walters

INTRODUCTION

The following provides assessment of vertical plume velocities for the Hydrogen Energy California (HECA) power plant project's cooling towers, gas turbine/heat recovery generator (HRSG), coal dryer, and gasification flare exhaust stack plumes. Staff completed calculations to determine the worst-case vertical plume velocities at different heights above the stacks based on the applicant's proposed facility design and expected operations.

PROJECT DESCRIPTION

The proposed project includes three large cooling towers, one MHI 501GAC combustion turbine-generator (CTG)/HRSG exhaust, a coal dryer exhaust, and a gasification flare. There are a few other proposed exhaust sources, including a couple of small flares, a CO_2 vent, an auxiliary boiler, and two emergency engines; however, staff analysis of these other exhaust sources found that these stacks have vertical plume velocity potentials that are well below 4.3 meters per second, which is the staff threshold of concern at 500 feet above ground level. Therefore, these sources are not discussed further in this analysis. This project is designed as a base load facility that would operate year round.

PLUME VELOCITY CALCULATION METHOD

Staff has selected a calculation approach from a technical paper (Best 2003) to estimate the worst-case plume vertical velocities for the HECA exhausts. The calculation approach, which is also known as the "Spillane approach", used by staff is limited to calm wind conditions, which are the worst-case wind conditions. The Spillane approach uses the following equations to determine vertical velocity for single stacks during dead calm wind (i.e. wind speed = 0) conditions:

(1) $(V*a)^3 = (V*a)_o^3 + 0.12*F_o*[(z-z_v)^2-(6.25D-z_v)^2]$

(2) $(V*a)_o = V_{exit}*D/2*(T_a/T_s)^{0.5}$

(3) $F_o = g*V_{exit}*D^2*(1-T_a/T_s)/4$

(4) $Z_v = 6.25D*[1-(T_a/T_s)^{0.5}]$

Where: V = vertical velocity (m/s), plume-average velocity
a = plume top-hat radius (m, increases at a linear rate of $a = 0.16*(z- z_v)$
F_o= initial stack buoyancy flux m^4/s^3
z = height above ground (m)
z_v= virtual source height (m)
V_{exit}= initial stack velocity (m/s)

D = stack diameter (m)
T_a= ambient temperature (K)
T_s= stack temperature (K)
g = acceleration of gravity (9.8 m/s^2)

Equation (1) is solved for V at any given height above ground that is above the momentum rise stage for single stacks (where z > 6.25D) and at the end of the plume merged stage for multiple plumes. This solution provides the plume-average velocity for the area of the plume at a given height above ground; the peak plume velocity would be two times higher than the plume-average velocity predicted by this equation. As can be seen the stack buoyancy flux (F_o) is a prominent part of Equation (1). The calm condition calculation basis clearly represents the worst-case conditions, and the vertical velocity will decrease substantially as wind speed increases from calm conditions.

For multiple stack plumes, where the stacks are equivalent, the multiple stack plume velocity during calm winds was calculated by staff in a simplified fashion, presented in the Best Paper as follows:

(5) $V_m = V_{sp} * N^{0.25}$

Where: V_m = multiple stack combined plume vertical velocity (m/s)
V_{sp} = single plume vertical velocity (m/s), calculated using Equation (1)
N = number of stacks

Staff notes that this simplified multiple stack plume velocity calculation method predicts somewhat lower velocity values than the full Spillane approach methodology as given in data results presented in the Best paper (Best 2003). However, the use of this approach on long linear cooling towers such as the power block and process cooling towers designed for the HECA project will likely over predict the combined plume velocities. To partially address this, although the process and power block cooling towers are aligned linearly to form a 25-cell cooling tower, staff has not combined the stacks for the adjacent power block and process cooling towers for the velocity analysis, and instead modeled them separately. Regardless, staff describes the plume dimensions below and points out that at 400 feet no more than 4 cells would overlap.

VERTICAL PLUME VELOCITY ANALYSIS

COOLING TOWERS DESIGN AND OPERATING PARAMETERS

The design and operating parameter data for the project’s three cooling towers are provided in **Plume Velocity Tables 1-3**.

Plume Velocity Table 1
ASU Cooling Tower Operating and Exhaust Parameters

Parameter		Cooling Tower Design Parameters		
Number of Cells per Tower		4 Cells (1 by 4 Linear Design)		
Cell Height		16.76 meters (55 feet)		
Cell Stack Diameter		9.14 meters (30 feet)		
Tower Housing Length		60.70 meters (199 feet)		
Tower Housing Width		18.29 meters (60 feet)		
Case	**Inlet Air Ambient Condition**	**Heat Rejection Rate (MW/hr)**	**Exhaust Flow Rate (klbs/hr)**	**Exhaust Temperature (°F)**
3 Cells	39°F, 82% RH	89.8	14,922	84
4 Cells	65°F, 55% RH	90.8	20,052	75
4 Cells	97°F, 20% RH	90.6	19,741	71

Case	**Inlet Air Ambient Condition**	**Heat Rejection Rate (MW/hr)**	**Exhaust Flow Rate (klbs/hr)**	**Exhaust Temperature (°F)**
10 Cells	39°F, 82% RH	292	48,497	71
13 Cells	65°F, 55% RH	293.7	65,129	75
13 Cells	97°F, 20% RH	294.5	64,197	84

Source: HECA 2012e, Section 5.11, Table 5.11-8

Plume Velocity Table 3
12-Cell Power Block Cooling Tower Operating and Exhaust Parameters

Parameter		**Cooling Tower Design Parameters**		
Number of Cells per Tower		12 Cells (1 by 12 Linear Design)		
Cell Height		16.76 meters (55 feet)		
Cell Stack Diameter		9.14 meters (30 feet)		
Tower Housing Length		183 meters (600 feet)		
Tower Housing Width		18.29 meters (60 feet)		
Inlet Air Ambient Condition	No. Cells in Operation	Heat Rejection Rate (MW/hr)	Exhaust Flow Rate (klbs/hr)	Exhaust Temperature (°F)
Hydrogen Rich Fuel with No Duct Firing				
39°F, 82% RH	9	248.1	45,077	70
65°F, 55% RH	12	253.8	60,310	74
97°F, 20% RH	12	260.9	59,223	83
Hydrogen Rich Fuel with Duct Firing				
39°F, 82% RH	9	269.5	44,767	71
65°F, 55% RH	12	271.1	60,155	75
97°F, 20% RH	12	271.8	59,223	84
Natural Gas with No Duct Firing				
39°F, 82% RH	9	--	--	--
65°F, 55% RH	12	--	--	--
97°F, 20% RH	12	149	81.4	81.4
Natural Gas with Duct Firing				
39°F, 82% RH	9	--	--	--
65°F, 55% RH	12	--	--	--
97°F, 20% RH	12	195.3	85.1	85.1

Source: HECA 2012e, Section 5.11, Table 5.11-7

For the worst-case analysis for these three plume sources, the 65°F ambient condition exhaust case was selected to determine the worst case exhaust velocity conditions. Additionally, for the power block cooling tower the hydrogen rich fuel with no duct firing operating case was selected. This ambient condition was selected because lower temperature cases would have large visible plumes that pilots would be able to see and avoid. Also, during colder conditions cooling tower cells would begin to shutdown decreasing flow rates and vertical velocities.

GAS TURBINE/HRSG DESIGN AND OPERATING PARAMETERS

The design and operating parameter data for the gas turbine/HRSG stack exhaust are provided in **Plume Velocity Table 4**.

Plume Velocity Table 4
Gas Turbine/HRSG Exhaust Parameters

Parameter	HRSG/Coal Drying Full Load Stack Exhaust Parameters					
Stack Height	213 feet (65 meters)					
Stack Diameter	23 feet (7 meters)					
Ambient Conditions	Moisture Content (% by weight)		Exhaust Flow Rate (klbs/hr)		Exhaust Temp (°F)	
Hydrogen Rich Fuel						
	Duct Firing	No Duct Firing	Duct Firing	No Duct Firing	Duct Firing	No Duct Firing
39°F	7.2	6.4	4,876	3,956	200	200
65°F	7.8	7.0	4,712	3,747	200	200
97°F	8.3	7.5	4,575	3,496	200	200

Source: HECA 2012e, Section 5.11, Table 5.11-6

For the worst-case analysis for this plume source, the 65°F ambient condition for the hydrogen rich fuel with duct firing operating case was selected to determine the worst-case velocity conditions. This operating case was selected because the use of hydrogen rich fuel should be the most frequent operating case and duct firing increases exhaust flow rates. Natural gas fuel operation should occur infrequently and has reduced vertical velocity potential relative to hydrogen rick fuel due to lower exhaust temperatures. Staff modeled the 39°F ambient condition without duct firing and determined worst case velocities did not exceed the results for 65°F with duct firing.

COAL DRYER DESIGN AND OPERATING PARAMETERS

The design and operating parameter data for the gas turbine/HRSG stack exhaust are provided in **Plume Velocity Table 5**.

Plume Velocity Table 5
Coal Dryer Exhaust Parameters

Parameter	HRSG/Coal Drying Full Load Stack Exhaust Parameters		
Stack Height	305 feet (92.96 meters)		
Stack Diameter	16 feet (4.88 meters)		
Ambient Conditions	Moisture Content (% by weight)	Exhaust Flow Rate (klbs/hr)	Exhaust Temp (°F)
39°F	10.8	800	200
65°F	10.8	800	200
97°F	10.8	800	200

Source: HECA 2012e, Section 5.11, Table 5.11-6

For the worst-case analysis for this plume source, the 39°F ambient condition case was selected to determine the worst-case velocity conditions because exhaust parameters are constant. Therefore, the colder ambient conditions would contribute to higher plume velocities.

GASIFICATION FLARE DESIGN AND OPERATING PARAMETERS

The design and operating parameter data for the gasification flare stack exhaust are provided in **Plume Velocity Table 6**.

Plume Velocity Table 6
Gasification Flare Exhaust Parameters

Ambient Case	Gasification Flare 65°F
Stack Height	250 feet (76.2 meters)
Stack Diameter	9.8 feet (2.99 meters)
Stack Velocity	65.5 ft/sec (20 m/s)
Exhaust Temperature	1,832°F (1,273°K)

Source: HECA 2012e, Appendix E-3, Flare Stack Parameters

For the worst-case analysis for this plume source, the 65°F ambient condition was selected for this intermittent emission source. The plume velocity is dominated by the high exhaust temperatures from the flare so an average annual ambient condition was used for the modeling.

PLUME VELOCITY CALCULATION RESULTS

Using the Spillane calculation approach, the plume average vertical velocity at different heights above ground was determined by staff for calm conditions. Staff's calculated plume average velocity values are provided in **Plume Velocity Table 7.** The combined cooling tower cell velocities are calculated by combining adjacent cells per Equation 5. For conservatism the values provided below assume that all cells within each cooling tower have completely merged. However, it is important to note that at 300 feet and 400 feet the plume diameters are approximately 24 meters and 34 meters respectively. This means that no more than 3 and 4 cooling tower cell plumes would overlap at 300 feet and 400 feet respectively, which would reduce plume velocities to levels similar to the ASU cooling tower.

Plume Velocity Table 7
HECA Exhaust Sources Worst-Case Predicted Plume Velocities (m/s)

	ASU Cooling Tower	Power Block Cooling Tower	Process Cooling Tower	Gas Turbine/HRSG	Coal Dryer	Gasification Flare
Height (ft)	**65°F**	**65°F**	**65°F**	**65°F**	**39°F**	**65°F**
300	4.55	5.99	6.11	[a]	[a]	[a]

1,900	1.67	2.20	2.24	2.84	1.71	2.72
2,000	1.64	2.16	2.20	2.78	1.68	2.66

Source: Staff calculations.
Note:
[a] – Plume velocities within the jet phase of the plume (within 6.25 diameters above the stack height) cannot be accurately determined using the calculation method employed by staff.

As explained in the Traffic and Transportation section, a plume average vertical velocity of 4.3 m/s has been determined by staff to be the critical velocity of concern to light aircraft. As shown in **Plume Velocity Table** 7, the cooling tower exhausts at 500 feet above ground are estimated to be 3.06 meters per second (m/s) for the ASU, 4.03 m/s for the gasification block and 4.11 m/s for the power block; each is below this threshold of concern. However, results for the gas turbine/HRSG and gasification flare exceed this threshold.

The gas turbine/HRSG plume average velocity is calculated to drop below 4.3 m/s at a height of approximately 730 feet. This is a worst-case value that assumes full load operation during cold ambient temperatures with dead calm wind conditions from ground level to 730 feet above the ground. For other operating scenarios and higher ambient temperatures the top height for the 4.3 m/s velocities would be somewhat lower than this maximum value.

The gasification flare plume average velocity is calculated to drop below 4.3 m/s at a height of approximately 690 feet. This is a worst-case value that assumes worst case operation during annual average ambient temperatures with dead calm wind conditions from ground level to 690 feet above the ground. The predicted plume velocities would be marginally higher for lower ambient temperature conditions.

The velocity values listed above in **Plume Velocity Table 7** are plume average velocities across the area of the plume. The maximum plume velocity, based on a normal Gaussian distribution, is two times the plume average velocities shown in the table.

WIND SPEED STATISTICS

Plume Velocity Table 8 provides the hourly average wind speed statistics for Bakersfield from meteorological data collected and processed by the SJVAPCD for 2005 through 2008. Calm winds for the purposes of the reported monitoring station statistics are those hours with average wind speeds below a threshold wind velocity, which is generally less than 2 to 3 knots (approximately 1 to 1.5 m/s). Calm or very low wind speeds can also occur for shorter periods of time within each of the monitored average hourly conditions.

Plume Velocity Table 8
Wind Speed Statistics for Bakersfield
(2005 through 2008)

Wind Speed Statistics	
Wind Speed	Percent
Calm	23.6%
≤ 1.5 m/s	35.8%
≤ 2.1 m/s	42.7%
≤ 2.6 m/s	51.7%

Source: Staff data reduction of SJVAPCD Bakersfield meteorological data from 2005-2008.

Calm/low wind speeds conditions averaging an hour or longer appear to be a frequent wind condition in the site area.

CONCLUSIONS

The calculated worst case calm wind condition vertical plume average velocities from the HECA cooling towers are not predicted to exceed 4.3 m/s at heights at or above 500 feet above ground level, except in cases where there would be large visible plumes for the power block cooling tower. The calculated worst case calm wind condition vertical plume average velocity for the HECA coal dryer is not predicted to exceed 4.3 m/s at heights at or above 500 feet above ground level. However, the calculated worst case calm wind condition vertical plume average velocities from the HECA gas turbine/HRSG and gasification flare are predicted to exceed 4.3 m/s at heights at or above 500 feet above ground level. Specifically, for the gas turbine/HRSG, this critical threshold is expected to be exceeded up to 730 feet above ground level and for the gasification flare, the critical threshold is expected to be exceeded up to 690 feet above ground level. There are a number of other plume sources at the site which would not have plume average velocities above 4.3 m/s at heights of concern, but these sources would add to the overall air turbulence that would be experienced above the HECA project site.

The vertical velocity from the equipment exhaust at a given height above the stack decreases as wind speed increases. However, the plume average vertical velocities for the gas turbine/HRSG and gasification flare will remain relatively high, and would exceed 4.3 m/s above 500 feet about ground level, during calm or very low wind speed conditions. These low wind speed conditions lasting an hour or more occur reasonably frequently at the site location. Additionally, shorter periods of dead calm winds, lasting long enough to increase the vertical plume average velocity height up to its peak height, can occur even more often during hours with low average wind speeds.

The reader should refer to the **Traffic and Transportation** Section for a discussion of impacts to aviation.

TRANSMISSION LINE SAFETY AND NUISANCE

Obed Odoemelam, Ph.D.

SUMMARY OF CONCLUSIONS

The applicant, Hydrogen Energy California, LLC, proposes to transmit power from the proposed Hydrogen Energy California project to Pacific Gas and Electric's 230-kV Midway Substation via the existing Midway-Wheeler Ridge transmission line and a new 230-kV PG&E switching station approximately 2 miles east of the project site. The proposed tie-in line would be a single-circuit 230-kV line. The applicant also proposes to use the same 230-kV line structures to support another 230-kV single-circuit line to import power into the project's on-site Air Separation Unit from the PG&E power grid. Since the 230-kV line to be used would be operated within the PG&E service area, it would be designed, constructed, operated, routed, and maintained according to PG&E's guidelines for line safety and field management which conform to applicable laws, ordinances, regulations and standards. The proposed route would traverse a mostly agricultural area with no nearby residents thereby eliminating the potential for residential electric and magnetic field exposures which have been of some health concern in recent years. With the four proposed conditions of certification, any safety and nuisance impacts from construction and operation of the proposed line would be less than significant along the route for the general population or an identified environmental justice population.

INTRODUCTION

The purpose of this staff analysis is to assess the transmission line design and operational plan for the proposed Hydrogen Energy California (HECA) project to determine whether its related field and non-field impacts would constitute a significant environmental hazard in the area around the proposed route. All related health and safety laws, ordinances, regulations, and standards (LORS) are currently aimed at minimizing such hazards. Staff's analysis focuses on the following issues taking into account both the physical presence of the line and the physical interactions of its electric and magnetic fields:

- aviation safety;
- interference with radio-frequency communication;
- audible noise;
- fire hazards;
- hazardous shocks;
- nuisance shocks; and
- electric and magnetic field (EMF) exposure.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

The potential magnitude of the field and non-field impacts of concern in this staff analysis depends on compliance with the listed design-related LORS and industry practices. These LORS and practices have been established to maintain impacts below levels of potential environmental significance. Thus, if staff determines that the project would comply with applicable LORS, we would conclude that any transmission line-related safety and nuisance impacts would be less than significant. The nature of these individual impacts is discussed below together with the potential for compliance with the LORS that apply.

Laws, Ordinances, Regulations, and Standards

The federal, state, and local laws and policies in the next section apply to the control of the field and non-field impacts of electric power lines. Staff's analysis examines the project's compliance with these requirements.

Transmission Line Safety and Nuisance (TLSN) Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable LORS	Description
Aviation Safety	
Federal	
Title 14, Part 77 of the Code of Federal Regulations (CFR),"Objects Affecting the Navigable Air Space"	Describes the criteria used to determine the need for a Federal Aviation Administration (FAA) "Notice of Proposed Construction or Alteration" in cases of potential obstruction hazards.
FAA Advisory Circular No. 70/7460-1G, "Proposed Construction and/or Alteration of Objects that May Affect the Navigation Space"	Addresses the need to file the "Notice of Proposed Construction or Alteration" (Form 7640) with the FAA in cases of potential for an obstruction hazard.
FAA Advisory Circular 70/7460-1G, "Obstruction Marking and Lighting"	Describes the FAA standards for marking and lighting objects that may pose a navigation hazard as established using the criteria in Title 14, Part 77 of the CFR.
Interference with Radio Frequency Communication	
Federal	
Title 47, CFR, section 15.2524, Federal Communications Commission (FCC)	Prohibits operation of devices that can interfere with radio-frequency communication.
State	
California Public Utilities Commission (CPUC) General Order 52 (GO-52)	Governs the construction and operation of power and communications lines to prevent or mitigate interference.
Audible Noise	
Local	
Kern County General Plan: Noise Element	References the county's Ordinance Code for noise limits.

Applicable LORS	Description
Kern County: Noise Ordinance	Establishes performance standards for planned residential or other noise-sensitive land uses.
Hazardous and Nuisance Shocks	
State	
CPUC GO-95, “Rules for Overhead Electric Line Construction”	Governs clearance requirements to prevent hazardous shocks, grounding techniques to minimize nuisance shocks, and maintenance and inspection requirements.
Title 8, California Code of Regulations (CCR) section 2700 et seq. “High Voltage Safety Orders”	Specifies requirements and minimum standards for safely installing, operating, working around, and maintaining electrical installations and equipment.
National Electrical Safety Code	Specifies grounding procedures to limit nuisance shocks. Also specifies minimum conductor ground clearances.
Industry Standards	
Institute of Electrical and Electronics Engineers (IEEE) 1119, “IEEE Guide for Fence Safety Clearances in Electric-Supply Stations”	Specifies the guidelines for grounding-related practices within the right-of-way and substations.
Electric and Magnetic Fields	
State	
GO-131-D, CPUC ”Rules for Planning and Construction of Electric Generation Line and Substation Facilities in California”	Specifies application and noticing requirements for new line construction including EMF reduction.
CPUC Decision 93-11-013	Specifies CPUC requirements for reducing power frequency electric and magnetic fields.
Industry Standards	
American National Standards Institute (ANSI/IEEE) 644-1944 Standard Procedures for Measurement of Power Frequency Electric and Magnetic Fields from AC Power Lines	Specifies standard procedures for measuring electric and magnetic fields from an operating electric line.
Fire Hazards	
State	
14 CCR sections 1250-1258, “Fire Prevention Standards for Electric Utilities”	Provides specific exemptions from electric pole and tower firebreak and conductor clearance standards and specifies when and where standards apply.

SETTING AND EXISTING CONDITIONS

As discussed by the applicant, Hydrogen Energy International, LLC, (HECA), the proposed project (HECA) would be located on a 453-acre land parcel approximately 1.5 miles northwest of the unincorporated community of Tupman in unincorporated Kern County. The line is proposed to be placed on one side of the tower structure to connect the project’s on-site switchyard and a new 230-kV PG&E switching station approximately 2 miles east of the project site. Connection to this new PG&E switching station line would allow for the looping connection to PG&E’s Midway Substation via the existing Midway-Wheeler Ridge lines. The other side of the same 230-kV line structure would be used to import energy from the PG&E power grid to the proposed project's on-site Air Separation Unit (ASU) which would be under separate ownership and located at the project site where it would obtain its own power directly from the PG&E power grid.

The project and its proposed tie-in line would be in an area primarily used for agricultural activities with the nearest residence approximately 1,400 feet away (HECA 2012e pp. 5.6-3 and 5.4-5) meaning that there would not be the type of residential field exposure that has been of health concern in recent years.

PROJECT DESCRIPTION

The proposed tie-in line would consist of the following individual segments:

- A new, 230-kV overhead transmission line consisting of two individual circuits on each side to connect the new 230-kV PG&E switching station 2 miles to the east while also connecting the on-site ASU to the PG&E power grid; and
- The project's on-site 230-kV switchyard from which the conductors would extend to their respective connecting points on the PG&E power system.

The proposed project line would have a 100-foot right-of-way within the proposed route. The interconnection point with the new PG&E switching station would be at the Olean Avenue and Elk Valley intersection, which was chosen to minimize the length of the line necessary for the related connection to the PG&E grid while maximizing the distance to areas of habitation (HECA 1202e pp. 4-1 and 4-5).

The line's conductors would be aluminum conductor, steel-reinforced cables located on single shaft galvanized tubular steel towers or steel poles as typical of similar PG&E lines. The applicant provided the details of the proposed support structures as related to line safety, maintainability, and field reduction efficiency. Fifteen support structures would be used for the off-site segment and 11 additional support structures would be used for the on-site segment. The support structures would be spaced 700 feet apart with a minimum ground clearance of 40 feet which is significantly more than the CPUC-specified minimum of 30 feet (HECA 2012e, pp.4-1, 4-2, and 4-8, and Figures 4-2 and 4-3).

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

DIRECT IMPACTS AND MITIGATION

Aviation Safety

Any potential hazard to area aircraft would relate to the potential for collision in the navigable airspace. The requirements in the LORS listed on **TLSN Table 1** establish the standards for assessing the potential for obstruction hazards within the navigable space and establish the criteria for determining when to notify the FAA about such hazards. These regulations require FAA notification in cases of structures over 200 feet from the ground, or if the structure were to be less than 200 feet in height but located within the restricted airspace in the approaches to public or military airports. For airports with runways longer than 3,200 feet, the restricted space is defined by the FAA as an area extending 20,000 feet from the runway. For airports with runways of 3,200 feet or less, the restricted airspace would be an area that extends 10,000 feet from this runway. For heliports, the restricted space is an area that extends 5,000 feet.

Buttonwillow Airport is located approximately 3.5 miles southwest of the connected Midway Substation potentially placing the proposed line's structures within the restricted airspace. However, to pose an aviation hazard according to FAA criteria, the line structure would have to be 160 feet in height or more and 3 miles away. At a maximum of 115-feet in height and 3.5 miles away, the erected line would not pose any aviation hazard within the proposed route (HECA 2012e, p. 4-10). The other area airports are Ford City, Bakersfield and Gottlieb Airports. The Ford City Airport is located 14 miles south of Tupman; the Bakersfield Airport is located approximately 22 miles east of Tupman, with Gottlieb approximately 14 miles east of Buttonwillow. None of these airports is close enough for any transmission line-related collision hazards. Therefore, staff does not recommend a condition of certification regarding aviation safety.

Interference with Radio-Frequency Communication

Transmission line-related radio-frequency interference is one of the indirect effects of line operation and is produced by the physical interactions of line electric fields. Such interference is due to the radio noise produced by the action of the electric fields on the surface of the energized conductor. The process involved is known as *corona discharge*, but is referred to as *spark gap electric discharge* when it occurs within gaps between the conductor and insulators or metal fittings. When generated, such noise manifests itself as perceivable interference with radio or television signal reception or interference with other forms of radio communication. Since the level of interference depends on factors such as line voltage, distance from the line to the receiving device, orientation of the antenna, signal level, line configuration and weather conditions, maximum interference levels are not specified as design criteria for modern transmission lines. The level of any such interference usually depends on the magnitude of the electric fields involved and the distance from the line. The potential for such impacts is therefore minimized by reducing the line electric fields and locating the line away from inhabited areas.

The proposed project line would be built and maintained according to standard practices that minimize surface irregularities and discontinuities. Moreover, the potential for such corona-related interference is usually of concern for lines of 345 kV and greater, and not for 230-kV lines such as the proposed line. The proposed low-corona designs are used for PG&E lines of similar voltage rating to reduce surface electric field gradients and the related potential for corona effects. Since the proposed lines would traverse a largely uninhabited agricultural area, staff does not expect any corona-related radio-frequency interference or complaints and does not recommend any related condition of certification.

Audible Noise

The noise-reducing designs related to electric field intensity are not specifically mandated by federal or state regulations in terms of specific noise limits. As with radio noise, such audible noise is limited instead through design, construction, or maintenance practices established from industry research and experience as effective without significant impacts on line safety, efficiency, maintainability, and reliability. As with radio noise, audible noise usually results from the action of the electric field at the surface of the line conductor and could be perceived as a characteristic crackling, frying, or hissing sound or hum, especially in wet weather. Since the noise level depends on the strength of the line electric field, the potential for perception can be assessed from estimates of the field strengths expected during operation. Such noise is usually generated during rainfall, but mainly from overhead lines of 345 kV or greater. It is, therefore, not generally expected at significant levels from lines of less than 345 kV as proposed for HECA. Research by the Electric Power Research Institute (EPRI 1982) has validated this by showing the fair-weather audible noise from modern transmission lines to be generally indistinguishable from background noise at the edge of a right-of-way of 100 feet or more; the proposed line right-of-way would be 100 feet (HECA 2012e, p. 4-5). Since the low-corona designs are also aimed at minimizing field strengths, staff does not expect the proposed line operation to add significantly to current background noise levels in the project area. For an assessment of the noise from the proposed project and related facilities, please refer to staff's analysis in the **Noise and Vibration** section.

Fire Hazards

The fire hazards addressed through the related LORS in **TLSN Table 1** are those that could be caused by sparks from conductors of overhead lines, or that could result from direct contact between the line and nearby trees and other combustible objects.

Standard fire prevention and suppression measures for similar PG&E lines would be implemented for the proposed project line (HECA 2012e, p. 4-8). The applicant's intention to ensure compliance with the clearance-related aspects of GO-95 would be an important part of this mitigation approach. Condition of Certification **TLSN-3** is recommended to ensure compliance with important aspects of the fire prevention measures.

Hazardous Shocks

Hazardous shocks are those that could result from direct or indirect contact between an individual and the energized line, whether overhead or underground. Such shocks are capable of serious physiological harm or death and remain a driving force in the design and operation of transmission and other high-voltage lines.

No design-specific federal regulations have been established to prevent hazardous shocks from overhead power lines. Safety is assured within the industry from compliance with the requirements specifying the minimum national safe operating clearances applicable in areas where the line might be accessible to the public.

The applicant's stated intention to implement the GO-95-related measures against direct contact with the energized line (HECA 2012e, p.4-8) would serve to minimize the risk of hazardous shocks. Staff's recommended Condition of Certification **TLSN-1** would be adequate to ensure implementation of the necessary mitigation measures.

Nuisance Shocks

Nuisance shocks are caused by current flow at levels generally incapable of causing significant physiological harm. They result mostly from direct contact with metal objects electrically charged by fields from the energized line. Such electric charges are induced in different ways by the line's electric and magnetic fields.

There are no design-specific federal or state regulations to limit nuisance shocks in the transmission line environment. For modern overhead high-voltage lines, such shocks are effectively minimized through grounding procedures specified in the National Electrical Safety Code (NESC) and the joint guidelines of the American National Standards Institute (ANSI) and the Institute of Electrical and Electronics Engineers (IEEE). For the proposed project line, the project owner will be responsible in all cases for ensuring compliance with these grounding-related practices within the right-of-way.

The potential for nuisance shocks around the proposed line would be minimized through standard industry grounding practices (HECA 2012a, p. 4-7). Staff recommends Condition of Certification **TLSN-4** to ensure such grounding for HECA.

Electric and Magnetic Field Exposure

The possibility of deleterious health effects from electromagnetic field (EMF) exposure has increased public concern in recent years about living near high-voltage lines. Both electric and magnetic fields occur together whenever electricity flows, and exposure to them together is generally referred to as *EMF exposure*. The available evidence as evaluated by the California Public Utilities Commission (CPUC), other regulatory agencies, and staff has not established that such fields pose a significant health hazard to exposed humans. There are no health-based federal regulations or industry codes specifying environmental limits on the strengths of fields from power lines. Most regulatory agencies believe, as staff does, that health-based limits are inappropriate at this time. They also believe that the present knowledge of the issue does not justify any retrofit of existing lines.

Staff considers it important, as does the CPUC, to note that while such a hazard has not been established from the available evidence, the same evidence does not serve as proof of a definite lack of a hazard. Staff therefore considers it appropriate, in light of present uncertainty, to recommend feasible reduction of such fields without affecting safety, efficiency, reliability, and maintainability.

While there is considerable uncertainty about EMF health effects, the following facts have been established from the available information and have been used to establish existing policies:

- Any exposure-related health risk to the exposed individual will likely be small.
- The most biologically significant types of exposures have not been established.
- Most health concerns are about the magnetic field.
- There are measures that can be employed for field reduction, but they can affect line safety, reliability, efficiency, and maintainability, depending on the type and extent of such measures.

State's Approach to Regulating Field Exposures

In California, the CPUC (which regulates the installation and operation of many high-voltage lines owned and operated by investor-owned utilities) has determined that only no-cost or low-cost measures are presently justified in any effort to reduce power line fields beyond levels existing before the present health concern arose. The CPUC has further determined that such reduction should be made only in connection with new or modified lines. It requires each utility within its jurisdiction to establish EMF-reducing measures and incorporate such measures into the designs for all new or upgraded power lines and related facilities within their respective service areas. The CPUC further established specific limits on the resources to be used in each case for field reduction. Such limitations were intended by the CPUC to apply to the cost of any redesign to reduce field strength or relocation to reduce exposure. Publicly owned utilities, which are not within the jurisdiction of the CPUC, voluntarily comply with these CPUC requirements. This CPUC policy resulted from assessments made to implement CPUC Decision 93-11-013.

The CPUC has recently revisited the EMF management issue to assess the need for policy changes to reflect the available information on possible health impacts. The findings specified in Decision D.06-1-42 of January 2006, did not point to a need for significant changes to existing field management policies.

Since there are no residences in the immediate vicinity of the proposed project line, there would not be the long-term residential EMF exposures mostly responsible for the health concern of recent years. The only project-related EMF exposures of potential significance would be the short-term exposures of plant workers, regulatory inspectors, maintenance personnel, visitors, or individuals in the vicinity of the line. These types of exposures are short term and well understood as not significantly related to the health concern.

In keeping with this CPUC policy, staff requires a showing that each proposed overhead line would be designed according to the safety and EMF-reducing design guidelines applicable to the utility service area involved. These field-reducing measures can impact line operation if applied without appropriate regard for environmental and other local factors bearing on safety, reliability, efficiency, and maintainability. Therefore, it is up to each applicant to ensure that such measures are applied in ways that prevent significant impacts on line operation and safety. The extent of such applications would be reflected by ground-level field strengths as measured during operation. When estimated or measured for lines of similar voltage and current-carrying capacity, such field strength values can be used by staff and other regulatory agencies to assess the effectiveness of the applied reduction measures. These field strengths can be estimated for any given design using established procedures. Estimates are specified for a height of one meter above the ground, in units of kilovolts per meter (kV/m), for the electric field, and milligauss (mG) for the companion magnetic field. Their magnitude depends on line voltage (in the case of electric fields), the geometry of the support structures, degree of cancellation from nearby conductors, distance between conductors, and, in the case of magnetic fields, amount of current in the line.

Since the CPUC currently requires that most new lines in California be designed according to safety and the EMF-reducing guidelines of the electric utility in the service area involved, their fields are required under this CPUC policy to be similar to fields from similar lines in that service area. Designing the proposed project line according to existing PG&E field strength-reducing guidelines would constitute compliance with the CPUC requirements for line field management.

Industry's and Applicant's Approach to Reducing Field Exposures

The present focus is on the magnetic field because unlike electric fields, it can penetrate the soil, buildings, and other materials to produce the types of human exposures at the root of the health concern of recent years. The industry seeks to reduce exposure, not by setting specific exposure limits, but through design guidelines that minimize exposure in each given case. As one focuses on the strong magnetic fields from the more visible high-voltage power lines, staff considers it important, for perspective, to note that an individual in a home could be exposed to much stronger fields while using some common household appliances than from high-voltage lines (National Institute of Environmental Health Services and the U.S. Department of Energy, 1998). The difference between these types of field exposures is that the higher-level, appliance-related exposures are short term, while the exposures from power lines are lower level, but long term. Scientists have not established which of these types of exposures would be more biologically meaningful in the individual. Staff notes such exposure differences only to show that high-level magnetic field exposures regularly occur in areas other than around high-voltage power lines.

As with similar PG&E lines, specific field strength-reducing measures would be incorporated into the proposed line's design to ensure the field strength minimization currently required by the CPUC in light of the concern over EMF exposure and health.

The field reduction measures to be applied include the following:

1. increasing the distance between the conductors and the ground to an optimal level;
2. reducing the spacing between the conductors to an optimal level;
3. minimizing the current in the line; and
4. arranging current flow to maximize the cancellation effects from interacting of conductor fields.

Since the route of the proposed project line would have no nearby residences, the long-term residential field exposures at the root of the health concern of recent years would not be a significant concern. The field strengths of most significance in this regard would be as encountered at the edge of the line's 100-foot right-of-way. These field intensities would depend on the effectiveness of the applied field-reducing measures. The applicant calculated the maximum electric and magnetic field intensities expected when one or both of the two proposed line circuits are energized (HECA 2012a, pp. 4-7 through 4-13 through 4-15 and Figures 4-10 through 4-12). The maximum electric field strength was calculated as 0.46 kV/m at the edge of the 100-foot right-of-way while the maximum operational magnetic field strength was calculated as 22.2 mG. These field strength values are similar to those of similar PG&E lines (as required under current

CPUC regulations) but, in the case of the magnetic field, the estimate is much less than the 200 mG currently specified by the few states with regulatory limits. The requirements in Condition of Certification **TLSN-2** for field strength measurements are intended to assess the applicant's assumed field reduction efficiency.

CUMULATIVE IMPACTS

Operating any given project may lead to significant adverse cumulative impacts when its effects are considered cumulatively considerable. "Cumulatively considerable" means in this context that the incremental field and non-field effects of an individual project would be significant when considered together with the effects of past, existing, and future projects (California Code Regulation, Title 14, section 15130). When field intensities are measured or calculated for a specific location, they reflect the interactive, and therefore, cumulative effects of fields from all contributing conductors. This interaction could be additive or subtractive depending on prevailing conditions. Since the proposed project's transmission line would be designed, built, and operated according to applicable field-reducing PG&E guidelines (as currently required by the CPUC for effective field management), any contribution to cumulative area exposures should be at levels expected for PG&E lines of similar voltage and current-carrying capacity and not considered environmentally significant in the present health risk-based regulatory scheme. The actual field strengths and contribution levels for the proposed line design would be assessed from the results of the field strength measurements specified in Condition of Certification **TLSN-2**. Since there are no nearby area lines, no cumulative safety and nuisance impacts from the combined interaction of fields from nearby lines are expected.

COMPLIANCE WITH LORS

As previously noted, current health-risk-driven CPUC policy on EMF management requires that any high-voltage line within a given area be designed to incorporate the field strength-reducing guidelines of the main area utility lines to be interconnected. The utility in the case of HECA is PG&E. Since the proposed project's 230-kV line and related switchyards would be designed according to the respective requirements of the LORS listed in **TLSN Table 1**, and operated and maintained according to current PG&E guidelines on line safety and field strength management, staff considers the proposed design and operational plan to be in compliance with the health and safety requirements of concern in this analysis. The actual contribution to the area's field exposure levels would be assessed for the proposed route from results of the field strength measurements required in Condition of Certification **TLSN-2**.

RESPONSE TO AGENCY AND PUBLIC COMMENTS

Staff received no public or agency comments on the transmission line nuisance and safety aspects of the proposed HECA.

NOTEWORTHY PUBLIC BENEFITS

Since the proposed tie-in line would pose specific, although insignificant risks of the field and nonfield effects of concern in this analysis, its building and operation would not yield any public benefits regarding the effort to minimize any human risks from these impacts.

FACILITY CLOSURE

If the proposed HECA were to be closed and decommissioned, and all related structures are removed as described in the **PROJECT DESCRIPTION** section, the minimal electric shocks and fire hazards from the physical presence of this tie-in line would be eliminated. Decommissioning and removal would also eliminate the line's field and non-field impacts assessed in this analysis in terms of aviation safety, interference with radio-frequency communication, audible noise, fire hazards, hazardous shocks, nuisance shocks and electric and magnetic field exposure. Since the line would be designed and operated according existing PG&E guidelines, these impacts would be as expected for PG&E lines of the same voltage and current-carrying capacity and therefore, at levels reflecting compliance with existing health and safety LORS.

DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the Applicant for the HECA Project. The Applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

CONCLUSIONS

Since staff does not expect the proposed 230-kV transmission tie-in line to pose an aviation hazard according to current FAA criteria, we do not consider it necessary to recommend specific location changes on the basis of a potential hazard to area aviation.

The potential for nuisance shocks would be minimized through grounding and other field-reducing measures that would be implemented in keeping with current PG&E guidelines (reflecting standard industry practices). These field-reducing measures would maintain the generated fields within levels not associated with radio-frequency interference or audible noise.

The potential for hazardous shocks would be minimized through compliance with the height and clearance requirements of CPUC's General Order 95. Compliance with Title 14, California Code of Regulations, section 1250, would minimize fire hazards while the use of low-corona line design, together with appropriate corona-minimizing construction practices, would minimize the potential for corona noise and its related interference with radio-frequency communication in the area around the route.

Since electric or magnetic field health effects have neither been established nor ruled out for the proposed HECA and similar transmission lines, the public health significance of any related field exposures cannot be characterized with certainty. The only conclusion to be reached with certainty is that the proposed line's design and operational plan would be adequate to ensure that the generated electric and magnetic fields are managed to an extent the CPUC considers appropriate in light of the available health effects information. The long-term, mostly residential, magnetic exposure of health concern in recent years would be insignificant for the proposed line given the absence of residences along the proposed route. On-site worker or public exposure would be short term and at levels expected for PG&E lines of similar design and current-carrying capacity. Such exposure is well understood and has not been established as posing a significant human health hazard.

Since the proposed project's line would be operated to minimize the health, safety, and nuisance impacts of concern to staff and would be routed through an area with no nearby residences, staff considers the proposed design, maintenance, and construction plan as complying with the applicable LORS. With implementation of the four recommended conditions of certification, any such impacts would be less than significant around the route for either the general population or any identified environmental justice population.

PROPOSED CONDITIONS OF CERTIFICATION

TLSN-1 The project owner shall construct the proposed 230-kV transmission line according to the requirements of California Public Utility Commission's GO-95, GO-52, GO-131-D, Title 8, and Group 2, High Voltage Electrical Safety Orders, sections 2700 through 2974 of the California Code of Regulations, and Pacific Gas and Electric's EMF reduction guidelines.

Verification: At least 30 days prior to start of construction of the transmission line or related structures and facilities, the project owner shall submit to the compliance project manager (CPM) a letter signed by a California registered electrical engineer affirming that the lines will be constructed according to the requirements stated in this condition.

TLSN-2 The project owner shall use a qualified individual to measure the strengths of the electric and magnetic fields from the line at the points of maximum intensity at the edge of the right-of-way as reflected in the estimates provided by the applicant. The measurements shall be made before and after energization according to the American National Standard Institute/Institute of Electrical and Electronic Engineers (ANSI/IEEE) standard procedures. The after measurement shall be completed no later than six months after the start of operations.

Verification: The project owner shall file copies of the pre-and post-energization measurements with the CPM within 60 days after completion of the measurements.

TLSN-3 The project owner shall ensure that the right-of-way for the proposed transmission line is kept free of combustible material, as required under the provisions of section 4292 of the Public Resources Code and section 1250 of Title 14 of the California Code of Regulations.

Verification: The project owner shall provide a summary of inspection results and any fire prevention activities carried out along the right-of-way and provide such summaries in the Annual Compliance Report on transmission line safety and nuisance-related requirements.

TLSN-4 The project owner shall ensure that all permanent metallic objects within the line right-of-way are grounded according to industry standards regardless of ownership.

Verification: At least 30 days before the lines are energized, the project owner shall transmit to the CPM a letter signed by a California registered electrical engineer confirming compliance with this condition.

SUMMARY OF CONCLUSIONS

Energy Commission staff has analyzed the potential visual impacts of the proposed Hydrogen Energy California, LLC (HECA) project and its adjoining Occidental of Elk Hills, Inc. (OEHI) component in accordance with the National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA). The two statutes are similar in their requirements concerning analysis of a project's impacts. Therefore, unless otherwise noted, staff's use of, and reference to, CEQA criteria and guidelines also encompasses and satisfies NEPA requirements for this environmental document.

Staff concludes that the proposed HECA project, after implementing all staff-recommended conditions of certification, would still have a significant and unavoidable adverse direct visual impact. Furthermore, the project would not be consistent with all applicable laws, ordinances, regulations, and standards (LORS).

Specifically, staff concludes that the HECA project would introduce a significant visual impact at Key Observation Point (KOP) 1 (HECA). KOP 1 is located on Station Road, approximately 2,600 feet east of the middle of the HECA project site.

The **Socioeconomics** section identifies an Environmental Justice community within the HECA sphere of influence. Staff has reviewed **Socioeconomics Figure 1** showing the environmental justice population is greater than 50 percent within a six-mile radius of the HECA project site. Additionally, a significant impact to visual resources has been identified at KOP 1 (HECA). However, the significant visual impact only affects one residence at KOP 1. Furthermore, the census block most likely affected by the visual impact[1] that contains said residence only contains a total of eight persons (including, two non-Hispanic white persons). Therefore, the relatively small environmental justice population within that radius (and even smaller in the affected census block) coupled with the fact that the visual impact affects only one residence at KOP 1, leads staff to the conclusion that there are 1.) no significant visual resource environmental justice issues related to the operation of this project, and 2.) no minority or low-income populations would be significantly or adversely impacted.

If the Energy Commission approves the project, staff recommends conditions of certification to minimize impacts to the greatest extent possible and to comply with applicable LORS pertaining to aesthetics or preservation and protection of sensitive visual resources.

INTRODUCTION

Visual resources consist of the viewable natural and built features of the environment. In this section staff evaluates the impacts on visual resources resulting from the

[1] Block 2612, Block Group 2, Census Tract 37 (U.S. Census 2010).

construction and operation of the HECA project and adjoining OEHI component. Staff bases its evaluation on information contained in the CEQA Guidelines, Aesthetics, to determine if the project would:

1. Cause a significant impact under CEQA.
2. Comply with applicable federal, state, and local LORS pertaining to aesthetics and preservation and protection of sensitive visual resources.

To provide a consistent framework for this analysis, a standard visual assessment methodology developed by staff and applied to numerous siting cases in the past was employed in this study. A description of this methodology is provided in **Appendix VR-1**.

REGIONAL SETTING

The proposed HECA project and its OEHI component would be located within the southwestern portion of the San Joaquin Valley, which stretches from the Sacramento-San Joaquin Delta in the north to the Tehachapi Mountains to the south. Various California coastal ranges line the valley to the west, including the Diablo and Santa Ynez, and the Sierra Nevada act as the eastern valley boundary.[2]

The proposed HECA project site is located on 453 acres of farmland, approximately 1.5 miles northwest of the unincorporated community of Tupman and four miles southeast of the unincorporated community of Buttonwillow. The site is bounded by Adohr Road on the north, Tupman Road on the east, irrigation canals and farmland to the south, and the Dairy Road right-of-way (ROW) to the west.

The proposed OEHI component is located a few miles southwest of the HECA project site on the existing 48,000-acre Elk Hills Oil Fields (EHOF). The EHOF is located 26 miles southwest of the city of Bakersfield in western Kern County. The project site is bounded by the California Aqueduct to the immediate north, Highway 5 (I-5) further to the north and east, Highways 119 and 33 to the south, Highway 33 to the west and Highway 58 to the northwest. Elk Hills Road runs north and south through the middle of the project site.

HECA

The topographic gradient of the area slopes gradually to the west. The generally flat terrain across the valley allows for open, panoramic views to the north, northwest, and east. Land immediately surrounding the HECA project site is primarily used for farming purposes. Highway commercial uses are located where Stockdale Highway intersects with Interstate 5 (I-5), more than 2 miles northeast of the project site. The California Aqueduct passes within approximately 1,900 feet of the southern boundary of the project site. The Elk Hills – Buttonwillow Airport is approximately 5 miles northwest of the project site. This airport covers approximately 216 acres, has one runway, and generally supports small private planes.

---

[2] **Visual Resources Figures 1** and **2** show the locations of the HECA and OEHI sites, respectively.

The western border of the Tule Elk State Natural Reserve (Reserve) is approximately 1,700 feet east of the project site. The approximately 955-acre Reserve provides protected habitat for the Tule Elk. The Tule Elk Reserve State Park is located at the north end of the Reserve and is approximately three-quarters of a mile from the project site. The Park includes a visitor center, shaded picnic areas, and an observation deck for visitors to view the Reserve area and to see the Tule Elk in their habitat. In 2011, a total of 4,618 people visited the Reserve. As of June 2012, 1,977 people have been recorded as visitors.[3]

OEHI

The topography of the OEHI site has been extensively altered to accommodate the large flat pads and access roadways required for operation and maintenance of the oil field. Elevations of hills on the project site vary and range up to 1,551 feet above mean sea level. The highest topographic feature in the region is Hillcrest Point, which rises to 1,542 feet above mean sea level in the EHOF, in the northwest corner of the OEHI project site.

The city of Buttonwillow and the California Aqueduct/West Side Canal are located directly to the north of the project site. Lands to the immediate east include Coles Levee Ecological Preserve, Kern Water Bank Authority, Tule Elk Reserve State Park, and the Kern River. To the west of the project site include McKittrick Valley and portions of Buena Vista Valley. Finally, to the south of the project site includes Buena Vista Valley, another large oil field, undeveloped areas, and, further south, the city of Taft.

PROJECT SITE

HECA

The proposed 453-acre HECA project site is predominantly used for agricultural purposes, including the cultivation of cotton, alfalfa and onions. The project's most publicly visible structures are identified below in **Visual Resources Table 1**.

Visual Resources Table 1
Summary of Most Publicly Visible Structures (HECA)

Component	Height (feet)	Diameter (feet)
Gasification Structure/Feedstock Dryer/Crusher	305	270 x 125
CO_2 Vent	260	4

[4] On April 10, 2013, staff was informed that the applicant intends to install a storage building for limestone fluxant at the project site. Since it is unlikely that the applicant could prepare materials in time for an adequate visual impact analysis by staff in the PSA, an analysis of the building will be performed during the FSA stage.

Visual Resources Table 1

LIGHT, GLARE, AND FLARE EFFECTS[5]

The lighting system for the HECA project would provide plant personnel with illumination in both normal and emergency conditions. The system would consist primarily of alternating current (AC) lighting and direct current (DC) lighting for activities and emergency egress required during an outage of the project's AC electrical system. Lighting for the project would generally be required in these areas of the project site:

- Building interior, office, control, and maintenance areas
- Building exterior entrances
- Outdoor equipment platforms and walkways
- Transformer and switchyard areas
- Entrance gate

The lighting system is intended to provide personnel with illumination for project operation under normal conditions, means of egress under emergency conditions, and emergency lighting to perform manual operations during a power outage of the normal

[5] The Federal Aviation Agency (FAA) has stated that: "Any temporary or permanent structure, including all appurtenances, that exceeds an overall height of 200 feet (61m) above ground level (AGL) or exceeds any obstruction standard contained in 14 CFR part 77, should normally be marked and/or lighted." Several major components for the HECA project would meet or exceed the 200-foot height limit, including: the CO_2 Vent (260 feet), SRU Flare (250 feet), Gasification Flare (250 feet), Rectisol Flare (250 feet), Gasification Structure/Feedstock Dryer/Crusher (305 feet), Gasification Structure (200 feet), and the AGR Methanol Wash Column (235 feet). On May 25, 2012, the FAA issued a set of "Determination(s) of No Hazard to Air Navigation" to the applicant stating that the proposed HECA power plant structures would not be a hazard to air navigation provided that the aforementioned structures are marked/lighted in accordance with FAA Advisory Circular 70/7460-1 K Change 2, Obstruction Marking and Lighting, paint/red lights - Chapters 3 (Marked), 4, 5 (Red), & 12 (See "HECA Applications for Notice of Proposed Construction or Alteration (Off Airport) (TN# 66029)").

power source. The lighting system would be designed and installed to meet Occupational Safety and Health Administration (OSHA) minimum standards, and to offer maximum illumination of operating work areas while minimizing off-site illumination.

The project includes flares for burning excess gas – for example, during start-up or emergency or upset conditions – including a gasification flare and a Sulfur Recovery Unit (SRU) flare. These flares could create additional lighting impact if operated at night.

VISIBLE WATER VAPOR PLUMES

Operation of the HECA power plant when the outside temperature is low and humidity is high could result in formation of a publicly visible water vapor plume(s) when waste heat (exhaust) is emitted from the project's cooling towers. Depending on local, seasonal weather conditions, the potential exists for vapor plumes to be visible from the following sources at the project site, including: the Air Separation Unit (ASU) cooling tower, 13-cell power block cooling tower, and coal dryer stack.[6]

ELECTRICAL TRANSMISSION LINE

A 230-kV transmission line would connect the HECA project to a future PG&E switching station approximately 2 miles east of the project site (Hydrogen Energy International 2012).[7] The transmission line route would leave the northeast corner of the project site, heading east to Tupman Road, continuing north to near Adohr Road, and finally east to the new Pacific Gas & Electric (PG&E) switching station near Elk Valley Road.

Construction of the transmission line would require installing approximately 26 (15 off-site and 11 on-site) tubular-steel transmission structures and the supporting foundations. The project intends to use single-pole, galvanized steel, tangent structures for the transmission towers. Each tower would range from 90 to 115 feet in height.

RAILROAD SPUR

Alternative 1 for the transportation of coal to the project site is an approximately 5-mile railroad spur that would connect the project site to the existing San Joaquin Valley Railroad (SJVRR) Buttonwillow railroad line, located north of the project site. The railroad spur would enter the northwest corner of the project site and would both deliver coal and export products during operations. If available, the railroad spur would also be used to deliver plant equipment during construction (Hydrogen Energy International 2012).

The newly constructed railroad spur would be a single track railroad and produce a temporary disturbance of 75 feet along the linear length (51.2 acres) plus three acres of the laydown area. After the project is completed, the spur would create a permanent disturbance 60 feet wide along the linear length (38.6 acres).

---

[6] Please see discussion below in **Visible Water Vapor Plumes** and **Appendix VR-2: Visible Plume Modeling Analysis** for a detailed visual plume analysis.

[7] See **Visual Resources Figure 3**.

CONSTRUCTION LAYDOWN AND STAGING AREA

The on-site construction area for the HECA project would include a construction laydown area, construction parking, offices, and warehouse. Construction access would be from Stockdale Highway north of the project site, then south along Dairy Road and east on Adohr Road. All construction laydown and parking areas would be located within the project area and the controlled area.[8]

CO_2 PIPELINE

A CO_2 pipeline would be constructed to transfer the CO_2 produced by the HECA project to the OEHI CO_2 Processing Facility. The CO_2 pipeline route would be constructed underground at a depth of 5 to 100 feet below grade and leave the southwestern portion of the HECA project site to the processing facility. The route is approximately 3 miles in length. No visible components of the CO_2 pipeline are anticipated.

OEHI

The proposed OEHI site is located within the approximately 48,000-acre EHOF site. This site is predominantly used for oil extraction purposes. The project's most publicly visible structures are identified below in **Visual Resources Table 2**.

Visual Resources Table 2

[8] See **Visual Resources Figure 4**.

CO_2 EOR PROCESSING FACILITY

The proposed CO_2 EOR Processing Facility (and its Tank Battery) would occupy 101.8 acres and be connected to the HECA project site via a proposed CO_2 pipeline (Occidental of Elk Hills 2012). The facility would be located approximately 2 miles southwest of the community of Tupman in Plot Section 27S. The facility would serve as a centralized hub for the incoming CO_2 from HECA and, subsequently, distribute the CO_2 to the various satellite facilities/wells.

LIGHT, GLARE, AND FLARE EFFECTS

Nighttime lighting presently in the area surrounding the project consists of low scattered lighting associated with rural residences, farming operations, surrounding communities, and headlights from motorists on area roadways. Developed oil production sites on the OEHI site currently produce substantial amounts of trespass and nighttime light.[9]
The CO_2 EOR Processing Facility would include security lighting capable of producing a substantial concentrated source of nighttime light. The lighting at the facility would be most visible from the city of Tupman and from a few locations along Tupman Road where views of the facility are not otherwise blocked by topography. The 13 satellite stations and well sites are not expected to have lighting. The facility would also be equipped with two flares that would have the potential to emit light during nighttime operations.

APPLICANT PROPOSED MITIGATION MEASURES

The applicant's discussion of the visual impacts of HECA and the OEHI component are found in Section 5.11.2.4 (pages 5.11-17 to -26) in the Application for Certification (AFC) and Section 4.1.5 (pages 4.1-17 and 4.1-19 to -22) in Appendix A, respectively. The applicant concludes that the following mitigation measures would reduce visual impacts to a less-than-significant level.

HECA

The applicant proposes the following design features and mitigation measures to reduce visual impacts to less-than-significant levels:

- Structures, stacks, buildings, and storage tanks will be painted in accordance with Energy Commission guidelines, and colors will be selected to blend in with the existing visual conditions.
- The colors will provide subtle variations and contrast. The selected color will help the project to blend more naturally with the natural setting.
- Reflectivity of surfaces will be reduced by using non-reflective elements where practical.
- Lighting on the project site will be limited to areas required for safety, will be directed on site to avoid backscatter, and will be shielded from public view to the extent practical.

[9] See Taft General Plan EIR, 2009.

- All lighting that is not required to be on during nighttime hours will be controlled with sensors or switches operated so that the lighting will be on only when needed.
- High-pressure sodium vapor fixtures will be used. These lights typically produce low-intensity amber light, which will reduce visual contrast with the night sky.
- Stacks and other tall project elements will be lit in accordance with FAA guidelines.
- After construction, areas where pavement or vegetation has been removed will be restored to be consistent with the surrounding area. Pipeline routes may also follow road rights-of-way and therefore will be placed under pavement or prepared dirt surfaces.
- While the project includes the above features that reduce visual impacts from its construction or operation, a potentially significant visual impact has been identified by the applicant for the nearest residential viewers to the project site (KOP 1). The applicant proposes to mitigate this impact with the following mitigation measure:
    - Prepare Conceptual Landscaping Plan for screening purposes. The plan will include information on the plant species proposed; their size, quantity, and spacing at planting; their expected heights at 5 years and at maturity; and their expected growth rates.[10]

OEHI

OEHI proposes the following mitigation measures to reduce visual impacts to less-than-significant levels:

- The surfaces of all structures, equipment, piping, and other associated above-ground project components will be given low reflectivity finishes with neutral colors to minimize the contrast of the structures with their backdrops.[11]
- In areas requiring major topographic adjustment (including but not limited to the CO2 EOR Processing Facility, satellite locations, new well sites, buried pipelines, etc.), topsoil from existing grade to be cut/filled/trenched will be removed and stockpiled during rough grading and/or trenching operations. Topsoil will be reapplied consistently across the new grades and stabilized to allow natural revegetation.[12]
- For any overhead transmission lines, lattice steel towers will not be used. If tubular steel poles are used (instead of wood) they will be painted light-gray colors or be dulled galvanized steel.[13]
- During construction, temporary construction areas, including construction parking, offices, and construction laydowns, will be located within OEHI existing operations and out of direct view of the public, to the maximum extent feasible.[14]

---

[10] See **Visual Resources Mitigation Measure 1 (VRMM-1)**.
[11] See **Mitigation Measure AES-1**.
[12] See **Mitigation Measure AES-2**.
[13] See **Mitigation Measure AES-3**.
[14] See **Mitigation Measure AES-4**.

- The project will utilize existing pipeline corridors, ROWs, roads, storage areas, and previously disturbed acreage to the maximum extent feasible. All project components will be designed to minimize disturbed footprint during construction.[15]
- All outdoor lighting will be the minimum required to meet safety and security standards. All light fixtures will be hooded and/or shielded to reduce potential for glare effects and to prevent light from spilling off the site or up into the sky.[16]

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

Visual Resources Table 3 generally describes LORS pertaining to aesthetics and protection of sensitive visual resources that are applicable to the proposed projects. Local LORS would apply to HECA. However, no federal or state LORS pertaining to visual resources would be applicable. The HECA project's consistency with specific policies and ordinances is discussed below under "Compliance with Laws, Ordinances, Regulations, and Standards."

Visual Resources Table 3
Applicable Visual Resources LORS

Source	Policy and Strategy Description
Kern County General Plan – Land Use, Open Space, and Conservation Element	
1.8 Industrial (Kern County Planning Department 2009)	Policy 6. Encourage upgrading the visual character of existing industrial areas through the use of landscape elements, screens, or buffers.
	Policy 7. Require that industrial uses provide design features such as screen walls, landscape elements, increased height and/or setbacks, and lighting restrictions between the boundaries of adjacent residential land use designations so as to reduce impacts to residential uses relating to light, noise, sound, and vibration.
1.10.7 General Provisions, Light and Glare (Kern County Planning Department 2009)	Light and Glare Policy 47. Ensure that light and glare from discretionary new development projects are minimized in rural as well as urban areas.
	Light and Glare Policy 48. Encourage the use of low-glare lighting to minimize nighttime glare effects on neighboring properties.
Kern County Zoning Ordinance – Chapter 19.12 Exclusive Agriculture (A) District	
19.12.120 Landscaping	States that no landscaping is required in the A District, except where the proposed use is subject to a plot plan review pursuant to Chapter 19.80, Special Development Standards, which establishes development standards for industrial and other land uses.

[15] See **Mitigation Measure AES-5**.
[16] See **Mitigation Measure AES-6**.

Visual Resources Table 3
Applicable Visual Resources LORS

Source	Policy and Strategy Description
19.12.110 Signs	Describes the types of signs that are permitted in the A District, in accordance with the requirements of Chapter 19.84, Signs. Various temporary signs are permitted, as are agricultural and institutional identification signs.
Kern County Zoning Ordinance – Chapter 19.81 Dark Skies Ordinance	
19.81.040 General Requirements	Describes general standards for all outdoor lighting fixtures subject to the dark skies ordinance. Applicable standards include those that address shielding, prohibited light source types, fixture height, fixture types, uplighting, and outdoor facilities, advertising signs, searchlights, and hours of operation.
Kern County Zoning Ordinance – Chapter 19.82 Off-Street Parking	
19.82.090 Parking Area Design and Development Standards	Section I addresses standards for landscaping of parking lots containing ten or more spaces. Section J addresses standards to prevent headlight glare to public streets or roads beyond the parking facility. Section K requires that parking area lighting be directed away from adjacent properties.
Kern County Zoning Ordinance – Chapter 19.84 Signs	
19.84.020, 19.84.030, and 19.84.040 Design and Development Standards – Monument Signs, Pole Signs, and Signs Attached to Buildings	These three sections of Chapter 19.84 address standards for freestanding monument and pole signs and signs attached to a building or wall. Specific standards are provided for the height, area, and spacing of signs; signage lighting; and other design details. Monument signs may not be located within any existing or designated future road right-of-way line.
Kern County Zoning Ordinance – Chapter 19.86 Landscaping	
19.86.020 Landscaping Standards – Generally	Requires compliance with the minimum standards for landscaping except as may be modified in connection with the approval of a discretionary development permit or as otherwise authorized by the Planning Director. Minimum plant and tree sizes are 15 gallons for trees, 5 gallons for shrubs, and 1 gallon for small shrubs and groundcovers. Landscaping and irrigation systems must be continuously maintained in good condition. Section 19.86.020 requires landscaping to be consistent with the State Fire Safe regulations contained in Section 4290 of the Public Resources Code and in Title 14, California Code of Regulations, Division 1.5, Chapter 7, Subchapter 2.
19.86.060 Landscaping Standards – Industrial Uses	A minimum of five percent (5%)of the developed area shall be landscaped. A maximum of one-half (1/2) of the five percent (5%) may be turf or an alternative ground cover. Along any interior property line abutting residentially zoned lots, trees shall be planted. The planters shall be sufficiently large and protected so that a parked car does not extend into the

Visual Resources Table 3
Applicable Visual Resources LORS

Source	Policy and Strategy Description
	minimum four- (4-) foot by four- (4-) foot tree planting area which shall be landscaped with ground cover, shrubs, and climbing plants. Planters or landscaped areas shall be provided in off-street parking areas in accordance with the requirements of Subsection I of Section 19.82.090 of this title. No plant material that will grow to a height of more than eighteen (18) inches shall be planted in the street right-of-way, except where authorized by the Kern County Roads Department. Within each planter or landscaped area, an irrigation system and live landscaping shall be provided and maintained, except that an irrigation system is not required to serve planters or landscaped areas devoted exclusively to native indigenous plants. Automatic timers shall be utilized and the use of drip irrigation systems shall be strongly encouraged. Landscaping materials and trees installed in planters or landscaped areas shall be selected based upon their adaptability to the climatic, geologic, and topographical conditions of the site. Use and protection of native plants and natural areas is highly encouraged. If more than 2,500 square feet of landscaping area will be required, landscaping and irrigation for the project shall comply with the Water Efficient Landscape requirements set forth in Sections 19.86.065, 19.86.070 and 19.86.080 of this chapter.
19.86.070 Landscape and Irrigation Plan – Required	Identifies classes of projects that are subject to preparation of landscape and irrigation plans, in accordance with the Kern County Water Efficient Landscape Guidelines. Industrial development projects with a cumulative landscape area of 2,500 square feet or more are included in the list of projects. Landscape plans must be prepared by either a licensed landscape architect or licensed landscape contractor. Irrigation plans must be prepared by a licensed landscape architect, certified irrigation designer, or licensed landscape contractor.
19.86.080 Landscape and Irrigation Plan – Review and Approval	Addresses submittal of conceptual landscape and irrigation plans for projects requiring a discretionary or ministerial approval. Addresses requirements relating to preparation and submittal of Landscape Documentation Packages. Required elements include details on the development area, landscape area, soil characteristics, and water supply and use.

Visual Resources Table 3
Applicable Visual Resources LORS

Source	Policy and Strategy Description
19.86.090 Landscape Installation – Timing	Requires installation of the landscape and irrigation systems or posting of an acceptable financial assurance prior to issuance of an occupancy permit. Also requires submittal of a properly executed Certificate of Completion to the Kern County Engineering, Surveying, and Permit Services Department/Building Inspection Division.

Note: The complete text of Kern County's general plan and zoning ordinance, is available at: http://www.co.kern.ca.us/planning/pdfs/kcgp/KCGP.pdf and http://www.co.kern.ca.us/planning/pdfs/KCZOJul12.pdf, respectively.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

This section includes information about the following:

- Method and threshold for determining significance
- Direct/indirect/induced impacts and mitigation
- Cumulative impacts and mitigation

METHOD AND THRESHOLD FOR DETERMINING SIGNIFICANCE

CEQA defines a "significant effect on the environment" to mean a "substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project including objects of historic or aesthetic significance" (California Code of Regulations, Title 14, Section 15382).

To determine whether there is a potentially significant visual resources impact generated by a project, Energy Commission staff reviews the project using the CEQA Guidelines Appendix G Environmental Checklist pertaining to "Aesthetics". The checklist questions include the following:

- Would the project have a substantial adverse effect on a scenic vista?
- Would the project substantially damage scenic resources, including, but not limited to trees, rock outcroppings, and historic buildings within a state scenic highway?
- Would the project substantially degrade the existing visual character or quality of the site and its surroundings?
- Would the project create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?

DIRECT/INDIRECT/INDUCED IMPACTS AND MITIGATION

Scenic Vista

For the purposes of this analysis, a scenic vista is defined as a distant view of high pictorial quality perceived through and along a corridor or opening, or from a designated scenic area. Staff has conducted site visits to the project area and researched national, state and local scenic vista designations in the vicinity of the project area.

The proposed HECA project would be constructed in a rural agricultural area in the San Joaquin Valley. The proposed OEHI component would be constructed in the existing EHOF, which is located 26 miles southwest of Bakersfield in western Kern County (County). Extensive areas in this region are generally free from urban encroachment. Similar rural areas away from major highway corridors may provide a restful and relatively benign visual environment for some viewers. However, there is no place in either project vicinity with the level of scenic appeal that would distinguish a specific view as a scenic vista.

Therefore, the proposed projects would have no impact to scenic vistas.

Scenic Resources

None of the elements of the proposed HECA or its OEHI component would be located near a designated scenic highway corridor or area where scenic resources could be damaged. According to the California Department of Transportation, the State Scenic Highway System includes a list of highways that are either eligible for designation as scenic highways or have been officially designated. Segments of State Routes (SRs) 14 and 58 in the eastern part of the county are on the list of eligible state scenic highways. These highways are east of the southern slope of the eastern Sierra Nevada. No views of the project site would be possible at this distance. No roadways near the project area are subject to aesthetic management goals or objectives of local jurisdictions. Further, there are no officially designated or eligible state scenic highways in proximity to the OEHI component that could be impacted by the proposed project. Therefore, the proposed projects would have no impact to scenic resources.

Visual Character or Quality

The method for this assessment of impacts on visual resources is primarily adapted from guidelines used by the U.S. Forest Service (USFS), the U.S. Bureau of Land Management, and the U.S. Department of Transportation. The process to evaluate the potential impacts to visual resources from implementation of the HECA project involves the following five steps:

- Define the visual environment, or visual sphere of influence (VSOI), within which visual impacts could occur.
- Describe sensitive viewpoints and the process to select key observation points (KOPs), or critical viewpoints, within the VSOI for the project.
- Evaluate the potential effects of the project on visual resources based on the estimated visual sensitivity of the viewing public.
- Evaluate the estimated magnitude of the visual change that would occur following project implementation.
- Evaluate the probability that the landscape would demonstrate a noticeable visual impact with project implementation

The ratings for overall visual sensitivity and overall visual change are combined to determine the visual impact for each KOP. The assessment of visual impacts by Energy Commission staff is based on the change that would occur from the introduction of new built elements in the VSOI. The overall visual change is based on an average of the values for contrast, dominance, and view blockage for each KOP. The rating scale to assess visual sensitivity and visual change ranges from low to high for each factor. An assessment of visual absorption capability (VAC) is also used to assess the capacity of the landscape for each KOP to absorb visual alterations without significantly affecting the visual character of the landscape (Bacon 1979).

VISUAL SPHERE OF INFLUENCE (VSOI)

The VSOI for the project represents the area within which the proposed HECA and OEHI component could be seen and where impacts to visual resources could potentially occur. Overall, the proposed HECA site would have a high visibility to several nearby residences and roadway users within 0.5 mile (foreground view), within 1.0 mile (middleground view), and other locations within the surrounding area, 3.5 to 5.0 miles and beyond (background view). The proposed OEHI site has the potential to be visible to several nearby residences and roadway users within 3.0 miles of the site. Beyond 5 miles, the facilities would be either not visible due to topography, natural and/or human-made screening, or of such a small size in the background that it would hardly be noticeable. It may be conceivable that both the HECA and OEHI sites could be simultaneously visible from several KOPs. However, due to the considerable distance and the elevated topography of the Elk Hills range in between the sites, it is highly unlikely that the sites could be simultaneously visible from any KOPs. In any event, the KOPs chosen represent the reasonable worst-case scenario for visual impacts resulting from each of the project components.

SENSITIVE VIEWPOINTS

Results of the VSOI analysis and photographic survey for the HECA project resulted in the conclusion that the most sensitive viewpoints within the VSOI were from those areas with middleground views of the project site. An inventory of stationary sensitive viewpoints (also referred to as sensitive receptors) within approximately 5 miles of the proposed HECA project site (and within approximately 2,000 feet of the proposed 230-kV transmission line) is provided below in **Visual Resources Table 4**. Because there are no designated scenic highways or roadways in the region, no such highway or roadway segments are included in the table. However, potential effects of the project on viewers traveling on nearby roads and highways are addressed below.

Visual Resources Table 4
Sensitive Receptors within Approximately 5 Miles of Proposed HECA Project Facilities

Type of Receptor	General Description and Location	Direction and Approximate Distance from Proposed HECA Project Facilities
Residences	Residences on two adjacent properties near the intersection of Station Road and Tule Park Road	1,500 feet east of the project site 2,200 feet south of the 230-kV transmission line

Visual Resources Table 4
Sensitive Receptors within Approximately 5 Miles of Proposed HECA Project Facilities

Type of Receptor	General Description and Location	Direction and Approximate Distance from Proposed HECA Project Facilities
Residence	Residence on east side of Tupman Road below Station Road	3,300 feet southeast of the project site
Tule Elk Reserve State Park	Picnic area and viewing platform on Station Road at the north end of the Reserve	1,700 feet east of the project site
Residences	Three or four residences on the south side of Stockdale Highway near the East Side Canal	1 mile north of the project site
Residence	Residence near the intersection of Dairy Road and Stockdale Highway	1.3 miles north of the project site
Residence and Horse Ranch	Residence and adjacent horse ranch on the north side of Stockdale Highway	1.5 miles northeast of the project site
Residences	Two or three residences on the north side of Stockdale Highway east of Dunford Road	1.5 miles northwest of the project site
Residences	Four residences on the north side of Stockdale Highway between Dunford and Freeborn Roads	2.25 miles northwest of the project site
Residence	Residence on Dunford Road above Stockdale Highway	2.25 miles northwest of the project site
Group of Housing Units	Group of 6–8 separate housing units on the south side of Stockdale Highway adjacent to the Weed Island drainage ditch	2.25 miles northwest of the project site
Elk Hills Elementary School	Kern Street on the west side of the community of Tupman	2.5 miles southeast of the project site
Residences	Two or three mobile homes on the west side of Elic Valley Road south of Stockdale Highway	2.5 miles northeast of the project site 1,800 feet north of the 230-kV transmission line

Source: Energy Commission Staff 2012

Results of the VSOI analysis and photographic survey for the OEHI component resulted in the conclusion that the most sensitive viewpoints within the VSOI were from those areas with background views of the project site. An inventory of stationary sensitive viewpoints (also referred to as sensitive receptors) within approximately 5 miles of the proposed OEHI site is provided in **Visual Resources Table 5**.[17] Because there are no

[15] In regards to the references made to distances/cardinal directions between the OEHI component and Sensitive Receptors in **VISUAL RESOURCES Table 5**, “Project Site” is considered to be the CO2 EOR Processing Facility, as this would be the most prominent/visible element of the OEHI project.

designated scenic highways or roadways in the region, no highway or roadway segments are included in the table. However, potential effects of the project on viewers traveling on nearby roads and highways are addressed below.

Visual Resources Table 5
Sensitive Receptors within Approximately 5 Miles of Proposed OEHI Facilities

Type of Receptor	General Description and Location	Direction and Approximate Distance from Proposed OEHI Project Site
Subdivision (Residences, School, Post Office, etc)	Subdivision near the intersection of Grace Avenue, Kern Street, and Emmons Boulevard	1.5 miles northeast of the project site;
Residences	Residences near the intersection of Taft Highway (State Highway 119) and Golf Course Road	3.5 miles southeast of the project site
Residences	Residences near the intersection of Taft Highway (State Highway 119) and Tank Farm Road	4 miles southeast of the project site
Residences	Residences near the intersection of Tank Road and Tank Farm Road	4 miles south of the project site
Residences	Residences near the intersection of Mesquite Street and Tamarisk Avenue	5 miles southwest of the project site
Residences	Residences near the intersection of Escudo Drive and Gibbs Street	5.3 miles southwest of the project site
Residences	Residences near the intersection of Airport Road and Valley West Road	5.4 miles southwest of the project site

HECA

KEY OBSERVATION POINTS

A KOP is selected to be representative of the most critical viewpoints from off-site locations where the project would be visible to the public, for example: recreational and residential areas, travel routes, bodies of water, as well as scenic and historic resources. Because it is not feasible to analyze all the views in which a proposed project would be seen, it is necessary to select a KOP that would most clearly display the visual effects of the proposed project. A KOP may also represent a primary viewer group(s) that would potentially be affected by the project. Staff evaluates the existing physical environmental setting, the KOP, and the visual change created by the proposed project to the VSOI.

The applicant has provided KOP photographs that show the existing physical condition without the HECA and its OEHI component, and has prepared photographic simulations to show how the proposed project would appear in both existing conditions. **Visual Resources Figure 5** shows the locations of the six KOPs used for this analysis:

- KOP 1 – View of the HECA project site, looking west from Station Road;
- KOP 2 – View of the HECA project site, looking south-southeast from Stockdale Highway;
- KOP 3 – View of the HECA project site, looking north-northwest from the Elk Hills Elementary School playground;
- KOP 4 – View of the HECA project site, looking south-southwest from the Stockdale Highway near the I-5 interchange;
- KOP 5 – View of the HECA project site, looking south-southwest from the southbound lane on I-5;[18] and
- KOP 6 – View of the HECA project site, looking south-southeast from Brite Road.

KOP 1

<u>Visual Sensitivity</u>

KOP 1 was photographed from Station Road near the eastern boundary of the HECA project site.[19] The middle of the HECA project site is approximately 2600 feet west of this viewpoint. The VSOI at this location includes views of flat, irrigated farmland extending from the foreground through the middleground of the view and in both directions to the left and right (south and north) of the viewer. Views are dominated by green cultivated cropland in the foreground and middleground that contrasts with the muted browns and relatively barren landscape of the Elk Hills in the middleground. A faint impression of the Temblor Range in the background repeats the form and line of the Elk Hills. Above-ground utility lines on wooden poles are visible in foreground and middleground views. Station Road is a two-lane blacktop road in the view at KOP 1.

A former organic fertilizer production facility northwest of the project site is visible from KOP 1. The complex of grain storage silos, buildings, and other structures is circled by palm trees and appears as a collection of irregular, built shapes compared to the surrounding open croplands. The surfaces of some of the structures are more reflective than other elements in the view.[20] Oil production work in the Elk Hills Oil Field Unit is generally too far away for equipment to be discernible in the VSOI.

Little variation is present in the form and line of landscape elements at this location. Qualities that are often associated with memorable or visually powerful landscapes are not present at KOP 1. In other words, the landscape lacks interesting visual features and variations in forms, textures, and patterns in the vegetation and landforms that are often present in high quality views. Although views at this location are somewhat harmonious due to the overall lack of urban encroachment, no particular landscape feature or landform draws the viewer's attention. Visual quality for KOP 1 is characterized as moderate.

---

[18] KOP 5 provides a view from a stationary point adjacent to the southbound lanes of I-5. This segment of I-5 in the vicinity of the project site is oriented to the southeast. Energy Commission staff has concluded that the project site would not be within view for motorists traveling south along this segment of I-5. Therefore, KOP 5 is not analyzed in this staff assessment.

[19] See **Visual Resources Figures 6a** and **6b**.

[20] See view of the former organic fertilizer production facility in **Visual Resources Figure 7a**.

Viewers at or near KOP 1 include residents at two adjacent properties near the intersection of Station Road and Tule Park Road and motorists on Station Road. Viewer concern for nearby residents is expected to be high whether or not their homes are oriented to permit direct and unscreened views of the project site. The Tule Elk Reserve State Park is approximately 2,000 feet east of the viewpoint for KOP 1. Visitors to the Reserve have direct, unscreened views of the project site during their trips to the area. Viewer concern for this viewer group is expected to be moderate to high. Motorists using local roadways include employees of agricultural, oil production, and other businesses whose focus is on their travels and daily pursuits. This viewer group is expected to have moderate viewer concern. For this combination of viewer groups, viewer concern for KOP 1 is considered moderate to high.

Under existing conditions, the site is generally not screened by landforms, vegetation, or built structures, and views of the project site from KOP 1 are unimpeded. Visibility of the project site at this location is high.

Viewers for KOP 1 include motorists, residents, and recreationists.[21] This visual resources analysis included a review of traffic volume data compiled by the Kern Council of Governments (Kern COG) for its Regional Transportation Monitoring Improvement Program. The most recent data compiled by Kern COG includes traffic counts on certain roadways in the project area. Traffic counts taken on Morris Road south of Stockdale Highway were included in the estimate of number of viewers for KOP 1. It is assumed that motorists on Morris Road include local residents as well as visitors to the Reserve. As of January 1, 2004, the annual average daily traffic (AADT) volume at this location was 370 (Kern COG 2012).[22]

Based on data maintained by California State Parks staff, a total of 4,618 people visited the Reserve in 2011 (an average of approximately 13 recreationists per day).[23] As of June 1, 2012, 1,977 people have been recorded as visitors.[24] It is estimated that between two and five residences are near the viewpoint for KOP 1. Based on Kern COG traffic data, estimated number of visitors to the Reserve, and the number of nearby residences, the rating for number of viewers at KOP 1 is considered low.

The duration of view for KOP 1 varies depending on whether the viewers are nearby residents, motorists, or visitors to the Reserve. Viewer duration is considered high for residents with a direct view of the project site at this location. Motorists on Morris Road and Station Road would be traveling at relatively low speeds and may have views of the project site lasting from 20 to 60 seconds. For this viewer group, the rating for duration of view is considered moderate. Recreationists would likely see the project site during their visits to the area and may have views lasting from 1 to 2 minutes. The rating for

[21] See **Appendix VR-1**.

[22] AADT is the total volume of traffic on a highway segment for 1 year divided by the number of days in the year. AADT volumes reported on the Kern COG website are typically a count conducted on a single day, adjusted using day-of-week and monthly factors from a control station to estimate the average volume over the year. AADT information can be located at: http://www.kerncog.org/cms/data/traffic-count-map.

[23] See Alluis, email communication, 2012.

[24] *Ibid*.

this duration of view is considered moderate to high. For this combination of viewer groups, duration of view for KOP 1 is considered moderate to high.

Although visibility of the project site is high, the number of viewers is low. Duration of view varies among the three identified viewer groups; average duration of view is moderate to high. Therefore, based on the ratings for visibility, number of viewers, and duration of view, *overall viewer exposure* for KOP 1 is considered moderate.

Visual quality is characterized as moderate. Viewer concern varies among the viewer groups; average viewer concern is moderate to high. Therefore, based on the ratings for the above visual sensitivity factors, *overall visual sensitivity* is considered moderate to high.

Visual Change

The visual simulation for KOP 1 shows buildings and structures as they would appear at the HECA project site for a viewer near the intersection of Station Road and Tule Park Road. The closest structures would be located approximately 3,600 feet west of the viewer just beyond the foreground. Some of the tallest structures at the plant site would be clearly visible from KOP 1. From south to north (left to right) some of the proposed structures would include: a urea ammonium nitrate storage structure, urea storage structure, transfer tower, feedstock barn, and another transfer tower.[25]

Construction of the HECA project structures would introduce a high degree of contrast into the VSOI. The low profile and simple horizontal forms and lines of the existing landscape created by the cropland and distant hills would be interrupted by the overall bulk, height, complexity, and geometry of the built structures at the project site. The uniformity of shapes and evenness of landforms created by the existing landscape for KOP 1 indicates low VAC for this view.[26] In other words, this landscape has a low capacity to visually withstand or absorb the new built elements into the VSOI.
The color contrast created by the gray tones and steel surfaces of the new structures would be strong in this environment. The hard surfaces of the constructed project components would contrast sharply with the relatively soft textures of the existing natural surfaces of the earth and vegetation. The degree of visual contrast that would be created by construction of the proposed project is considered high.

The simulation for KOP 1 shows the proportionate size of the HECA project structures as a whole relative to the existing visible natural and built features in the VSOI.[27] The new built structures would dominate the landscape. The existing expansive view of the Elk Hills and Temblor Range in the middleground and background would be partially blocked at this location. The degree of dominance and view blockage that would be created by the project is considered moderate to high. Therefore, for KOP 1, the *overall visual change* would be moderately high.

---

[25] See **Visual Resources Figure 17**.
[26] See the discussion under “Contrast” in **Appendix VR-1**.
[27] See **Visual Resources Figure 6b**.

Visual Impact Determination

Overall visual sensitivity for KOP 1 is considered moderate to high and *overall visual change* is considered moderately high. Energy Commission staff concludes that introducing the publicly visible project structures into the existing view at KOP 1 would cause substantial degradation of the existing visual character of the site and its surroundings. Additionally, the applicant characterizes visual impact susceptibility and severity as "high" at KOP 1 and identifies a significant impact to visual resources at this location (Hydrogen Energy International 2012). Therefore, a significant impact to visual resources is identified for KOP 1.

The Amended AFC includes a visual resources mitigation measure (VRMM-1) recommending preparation of a conceptual landscape plan to screen views of the project site (Hydrogen Energy International 2012). However, during a discussion with Energy Commission staff on January 29, 2013, the applicant demonstrated that using landscaping for visual screening at KOP 1 would be difficult due to irrigation requirements.[28] As such, the applicant intends to provide an alternative mitigation measure – one that would provide off-site visual screening (landscaping) at the properties located at the intersection of Station Road and Tule Park Road. The applicant believes that this alternative mitigation measure would reduce visual impacts at KOP 1 to less-than-significant levels.[29] Further, the applicant has stated that it would "study the possibility of incorporating cost-effective architectural enhancements to the feedstock storage [structure]. . .to reduce contrast in color and texture. . .and exterior components to reduce contrast in storage area lines."[30]

Consistent with the applicant's proposed alternative mitigation measure, Energy Commission staff requests that the applicant prepare and submit an electronic copy of a conceptual off-site landscape plan and/or architectural enhancements to the feedstock storage structure for review by staff at least two months prior to publication of the Final Staff Assessment (FSA) for the project. The primary purpose of the off-site landscape plan and/or the architectural enhancements would be to show how they would contribute to screening views of the project to the maximum extent feasible at KOP 1 – including both the residences located at the intersection of Station Road and Tule Park Road and the Tule Elk Reserve State Park public use areas.[31] To ensure that the information provided in the off-site landscaping and/or architectural enhancements would allow for a thorough assessment of this impact, both items would need to include, at a minimum, the following elements:

- Information on the type of plant species proposed: size, quantity, and spacing at planting; expected height at 5 years and maturity; and expected growth rates. Staff

[28] See Rushmore et al., conference call, 2013. According to the applicant, the landscaping would be placed on top of the berm at the eastern border of the project site. Placing the landscaping on top of the berm would require an increased amount of water for irrigation purposes. However, according to the applicant, this increased demand for water to irrigate the landscaping cannot be accommodated within current potable water limits set forth by Kern County.

[29] See Response to CEC Data Request Set One: No. A117 (TN# 69490).

[30] *Ibid*.

[31] Staff requests that the plan be consistent with applicable sections of Chapter 19.86, Landscaping, of the Kern County Zoning Ordinance (**http://www.co.kern.ca.us/planning/pdfs/KCZOJul12.pdf**).

requires preparation of this information by a qualified professional arborist or botanist familiar with local growing conditions.

- Conceptual landscape plan.
- Use of a decorative wall or similar permanent built structure combined with landscape plantings and/or other built screening devices to maximize the effectiveness of the landscape plan. The decorative screen or wall shall be high enough to interrupt views of vertical project features to the maximum extent feasible for a person standing at or near KOP 1. The plan shall address and incorporate required setbacks of plantings and screening structures from public utilities and the road.
- Electronic and paper copies of 11-inch by 17-inch color photographic simulations at life size scale showing the landscaping 5 years after planting and at maturity from the residences located at KOP 1.
- Official copy of recorded agreement between the landowner(s) at KOP 1 and HECA, LLC detailing the applicant's conceptual landscape plan and the landowner(s) approval of said plan.
- Electronic and paper copies of 11-inch by 17-inch color photographic simulations at life size scale showing any architectural enhancements to the feedstock storage structure.

Staff may prepare a condition of certification to include in the FSA requiring implementation of the above landscape plan and/or architectural enhancements. The visual resources analysis in the FSA would assess effectiveness of the proposed off-site landscape plan, architectural enhancements, and other proposed conditions of certification to reduce the impact at KOP 1 to a less-than-significant level.

KOP 2

Visual Sensitivity

KOP 2 was photographed from the north side of Stockdale Highway between Dairy Road and Dunford Road.[32] The HECA project site is approximately 1.5 miles southeast of this viewpoint. Visible in the middleground of the VSOI, lie the complex of structures associated with the former organic fertilizer production facility.

Similar to KOP 1, views from KOP 2 are dominated by cultivated cropland in the foreground and middleground against the medium brown tones of the Elk Hills in distant middleground views. The edges of fields planted in orchards add slight variation in views to the west on either side of Stockdale Highway. The ridgeline of the Temblor Range is visible in the background to the west. Above-ground utility lines on wooden poles are visible along roadways and other rights-of-way in foreground and middleground views. Stockdale Highway is a two-lane blacktop roadway in the view at this location.

---

[32] See **Visual Resources Figures 7a** and **7b**.

Similar to KOP 1, little variation is apparent in the form and line of landscape elements at KOP 2. No particular landscape feature or landform draws the viewer's attention. Visual quality for KOP 2 is characterized as moderate.
Viewers at or near KOP 2 include residents at two adjacent properties on the north side of Stockdale Highway directly behind (north of) the viewpoint for this photograph and motorists on Stockdale Highway. Other residential properties are near the viewpoint for KOP 2; one is near the intersection of Dairy Road and the highway, and the other is on Dunford Road north of the highway. Viewer concern for residents is considered high. Stockdale Highway is a major east-west thoroughfare that extends from State Route (SR) 99 in Bakersfield to the west side of the San Joaquin Valley. Truck traffic is a daily presence on the highway. It is assumed that other motorists include residents of the area and employees of businesses in the area. Motorists on the highway are expected to have moderately low viewer concern. For this combination of viewer groups, viewer concern is estimated to be moderate to moderately high.

Under existing conditions, views of the site are partially interrupted by the built structures at the organic fertilizer production facility. Because the project site is approximately 1½ miles southeast of the viewer from the viewpoint of KOP 2, and due to the presence of intervening built structures, visibility of the project site at this location is moderate to high.

Viewers for KOP 2 include motorists and residents. Traffic data compiled by Kern COG includes traffic counts for 2012 on Stockdale Highway west of the I-5 ramps. Traffic counts were considered in the estimate of number of viewers for KOP 2. As of April 12, 2011, the AADT volume at this location was approximately 1,494 (Kern COG 2012). The rating for number of viewers at KOP 2 is estimated to be moderately low. Viewer duration is considered high for residents with a direct view of the project site from KOP 2. Motorists on Stockdale Highway could be traveling close to highway speed or more slowly, depending on the habits of the drivers. Views of the project site from the highway would mostly be in the periphery of views for drivers heading east or west on the road, with views of the project site lasting from 10 to 20 seconds. For this viewer group, the rating for duration of view is considered low to moderate. For this combination of viewer groups, duration of view is estimated to be moderate to high.

Visibility of the project site from KOP 2 is moderate to high, and the number of viewers is moderately low. Duration of view is high for residents and low to moderate for motorists; the average duration of view is moderate to high. Therefore, based on the ratings for visibility, number of viewers, and duration of view, *overall viewer exposure* for KOP 2 is considered moderate. Visual quality is characterized as moderate. Viewer concern varies among the viewer groups; average viewer concern is moderate to moderately high. Therefore, based on the ratings for visual quality, viewer concern, and overall viewer exposure, *overall visual sensitivity* is considered moderate.

<u>Visual Change</u>

The visual simulation for KOP 2 shows the proposed project site as it would appear for a stationary viewer along Stockdale Highway between Dairy Road and Dunford Road. The closest HECA project structures would be approximately 1.75 miles southeast of the viewer in the middleground. Some of the tallest structures at the new plant site would be visible above the ridgeline of the Elk Hills in the far middleground.

Implementation of the HECA project and development of the site would introduce a moderate to high degree of contrast into the VSOI. The low profile and basic horizontal forms and lines of the existing landscape would be interrupted by the height and complexity of the structures that would be erected at the plant site. The uniformity of shapes and evenness of landforms created by the existing landscape for KOP 2 indicates low VAC for the view.

The distance to the project site from the viewpoint of KOP 2 would temper the color contrast created by the gray tones and steel surfaces of the proposed structures, however, the hard surfaces of the constructed project components would contrast notably with the relatively soft textures of the existing natural surfaces of the earth and vegetation. The level of visual contrast that would be created by construction of the proposed project is considered moderate to high.

The photographic simulation shows the proportionate size of the HECA project structures as a whole relative to the existing natural and built features in the field of view for KOP 2. The existing structures at the former organic fertilizer production facility are noticeable at the center of the field of view. Although the addition of new built structures would increase the density and mass of structures in the center of the view, the new structures would not completely dominate the landscape due to their distance from the viewer, and dominance of the proposed project in the view is rated as moderate. The open views of the Elk Hills and Temblor Range in the distant middleground of the view would be blocked to a degree at this location. For KOP 2, view blockage that would be created by the project is considered moderate. Therefore, for KOP 2, the *overall visual change* would be moderate.

Visual Impact Determination

Overall visual sensitivity for KOP 2 is considered moderate and *overall visual change* is considered moderate. Energy Commission staff concludes that introducing the publicly visible project structures into the existing view at KOP 2 would not cause substantial degradation of the existing visual character of the site and its surroundings. Therefore, a less-than-significant impact to visual resources is identified for KOP 2. No mitigation is required.

KOP 3

Visual Sensitivity

KOP 3 was photographed from the play field at Elk Hills Elementary School in the community of Tupman.[33] The HECA project site is approximately 2.5 miles northwest of this viewpoint. The school site is situated at a slightly higher elevation than the valley floor, which allows for expansive views across the landscape from the campus. Foreground views north and northwest from KOP 3 include views of disturbed valley saltbush scrub and light-colored sandy soils. The property below and next to the play

[33] See **Visual Resources Figures 8a** and **8b**.

field is sometimes used by motorized vehicles, and tire tracks are visible in the area. Tupman Road and the California Aqueduct cross the area in the foreground. Above-ground utility lines on wooden poles parallel Tupman Road. The open space in the Reserve fills the middleground of the view to the north. Structures at the organic fertilizer production facility and the surrounding palm trees beyond the northwest corner of the HECA project site are partially visible on the horizon.

Foreground views at KOP 3 are characterized by sparse low-lying vegetation and open areas that have been altered by development and urban uses. No landscape feature or landform in the middleground or background of the view draws the viewer's attention from KOP 3. Visual quality for KOP 3 is characterized as moderately low.

Viewers at KOP 3 include elementary school staff, students, and families of students.[34] The play field is used intermittently during school recesses and sporting events. Recreational viewers engaged in or observing active sport activities are likely to be attentive to the on-site activity rather than the aesthetics of the environment. However, viewer concern for viewers at KOP 3 would still be considered high.

Views of the project site from this location are unimpeded. Because the project site is approximately 2½ miles northwest of the view from KOP 3, and features in the VSOI at that distance do not dominate the view, visibility of the project site at this location is low to moderate.

Approximately 75 students are enrolled at Elk Hills Elementary School. The rating for the number of viewers at KOP 3 is estimated to be moderate. This estimate accounts for staff and families of students who may be preset on the play field with the students.

Children and adults using the play field would have opportunities to view the project site for extended periods of time during recesses and sport events, therefore, viewer duration is considered high for KOP 3.

Visibility of the project site from KOP 3 is low to moderate, and the number of viewers is moderate. Due to the expected presence of students and staff on the play field for extended periods, duration of view is high. Therefore, based on the ratings for visibility, number of viewers, and duration of view, *overall viewer exposure* for KOP 3 is moderate. Visual quality is rated as moderately low and viewer concern is high. Therefore, based on the ratings for visual quality, viewer concern, and overall viewer exposure, *overall visual sensitivity* is considered moderate.

<u>Visual Change</u>

The visual simulation for KOP 3 shows the proposed project site as it would appear for a viewer from the play field at Elk Hills Elementary School. The closest HECA project structures would be approximately 2.5 miles northwest of the viewer in the far middleground.

---

[34] See **Appendix VR-1**.

The low profile and evenness of landforms created by the existing landscape for KOP 3 indicates low VAC for the view. Although the bold, angular shapes of the new structures may draw the attention of viewers in the vicinity of KOP 3, the considerable distance to the project site from KOP 3 and the seasonal hazy atmosphere in the valley would subdue the effects of form, color, and textural contrast created by the inorganic surfaces that would define the structures at the project site. The degree of visual contrast that would be created by construction of the proposed project is considered moderate for KOP 3.

Although the addition of new built structures in the view for KOP 3 would increase the density and mass of structures in the center of the view, the new structures would not dominate the landscape due to their distance from the viewer, and dominance of the proposed project in the view is rated as moderate. For KOP 3, view blockage that would be created by the project is considered low to moderate. Therefore, for KOP 3, the *overall visual change* would be moderately low to moderate.

Visual Determination

Overall visual sensitivity for KOP 3 is considered moderate and *overall visual change* is considered moderately low to moderate. Energy Commission staff concludes that introducing the publicly visible structures into the existing view at KOP 3 would not cause substantial degradation of the existing visual character of the site and its surroundings. Therefore, a less-than-significant impact to visual resources is identified for KOP 3. No mitigation is required.

KOP 4

Visual Sensitivity

KOP 4 was photographed from the shoulder of the westbound lane of Stockdale Highway near the I-5 interchange.[35] The HECA project site is approximately 2.5 miles southwest of KOP 4.

Views to the west and southwest from KOP 4 are characterized by sparse low-lying vegetation, sandy loamy soils in the foreground, and open terrain extending from the foreground through the middleground. North and south trending high-voltage transmission lines extending between tall lattice towers are visible in distant foreground views from KOP 4. A few trees and isolated buildings and other structures are visible in views across the valley. The Elk Hills are outlined in the background. The area is characterized by little color variation. Similar to KOP 2, Stockdale Highway is a two-lane blacktop roadway in the view at KOP 4. The project site is visible to the southwest for motorists heading west on the highway.

The views at KOP 4 are typical of many areas in the San Joaquin Valley along the I-5 corridor. The transportation network and structures for various utilities overpower subtle variations in the form and line of landscape elements. No particular landscape feature or landform draws the viewer's attention. Visual quality for KOP 4 is characterized as low to moderate.

---

[35] See **Visual Resources Figures 9a** and **9b**.

As described above, various types of trucks are regularly present on Stockdale Highway. Other motorists include residents of the area and employees of nearby businesses. No residences are located nearby, and most of the highway commercial development adjacent to this interchange is on the east side of I-5. As such, motorists on the highway are expected to have low to moderate viewer concern, depending on their preferences.

Under existing conditions, views of the HECA project site from KOP 4 are partially interrupted by the high-voltage transmission lines that cross the landscape. Because the project site is approximately 2½ miles southwest of the viewer from the viewpoint for KOP 4, and due to the presence of intervening built structures, visibility of the project site at this location is low to moderate.

Based on Kern COG data for 2012, the AADT volume on Stockdale Highway west of the I-5 ramps was approximately 1,277 (Kern COG 2012). The rating for number of viewers at KOP 4 is estimated to be moderately low.

Motorists on Stockdale Highway could be traveling at speeds over 45 miles per hour. Brief views of the project site from the highway would be possible for motorists heading west or east on the highway. It is estimated that views of the project site for this viewer group would last from 10 to 20 seconds. For this viewer group, the rating for duration of view is considered moderately low.

Visibility of the project site from KOP 4 is low to moderate. Number of viewers and duration of views are each rated as moderately low. Therefore, based on the ratings for these three variables, *overall viewer exposure* for KOP 4 is moderately low.
Visual quality is characterized as low to moderate. Viewer concern is rated low to moderate. Therefore, based on the ratings for visual quality, viewer concern, and overall viewer exposure, *overall visual sensitivity* for KOP 4 is also considered moderately low.

Visual Change

The visual simulation for KOP 4 shows the proposed project site as it would appear for a viewer from Stockdale Highway near I-5. The closest HECA project structures would be approximately 2.5 miles southwest of the viewer in the far middleground.

Although the angular, vertical shapes of the new structures may draw the attention of viewers in the vicinity of KOP 4, the considerable distance to the project site from this viewpoint and the atmospheric haze that is frequently present in the valley would subdue the effects of form, color, and textural contrast created by the inorganic surfaces of new structures at the project site. The degree of visual contrast that would be created by construction of the proposed project is considered low to moderate for KOP 4.

The photographic simulation shows the proportionate size of the HECA project structures as a whole relative to the existing features in the view for KOP 4. Although the addition of new built structures would increase the density and mass of structures in the center of the view, the new structures would not dominate the landscape due to their distance from the viewer and the existing high-voltage transmission lines that cross the foreground of the landscape between the viewpoint for KOP 4 and the project site. Dominance of the proposed project in the view is rated as low to moderate, and view blockage that would be created by the project is considered low to moderate. Therefore, for KOP 4, the *overall visual change* would be moderately low.

Visual Determination

Overall visual sensitivity for KOP 4 is considered moderately low and *overall visual change* is also considered moderately low. Energy Commission staff concludes that introducing the publicly visible structures into the existing view at KOP 4 would not cause substantial degradation of the existing visual character of the site and its surroundings. Therefore, a less-than-significant impact to visual resources is identified for KOP 4. No mitigation is required.

KOP 6

Visual Sensitivity

KOP 6 was photographed from the shoulder of the eastbound lane of Brite Road, approximately 1 mile east of Wasco Way.[36] The HECA project site is approximately 3 miles southeast of KOP 6.

Views to the southeast from KOP 6 are characterized by a relatively flat topography with sandy loamy soils in the foreground, and open terrain extending from the foreground through the middleground. In the background, there are a few above-ground utility lines on wooden poles are visible along roadways and isolated structures. The area is characterized by little color variation with mostly natural sparse and striated vegetation, and has a low to moderate contrast of generally flat tones. Brite Road is a two-lane blacktop roadway in the view at this location.

Little variation is apparent in the form and line of landscape elements at KOP 6. No particular landscape feature or landform draws the viewer's attention. Visual quality for KOP 6 is characterized as moderately low.

Viewers at or near KOP 6 includes two residences and motorists. The first residence is located at a property on the north side of Brite Road, northwest of the viewpoint for this photograph. The second residence is located at a property on the south side of Brite Road, directly west of the viewpoint for this photograph. Other residential properties are located near the viewpoint for KOP 6. One property is located on the north side of Brite Road, approximately 800 feet east of the first residential property mentioned above. Viewer concern for residents is considered high. Motorists using local roadways include employees of agricultural, oil production, and other businesses whose focus is on their travels and daily pursuits. Motorists on the highway are expected to have low to moderate viewer concern. For this combination of viewer groups, viewer concern is estimated to be moderate to moderately high.

Under existing conditions, views of the site are partially interrupted by the built structures at the organic fertilizer production facility. Because the project site is

---

[36] See **Visual Resources Figures 10a** and **10b**.

approximately 3 miles southeast of the viewer from the viewpoint of KOP 6, and due to the presence of intervening built structures, visibility of the project site at this location is moderate to moderately high.

Viewers for KOP 6 include motorists and residents. Traffic data compiled by Kern COG includes traffic counts for 2012 on Brite Road and Mirasol Avenue. Traffic counts were considered in the estimate of number of viewers for KOP 6. As of August 1, 2012, the AADT volume at this location was approximately 920 (Kern COG 2012). The rating for number of viewers at KOP 6 is estimated to be moderately low.

Viewer duration is considered high for residents with a direct view of the project site from KOP 6. Motorists on Brite Road would be traveling at relatively low speeds and may have views of the project site lasting from 20 to 60 seconds. For this viewer group, the rating for duration of view is considered moderate. For this combination of viewer groups, duration of view is estimated to be moderate to high.

Visibility of the project site from KOP 6 is moderate to moderately high, and the number of viewers is moderately low. Duration of view is high for residents and low to moderate for motorists; the average duration of view is moderate to high. Based on the ratings for visibility, number of viewers, and duration of view, *overall viewer exposure* for KOP 6 is considered moderate.

Visual quality is characterized as moderately low. Viewer concern varies among the viewer groups; average viewer concern is moderate to moderately high. Therefore, based on the ratings for visual quality, viewer concern, and overall viewer exposure, *overall visual sensitivity* is considered moderate.

Visual Change

The visual simulation for KOP 6 shows the proposed project site as it would appear for a stationary viewer along the eastbound lane of Brite Road, approximately 1 mile east of Wasco Way. The closest HECA project structures would be approximately 3 miles southeast of the viewer in the far middleground.

Implementation of the HECA project and development of the site would introduce a moderate to high degree of contrast into the VSOI. The low profile and basic horizontal forms and lines of the existing landscape would be interrupted by the height and complexity of the structures that would be erected at the plant site. The uniformity of shapes and evenness of landforms created by the existing landscape for KOP 6 indicates low VAC for the view.

The distance to the project site from the viewpoint of KOP 6 would temper the color contrast created by the gray tones and steel surfaces of the proposed structures, however, the hard surfaces of the constructed project components would contrast notably with the relatively soft textures of the existing natural surfaces of the earth and vegetation. The level of visual contrast that would be created by construction of the proposed project is considered moderate to high.

The photographic simulation shows the proportionate size of the HECA project structures as a whole relative to the existing natural and built features in the field of view for KOP 6. The existing structures at the former organic fertilizer production facility are slightly noticeable at the right of the field of view. There is an existing residential structure that is noticeable at the center of the view and several others at the left of the view that are only somewhat noticeable. Although the addition of new built structures would increase the density and mass of structures on the right of the view, the new structures would not completely dominate the landscape due to their distance from the viewer and other existing (residential) structures in the same view. As such, dominance of the proposed project in the view is rated as low to moderate. Due to the distance between KOP 6 and the project site, there are no open views of the Elk Hills or Temblor Range in the background. As such, for KOP 6, view blockage that would be created by the project is considered low to moderate. Therefore, for KOP 6, the *overall visual change* would be moderately low to moderate.

Visual Impact Discussion

Overall visual sensitivity for KOP 6 is considered moderately low to moderate and *overall visual change* is also considered moderate. Energy Commission staff concludes that introducing the publicly visible structures into the existing view at KOP 6 would not cause substantial degradation of the existing visual character of the site and its surroundings. Therefore, a less-than-significant impact to visual resources is identified for KOP 6. No mitigation is required.

Visual Character and Quality – Conclusion (HECA)

Energy Commission staff evaluated the proposed project's effects on visual resources at the six selected KOPs. The visual impact determinations are focused on the overall visual sensitivity for each KOP and whether the HECA project would cause substantial degradation of the existing visual character of the site and its surroundings.

Staff determined that the impacts at KOP 2, KOP 3, KOP 4, and KOP 6 did not meet or exceed the criterion set forth in the discussion above. Therefore, the project would not cause substantial degradation of the existing visual character of the site and its surroundings at these four KOPs. However, as the project would cause substantial degradation of the existing visual character of the site and its surroundings at KOP 1, a significant impact to visual resources is identified at KOP 1.

VISIBLE WATER VAPOR PLUMES

HRSG Stack

Publicly visible water vapor plumes that would emit from the HRSG would vary in frequency and size depending on whether the fuel source is hydrogen rich fuel or natural gas and if duct firing is occurring or not. As shown below in **Visual Resources Table 6**, plume frequency during seasonal daylight clear hours would not exceed 20 percent for the operation with duct firing.[37]

[37] See Table 11 in **Appendix VR-2**.

Visual Resources Table 6
Plume Frequency for the HRSG

Fuel Type	Plume Frequency Percent with Duct Firing	Plume Frequency Percent with No Duct Firing
Hydrogen Rich Fuel	9%	4%

Source: Energy Commission Staff 2010

Since the plume frequency is below 20% of seasonal daylight clear hours for the operation with and without duct firing, the corresponding plume dimensions have not been included.

Air Separation Unit Cooling Tower

Publicly visible water vapor plumes from the ASU cooling tower are predicted to occur approximately 37 percent of the time during seasonal daylight clear hours.[38] Because the plume frequency would exceed 20 percent, Energy Commission staff calculated (modeled) the 20th percentile plume dimensions using the combustion stack visible plume (CSVP) model. For the ASU cooling tower, the 20th percentile plume dimensions are predicted to be approximately 276 feet high, 142 feet in length, and 78 feet wide.[39] Because the cooling tower structure would be 55 feet tall, the visible plume above the cooling tower would be approximately 221 feet tall.

13-Cell Power Block Cooling Tower

Publicly visible water vapor plumes from the 13-cell power block cooling tower are predicted to occur approximately 37 percent of the time during seasonal daylight clear hours.[40] Because the plume frequency exceeds 20 percent, staff modeled the 20th percentile plume dimensions. For the 13-cell power block cooling tower, the 20th percentile plume dimensions are predicted to be approximately 393 feet high, 352 feet in length, and 186 feet wide.[41] Because the cooling tower structure would be 55 feet tall, the visible plume above the cooling tower would be approximately 338 feet tall.

Coal Dryer Stack

Publicly visible water vapor plumes from the coal dryer are predicted to occur approximately 40 percent of the time during seasonal daylight clear hours.[42] Because the plume frequency exceeds 20 percent, staff modeled the 20th percentile plume dimensions. For the coal dryer, the 20th percentile plume dimensions are predicted to be approximately 554 feet high, 132 feet in length, and 73 feet wide.[43] Because the cooling tower structure would be 305 feet tall, the visible plume above the cooling tower would be approximately 249 feet tall.

[38] See Table 2 in **Appendix VR-2**.
[39] See Table 3 in **Appendix VR-2**.
[40] See Table 7 in **Appendix VR-2**.
[41] See Table 8 in **Appendix VR-2**.
[42] See Table 13 in **Appendix VR-2**.
[43] See Table 14 in **Appendix VR-2**.

Conclusion for Effects Relating to the Water Vapor Plumes[44]

Publicly visible water vapor plumes for the project's ASU cooling tower, the 13-cell power block cooling tower, and coal dryer stack are predicted to occur more than 20 percent of the time during seasonal daylight clear hours. As such, the visual resources analysis below addresses the worst-case maximum facility operating condition for each of these three structures.

Visual Resources Table 1 shows the dimensions of proposed structures at the project site. Many of the structures would be at least 100 feet tall, and several would be over 200 feet tall. The overall mass of the built structures would dominate views of the project site relative to the water vapor plumes. Plumes emanating from the proposed project's ASU cooling tower, 13-cell power block cooling tower, and coal dryer are predicted to be relatively small and visually subordinate to the permanent structures that would be installed at the project site. Energy Commission staff concludes that the magnitude of the change to visual resources from introduction of water vapor plumes into the project VSOI would not substantially degrade the existing visual character or quality of the site and its surroundings. Therefore, staff considers publicly visible water vapor plumes to be a less-than-significant impact of the project. No mitigation is required.

The ground fogging plume analysis predicts that ground fogging plumes from the proposed process cooling tower and power block cooling tower would not reach any of the nearby roads. Therefore, staff considers publicly visible ground fogging plumes to be a less-than-significant impact of the project. No mitigation is required.

ELECTRICAL TRANSMISSION LINE

Installation of the proposed transmission line and tangent structures would increase overhead utility lines near the project area. The tangent and dead-end structures supporting the lines would stand 90 to 106 feet tall and 115 feet tall, respectively. Most publicly visible areas in the project VSOI include views of various above-ground utility lines along local roadways and other utility corridors. The addition of the new transmission line would augment the existing condition for visible utility lines.
Several residences are located within approximately 2,000 feet of the route for the proposed transmission line.[45] Viewer concern for residents who would have views of the transmission line is expected to be high. Depending on the angle of view and the presence of existing screening (e.g., mature trees), the poles could be highly visible from viewpoints at and near local residences. Viewer concern for visitors to the Tule Elk Reserve State Park is considered moderate to high. These viewers may have unobstructed views of the transmission line from the Reserve.

Although viewer concern is high or moderate to high, overhead utility lines are a common visual element in the project area, and, when compared to the existing condition, the change to the visual environment from construction of the transmission

---

[44] Please refer to the Air Quality section of this staff assessment for a discussion of the potential visibility impacts of the proposed project relating to gaseous emissions.

[45] See **Visual Resources Table 4**.

line would not be substantial. Therefore, Energy Commission staff concludes that introducing the transmission line and pole structures into the visual environment near the project site would be a less-than-significant impact of the project. No mitigation is required.

RAILROAD SPUR

Construction of the railroad spur would introduce railcars into the VSOI. Rail deliveries would either be delivered directly to the project site via a railroad spur or be off-loaded and transported by a specialized heavy-haul contractor near Buttonwillow to the project site. Because the railroad spur would be constructed on the ground plane, this feature is not expected to result in visual contrast. Rail traffic would be visible from locations south of the community of Buttonwillow. According to the applicant, the HECA facility would operate 24 hours/day and 333 days/year.[46] Within a given 24-hour operational period, there would be a total of three on-site trains (one coal train and two product trains).[47] Under normal daily operations, each train would contain a total of approximately 57 railcars.[48] Under maximum daily operations, each train would contain a total of 242 rail cars.[49] However, each coal train and product train would take approximately two hours and one hour, respectively, to load/unload its cargo.[50] As such, it is likely that any views of trains within the VSOI would be intermittent, temporary, and potentially negligible (as train traffic could occur at night). Therefore, Energy Commission staff concludes that introducing the railroad spur into the VSOI would be a less-than-significant impact. No mitigation is required.

CONSTRUCTION-RELATED EFFECTS

The presence and movement of heavy construction equipment and construction-related generation of dust would have the potential to temporarily degrade the existing visual character and quality of views in the project VSOI. Viewer groups in the project construction areas include motorists on local roadways and highways, occupants of rural residences, employees of businesses in the area, and recreationists. Residents and recreationists are considered to have the highest viewer concern of these viewer groups.

Although construction would occur over a 49-month construction period, the work would be phased and often limited to particular types of activities or areas within the whole site. Although construction activities during a particular construction phase could be clearly visible from several viewpoints in the project VSOI, the work would be relatively short term and temporary in nature. Changes in visual resources conditions would occur along segments of pipelines and the transmission line alignment as construction progressed and continued through the area. Energy Commission staff concludes that the temporary nature of construction activities at the project site and along linear facilities would not cause substantial degradation of the existing visual character or

[46] See **Amended AFC for HECA - Air Quality Table 5.1-19**.
[47] *Ibid*.
[48] See **Amended AFC for HECA** - **Appendix E-3: Air Quality**, page 24.
[49] *Ibid*.
[50] *Ibid*, page 30.

quality of the site and its surroundings. Therefore, construction-related impacts are considered less-than-significant. No mitigation is required.

OEHI

KEY OBSERVATION POINTS – OEHI

Visual Resources Figure 2 shows the locations of the six KOPs used for this analysis:

- KOP 1 – View of the OEHI site, looking north-northwest from the intersection of Highway 119 and Golf Course Road;
- KOP 2 – View of the OEHI site, looking north from the intersection of Highway 119 and Tank Farm Road;
- KOP 3 – View of the OEHI site, looking north from Airport Road;
- KOP 4 – View of the OEHI site, looking northwest from Elk Hills Road;
- KOP 5 – View of the OEHI site, looking southwest from Grace Avenue; and
- KOP 6 – View of the OEHI site, looking south-southwest from the U.S. Post Office.[51]

KOP 1[52]

Visual Sensitivity

KOP 1 was photographed from the shoulder of the westbound lane of Golf Course Road, at the intersection of Golf Course Road and Highway 119.[53] The OEHI component is approximately 3 miles north-northeast of KOP 1.

Views to the north-northeast from KOP 1 are characterized by Highway 119 and telephone poles in the foreground and the relatively undisturbed scrub covered base of the Elk Hills through the middleground. In the background are the Elk Hills. The area is characterized by little color variation with sparse shrub vegetation. Highway 119 is a two-lane blacktop roadway in the view at this location.

Little variation is apparent in the form and line of landscape elements at KOP 1. No particular landscape feature or landform draws the viewer's attention. Visual quality for KOP 1 is characterized as moderately low to moderate.

Viewers at or near KOP 1 include several residents and motorists. The first four residences are located to the south of Golf Course Road, near the intersection of Golf Course Road and Highway 119. The second residence is located at a property on the north side of Golf Course Road, near the intersection of Golf Course Road and Highway 119. Other residential properties are located near the viewpoint for KOP 1. Viewer

---

[51] The U.S. Post Office is located at 337 Emmons Boulevard Tupman, CA 93276.

[52] The following references made to distances/cardinal directions between the OEHI component and KOP 1, are in regards to the CO_2 EOR Processing Facility, as this would be the most prominent/visible element of the OEHI site.

[53] See **Visual Resources Figures 11a** and **11b**.

concern for residents is considered high. Motorists using local roadways include local residents, employees of oil and gas production, gravel mining, and other businesses whose focus is on their travels and daily pursuits. Motorists on the highway are expected to have low to moderate viewer concern. For this combination of viewer groups, viewer concern is estimated to be moderate to moderately high.

Under existing conditions, views of the project site are only slightly interrupted by two street signs and three telephone poles. However, because the project site is approximately 3 miles north-northeast of the viewer from the viewpoint of KOP 1, and small intervening built structures are also in the VSOI, visibility of the project site at this location is low to moderate.

Viewers for KOP 1 include motorists and residents. Traffic data compiled by Kern COG includes traffic counts for 2012 on Golf Course Road and Highway 119. Traffic counts were considered in the estimate of number of viewers for KOP 1. As of August 1, 2012, the AADT volume at this location was approximately 800 (Kern COG 2012). The rating for number of viewers at KOP 1 is estimated to be moderately low.

Viewer duration is considered high for residents with a direct view of the project site from KOP 1. Motorists on Highway 119 could be traveling close to highway speed or more slowly, depending on the habits of the drivers. Views of the project site from Highway 119 would mostly be in the periphery of views for drivers heading southwest or northeast on the road, with views of the project site lasting from 10 to 20 seconds. For this viewer group, the rating for duration of view is considered low to moderate. For this combination of viewer groups, duration of view is estimated to be moderate to moderately high.

Visibility of the project site from KOP 1 is low to moderate, and the number of viewers is moderately low. Duration of view is high for residents and low to moderate for motorists; the average duration of view is moderate to moderately high. Based on the ratings for visibility, number of viewers, and duration of view, overall viewer exposure for KOP 1 is considered moderately low to moderate.

Visual quality is characterized as moderately low to moderate. Viewer concern varies among the viewer groups; average viewer concern is moderate to moderately high. Based on the ratings for visual quality, viewer concern, and overall viewer exposure, overall visual sensitivity is considered moderately low to moderate.

Visual Change

For KOP 1, the far middle ground and background topography would limit most, if not virtually all, views of any proposed project elements both during construction and operations. Therefore, for KOP 1, the *overall visual change* would be low.

Visual Impact Discussion

Overall visual sensitivity for KOP 1 is considered moderately low to moderate and *overall visual change* is considered low. Energy Commission staff concludes that introducing the publicly visible project structures into the existing view at KOP 1 would not cause substantial degradation of the existing visual character of the site and its surroundings. Therefore, a less-than-significant impact to visual resources is identified for KOP 1. No mitigation is required.

KOP 2[54]

Visual Sensitivity

KOP 2 was photographed from the shoulder of the westbound lane of Golf Course Road, at the north side of the intersection of Tank Farm Road and Highway 119.[55] The OEHI site is approximately 3 miles north of KOP 2.

Views to the north from KOP 2 are characterized by relatively flat visually intact grasslands with sparse shrub vegetation extending from the foreground to the middle ground. In the middle ground, approximately one-mile away, aboveground sections of a pipeline can be seen as a dark weathered-steel line contrast against the tan colored grasses. In the background are the Elk Hills and EHOF with evidence of significant topographic disturbance from roadway cuts and the cut/fill slopes of engineered pads for buildings and extraction equipment. On the horizon are many tall vertical structures such as derricks, power poles, communication towers, etc.

Due to some of the EHOF structures in the background, some variation is apparent in the form and line of landscape elements at KOP 2. However, no particular landscape feature or landform draws the viewer's attention. Therefore, the visual quality for KOP 2 is characterized as low to moderately low.

Viewers at or near KOP 2 include several residents and motorists. Residents on both the east (abutting Tank Farm Road) and west (abutting Sun Ridge Avenue) of Highway 119 would have views of the project site. Viewer concern for residents is considered high. Motorists using local roadways include employees of oil and gas production, gravel mining, and other businesses whose focus is on their travels and daily pursuits. Motorists on the highway are expected to have low to moderate viewer concern. For this combination of viewer groups, viewer concern is estimated to be moderate to moderately high.

Under existing conditions, views of the project site are slightly interrupted by the pipeline and other vertical built structures mentioned above. However, visibility of these structures is lessened due to their relatively far distance to KOP 2 (2.5-3 miles). Therefore, visibility of the project site at this location is low to moderate.

Viewers for KOP 2 include motorists and residents. Traffic data compiled by Kern COG includes traffic counts for 2012 on Tank Farm Road and Highway 119. Traffic counts were considered in the estimate of number of viewers for KOP 2. As of August 1, 2012, the AADT volume at this location was approximately 65 (Kern COG 2012). The rating for number of viewers at KOP 2 is estimated to be low.

---

[54] The following references made to distances/cardinal directions between the OEHI component and KOP 2, are in regards to the CO_2 EOR Processing Facility, as this would be the most prominent/visible element of the OEHI site.

[55] See **Visual Resources Figures 12a** and **12b**.

Viewer duration is considered high for residents with a direct view of the project site from KOP 2. Motorists on Highway 119 could be traveling close to highway speed or more slowly, depending on the habits of the drivers. Motorists on Tank Farm Road (or Sun Ridge Avenue) could be traveling at a more moderate speed, depending on the habits of the drivers. Views of the project site from Highway 119 would mostly be in the periphery of views for drivers heading southwest or northeast on the road, with views of the project site lasting from 10 to 20 seconds. Views of the project site from Tank Farm Road (or Sun Ridge Avenue) would mostly be in the periphery of views for drivers heading west or east on the road(s), with views of the project site lasting from 20 to 60 seconds. For this viewer group, the rating for duration of view is considered moderate. For this combination of viewer groups, duration of view is estimated to be moderately high.

Visibility of the project site from KOP 2 is low to moderate, and the number of viewers is low. Duration of view is high for residents and moderate for motorists; the average duration of view is moderately high. Based on the ratings for visibility, number of viewers, and duration of view, *overall viewer exposure* for KOP 2 is considered moderately low.

Visual quality is characterized as moderately low. Viewer concern varies among the viewer groups; average viewer concern is moderate to moderately high. Based on the ratings for visual quality, viewer concern, and overall viewer exposure, *overall visual sensitivity* is considered moderately low to moderate.

Visual Change

For KOP 2, some proposed pipeline installation areas would be visible from SR 119 and Tank Farm Road and present a visual change to the VSOI. However, a majority of the pipelines would run parallel to an existing pipeline in the middle ground of this KOP. Further, most of the proposed project components would be replacing existing oil extraction equipment (Occidental of Elk Hills 2012). Thus, it is likely that the pipeline installation areas which would be visible from KOP 2 would offer little contrast, dominance or view blockage to the existing VSOI. Therefore, for KOP 2, the *overall visual change* would be moderately low.

Visual Impact Determination

Overall visual sensitivity for KOP 2 is considered moderately low and *overall visual change* is considered moderately low to moderate. Energy Commission staff concludes that introducing the publicly visible project structures into the existing view at KOP 2 would not cause substantial degradation of the existing visual character of the site and its surroundings. Therefore, a less-than-significant impact to visual resources is identified for KOP 2. No mitigation is required.

KOP 3[56]

<u>Visual Sensitivity</u>

KOP 3 was photographed from Airport Road looking north.[57] The OEHI site is approximately 5.5 miles north of KOP 3.

Views to the north from KOP 3 are characterized by a dirt/gravel road and telephone poles in the immediate foreground. Views extending from the foreground to the middle ground are characterized by relatively flat visually intact grasslands with sparse shrub vegetation. In the far middle ground there is a substantial collection of large white cylindrical tanks used for oil separation. In the background are the Elk Hills and EHOF with evidence of significant topographic disturbance from roadway cuts and the cut/fill slopes of engineered pads for buildings and extraction equipment. On the horizon are many tall vertical structures such as derricks, power poles, communication towers, etc.

Due to the road, telephone poles, collection of large white cylindrical tanks, etc. some variation is apparent in the form and line of landscape elements at KOP 3. However, no particular landscape feature or landform draws the viewer's attention. Therefore, the visual quality for KOP 3 is characterized as low to moderately low.

Viewers at or near KOP 3 include motorists. Motorists using local roadways include employees of oil and gas production, gravel mining, and other businesses whose focus is on their travels and daily pursuits. Motorists on the highway are expected to have low to moderate viewer concern.

Under existing conditions, views of the project site are interrupted by the road, telephone poles, collection of large white cylindrical tanks, and other vertical built structures mentioned above. However, visibility of the background structures is lessened due to their relatively far distance to KOP 3 (3-3.5 miles). However, it remains apparent that man-made alterations have been made in the immediate area. Therefore, visibility of the project site at this location is moderately low to moderate.

Viewers for KOP 3 include motorists. Traffic data compiled by Kern COG includes traffic counts for 2012 on Airport Road, east of Highway 119. Traffic counts were considered in the estimate of number of viewers for KOP 3. As of August 1, 2012, the AADT volume at this location was approximately 750 (Kern COG 2012). The rating for number of viewers at KOP 3 is estimated to be moderately low.

Motorists on Airport Road would likely be traveling at lower than highway speeds, as the road shown in KOP 3 is unpaved. Views of the project site from Airport Road would include frontal and peripheral views, with views of the project site lasting from 1 to 2 minutes or longer. For this viewer group, the rating for duration of view is considered moderate to high.

---

[56] The following references made to distances/cardinal directions between the OEHI component and KOP 3, are in regards to the CO_2 EOR Processing Facility, as this would be the most prominent/visible element of the OEHI site.

[57] See **Visual Resources Figures 13a** and **13b**.

Visibility of the project site from KOP 3 is moderately low to moderate, and the number of viewers is moderately low. Duration of view is moderate to high for motorists. Based on the ratings for visibility, number of viewers, and duration of view, *overall viewer exposure* for KOP 3 is considered moderately low to moderate.

Visual quality is characterized as low to moderately low. Viewer concern is low to moderate. Based on the ratings for visual quality, viewer concern, and overall viewer exposure, *overall visual sensitivity* is considered moderately low.

Visual Change

For KOP 3, some proposed pipeline installation areas would introduce a visual change into the VSOI. Further, in the distant background, new and upgraded equipment may be partially visible in addition to one or more of the new satellite facilities. However, a majority of the proposed pipeline length would run parallel to an existing pipeline in the middle ground of this KOP. This existing pipeline which runs at grade above-ground through the middle ground of this KOP is not visible due to the dense shrub vegetation. Thus, it is likely that the pipeline installation areas which would be visible from KOP 3 would offer little contrast, dominance or view blockage to the existing VSOI. Therefore, for KOP 3, the *overall visual change* would be moderately low.

Visual Impact Determination

Overall visual sensitivity for KOP 3 is considered moderately low to moderate and *overall visual change* is considered moderately low. Energy Commission staff concludes that introducing the publicly visible project structures into the existing view at this KOP would not cause substantial degradation of the existing visual character of the site and its surroundings. Therefore, a less-than-significant impact to visual resources is identified for KOP 3. No mitigation is required.

KOP 4

Visual Sensitivity

KOP 4 was photographed along Elk Hills Road looking west-northwest.[58] KOP 4 is located within the EHOF, approximately 5 miles west-northwest of the proposed CO_2 Processing Facility.

Views to the north from KOP 4 are characterized by fence lines, unpaved roadways, and utility poles in the immediate foreground. Views extending from the foreground to the middle ground include an existing pipeline that passes under Elk Hills Road and extends to a white cylindrical tower. In the far middle ground exists views of the Elk Hills, which include several unpaved roadways, engineering pads, and power poles. Views of the Elk Hills continue into the background and include a few derricks and power poles up against the ridgeline. Views of the Temblor Range can be seen in the distant background.

---

[58] See **Visual Resources Figures 14a** and **14b**.

Due to the fence lines, roads (paved and unpaved), power poles, pipeline, pads, white cylindrical tanks, and other built structures, etc. some variation is apparent in the form and line of landscape elements at KOP 4. However, no particular landscape feature or landform draws the viewer's attention. Therefore, the visual quality for KOP 4 is characterized as low to moderately low.

As KOP 4 is located within the EHOF boundaries, viewers at or near KOP 4 would be motorists. Motorists using local roadways include employees of oil and gas production, gravel mining, and other businesses whose focus is on their travels and daily pursuits. Motorists on the highway are expected to have low to moderate viewer concern.

Under existing conditions, views of the project site are interrupted by man-made alterations, including: fence lines, a paved two-lane road, unpaved roads, power poles, pipeline, pads, white cylindrical tanks, and other built structures. Therefore, visibility of the project site at this location is moderate.

Viewers for KOP 4 include motorists. Traffic data compiled by Kern COG includes traffic counts for 2012 on Elk Hills Road, north of Skyline Road. Traffic counts were considered in the estimate of number of viewers for KOP 4. As of August 1, 2012, the AADT volume at this location was approximately 1200 (Kern COG 2012). The rating for number of viewers at KOP 4 is estimated to be moderately low.

Motorists on Elk Hills Road could be traveling close to highway speed or more slowly, depending on the habits of the drivers. Views of the project site from Elk Hills Road would mostly be in the periphery of views for drivers heading north-northwest, with views of the project site likely lasting from 20 to 60 seconds. For this viewer group duration of view is estimated to be moderate.

Visibility of the project site from KOP 4 is moderate, and the number of viewers is moderately low. Duration of view for motorists is moderate. Based on the ratings for visibility, number of viewers, and duration of view, *overall viewer exposure* for KOP 4 is considered moderately low to moderate.

Visual quality is characterized as low to moderately low. Viewer concern is low to moderate. Based on the ratings for visual quality, viewer concern, and overall viewer exposure, *overall visual sensitivity* is considered moderately low.

<u>Visual Change</u>

For KOP 4, the only visual change introduced into the VSOI would be the alterations required during the construction of, and before reestablishment of, vegetation near the pipeline mentioned above. The pipeline would follow the alignment of the existing pipeline under the roadway and, subsequently, proceed along a new alignment across the hillsides. Although the middle ground view would be substantially altered, an effort would be made to align the pipeline adjacent to existing alterations, such as the existing roadways. Further, from KOP 4, the far middle ground and background topography would limit most, if not virtually all, views of any proposed project elements in the northwest portion of the project site both during construction and operations. It is likely that the vegetation and pipeline which would be visible from KOP 4 would offer little contrast, dominance or view blockage to the existing VSOI. Therefore, for KOP 4, the *overall visual change* would be moderately low.

Visual Impact Determination

Overall visual sensitivity for KOP 4 is considered moderately low and *overall visual change* is considered moderately low. Energy Commission staff concludes that introducing the publicly visible project structures into the existing view at this KOP would not cause substantial degradation of the existing visual character of the site and its surroundings. Therefore, a less-than-significant impact to visual resources is identified for KOP 4. No mitigation is required.

KOP 5[59]

Visual Sensitivity

KOP 5 was photographed along Grace Avenue and Elk Hills Elementary looking southwest to the OEHI site.[60] Views to the southwest from KOP 5 are characterized by a chain-link fence in the immediate foreground. The view extending from the foreground to the middle ground consists of the grass covered topography of the Elk Hills. The distant middle ground and background views are of the higher elevations of the Elk Hills, which have been substantially altered by decades of oil production operations. Large undeveloped areas are divided by unpaved roads and steep cut-fill slopes anchor industrial buildings and various configurations of extraction machinery. The dark profiles of these man-made elements project above the horizon line in contrast to the sky beyond.

Due to the fence, unpaved roads, extraction equipment, and other built structures, etc. some variation is apparent in the form and line of landscape elements at KOP 5. However, no particular landscape feature or landform draws the viewer's attention. Therefore, the visual quality for KOP 5 is characterized as low to moderately low.

Viewers at KOP 5 include elementary school staff, students, and families of students. The play field is used intermittently during school recesses and sporting events. Recreational viewers engaged in or observing active sport activities are likely to be attentive to the on-site activity rather than the aesthetics of the environment. However, viewer concern for viewers at KOP 5 would still be considered high.

Additionally, viewers at or near KOP 5 include residents and motorists. Residents with open southwest views from Kern Street and Grace Street would likely have views of the project site (particularly the CO_2 EOR Processing Facility). Viewer concern for residents is considered high. Motorists using local roadways include local residents, employees of oil and gas production, gravel mining, and other businesses whose focus is on their travels and daily pursuits. Due to the relatively short distances of nearby streets,

---

[59] The following references made to distances/cardinal directions between the OEHI component and KOP 5, are in regards to the CO_2 EOR Processing Facility, as this would be the most prominent/visible element of the OEHI site.

[60] See **Visual Resources Figures 15a** and **15b**.

viewers are expected to have moderate viewer concern. For this combination of viewer groups, viewer concern is estimated to be moderately high.

Under existing conditions, views of the project site are only slightly obstructed by a chain-link fence. Furthermore, KOP 5 is approximately 1.5 miles from the project site. Therefore, visibility of the project site at this location is moderate to moderately high.

Viewers for KOP 5 include motorists. Traffic data compiled by Kern COG includes traffic counts for 2012 on Tupman Road, north of Taft Highway.[61] Traffic counts were considered in the estimate of number of viewers for KOP 5. As of August 1, 2012, the AADT volume at this location was approximately 690 (Kern COG 2012). The rating for number of viewers at KOP 5 is estimated to be moderately low.

Motorists on Grace Avenue would likely be traveling at residential speeds, depending on the habits of the drivers. Views of the project site from Tupman Road would mostly be in the periphery of views for drivers heading southwest, with views of the project site likely lasting from 10 to 20 seconds. For this viewer group duration of view is estimated to be moderately low.

Visibility of the project site from KOP 5 is moderate to moderately high, and the number of viewers is moderately low. Duration of view for motorists is moderately low. Based on the ratings for visibility, number of viewers, and duration of view, *overall viewer exposure* for KOP 5 is considered moderately low to moderate.

Visual quality is characterized as low to moderately low. Viewer concern is moderately high. Based on the ratings for visual quality, viewer concern, and overall viewer exposure, *overall visual sensitivity* is considered moderately low to moderate.

<u>Visual Change</u>

For KOP 5, the most prominent visual change introduced into the VSOI would be the proposed CO_2 EOR Processing Facility. Relative to the six KOPs, viewers at KOP 5 would have the clearest, least obstructed view of the Facility. The following Facility components would be visible from KOP 5, including: rooflines of the Administration/Control building and the Compressor Shelter (CRP) and the tops of the CO_2 Absorber, NGL Stabilizer, De-methanizer, and Flare Stack structures. Due to the up-slope view of the facility from KOP 5 and surrounding topography, visibility of the above mentioned components would be limited. However, due to the size and magnitude of the Facility structures, it is likely that the Facility would offer some contrast, dominance or view blockage to the existing VSOI. Therefore, for KOP 5, the *overall visual change* would be moderate.

<u>Visual Impact Determination</u>

Overall visual sensitivity for KOP 5 is considered moderately low to moderate and *overall visual change* is considered moderate. Energy Commission staff concludes that introducing the publicly visible project structures into the existing view at this KOP would not cause substantial degradation of the existing visual character of the site and its

[61] The closest AADT volume count to Grace Avenue is Tupman Road, north of Taft Highway.

surroundings. Therefore, a less-than-significant impact to visual resources is identified for KOP 5. No mitigation is required.

KOP 6[62]

Visual Sensitivity

KOP 6 was photographed just south of the U.S. Post Office looking southwest to the OEHI site.[63] Views to the southwest from KOP 6 are characterized by a chain-link fence in the immediate foreground. The view extending from the foreground to the middle ground consists of relatively flat visually intact grasslands with low to no shrub vegetation. The far middle ground and background are very similar to KOP 6; however, some middle ground topography partially screens these views.

Due to the fence, unpaved roads, extraction equipment, and other built structures, etc. some variation is apparent in the form and line of landscape elements at KOP 6. However, no particular landscape feature or landform draws the viewer's attention. Therefore, the visual quality for KOP 6 is characterized as low to moderately low.

Viewers at or near KOP 6 include residents and motorists. Residents with open southwest views from near the U.S. Post Office would likely have views of the project site. Viewer concern for residents is considered high. Motorists using local roadways include local residents, employees of oil and gas production, gravel mining, and other businesses whose focus is on their travels and daily pursuits. Due to the relatively short distances of nearby streets, viewers are expected to have low to moderate viewer concern. For this combination of viewer groups, viewer concern is estimated to be moderate to moderately high.

Under existing conditions, views of the project site are only slightly obstructed by a chain-link fence. Further, some middle ground topography partially screens these views. Therefore, visibility of the project site at this location is moderately low.

Viewers for KOP 6 include motorists. Traffic data compiled by Kern COG does not include traffic counts for 2012 on Emmons Boulevard. Traffic data compiled by Kern COG includes traffic counts for 2012 on Tupman Road, north of Taft Highway.[64] Traffic counts were considered in the estimate of number of viewers for KOP 6. As of August 1, 2012, the AADT volume at this location was approximately 690 (Kern COG 2012). The rating for number of viewers at KOP 6 is estimated to be moderately low.

Motorists near the U.S. Post Office would likely be traveling at residential speeds, depending on the habits of the drivers. Views of the project site from the U.S. Post Office would mostly be in the periphery of views for drivers heading southwest, with views of the project site likely lasting from 10 to 20 seconds. For this viewer group duration of view is estimated to be moderately low.

---

[62] The following references made to distances/cardinal directions between the OEHI component and KOP 6, are in regards to the CO_2 EOR Processing Facility, as this would be the most prominent/visible element of the OEHI site.

[63] See **Visual Resources Figures 16a** and **16b**.

[64] The closest AADT volume count to the U.S. Post Office is Tupman Road, north of Taft Highway.

Visibility of the project site from KOP 6 is moderately low, and the number of viewers is moderately low. Duration of view for motorists is moderately low. Based on the ratings for visibility, number of viewers, and duration of view, overall viewer exposure for KOP 6 is considered moderately low to moderate.

Visual quality is characterized as low to moderately low. Viewer concern is moderate to moderately high. Based on the ratings for visual quality, viewer concern, and overall viewer exposure, overall visual sensitivity is considered moderately low to moderate.

Visual Change

For KOP 6, the most prominent visual change introduced into the VSOI would be construction equipment involved in injection and production well installations in the distant hills. However, equipment used for these activities are already part of current daily operations and would not substantially alter the existing VSOI. It is likely that the construction equipment that might be visible from KOP 6 would offer little contrast, dominance or view blockage to the existing VSOI. Therefore, for KOP 6, the *overall visual change* would be moderately low.

Visual Impact Determination

Overall visual sensitivity for KOP 6 is considered moderately low and *overall visual change* is considered moderately low. Energy Commission staff concludes that introducing the publicly visible project structures into the existing view at KOP 6 would not cause substantial degradation of the existing visual character of the site and its surroundings. Therefore, a less-than-significant impact to visual resources is identified for KOP 6. No mitigation is required.

VISUAL CHARACTER AND QUALITY – CONCLUSION (OEHI)

Energy Commission staff evaluated the proposed OEHI component's effects on visual resources at the six selected OEHI KOPs. The visual impact determinations are focused on the overall visual sensitivity for each KOP and whether the OEHI component would cause substantial degradation of the existing visual character of the site and its surroundings.

Staff determined that the impacts at KOP 1, KOP 2, KOP 3, KOP 4, KOP 5, and KOP 6 did not meet or exceed the criterion set forth in the discussion above. Therefore, the project would not cause substantial degradation of the existing visual character of the site and its surroundings at these six KOPs.

New Source of Substantial Light or Glare

Implementation of both the proposed HECA and its OEHI component would introduce new sources of light and glare into the VSOI. Lighting of new structures and buildings would be required, and construction of the projects would introduce new reflective surfaces in the project area. Exterior lighting would serve the function of promoting worker and aviation safety[65] and security at the HECA plant site and the OEHI CO_2 Processing Facility. Light and glare from the HECA plant site and facility could adversely affect the daytime and nighttime views of nearby residents and other viewer groups with foreground and middleground views of the project site. Energy Commission staff considers this to be a significant impact to visual resources.

However, the combination of broad geographic distribution, topographic variations of the existing landscape, and the fact that the nighttime character of the areas where this new lighting would occur is already developed with significant lighting, would likely result in minimal noticeable impacts for sensitive viewers. Further, **VIS-4** is proposed requiring preparation and implementation of a lighting management plan to minimize potential effects relating to light trespass beyond the project site. **VIS-6** is proposed requiring all lights used to illuminate the interior parking area to be directed away from any adjacent properties and streets. Therefore, Energy Commission staff concludes that, with the above conditions of certifications, combined with applicant's proposed mitigation measures,[66] impacts relating to light would be reduced to less-than-significant levels. No substantial sources of day or nighttime glare are expected to be created by the elements of the proposed project. However, because of the potential for the proposed HECA transmission line pole structures to cause glint and glare effects, **VIS-1** includes a recommendation that a non-reflective (e.g., matte or dull gray), bare galvanized finish be used for the tapered steel poles supporting the transmission lines. Further, conductors and insulators are required to be non-specular and non-reflective. **VIS-3** is proposed requiring all publicly visible signage to be colored, treated, and finished to prevent excessive glare. These measures ensure that distracting or hazardous reflections from the structures would not occur and to minimize the contrast of the structures with their backdrops. Therefore, Energy Commission staff concludes that impacts relating to glare would be reduced to less-than-significant levels. Construction activities would cover portions of both project construction sites depending on the construction activity, and any necessary work at night would require lighting to cover limited portions of the whole project site. Energy Commission staff considers lighting of construction areas to be a potentially significant impact to visual resources. Project construction for the HECA project is expected to begin in the third quarter of 2013 and continue for 42 months. Commissioning and Start-Up is expected to continue for an additional 7 months (total 49 months). The schedule has been estimated on a single-shift, 5-day basis, beginning at 6 a.m., Monday through Friday. Additional hours and/or a second shift may be necessary to make up weather delays, schedule deficiencies or to complete critical construction activities. During start-up and testing, some activities may continue up to 24 hours per day, 7 days per week (Hydrogen Energy International 2012). Condition of Certification **VIS-5** requires operation of lighting during project construction to minimize potential effects relating to light trespass beyond the construction areas. Therefore, with implementation of **VIS-5**, Energy Commission staff concludes that impacts relating to light and glare during construction activities would be reduced to less-than-significant levels.

---

[65] See FAA Advisory Circular 70/7460-1 K Change 2, Obstruction Marking and Lighting, paint/red lights - Chapters 3 (Marked), 4, 5 (Red), & 12 (See "HECA Applications for Notice of Proposed Construction or Alteration (Off Airport) (TN# 66029)").
[66] See **Mitigation Measure AES-1** and **-3**.

The proposed HECA project is being designed to avoid flaring during steady state operations and to minimize flaring during startup and shut-down operations (Hydrogen Energy International 2012). The occasional operation of flares at night could be visible to viewer groups with foreground and middleground views of the project site. Flaring at the project site would be infrequent and is not expected to increase the magnitude of the overall impact relating to lighting effects. In relation to the OEHI component, the CO_2 EOR Processing Facility would be equipped with two emergency flares that have the potential to emit light during nighttime operations. There are existing emergency flares currently being operated within the EHOF. The addition of two emergency flares at the facility is not expected to substantially alter the amount of light being emitted from the EHOF. Therefore, Energy Commission staff considers flaring to be a less-than-significant impact of the project. No mitigation is required.

CUMULATIVE IMPACTS AND MITIGATION

Section 15130 of the State CEQA Guidelines requires a discussion of cumulative impacts of a project when the project's incremental effect is cumulatively considerable. According to State CEQA Guidelines Section 15065, "[c]umulatively considerable means that the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects." Sections 15130 and 15355 of the State CEQA Guidelines both stress cumulative impacts in the context of *closely related* projects and from projects *causing related impacts*. The goal of such an analysis is twofold: first, to determine whether the overall long-term impacts of all such projects would be cumulatively significant; and second, to determine whether the HECA power plant project itself would cause a "cumulatively considerable" (and thus significant) incremental contribution to any such cumulatively significant impacts.

Based on Section 15130(b) of the State CEQA Guidelines, this analysis of cumulative impacts relies on the use of a list of projects producing related or cumulative impacts. Because of the rural nature of the project area and the lack of developed uses, the contributions of past and present projects to visual resources conditions are adequately captured in the description of the existing setting and need not be listed here. This analysis of cumulative effects on visual resources addresses the potential incremental impacts of the proposed HECA and its OEHI component in combination with similar effects of other probable future projects. For visual resources, the geographic scope of the area that could be affected by the cumulative effect is considered to be the project VSOI where light and glare generated by multiple projects might interact on a cumulative basis.

Energy Commission staff has prepared a list of probable future projects within the VSOI (a six-mile radius of the HECA project site and its OEHI component).[67] Within the VSOI, changes to visual resources from the other projects could combine with visual resources impacts of the HECA project to cause a cumulatively considerable effect. Staff finds no probable future projects within the VSOI that could cause significant adverse impacts to visual resources. Therefore, although a significant visual impact has been identified at

[67] See **Visual Resources Figure 18**.

KOP 1 (HECA), there are no other probable future projects within the VSOI that, in conjunction with the significant impact at KOP 1, would cause a cumulatively considerable impact to visual resources.

COMPLIANCE WITH LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

Visual Resources Table 7 addresses consistency of the proposed HECA project with LORS relating to protection of visual resources. The proposed HECA project is being planned and would be implemented to comply with the Kern County General Plan and Title 19, Zoning, of the Kern County Zoning Ordinance.

In July of 2012, the Kern County Planning Department amended its zoning ordinance to include a Dark Skies Ordinance and revisions to Chapter 19.86, Landscaping. The HECA project's consistency with the proposed Dark Skies Ordinance and applicable portions of Chapter 19.86, are addressed in **Table 7**. Preparation and submittal of a lighting management plan as described below under Condition of Certification **VIS-4** would ensure compliance with Kern County requirements for lighting of the project site. In **Table 7**, applicable chapters and sections of the Kern County Zoning Ordinance are briefly described under the column, "Policy and Strategy Description."

The Energy Commission has the exclusive authority to license power plants in the state with a generating capacity of 50 megawatts or greater. Therefore, all required local approvals and entitlements for the HECA project would be covered under the Energy Commission's in lieu permitting authority.

Visual Resources Table 7
Project Compliance with Applicable Visual Resources LORS

Source	Policy and Strategy Description	Consistency Determination	Basis for Consistency
Kern County General Plan – Land Use, Open Space, and Conservation Element			
1.8 Industrial (Kern County Planning Department 2009)	Policy 6. Encourage upgrading the visual character of existing industrial areas through the use of landscape elements, screens, or buffers.	Yes, as conditioned	Consistent, with implementation of Conditions of Certification **VIS-1**, **VIS-2**, **VIS-3**, and **VIS-6.**
	Policy 7. Require that industrial uses provide design features such as screen walls, landscape elements, increased height and/or setbacks, and lighting restrictions	No	Conditions of Certification **VIS-1**, **VIS-2**, **VIS-3**, **VIS-4** and **VIS-6** will mitigate some of the project's effects on the visual character and quality in the area where the project would be sited. However, the visual impact of the project at KOP 1 is, at present, significant and unavoidable.

Visual Resources Table 7
Project Compliance with Applicable Visual Resources LORS

	between the boundaries of adjacent residential land use designations so as to reduce impacts to residential uses relating to light, noise, sound, and vibration.		
1.10.7 General Provisions, Light and Glare (Kern County Planning Department 2009)	Light and Glare Policy 47 and 48. Ensure that light and glare from discretionary new development projects are minimized in rural as well as urban areas. Encourage the use of low-glare lighting to minimize nighttime glare effects on neighboring properties.	Yes, as conditioned	Consistent, with implementation of Conditions of Certification **VIS-1**, **VIS-3**, **VIS-4**, **VIS-5**, and **VIS-6**.
Kern County Zoning Ordinance – Chapter 19.12 Exclusive Agriculture (A) District			
19.12.110 Signs	Describes the types of signs that are permitted in the A District, in accordance with the requirements of Chapter 19.84, Signs.	Yes, as conditioned	Consistent, with implementation of Condition of Certification **VIS-3**.

Visual Resources Table 7
Project Compliance with Applicable Visual Resources LORS

Source	Policy and Strategy Description	Consistency Determination	Basis for Consistency
Kern County Zoning Ordinance – Chapter 19.81 Dark Skies Ordinance			
19.81.040 General Requirements	Describes general standards for all outdoor lighting fixtures subject to the dark skies ordinance.	Yes, as conditioned	Consistent, with implementation of Condition of Certification **VIS-4**.
Kern County Zoning Ordinance – Chapter 19.82 Off-Street Parking			
19.82.090 Parking Area Design and Development Standards	Addresses standards for landscaping of parking lots, glare, and lighting.	Yes, as conditioned	Consistent, with implementation of Conditions of Certification **VIS-6**.
Kern County Zoning Ordinance – Chapter 19.84 Signs			
19.84.020, 19.84.030, and 19.84.040 Design and Development Standards – Monument Signs, Pole Signs, and Signs Attached to Buildings	These three sections of Chapter 19.84 address standards for freestanding monument and pole signs and signs attached to a building or wall.	Yes, as conditioned	Consistent, with implementation of Condition of Certification **VIS-3**.
Kern County Zoning Ordinance – Chapter 19.86 Landscaping			
19.86.020 Landscaping Standards – Generally	Describes minimum plant and tree sizes for landscaping.	Yes, as conditioned	Consistent with implementation of Condition of Certification **VIS-2**.

Visual Resources Table 7
Project Compliance with Applicable Visual Resources LORS

Source	Policy and Strategy Description	Consistency Determination	Basis for Consistency
19.86.060 Landscaping Standards – Industrial Uses	Describes minimum standards for landscaping for industrial uses.	Yes, as conditioned	Consistent with implementation of Condition of Certification **VIS-2**. The project site has no property lines abutting any residentially zoned lots.
19.86.070 Landscape and Irrigation Plan – Required	Identifies classes of projects that are subject to preparation of landscape and irrigation plans.	Yes, as conditioned	Consistent with implementation of Condition of Certification **VIS-2**.
19.86.080 Landscape and Irrigation Plan – Review and Approval	Addresses submittal of conceptual landscape and irrigation plans for projects requiring a discretionary or ministerial approval.	Yes, as conditioned	Consistent with implementation of Condition of Certification **VIS-2**.
19.86.090 Landscape Installation – Timing	Requires installation of the landscape and irrigation systems or posting of an acceptable financial assurance prior to issuance of an occupancy permit.	Yes, as conditioned	Consistent with implementation of Condition of Certification **VIS-2**.

Note: The complete text of Kern County's general plan and zoning ordinance, are available at http://www.co.kern.ca.us/planning/pdfs/kcgp/KCGP.pdf and http://www.co.kern.ca.us/planning/pdfs/KCZOJul12.pdf, respectively.

NOTEWORTHY PUBLIC BENEFITS

Neither the applicant nor staff has identified any visual benefits associated with the proposed HECA project. The proposed project would introduce several landscaping, surface treatment, lighting, and signage mitigation measures (Conditions of Certification **VIS-1** to **VIS-6**). However, all are necessary to mitigate potential visual impacts caused by the project, and, therefore, are not considered to be public benefits.

DEPARTMENT OF ENERGY'S FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, the Department of Energy (DOE) would not provide financial assistance to the applicant for the HECA project. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

RESPONSE TO PUBLIC AND AGENCY COMMENTS

As of this PSA/DEIS, no agency or public comments have been received regarding visual resources.

STAFF'S CONCLUSIONS

Impacts to visual resources for the proposed HECA project and its OEHI component were assessed based on the magnitude of the anticipated changes to the visual environment and the estimated effects of those changes on viewer groups with foreground and middleground views of the project site. The visual resources analysis was conducted in accordance with CEQA (Pub. Resources Code § 21000 et seq.) and the State CEQA Guidelines (14 Cal. Code Regs. § 15000 et seq.).

Energy Commission staff concludes that the HECA project would not comply with all applicable visual resource standards under CEQA or LORS, as a significant impact to visual resources is identified at KOP 1 (HECA). Conditions of Certification **VIS-1**, **VIS-2**, **VIS-3**, **VIS-4**, and **VIS-6** address surface treatments for structures and buildings at the power plant site, landscaping, requirements for project signage, lighting management plan, and landscape and irrigation requirements for the interior parking area, respectively. Implementation of these above conditions would not reduce the impact at KOP 1 to a less-than-significant level. Staff concludes that additional project information is necessary to adequately assess whether implementation of all feasible mitigation would reduce the impact at KOP 1 to a less-than-significant level.

The visual impact discussion for KOP 1 (HECA) describes applicant's intention to prepare and submit an off-site conceptual landscape plan to mitigate the significant impact at KOP 1. If the off-site conceptual landscape plan was reviewed and, subsequently approved, a new condition of certification would be added to the FSA/FEIS for the project requiring implementation of the off-site landscape plan. Further, the visual resources analysis in the FSA/FEIS would include an assessment of the effectiveness of the proposed conditions of certification, including the off-site landscape plan, and whether the impact would be reduced to a less-than-significant level.

Energy Commission staff concludes that introducing the publicly visible structures into the existing views at KOP 2, KOP 3, KOP 4, KOP 6 (and all six of the KOPs for the project's OEHI component) would not cause substantial degradation of the visual character of the site and its surroundings. Therefore, the impacts to visual resources from these KOPs are less-than-significant.

Staff evaluated the potential effects of publicly visible water vapor plumes on visual resources. Based on results of the visible plume modeling analysis prepared by staff for the HECA project, plumes from the HRSG stack are predicted to occur less than 20 percent of the time during "seasonal daylight clear" hours. Additionally, plumes from the ASU cooling tower, the 13-cell power block cooling tower, and coal dryer stack are predicted to occur more than 20 percent of the time during seasonal daylight clear hours. However, further analysis resulted in the conclusion by staff that the plumes from the ASU cooling tower, the 13-cell power block cooling tower, and coal dryer stack would be visually subordinate compared to the other built structures that would be installed at the project site, and that introduction of visible vapor plumes in the environment is considered a less-than-significant impact of the project.

Light and glare effects from the plant site (during its construction and operational phases) could adversely affect the daytime and nighttime views for nearby residents and other viewer groups. With implementation of Conditions of Certification **VIS-1**, **VIS-3**, **VIS-4**, **VIS-5**, and **VIS-6**, potential nighttime light and daytime glare effects would be reduced to a less-than-significant level.

The following proposed conditions of certification for the HECA project is intended to mitigate impacts of the project on visual resources, in accordance with the State CEQA Guidelines. Mitigation is defined as:

(a) Avoiding the impact altogether by not taking a certain action or parts of an action.

(b) Minimizing impacts by limiting the degree or magnitude of the action and its implementation.

(c) Rectifying the impact by repairing, rehabilitating, or restoring the impacted environment.

(d) Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action.

(e) Compensating for the impact by replacing or providing substitute resources or environments (14 Cal. Code Regs. § 15370).

To meet these standards for mitigation of impacts, Energy Commission staff recommends implementing Conditions of Certification **VIS-1** through **VIS-6**.

PROPOSED CONDITIONS OF CERTIFICATION

VIS-1 **Surface Treatment of Project Structures and Buildings**

The project owner shall prepare and implement a surface treatment plan for the project. The project owner shall color, treat, and finish the surfaces of all project structures, buildings, and fences visible to the public to ensure that visual intrusion and contrast with the landscape is minimized to the extent feasible, and glare from treated surfaces is minimized.

The surface treatment plan shall include, at a minimum, the following plan elements:

a.) Description of the overall rationale for the proposed surface treatments, including selection of the proposed colors and finishes;

b.) Proposed opportunities and options for enhancing design quality and visual interest of project structures, consistent with project objectives;

c.) Inventory of major project structures and buildings (e.g., buildings, tanks, and pipes; transmission line towers and/or poles; and fencing) specifying the proposed colors and finishes. Colors must be identified by vendor, name, and number, or according to a universal designation system;

d.) One set of color brochures or color chips showing each proposed color and finish;

e.) One set of 11-inch by 17-inch color photographic simulations at life size scale of the treatment proposed for use on project structures at the main plant site, including structures treated during manufacture, from KOP 1;

f.) Schedule for completing the surface treatments; and

g.) Procedure to ensure proper treatment maintenance for the life of the project.

The transmission line conductors and insulators shall be non-specular and non-reflective. The tapered steel poles supporting the transmission lines shall be the type that are galvanized using the hot dip zinc or equivalent process to produce a matte gray surface finish. No galvanizing process shall be used that produces a reflective metallic finish.

Verification: At least 90 calendar days prior to submitting specifications for colors, finishes, and other surface treatments to manufacturers or vendors of project structures, and/or ordering prefabricated project structures, the project owner shall submit the surface treatment plan to the Compliance Project Manager (CPM) for review and comment. If the CPM determines that the plan requires revision, the project owner shall provide a plan with the specified revision(s) for review and approval by the CPM. No work to implement the project's surface treatment plan shall begin until final plan approval is received from the CPM.

Prior to the start of commercial operation of the project, the project owner shall notify the CPM that surface treatments of all publicly visible structures and buildings identified in the surface treatment plan have been completed and that the facilities are ready for inspection. Prior to the scheduled inspection, the project owner shall prepare and submit one set of electronic color photographs of the project site from the viewpoint for KOP 1. The project owner shall obtain written confirmation from the CPM that the project complies with the surface treatment plan. The project owner shall provide a status report regarding surface treatment maintenance in the Annual Compliance Report. At a minimum, the report shall specify:

- condition of the surfaces of all structures at the main plant site for the reporting year,
- major maintenance activities that occurred during the reporting year, and
- a schedule for major maintenance activities for the next year.

VIS-2 **Landscaping**

The project owner shall prepare and implement a landscape plan consistent with the zoning ordinances of Kern County, specifically section 19.86 et al. The project owner and/or the construction manager for landscaping shall review section19.86 et al to ensure compliance with all applicable sections of the ordinance. At a minimum, the landscape plan shall satisfy these criteria:

a.) Minimum plant and tree sizes for landscaping are as follows: trees (15 gallons), shrubs (5 gallons), and small shrubs and groundcovers (1 gallon).

b.) A minimum of five percent of the developed area shall be landscaped. A maximum of one-half of the five percent may be turf or an alternative ground cover.

c.) Within each planter or landscaped area, an irrigation system and landscaping shall be provided and maintained.

d.) Landscaping materials and trees installed in planters or landscaped areas shall be selected based upon their adaptability to the climatic, geologic, and topographical conditions of the site.

e.) Landscaping and irrigation for the project shall comply with the County's Water Efficient Landscape requirements.

f.) Maintenance procedures shall be specified, including any needed irrigation and a plan for routine annual or semi-annual debris removal for the life of the project.

g.) A procedure for monitoring and replacing unsuccessful plantings for the life of the project shall be described.

h.) After construction, areas where vegetation has been removed will be restored consistent with the surrounding area.

<u>**Verification**</u>: Prior to commercial operation and at least 45 days prior to installing the landscaping plan, the project owner shall submit the landscaping plan to the CPM for approval and simultaneously to the Kern County Planning Director (Director) for comment. The project owner shall provide a copy of the Planning Director's comments to the CPM prior to the installation of the landscaping.

The project owner shall allow the Director 30 days to provide comment on the submitted surface treatment plan. The project owner shall provide a copy of the Director's comments to the CPM.

If the CPM determines that the plan requires revision, the project owner shall provide to the CPM and the Director a plan with the specified revision(s) for review and approval by the CPM before the plan is implemented.

Landscape elements and irrigation shall be installed prior to the start of commercial operation of the project. The project owner shall simultaneously notify the CPM and the Director that the landscaping is ready for inspection within seven days after completing installation of the landscaping.

The project owner shall report landscape maintenance activities, including replacement of dead vegetation, for the previous year of operation in the Annual Compliance Report for the project.

VIS-3 **Publicly Visible Project Signage**

The project owner shall prepare and implement a signage plan for the project. Any publicly visible project-related signage shall be colored, treated, and finished to minimize visual contrast and intrusion and prevent excessive glare. The project owner shall ensure that the signage plan complies with Chapter 19.84, Signs, of the Kern County Zoning Ordinance. The design of any signs required by safety regulations shall conform to the criteria established by the zoning ordinance. The project owner and/or the construction manager shall review Chapter 19.84 to ensure compliance with all applicable sections of the ordinance.

The signage plan shall be submitted to the Director and the CPM for simultaneous review and comment. If the Director submits comments in the signage plan, a copy of those comments shall be provided to the CPM. The project owner shall not implement the signage plan until written approval of the final plan is received from the CPM.

Verification: At least 30 calendar days before ordering signage for the project, the project owner shall submit the signage plan to the CPM and the Director for simultaneous review and comment. The project owner shall provide to the CPM a copy of the transmittal letter submitted to the Kern County Planning Department requesting the Director's review of the signage plan.

If the CPM determines that the plan requires revision, the project owner shall provide a plan with the specified revision(s) for review and approval by the CPM and provide a copy of the revised plan to the Director. No work to implement the signage plan shall begin until final plan approval is received from the CPM.

Installation of signs must be completed by the start of commercial operation of the project. Within 14 calendar days of installing project signage, the project owner shall simultaneously notify the CPM and the Director that publicly visible signs have been installed and provide the CPM and the Director with electronic color photographs of the installed signage. The project owner shall obtain written confirmation from the CPM that the sign installations comply with the signage plan for the project.

The project owner shall include information on any required repairs or replacement of project signage in the Annual Compliance Report for the project.

VIS-4 Permanent Exterior Lighting

The project owner shall prepare and implement a lighting management plan for the project. Consistent with safety and security considerations, commercial availability of lighting products, and project objectives, the project owner shall design, install, and maintain all permanent exterior lighting such that:

a.) light fixtures do not cause obtrusive spill light (i.e., light trespass) beyond the project site;

b.) lighting does not cause excessive reflected glare;

c.) direct lighting of the project does not illuminate the nighttime sky;

d.) illumination of the project and its immediate vicinity is minimized;

e.) lights in high illumination areas not occupied on a continuous basis (such as maintenance platforms) include switches, timer switches, or motion detectors so that the lights are operated only when the area is occupied;

f.) lighting fixtures are kept in good working order and continuously maintained according to the original design intent of the lighting system;

g.) lighting is consistent with Kern County's Dark Sky Ordinance.

h.) lights used to illuminate parking area shall be directed away from any adjacent properties and streets;

i.) High-pressure sodium vapor fixtures will be used which will reduce visual contrast with the night sky; and

j.) Stacks and other tall project elements will be lit in accordance with FAA guidelines.

Topics to address in the lighting management plan shall include, at a minimum, fixture and control schedules, fixture and control cut sheets and specifications, a photometric plan showing vertical and horizontal footcandles at all property lines to a height of 20 feet, and the proposed time clock schedule for lighting.

The lighting management plan shall also describe the process to prepare and submit nuisance complaints relating to lighting at the project sites. The report of complaint shall include a proposal to resolve the complaint and an implementation schedule. The project owner shall notify the CPM when any necessary actions to resolve the complaint have been completed.

The lighting management plan shall be submitted to the Director and the CPM for simultaneous review and comment. If the Director submits comments on the lighting management plan, a copy of those comments shall be provided to the CPM. The project owner shall not purchase or order any permanent exterior lighting until written approval of the final plan is received from the CPM.

Verification: At least 90 calendar days before ordering any permanent exterior lighting, the project owner shall contact the CPM to discuss the lighting management plan, including the standards and specifications described above. At least 60 calendar days prior to ordering any permanent exterior lighting, the project owner shall submit a lighting management plan to the CPM and the Director for simultaneous review and comment. The project owner shall provide to the CPM a copy of the transmittal letter submitted to the Kern County Planning Department requesting the Director's review of the lighting management plan.

If the CPM determines that the plan requires revision, the project owner shall provide a plan with the specified revision(s) for review and approval by the CPM and provide a copy of the revised plan to the Director. No work to implement the plan (e.g., purchasing of fixtures) shall begin until final plan approval is received from the CPM.

Prior to the start of commercial operation of the project, the project owner shall simultaneously notify the CPM and the Director that installation of permanent exterior lighting for the project has been completed and that the system is ready for inspection. If the CPM notifies the project owner that modifications to the lighting system are required, within 30 days of receiving that notification, the project owner shall implement all specified changes and notify the CPM that the modified lighting system is ready for inspection.

Within 48 hours of receiving a project-related lighting complaint, the project owner shall complete a lighting complaint resolution form for submittal to the CPM. The form shall include a proposal to resolve the complaint. The project owner shall notify the CPM within 48 hours of completing implementation of the proposal. A copy of the complaint resolution form report shall be submitted to the CPM within 30 calendar days of complaint resolution. The project owner shall report any lighting complaints and documentation of resolution for the previous year of operation in the Annual Compliance Report for the project. All records of lighting complaints shall be kept in the on-site compliance file for the project.

VIS-5 Construction Activity Lighting

Consistent with safety and security considerations and project objectives, the project owner shall ensure that lighting of construction areas minimizes potential night lighting impacts by implementing the following measures:

a.) All fixed position lighting shall be hooded and shielded to direct light downward and toward the area to be illuminated to prevent illumination of the night sky and minimize light trespass.

b.) Wherever and whenever feasible, lighting shall be kept off when not in use.

Any complaints about construction lighting shall be conveyed to the project owner and the CPM. The project owner shall complete a lighting complaint resolution form for submittal to the CPM. The complaint resolution form shall be used to record each lighting complaint and document resolution of the complaint. The project owner shall provide a copy of each completed complaint form to the CPM.

Verification: Within 7 calendar days after the first use of construction lighting, the project owner shall notify the CPM that the lighting is ready for inspection. If the CPM determines that modifications to the lighting are needed, within 14 days of receiving that notification, the project owner shall correct the lighting and notify the CPM that modifications have been completed.

Within 48 hours of receiving a lighting complaint, the project owner shall provide to the CPM:

- a report of the complaint,
- a proposal to resolve the complaint, and
- a schedule for implementing the proposal.

The project owner shall notify the CPM within 48 hours of implementing the proposal. The project owner shall provide a copy of the completed complaint resolution form to the CPM in the Monthly Compliance Report for the following month.

VIS-6 Landscaped Interior Parking Area

The project owner shall prepare and implement a landscape plan for the interior parking area consistent with the zoning ordinances of Kern County, specifically section 19.82.090. The project owner and/or the construction manager for landscaping shall review section 19.82.090 to ensure compliance with all applicable sections of the ordinance. At a minimum, the landscape plan shall satisfy these criteria:

a.) For all parking lots containing ten (10) or more spaces, at least five percent of the total interior area devoted to parking shall be landscaped.

b.) Trees shall be planted and maintained throughout the parking area at a minimum ratio of one tree per six parking spaces placed at a maximum of 65-foot intervals. The minimum tree size shall be a 15-gallon container.

c.) Unless otherwise permitted under a discretionary permit, minimum plant and tree sizes for landscaping are as follows: trees (15 gallon), shrubs (5 gallon), and small shrubs and groundcovers (1 gallon).

Within each planter or landscaped area, an irrigation system and live landscaping shall be provided and maintained.

d.) If the parking facility includes diagonal or perpendicular parking spaces that abut a public street or road, an ornamental fence, wall, evergreen landscaping or berm, or any combination of the above, of not more than 4 feet in total height shall be erected between the parking facility and the street or road to eliminate headlight glare.

e.) Lights used to illuminate parking area shall be directed away from any adjacent properties and streets.

f.) Species of trees shall be selected to ensure that tree canopies of mature trees shade a minimum of 40 percent of the total parking lot area. Selected tree species shall be native to the region, non-invasive, and drought tolerant.

Verification: The landscape and irrigation plan for the interior parking area shall be submitted by the HECA project owner to the Director and the CPM for simultaneous review and comment. If the Director submits comments on the landscape plan for the parking area, the project owner shall provide a copy of those comments to the CPM. The project owner shall not implement the plan until written approval of the final plan is received from the CPM. Modifications to the landscape plan for the interior parking area are prohibited without approval from the CPM. At least 90 calendar days before beginning installation of irrigation and landscape elements for the parking area, the project owner shall submit the plan to the CPM and the Director for simultaneous review and comment. The project owner shall provide to the CPM a copy of the transmittal letter submitted to the Kern County Planning Department requesting the Director's review of the parking area landscape plan.

If the CPM determines that the plan requires revision, the project owner shall provide a plan with the specified revision(s) for review and approval by the CPM. A copy of the revised plan shall be provided to the Director.

Landscape elements and irrigation shall be installed prior to the start of commercial operation of the project. Within 14 calendar days of completing the landscape work for the interior parking area, the project owner shall simultaneously notify the CPM and the Director that installation of landscape elements and irrigation has been completed and that the system is ready for inspection. Required modifications to the plantings and installed irrigation system shall be implemented within 30 calendar days of the inspection. The project owner shall obtain written confirmation from the CPM that the project complies with the landscape plan for the parking area.

APPENDIX VR-1

ENERGY COMMISSION VISUAL RESOURCE ANALYSIS EVALUATION CRITERIA

Energy Commission staff conducts a visual resource analysis according to Appendix G, “Environmental Checklist Form—Aesthetics,” California Environmental Quality Act (CEQA). The CEQA analysis requires that commission staff make a determination of impact ranging from “Adverse and Significant” to “Not Significant.”

Staff’s analysis is based on Key Observation Points or KOPs. KOPs are photographs of locations within the project area that are highly visible to the public—for example, travel routes; recreational and residential areas; and bodies of water as well as other scenic and historic resources.

Those photographs are taken to indicate existing conditions without the project and then modified to include a simulation of the project. Consequently, staff has a visual representation of the viewshed before and after a project is introduced and makes its analysis accordingly. Information about that analytical process follows.

Visual Resource Analysis Without Project

When analyzing KOPs of existing conditions without the project, staff considers the following conditions: visual quality, viewer concern, visibility, number of viewers, duration of view. Those conditions are then factored into an overall rating of viewer exposure and viewer sensitivity. Information about each condition and rating follows.

VISUAL QUALITY

An expression of the visual impression or appeal of a given landscape and the associated public value attributed to the resource. Visual quality is rated from *high* to *low*. A high rating is generally reserved for landscapes viewers might describe as picture-perfect.

Landscapes rated high generally are memorable because of the way the components combine in a visual pattern. In addition, those landscapes are free from encroaching elements, thus retaining their visual integrity. Finally, landscapes with high visual quality are visually coherent and harmonious when each element is considered as part of the whole. On the contrary, landscapes rated *low* are often dominated by visually discordant human alterations.

VIEWER CONCERN

Viewer concern represents the reaction of a viewer to visible changes in the viewshed, the area of land visible from a fixed vantage point. For example, viewers have a high expectation for views formally designated as a scenic area or travel corridor as well as for recreational and residential areas. Viewers generally expect that those views would be preserved. Travelers on highways and roads, including those in agricultural areas, are generally considered to have moderate viewer concerns and expectations. However, viewers tend to have low-to-moderate viewer concern when viewing commercial buildings. And industrial uses typically have the lowest viewer concern. Regardless, the level of concern could be lower if the existing landscape contains discordant elements. In addition, some areas of lower visual quality and degraded visual character may contain particular views of substantially higher visual quality or interest to the public.

VISIBILITY

Visibility is a measure of how well an object can be seen. Visibility depends on the angle or direction of views; extent of visual screening; and topographical relationships between the object and existing homes, streets, or parks. In that sense, visibility is determined by considering any and all obstructions that may be in the sightline—trees and other vegetation; buildings; transmission poles or towers; general air quality conditions such as haze; and general weather conditions such as fog.

NUMBER OF VIEWERS

Number of viewers is a measure of the number of viewers per day who would have a view of the proposed project. *Number of viewers* is organized into the following categories: residential according to the number of residences; motorist according to the number of vehicles; and recreationists.

DURATION OF VIEW

Duration of view is the amount of time to view the site. For example, a high or extended view of a project site is one reached across a distance in two minutes or longer. In contrast, a low or brief duration of view is reached in a short amount of time—generally less than ten seconds.

VIEWER EXPOSURE

Viewer exposure is a function of three elements previously listed, *visibility*, *number of viewers*, and *duration of view*. Viewer exposure can range from a *low* to *high*. A partially obscured and brief background view for a few motorists represents a low value; and unobstructed foreground view from a large number of residences represents a high value.

VISUAL SENSITIVITY

Visual sensitivity is comprised of three elements previous listed, *visual quality*, *viewer concern*, and *viewer exposure*. Viewer sensitivity tends to be higher for homeowners or people driving for pleasure or engaged in recreational activities and lower for people driving to and from work or as part of their work.

Visual Resource Analysis with Project

Visual resource analyses with photographic simulations of the project involve the elements of contrast, dominance, view disruption, and visual change. Information about each element follows.

CONTRAST

Contrast concerns the degree to which a project's visual characteristics or elements — form, line, color, and texture — differ from the same visual elements in the existing landscape. The degree of contrast can range from *low* to *high*. A landscape with forms, lines, colors, and textures similar to those of a proposed energy facility is more visually absorbent; that is, more capable of accepting those characteristics than a landscape in which those elements are absent. Generally, visual absorption is inversely proportional to visual contrast.

DOMINANCE

Dominance is a measure of (a) the proportion of the total field of view occupied by the field; (b) a feature's apparent size relative to other visible landscape features; and (c) the conspicuousness of the feature due to its location in the view.

A feature's level of dominance is lower in a panoramic setting than in an enclosed setting with a focus on the feature itself. A feature's level of dominance is higher if it is (1) near the center of the view; (2) elevated relative to the viewer; or (3) has the sky as a backdrop. As the distance between a viewer and a feature increases, its apparent size decreases; and consequently, its dominance decreases. The level of dominance ranges from *low* to *high*.

VIEW DISRUPTION

The extent to which any previously visible landscape features are blocked from view constitutes view disruption. The view is also disrupted when the continuity of the view is interrupted. When considering a project's features, higher quality landscape features can be disrupted by lower quality project features, thus resulting in adverse visual impacts. The degree of view disruption can range from *none* too *high*.

VISUAL CHANGE

Visual change is a function of *contrast*, *dominance*, and *view disruption*. Generally, *contrast* and *dominance* contribute more to the degree of visual change than does *view disruption*.

APPENDIX VR-2: VISIBLE PLUME MODELING ANALYSIS[68]

INTRODUCTION

The following provides the assessment of the Hydrogen Energy California Project (HECA) gas turbine heat recovery steam generator (HRSG), coal dryer, and cooling tower exhaust stacks visible plumes. Staff completed a modeling analysis for the applicant's proposed unabated gas turbine/HRSG, coal dryer and cooling towers.

PROJECT DESCRIPTION

The applicant has proposed one MHI 501GAC combustion turbine-generator (CTG)/HRSG with duct burners. The applicant has not proposed to use any methods to abate visible plumes from the HRSG exhaust, and none seem to be warranted given the visual impact analysis conducted by staff.

For project cooling the applicant has proposed a four-cell air separation unit cooling tower, a 12-cell power block cooling tower and a 13-cell process cooling tower. All cooling towers are linear (one by four, etc.) design. The 12-cell cooling tower and the 13-cell cooling tower are aligned as if they comprise one 25-cell tower in a west-east direction. The applicant has not proposed to use any methods to abate visible plumes from the three cooling towers.

The facility would also consist of a manufacturing complex, proposed to create low-carbon nitrogen-based agricultural products. Sources in the manufacturing complex that have visible plume potential include the urea unit absorber vent and the urea ammonia nitrate complex vent scrubber. However, the visible impact would be insignificant for these sources in comparison to the project's larger HRSG and cooling tower impacts.

Finally, Occidental of Elk Hills, inc. (OEHI) would receive the carbon dioxide (CO_2) from HECA and use it for enhanced oil recovery operations. This would include a CO_2 recovery unit to separate CO_2 from recovered crude oil. Sources associated with the CO_2 recovery unit that have visible plume potential include the refrigeration system and discharge cooler. But again, the visible impact would be insignificant for these sources in comparison to the project's larger HRSG and cooling tower impacts.

VISIBLE PLUME MODELING METHODS

PLUME FREQUENCY AND DIMENSION MODELING

The Combustion Stack Visible Plume (CSVP) model was used to estimate plume frequency for the HRSG and plume frequency and plume size for the cooling tower and coal dryer exhausts. This model provides conservative estimates of both plume frequency and plume size. This model utilizes hourly HRSG, coal dryer, and cooling tower exhaust parameters and hourly ambient condition data to determine the plume

[68] Analysis conducted by Joseph Hughes and William Walters (March 2013).

frequency. This model is based on the algorithms of the Industrial Source Complex model (Version 2), that determine conditions at the plume centerline, but this model does not incorporate building downwash.

The modeling method combines the cooling tower cell exhausts into an equivalent single stack. This method may overestimate cooling tower plume size (particularly height) during plume hours with higher winds due to little cell interaction and the potential for building downwash, but will be more accurate during low wind and calm periods when the exhausts from the cooling tower cells will combine into one coherent body. Wind speeds are set to 1 m/s during calm hours.

The Seasonal/Annual Cooling Tower Impacts (SACTI) model was used to determine frequency and direction of potential plume ground fogging events that could impact traffic safety, in this case Adohr Road, Dairy Road and Tupman Road, adjacent to the project site.

CLOUD COVER DATA ANALYSIS METHOD

A plume frequency of 20 percent of seasonal (November through April) daylight no rain/fog high visual contrast (i.e. “clear”) hours is used to determine potential plume impact significance. The methodology used to determine high visual contrast hours is provided below:

> Energy Commission staff has identified a “clear” sky category during which visible plumes have the greatest potential to cause adverse visual impacts. For this project the meteorological data set[69] used in the analysis categorizes sky cover in 10 percent increments. Staff has included in the “Clear” category a) all hours with sky cover equal to or less than 10 percent plus b) half of the hours with total sky cover 20-90 percent. The rationale for including these two components in this category is as follows: a) visible plumes typically contrast most with sky under clear conditions and, when total sky cover is equal to or less than 10 percent, clouds either do not exist or they make up such a small proportion of the sky that conditions appear to be virtually clear; and b) for a substantial portion of the time when total sky cover is 20-90 percent the opacity of sky cover is relatively low (equal to or less than 50 percent), so this sky cover does not always substantially reduce contrast with visible plumes; staff has estimated that approximately half of the hours meeting the latter sky cover criteria can be considered high visual contrast hours and are included in the “clear” sky definition.

If it is determined that the seasonal daylight clear hour plume frequency is greater than 20 percent then plume dimensions are calculated, and a significance analysis of the plumes is included in the **Visual Resources** section of the Staff Assessment.

---

[69] This analysis uses four years (2005-2008) of meteorological data from Bakersfield provided by the applicant. Hours with missing data were excluded.

COOLING TOWER VISIBLE PLUME MODELING ANALYSIS

AIR SEPARATION UNIT COOLING TOWER DESIGN AND OPERATING PARAMETERS

The following cooling tower design characteristics, presented below in **Visible Plume Table 1**, were determined through a review of the applicant's Amended AFC (HECA 2012e), modeling files (HECA 2012d), and data responses (HECA 2012q). The data presented in **Visible Plume Table 1** was used to model the air separation unit (ASU) cooling tower plume frequency and dimensions.

Visible Plume Table 1
ASU Cooling Tower Operating and Exhaust Parameters[a]

Parameter		Cooling Tower Design Parameters		
Number of Cells per Tower		4 Cells (1 by 4 Linear Design)		
Cell Height		16.76 meters (55 feet)		
Cell Stack Diameter		9.14 meters (30 feet)		
Tower Housing Length		60.70 meters (199 feet)		
Tower Housing Width		18.29 meters (60 feet)		
Case	**Inlet Air Ambient Condition**	**Heat Rejection Rate (MW/hr)**	**Exhaust Flow Rate (klbs/hr)**	**Exhaust Temperature (°F)**
3 Cells	39°F, 82% RH	89.8	14,922	84
4 Cells	65°F, 55% RH	90.8	20,052	75
4 Cells	97°F, 20% RH	90.6	19,741	71

Source: HECA 2012e, Section 5.11, Table 5.11-9, and Staff calculations.
Notes:
a. Values were extrapolated or interpolated between hourly ambient condition data points.

AIR SEPARATION UNIT COOLING TOWER VISIBLE PLUME MODELING RESULTS

Visible Plume Table 2 provides the CSVP model visible plume frequency results for year round full load operation using a four-year (2005-2008) Bakersfield meteorological data set.

Visible Plume Table 2
Predicted Hours with ASU Cooling Tower Visible Plumes
Year Round Full Load Operation
Bakersfield 2005-2008 Meteorological Data

CASE	Available (hr)	Plume (hr)	Percent (%)
All Hours	35,006	12,528	36%
Daylights Hours	17,658	4,044	23%
Daylight No Rain No Fog	17,418	3,889	22%
Seasonal Daylight Hours*	7,976	3,646	46%
Seasonal Daylight No Rain No Fog*	7,765	3,504	45%
Seasonal Daylight Clear**	6,041	2,254	37%

*Seasonal conditions occur anytime from November through April.
**Available hours based on seasonal daylight clear hours.

Since the plume frequency is above 20% of the seasonal daylight clear conditions, the corresponding plume dimensions were estimated. The plume dimensions are estimated by the CSVP model and presented in Visible Plume Table 3.

Visible Plume Table 3
Predicted ASU Cooling Tower Visible Plume Dimensions

	ASU Cooling Tower Seasonal "Clear" Hours Plume Dimensions in Meters (feet)		
Percentile	**Length**	**Height**	**Width**
1%	137.18 (450.06)	239.45 (785.60)	55.78 (182.99)
5%	92.77 (304.36)	150.09 (492.43)	40.59 (133.15)
10%	74.54 (244.54)	114.27 (374.89)	34.69 (113.80)
15%	57.59 (188.93)	96.10 (315.27)	28.56 (93.71)
20%	**43.41 (142.42)**	**84.01 (275.61)**	**23.69 (77.73)**
30%	35.33 (115.92)	70.74 (232.08)	21.23 (69.65)

*Results include the cooling tower stack height of 16.76 meters (55 feet), see Visible Plume Table 1.

The plume dimension results shown in **Visible Plume Table 3** correspond only to the defined daylight “clear” weather conditions. The cooling tower plumes can be much larger than those indicated in the table on occasion, particularly during weather events such as rain or fog, or early in morning or at night when it is cold, the relative humidity is high, and the winds are low or dead calm.

AIR SEPARATION UNIT COOLING TOWER GROUND FOGGING MODELING RESULTS

Visible Plume Table 4 provides the worst case hours of plume ground fogging modeled using SACTI model. Staff modeled different operating conditions to determine worst case impacts. The worst case impacts for the ASU cooling tower was at colder ambient conditions when 3 of the 4 cells would be in operation.

The center of ASU cooling tower is located approximately 1,050 meters south of the intersection of Dairy Road and Adohr Road, and 1,520 meters west of Tupman Road. Ground fogging plume is predicted only up to 500 meters away from the center of the 4-cell cooling tower for less than one hour for the four years of meteorological data modeled. Therefore, there would be no interference with traffic visibility on any road.

13-CELL PROCESS COOLING TOWER AND 12-CELL POWER BLOCK COOLING TOWER DESIGN AND OPERATING PARAMETERS

The following cooling tower design characteristics, presented below in **Visible Plume Table 5** and **Visible Plume Table 6**, were determined through a review of the applicant's AFC (HECA 2012e), modeling files (HECA 2012d), and data responses (HECA 2012q). The data presented in **Visible Plume Table 5** and **Visible Plume Table 6** was used to model the 13-cell process cooling tower and adjacent 12-cell power block cooling tower plume frequency and dimensions. Because the two cooling towers have similar exhaust parameters and are adjoined linearly, staff modeled the two towers as one 25-cell linear cooling tower to determine conservative plume frequency and dimension results.

Visible Plume Table 5
13-Cell Process Cooling Tower Operating and Exhaust Parameters[a]

Parameter		Cooling Tower Design Parameters		
Number of Cells per Tower		13 Cells (1 by 13 Linear Design)		
Cell Height		16.76 meters (55 feet)

Seasonal Daylight Clear**	6,041	2,254	37%

*Seasonal conditions occur anytime from November through April.
**Available hours based on seasonal daylight clear hours.

Since the plume frequency is above 20% of the seasonal daylight clear hours for the operation with duct firing the corresponding plume dimensions were estimated. The plume dimensions are estimated by the CSVP model and presented in **Visible Plume Table 8**.

Visible Plume Table 8
Predicted 25-Cell Power Block and Process Cooling Tower
Visible Plume Dimensions

	25-Cell Cooling Tower Seasonal "Clear" Hours Plume Dimensions in Meters (feet)		
Percentile	**Length**	**Height**	**Width**
1%	352.29 (1155.80)	284.16 (932.30)	136.95 (449.31)
5%	209.40 (687.02)	185.46 (608.46)	87.91 (288.42)
10%	160.98 (528.16)	149.98 (492.05)	73.40 (240.82)
15%	135.96 (446.08)	131.03 (429.89)	64.69 (212.24)
20%	**107.51 (352.72)**	**119.83 (393.13)**	**56.79 (186.31)**
30%	97.28 (319.16)	105.22 (345.20)	54.33 (178.25)

*Results include the cooling tower stack height of 16.76 meters (55 feet), see Visible Plume Tables 5 and 6.

The plume dimension results shown in **Visible Plume Table 8** correspond only to the defined daylight “clear” weather conditions. The cooling tower plumes can be much larger than those indicated in the table on occasion, particularly during weather events such as rain or fog, or early in morning or at night when it is cold, the relative humidity is high, and the winds are low or dead calm.

13-CELL PROCESS COOLING TOWER AND 12-CELL POWER BLOCK COOLING TOWER GROUND FOGGING MODELING RESULTS

Visible Plume Table 9 provides the SACTI model predicted hours of plume ground fogging with various wind directions. Staff modeled different operating conditions to determine worst case impacts. The worst case impacts for the 12-cell and 13-cell cooling towers was at colder ambient conditions when a total of 19 of the 25 cells would be in operation. Staff assumed complete plume merging from the two towers and modeled them as a single source.

The center of the 25-cell cooling tower is located approximately 1,280 meters south of Adohr Road, and 890 meters west of Tupman Road. Ground fogging plume is not predicted to reach these distances in the directions of the nearby roads. Therefore, there would be no interference with traffic visibility on any road. Ground fogging plume is predicted to reach up to 1,300 meters away from the center of the 25-cell cooling tower heading in the south-south east direction. However, ground fogging plumes exceeding 1,000 meters were only predicted to occur approximately 30 minutes out of the four years of meteorological data modeled and ground fogging plumes reaching 1,300 meters were only predicted to occur approximately 12 minutes out of the four years of meteorological data modeled.

HRSG AND COAL DRYER VISIBLE PLUME MODELING ANALYSIS

Staff evaluated the Applicant's Amended AFC (HECA 2012e) and performed an independent psychrometric analysis. The Combustion Stack Visible Plume (CSVP) model was used to estimate the worst-case potential plume frequency for the proposed HRSG and coal dryer stacks.

HRSG PARAMETERS

Based on the stack exhaust parameters anticipated by the Applicant, the frequency of visual plumes can be estimated. The operating data for these stacks are provided in **Visible Plume Table 10**.

Visible Plume Table 10
HRSG Exhaust Parameters[a]

Parameter	HRSG Exhaust Parameters		
Stack Height	65 meters (213 feet)		
Stack Diameter	7 meters (23 feet)		
Ambient Conditions	Moisture Content (% by weight)	Exhaust Flow Rate (klbs/hr)	Exhaust Temp (°F)
Hydrogen Rich Fuel with No Duct Firing			
39°F	6.4	3,956	200
65°F	7.0	3,747	200
97°F	7.5	3,496	200

Visible Plume Table 10
HRSG Exhaust Parameters[a]

Hydrogen Rich Fuel with Duct Firing			
39°F	7.2	4,876	200
65°F	7.8	4,712	200
97°F	8.3	4,575	200

Source: HECA 2012e, HECA 2012d, HECA 2012q.
Note:
a. Values were extrapolated or interpolated between hourly ambient condition data points as necessary.

HRSG VISIBLE PLUME MODELING ANALYSIS

Staff modeled the HRSG plumes using the CSVP model with a four-year meteorological data set from Bakersfield. **Visible Plume Table 11** provides the CSVP model visible plume frequency results for full load operations, with and without duct firing.

Visible Plume Table 11
Staff Predicted Hours with HRSG Steam Plumes
Bakersfield 2005-2008 Meteorological Data

Case	Available (hr)	Full Load with Duct Firing		Full Load with No Duct Firing	
		Plume (hr)	Percent	Plume (hr)	Percent
Hydrogen Rich Fuel					
All Hours	35,006	5,078	15%	3,095	9%
Daylight Hours	17,658	1,090	6%	579	3%
Daylight No Rain No Fog	17,418	1,039	6%	556	3%
Seasonal Daylight Hours*	7,976	1,081	14%	578	7%
Seasonal Daylight No Rain No Fog*	7,765	1,032	13%	555	7%
Seasonal Daylight Clear**	6,041	525	9%	251	4%

*Seasonal conditions occur anytime from November through April.
**Available hours based on seasonal daylight clear hours.

Since the plume frequency is below 20% of the seasonal daylight clear hours for the operation with and without duct firing the corresponding plume dimensions were not estimated.

COAL DRYER PARAMETERS

Based on the stack exhaust parameters anticipated by the Applicant, the frequency of visual plumes can be estimated. The operating data for this stack is provided in **Visible Plume Table 12**.

Visible Plume Table 12
Coal Dryer Exhaust Parameters

Parameter	HRSG Exhaust Parameters		
Stack Height	92.96 meters (305 feet)		
Stack Diameter	4.88 meters (16 feet)		
Ambient Conditions	Moisture Content (% by weight)	Exhaust Flow Rate (klbs/hr)	Exhaust Temp (°F)
39°F	10.8	800	200
65°F	10.8	800	200
97°F	10.8	800	200

Source: HECA 2012e, HECA 2012d, HECA 2012q.

COAL DRYER VISIBLE PLUME MODELING ANALYSIS

Staff modeled the coal dryer plumes using the CSVP model with a four-year meteorological data set from Bakersfield. **Visible Plume Table 13** provides the CSVP model visible plume frequency results for full load operations.

Visible Plume Table 13
Staff Predicted Hours with Coal Dryer Visible Plumes
Bakersfield 2005-2008 Meteorological Data

CASE	Available (hr)	Plume (hr)	Percent (%)
All Hours	35,006	13,199	38%
Daylights Hours	17,658	4,266	24%
Daylight No Rain No Fog	17,418	4,094	24%
Seasonal Daylight Hours*	7,976	3,939	49%
Seasonal Daylight No Rain No Fog*	7,765	3,781	47%
Seasonal Daylight Clear*	6,041	2,442	40%

*Seasonal conditions occur anytime from November through April.
**Available hours based on seasonal daylight clear hours.

Since the plume frequency is above 20% of the seasonal daylight clear hours for the operation the corresponding plume dimensions were estimated. The plume dimensions are estimated by the CSVP model and presented in **Visible Plume Table 14**.

Visible Plume Table 14
Predicted Coal Dryer Visible Plume Dimensions Firing

	Coal Dryer Seasonal "Clear" Hours Plume Dimensions in Meters (feet)		
Percentile	**Length**	**Height**	**Width**
1%	177.61 (582.65)	303.88 (996.89)	69.09 (226.65)
5%	91.47 (300.07)	227.08 744.94)	39.04 (128.06)
10%	63.22 (207.38)	196.97 (646.15)	30.43 (99.84)
15%	48.59 (159.39)	180.75 (592.95)	25.88 (84.88)
20%	**40.23 (131.96)**	**168.81 (553.79)**	**22.22 (72.89)**
30%	38.55 (126.47)	154.66 (507.37)	20.66 (67.78)

*Results include the coal dryer stack height of 92.96 meters (305 feet), see VISIBLE PLUME Table 16.

The plume dimension results shown in **Visible Plume Table 14** correspond only to the defined daylight “clear” weather conditions. The cooling tower plumes can be much larger than those indicated in the table on occasion, particularly during weather events such as rain or fog, or early in morning or at night when it is cold, the relative humidity is high, and the winds are low or dead calm.

CONCLUSIONS

Visible water vapor plumes from all of the proposed HECA cooling towers are predicted to occur more than 20 percent of seasonal daylight clear hours considering the worst-case maximum facility operation. Therefore, further visual impact analysis of the expected twenty percentile plume size has been completed for each cooling tower.

The ground fogging plume analysis predicts that ground fogging plumes from the proposed process cooling tower and power block cooling tower could reach the nearby Tupman Road during worst case merging conditions. However, the model predicts very low frequencies at distances that could reach roads over the four years of meteorological data modeled.

Visible water vapor plumes from the proposed HECA gas turbine/HRSG exhausts would likely not occur more than 20 percent of seasonal daylight clear hours, therefore, no further visual impact analysis was completed.

Visible water vapor plumes from the proposed HECA coal dryer exhaust would likely occur more than 20 percent of seasonal daylight clear hours. Therefore, further visual impact analysis of the expected twenty percentile plume size has been completed.

WASTE MANAGEMENT

Ellen Townsend-Hough

SUMMARY OF CONCLUSIONS

The Hydrogen Energy California (HECA) Project would produce thousands of tons per year of waste during the operation of the facility. The majority of the waste would be gasification solids. HECA is expected to generate a maximum of 850 tons per day of gasification waste (vitrified slag). HECA is currently investigating three potential markets for beneficial reuse of this material; 1) roofing granules, 2) blasting grit, 3) pozzolanic admixtures in cement manufacture. The large quantity of waste would significantly impact Kern County landfills and possibly compromise the county's compliance with Public Resources Code section 40000 et seq. and Senate Bill (SB) 1016 (Stats. 2008, ch. 343.) and implementing regulations. The HECA project owner has not produced a comprehensive plan for the reuse and disposal of the gasifier solids. To avoid significant waste management impacts the project owner would have to work with Energy Commission, Kern County and CalRecycle staff to establish an operational waste diversion program. This plan must be completed and approved by the coordinating agencies prior to staff's publication of the Final Staff Assessment. HECA tested the gasification solids and they are considered non-hazardous according to federal standards. California testing standards should be used to determine if the HECA gasification solids are non-hazardous.

The results of soil sampling and analytical testing at the HECA project site indicate there are elevated concentrations of petroleum hydrocarbons and other contaminants affected by previous site activities. Staff is recommending the site be appropriately characterized prior to the Final Staff Assessment. Staff has reviewed the waste management aspects of the Occidental of Elk Hills, Inc. CO_2 Enhanced Oil Recovery (OEHI CO_2 EOR) Project for construction and operation, as described in the Supplemental Environmental Information (SEI) report (HECA 2012e, Volume II). Nonhazardous and hazardous waste would be generated during construction and operation of the OEHI CO_2 EOR. In order to verify that Kern County has enough landfill capacity to accommodate the project's solid waste disposal needs staff requires the project owner to provide information on the quantity of project waste that would be disposed of in local landfills.

The former Naval Petroleum Reserve No.1 (NPR-1) (a.k.a. the Elk Hills Oil Field (EHOF)) was formerly owned by the United States Department of Energy (DOE) and Chevron Oil Company. During their past operations at the EHOF, wastes were disposed of at "legacy waste sites". As a result of the land transfer to Occidental, California Department of Toxic Substances Control (DTSC) entered into a Corrective Action Consent Agreement with DOE for corrective and/or remediation of several of the legacy waste sites within the Elk Hills Oil Field. DOE agreed to head up an environmental and human health risk assessment of the entire site with remediation to address the effects of past practices at the site. The project owner would keep employees, contractors and DTSC aware of health and safety risks when work is proposed on contaminated areas of the project site.

The **Socioeconomic Resources** section has identified an environmental justice population as defined by the 'Environmental Justice: Guidance under the National Environmental Policy Act'. Staff has identified a significant adverse direct and cumulative impact resulting from the operation of the proposed project, but the impact does not significantly or adversely affect the identified environmental justice community.

The proposed HECA project would cause a significant impact because the volume of waste would place Kern County in jeopardy of non-compliance with California mandated diversion/recycling goals (Public Resources Code section 40000 et seq.). The HECA Application for Certification (AFC) indicates that the gasification solids can be recycled/reused, disposed of locally or exported to another state. Determination of beneficial uses or disposal of the gasification solids is dependent on the chemical and physical characteristics of solids. The solids characteristics are variable and dependent on the feedstock and processing methods.

Staff concludes HECA should evaluate characteristics of the gasification solids based on a similar representative facility using the same feedstock and processing methods. They should then conduct a market analysis of potential uses of the solids so some portion of waste can be diverted from landfills. The gasification waste could be excluded from hazardous waste regulations (i.e., 40 CFR Section 261.4 (b) (7) (ii) (F) and Title 22 CCR Section 66261.4(b) (5) (A). However, prior to acceptance of the gasification solids into a Kern County owned and operated landfill the solids must be analyzed and classified as non-hazardous or hazardous waste. If the solids are determined to be hazardous, the amount of hazardous waste would be burdensome to the State of California and disposal would be costly to the applicant. If they are determined to be non-hazardous according to Title 14 regulations, nonhazardous waste quantities generated and/or disposed of in Kern County would count against the County's waste diversion goals. The expected volume of waste would likely result in the Kern County exceeding their state mandated waste diversion goals. The applicant has proposed to export waste for disposal so the diversion goals can be met. However, CalRecycle has indicated Kern County would still be responsible for the waste generated in the county. Staff encourages Kern County and CalRecycle to discuss how Kern County would be able to comply with Title 14, California Code of Regulations sections 18800 through 18814.11. Staff also recommends that the HECA project owner and Kern County work together to design an operational waste diversion program prior to preparation of the Final Staff Assessment.

INTRODUCTION

This Preliminary Staff Assessment/Draft Environmental Impact Statement (PSA/DEIS) presents an analysis of issues associated with wastes generated from the proposed construction and operation of HECA. The technical scope of this analysis encompasses solid wastes existing on site and wastes that would likely be generated during facility construction and operation. Management and discharge of wastewater is addressed in the **Soils and Surface Water** section of this document. Additional information related to waste management may also be covered in the **Worker Safety** and **Hazardous Materials Management** sections of this document.

The California Energy Commission (Energy Commission) staff's objectives in conducting this waste management analysis are to ensure that:

- The management of project wastes would be in compliance with all applicable laws, ordinances, regulations, and standards.

- The disposal of project wastes would not result in significant adverse impacts to existing waste disposal facilities, or result in other waste-related significant adverse effects on the environment.
- Upon project completion, the site would be managed in such a way that project wastes and waste constituents would not pose a significant risk to humans or the environment.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

The following federal, state, and local environmental laws, ordinances, regulations and standards (LORS) in **Waste Management Table 1** have been established to ensure the safe and proper management of both solid and hazardous wastes in order to protect human health and the environment. Project compliance with the various LORS is a major component of staff's determination regarding the significance and acceptability of HECA with respect to management of waste.

Waste Management Table 1
Laws, Ordinances, Regulations, and Standards

Applicable Law	Description
Federal	
Title 42, United States Code (U.S.C.), §6901, et seq. Solid Waste Disposal Act of 1965 (as amended and revised by the Resource Conservation and Recovery Act of 1976, et al.)	The Solid Waste Disposal Act, as amended and revised by the Resource Conservation and Recovery Act (RCRA) et al., establishes requirements for the management of solid wastes (including hazardous wastes), landfills, underground storage tanks, and certain medical wastes. The statute also addresses program administration, implementation and delegation to states, enforcement provisions, and responsibilities, as well as research, training, and grant funding provisions. RCRA Subtitle C establishes provisions for the generation, storage, treatment, and disposal of hazardous waste, including requirements addressing: • Generator record keeping practices that identify quantities of hazardous wastes generated and their disposition; • Waste labeling practices and use of appropriate containers; • Use of a manifest when transporting wastes; • Submission of periodic reports to the United States Environmental Protection Agency (U.S. EPA) or other authorized agency; and • Corrective action to remediate releases of hazardous waste and contamination associated with RCRA-regulated facilities. RCRA Subtitle D establishes provisions for the design and operation of solid waste landfills. RCRA is administered at the federal level by the United States Environmental Protection Agency (U.S. EPA) and its 10 regional offices. The Pacific Southwest regional office (Region 9) implements U.S. EPA programs in California, Nevada, Arizona, and Hawaii.
Title 42, U.S.C., §9601, et seq. Comprehensive	The Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), also known as *Superfund*, establishes authority and funding mechanisms for cleanup of uncontrolled or abandoned hazardous waste sites, as well as cleanup of accidents, spills, or

Environmental Response, Compensation and Liability Act	emergency releases of pollutants and contaminants into the environment. Among other things, the statute addresses: • Reporting requirements for releases of hazardous substances; • Requirements for remedial action at closed or abandoned hazardous waste sites, and brownfields; • Liability of persons responsible for releases of hazardous substances or waste; and • Requirements for property owners/potential buyers to conduct “all appropriate inquiries” into previous ownership and uses of the property to 1) determine if hazardous substances have been or may have been released at the site, and 2) establish that the owner/buyer did not cause or contribute to the release. A Phase I Environmental Site Assessment is commonly used to satisfy CERCLA “all appropriate inquiries” requirements.
Title 40, Code of Federal Regulations (CFR), Subchapter I – Solid Wastes	These regulations were established by U.S. EPA to implement the provisions of the Solid Waste Disposal Act and RCRA (described above). Among other things, the regulations establish the criteria for classification of solid waste disposal facilities (landfills), hazardous waste characteristic criteria and regulatory thresholds, hazardous waste generator requirements, and requirements for management of used oil and universal wastes. • Part 257 addresses the criteria for classification of solid waste disposal facilities and practices. • Part 258 addresses the criteria for municipal solid waste landfills. • Parts 260 through 279 address management of hazardous wastes, used oil, and universal wastes (i.e., batteries, mercury-containing equipment, and lamps). U.S. EPA implements the regulations at the federal level. However, California is an RCRA-authorized state, so most of the solid and hazardous waste regulations are implemented by state agencies and authorized local agencies in lieu of U.S. EPA.
Title 49, CFR, Parts 172 and 173. Hazardous Materials Regulations	These regulations address the United States Department of Transportation (DOT) established standards for transport of hazardous materials and hazardous wastes. The standards include requirements for labeling, packaging, and shipping of hazardous materials and hazardous wastes, as well as training requirements for personnel completing shipping papers and manifests. Section 172.205 specifically addresses use and preparation of hazardous waste manifests in accordance with Title 40, CFR, Section 262.20.
40 CFR §261.4(b)(7)(ii)(F): Exclusions: Solid Wastes which are Not Hazardous Wastes Coal gasification	This law excludes gasifier ash from coal gasification and process wastewater from coal gasification from being considered as a hazardous waste.
State	
California Health and Safety Code (HSC), Chapter 6.5, §25100, et seq.	This California law creates the framework under which hazardous wastes must be managed in California. The law provides for the development of a state hazardous waste program that administers and implements the provisions of the federal RCRA program. It also provides for the designation of California-only hazardous wastes and development of

Hazardous Waste Control Act of 1972, as amended	standards (regulations) that are equal to or, in some cases, more stringent than federal requirements. The California Environmental Protection Agency (Cal/EPA), Department of Toxic Substances Control (DTSC) administers and implements the provisions of the law at the state level. Certified Unified Program Agencies (CUPAs) implement some elements of the law at the local level.
Title 22, California Code of Regulations (CCR), Division 4.5. Environmental Health Standards for the Management of Hazardous Waste	These regulations establish requirements for the management and disposal of hazardous waste in accordance with the provisions of the California Hazardous Waste Control Act and federal RCRA. As with the federal requirements, waste generators must determine if their wastes are hazardous according to specified characteristics or lists of wastes. Hazardous waste generators must obtain identification numbers; prepare manifests before transporting the waste off site; and use only permitted treatment, storage, and disposal facilities. Generator standards also include requirements for record keeping, reporting, packaging, and labeling. Additionally, while not a federal requirement, California requires that hazardous waste be transported by registered hazardous waste transporters. The standards addressed by Title 22, CCR include: • Identification and Listing of Hazardous Waste (Chapter 11, §66261.1, et seq.). • Standards Applicable to Generator of Hazardous Waste (Chapter 12, §66262.10, et seq.). • Standards Applicable to Transporters of Hazardous Waste (Chapter 13, §66263.10, et seq.). • Standards for Universal Waste Management (Chapter 23, §66273.1, et seq.). • Standards for the Management of Used Oil (Chapter 29, §66279.1, et seq.). • Requirements for Units and Facilities Deemed to Have a Permit by Rule (Chapter 45, §67450.1, et seq.). The Title 22 regulations are established and enforced at the state level by DTSC. Some generator and waste treatment standards are also enforced at the local level by CUPAs.
HSC, Chapter 6.11 §§25404 – 25404.9 Unified Hazardous Waste and Hazardous Materials Management Regulatory Program (Unified Program)	The Unified Program consolidates, coordinates, and makes consistent the administrative requirements, permits, inspections, and enforcement activities of the six environmental and emergency response programs listed below. • Aboveground Petroleum Storage Act requirements for Spill Prevention, Control, and Countermeasure (SPCC) Plans. • Hazardous Materials Release and Response Plans and Inventories (Business Plans). • California Accidental Release Prevention (CalARP) Program. • Hazardous Material Management Plan / Hazardous Material Inventory Statements. • Hazardous Waste Generator / Tiered Permitting Program. • Underground Storage Tank Program. The state agencies responsible for these programs set the standards for

	their programs while local governments implement the standards. The local agencies implementing the Unified Program are known as CUPAs. Note: The Waste Management analysis only considers application of the Hazardous Waste Generator/Tiered Permitting element of the Unified Program.
Title 27, CCR, Division 1, Sub-division 4, Chapter 1, §15100, et seq. Unified Hazardous Waste and Hazardous Materials Management Regulatory Program	While these regulations primarily address certification and implementation of the program by the local CUPAs, the regulations do contain specific reporting requirements for businesses. • Article 9 – Unified Program Standardized Forms and Formats (§§ 15400–15410). • Article 10 – Business Reporting to CUPAs (§§15600–15620).
Hazardous Waste Source Reduction and Management Review Act of 1989 HSC, Division 20, Chapter 6.5, Article 11.9, §25244.12, et seq.	This law was enacted to expand the state's hazardous waste source reduction activities. Among other things, it establishes hazardous waste source reduction review, planning, and reporting requirements for businesses that routinely generate more than 12,000 kilograms (approximately 26,400 pounds) of hazardous waste in a designated reporting year. The review and planning elements are required to be done on a four-year cycle, with a summary progress report due to DTSC every fourth year.
Title 22, CCR, §67100.1 et seq. Hazardous Waste Source Reduction and Management Review	These regulations further clarify and implement the provisions of the Hazardous Waste Source Reduction and Management Review Act of 1989 (noted above). The regulations establish the specific review elements and reporting requirements to be completed by generators subject to the act.
Title 14, CCR, Division 7, §17200, et seq. California Integrated Waste Management Board	These regulations implement the provisions of the California Integrated Waste Management Act (CIWMA) and set forth minimum standards for solid waste handling and disposal. The regulations include standards for solid waste management, as well as enforcement and program administration provisions. • Chapter 3 – Minimum Standards for Solid Waste Handling and Disposal. • Chapter 3.5 – Standards for Handling and Disposal of Asbestos Containing Waste. • Chapter 7 – Special Waste Standards. • Chapter 8 – Used Oil Recycling Program. • Chapter 8.2 – Electronic Waste Recovery and Recycling. Section 40052 of the Public Resources Code, the purpose of California Integrated Waste Management Act of 1989 (CIWMA) is to "reduce, recycle, and reuse solid waste generated in the state to the maximum extent feasible in an efficient and cost-effective manner to conserve water, energy and other natural resources.

Public Resources Code, Division 30, §40000, et seq. California Integrated Waste Management Act of 1989. Title 14, California Code of Regulations, section 18720 et seq.	The California Integrated Waste Management Act of 1989 (as amended) establishes mandates and standards for management of solid waste. Among other things, the law includes provisions addressing solid waste source reduction and recycling, standards for design and construction of municipal landfills, and programs for county waste management plans and local implementation of solid waste requirements. The act was amended in 2011 (AB 341) to include a legislative declaration of a state policy goal that not less than 75 percent of solid waste generated be source reduced, recycled, or composted by the year 2020. The 2011 amendments expand recycling to businesses and apartment buildings; require the state to develop programs to recycle three-quarters of generated waste; and require commercial and public entities that generate more than four cubic yards of commercial solid waste per week, and multifamily residential dwellings of five units or more, to arrange for recycling services beginning July 1, 2012.
Public Resources Code Section 42920 - 42927 (SB1016) Per Capita Disposal Measurement Act	This changed the way State agencies and local governments measure their progress toward meeting the statutory waste diversion mandates. Under this Act, State agencies are still required to maintain the 50 percent waste diversion requirement as mandated by AB 75 (Strom-Martin, Chapter 764, Statutes of 1999). However, State agencies and large State facilities would now use per capita disposal as an indicator of their progress toward meeting the mandate.
Title 24, CCR, Part 11 2010 Green Building Standards Code (CalGreen)	The code is established to reduce construction waste, make buildings more efficient in the use of materials and energy, and reduce environmental impact during and after construction. Effective January 1, 2011, in jurisdictions without a construction and demolition (C&D) ordinance requiring the diversion of 50 percent of construction waste, the owners/builder of newly constructed buildings within the covered occupancies are required to develop a waste management plan and divert 50 percent of the construction waste materials generated during the project.
Title 22 California Code of Regulations§ 66261.4(b) (5) (A) (6) & (7) Exclusions.	(b) Wastes which are not hazardous wastes. The following wastes are not hazardous wastes: (5)(A) Wastes, which meet the criteria for classification as a RCRA hazardous waste set forth in section 66261.100(a)(1), (a)(2), or (a)(3), resulting from the extraction, beneficiation, and processing of ores and minerals (including coal, phosphate rock and overburden from the mining of uranium ore), except as provided by 40 CFR section 266.112 for facilities that burn or process hazardous waste, are not hazardous wastes and are not subject to the requirements of this division or of Chapter 6.5 of Division 20 of the Health and Safety Code. However, these wastes remain subject to Article 9.5 of Chapter 6.5 of the Health and Safety Code if the wastes would otherwise be classified as hazardous wastes pursuant to section 25117 of the Health and Safety Code or pursuant to this division. For purposes of this paragraph, beneficiation of ores and minerals is restricted to the following activities: Crushing; grinding; washing; dissolution; crystallization; filtration; sorting; sizing; drying; sintering; pelletizing; briquetting; calcining to remove water and/or carbon dioxide; roasting; autoclaving, and/or chlorination in preparation for

	leaching (except where the roasting (and/or autoclaving and/or chlorination)/leaching sequence produces a final or intermediate product that does not undergo further beneficiation or processing); gravity concentration; magnetic separation; electrostatic separation; flotation; ion exchange; solvent extraction; electrowinning; precipitation; amalgamation; and heap, dump, vat, tank, and in situ leaching. For the purpose of this paragraph, solid waste from the processing of ores and minerals includes only the following wastes: 6. Gasifier ash from coal gasification; 7. Process wastewater from coal gasification;
Policies	
Kern County, Code of Ordinance, Title 8, Health and Safety, Chapter 8.28 Solid Waste	Kern County would ensure all new development complies with applicable provisions of County Integrated Solid Waste Management Plan.
Kern County and Incorporated Cities Integrated Waste Management Plan	The Kern County and Incorporated Cities Integrated Waste Management Plan addresses issues pertaining to nonhazardous waste disposal and other waste facilities.

SETTING

Proposed Project

As noted in the **Project Description** section of this document, the proposed project would consist of the construction and operation of HECA, a new baseload electric generating plant, which would demonstrate Integrated Gasification Combined Cycle (IGCC) technology. The project would gasify a 75 percent coal and 25 percent petroleum coke fuel blend to produce synthesis gas. The synthesis gas would be purified to a hydrogen-rich fuel. The hydrogen rich fuel would produce 300 megawatts (MW) nominal low-carbon baseload electricity in a Combined Cycle Power Block, low-carbon nitrogen-based products in an integrated Manufacturing Complex, and carbon dioxide for use in enhanced oil recovery with carbon capture and sequestration on a commercial scale. Linear facilities include a 2-mile electrical transmission line, a 13-mile Pacific Gas and Electric Company (PG&E) natural gas pipeline, a 15-mile pipeline for process water (brackish groundwater from the Buena Vista Water Storage District (BVWSD)), a 1-mile potable West Kern Water District line, and a 3-mile carbon dioxide (CO_2) pipeline (HECA 2012e, page 5.13-2). The coal would be delivered to the project site either by train on an industrial railroad spur extending five miles to the site or trucked from an existing coal trans-loading facility 27 miles from the site (HECA 2012e, page 5.13-2).

A fuel blend of 75 percent bituminous coal and 25 percent California petroleum coke (petcoke) would be gasified to produce synthetic gas (syngas) that would be further processed and cleaned in an Integrated Gasification Combined-Cycle gasifer to produce hydrogen-rich fuel. Ninety percent of the carbon would be captured in a high-purity CO_2 stream. Occidental of Elk Hills, Inc (OEHI) is proposing to extend the life of its Enhanced Oil Recovery (EOR) operations in the Elk Hills Unit by utilizing carbon dioxide (CO_2). Carbon dioxide (CO_2) would be purchased from HECA project. The CO_2 would be compressed and delivered via pipeline to OEHI's EOR Processing Facility. The compressed CO_2, which has the same characteristics as a liquid, is injected into an oil reservoir via injection wells designed for CO_2 injection. The CO_2 flows from the injection well and dissolves in the oil. CO_2 mixes with oil, resulting in lower oil viscosity, enhanced oil mobility and lower interfacial tension when compared to oil extraction without CO_2 EOR. A technique of alternating cycles of water injection with cycles of CO_2 injection may be used to enhance the oil recovery.

Construction of the HECA Project is estimated to take 42 months (HECA 2012e, page 2-56). Once constructed, the plant would be capable of operating seven days a week, 24 hours a day, with a planned operational life of 25 years (HECA 2012e, page 5.13-11). Construction activities associated with the HECA Project would produce a variety of mixed nonhazardous wastes, such as soil, wood, metal, concrete, etc. Waste would be recycled, where practical, and non-recyclable waste would be deposited in a California Class III landfill. The hazardous waste generated during this phase of the project would consist of used oils, universal wastes, solvents, and empty hazardous waste materials. Universal wastes are hazardous wastes that contain mercury, lead, cadmium, copper, and other substances hazardous to human and environmental health. Examples of universal wastes are batteries, fluorescent tubes, and some electronic devices. Hazardous waste would be disposed of in a California hazardous waste landfill.

Operation and maintenance of the plant and associated facilities would generate a variety of wastes, including hazardous wastes. The project is expected to produce a large quantity of gasification solids, 246, 016 cubic yards per year. Sanitary wastes would be discharged to a new, on-site septic system and leach field (HECA 2012e, page 5.13-9). Wastewater would be generated from the cooling tower blowdown, raw water treatment, gasifier condensate wastewater, the sour water stripper, the Acid Gas Removal unit , and the Urea plant (HECA 2012b, page 5.13-9) To control air pollutant emissions from the combustion of the hydrogen rich fuel and the natural gas used to run the turbines, the project would employ selective catalytic reduction (SCR) and oxidation catalyst equipment and chemicals, which generate both nonhazardous and hazardous wastes.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

METHOD AND THRESHOLD FOR DETERMINING SIGNIFICANCE

As discussed in the Introduction, this document analyzes the project's impacts pursuant to both the National Environmental Policy Act (NEPA) and CEQA. The two statutes are similar in their requirements concerning analysis of a project's impacts. Therefore, unless otherwise noted, staff's use of, and reference to, CEQA criteria and guidelines also encompasses and satisfies NEPA requirements for this environmental document.

This **Waste Management** analysis addresses a) existing project site conditions and the potential for contamination associated with prior activities on or near the project site and b) the impacts from the generation and management of wastes during project construction and operation.

a) For any site in California proposed for the construction of a power plant, the applicant must provide documentation about the nature of any potential or existing releases of hazardous substances or contamination at the site. If potential or existing releases or contamination at the site are identified, the significance of the release or contamination would be determined by site-specific factors, including, but not limited to: the amount and concentration of contaminants or contamination; the proposed use of the area where the contaminants/contamination are found; and any potential exposure pathways for workers, the public, or sensitive species or environmental areas that may be exposed to the contaminants. Any unmitigated contamination or releases of hazardous substances that pose a risk to human health or environmental receptors would be considered significant by Energy Commission staff.

As a first step in documenting existing site conditions, the Energy Commission's power plant site certification regulations require that a Phase I Environmental Site Assessment (ESA) be prepared[1] and submitted as part of an application for certification. The Phase I ESA is conducted to identify any conditions indicative of releases or threatened releases of hazardous substances at or near the site and to identify any areas known to be contaminated (or a source of contamination) at or near the site.

In general, the Phase I ESA uses a qualified Environmental Professional (EP) to conduct inquiries into past uses and ownership of the property, research history of hazardous substance releases or hazardous waste disposal at the site and within a certain distance of the site, and visually inspect the property, making observations about the potential for contamination and possible areas of concern. After conducting necessary file reviews, interviews, and site observations, the EP then provides findings about the environmental conditions at the site. In addition, since the Phase I ESA does not include sampling or testing, the EP may also give an opinion about the potential need for any additional investigation. Additional investigation may be needed, for example, if there were significant gaps in the information available about the site, an ongoing release is suspected, or to confirm an existing environmental condition.

In conducting its assessment of a proposed project, Energy Commission staff reviews the project's Phase I ESA and works with the appropriate oversight agencies, as necessary, to determine if additional site characterization work is needed. If additional investigation is needed to identify the extent of possible contamination, a Phase II ESA may be required. The Phase II ESA usually includes sampling and testing of potentially contaminated media to verify the level of contamination and the need for remediation at the site. If a hazardous substance release or contamination is identified at the site, staff would again work with the appropriate oversight agencies to identify what mitigation, if any, may be necessary to protect human health and the environment from any releases or contamination identified.

b) Regarding the management of project-related wastes generated during construction and operation of the proposed project, staff reviews the applicant's proposed solid and hazardous waste management methods and determines if the methods proposed are consistent with the LORS identified for waste disposal and recycling. The federal, state, and local LORS represent a comprehensive regulatory system designed to protect human

[1] Title 20, California Code of Regulations, section 1704(c) and Appendix B, section (g)(12)(A). Note that the Phase I ESA must be prepared according to American Society for Testing and Materials protocol or an equivalent method agreed upon by the applicant and the Energy Commission staff.

health and the environment from impacts associated with management of both nonhazardous and hazardous wastes. Absent any unusual circumstances, staff considers project compliance with LORS to be sufficient to ensure that no significant impacts would occur as a result of project waste management. Staff then reviews the capacity available at off-site treatment and disposal sites and determines whether or not the proposed power plant's waste would have a significant impact on the volume of waste a facility is permitted to accept. When project-related waste disposal approaches or exceeds a threshold of ten percent of a county's available landfill capacity, staff would consider it a potentially significant impact and would evaluate other information that may help to determine the significance of the project's waste disposal impacts.

DIRECT/INDIRECT IMPACTS AND MITIGATION

Existing Site Conditions and Possible Contamination

The HECA site is located in the west-central portion of Kern, County, California, Section 10 of Township 30 South, Range 24 East within the San Joaquin Valley. The San Joaquin Valley is California's leading agricultural producing region. The project is seven miles west of the city of Bakersfield and 1.5 miles northwest of the unincorporated community of Tupman. The Elk Hills Oil Field is a hydrocarbon producing area located approximately 1 mile south of the project site. The project site is located approximately 1 mile south of the Stockdale Highway, and approximately 2 miles southwest of Interstate 5. The project site is largely agricultural land and is primarily surrounded by agricultural land. The land adjacent to the northwestern corner of the project site contains the Port Organics Ltd. (PO) Products Natural Fertilizer Manufacturing Plant. Approximately 0.8 acre of the PO plant is located on the HECA project site (HECA 2012e, page 5.13-4). The East Side Canal lies to the east of the northeastern corner of the site. Located southwest of the site are the West Side Canal, the Outlet Canal, and the California Aqueduct (HECA 2012e, Figure 2-4).

Three Phase I Environmental Site Assessments (ESAs) and one Phase II ESA were completed for the proposed project site. The last Phase I ESA was dated April 2012 and was prepared by URS for the 453 acre project site. The ESA was completed in accordance with the American Society for Testing and Materials Standard Practice E 1527-05 for ESAs. The December 2010 Phase II ESA, prepared by AECOM, was completed to evaluate the recognized environmental conditions (RECs) that were identified in the April 2009 and August 2010 HECA Phase I ESAs. A REC is considered to be the presence or likely presence of any hazardous substances or petroleum products on a property under conditions that indicated an existing release, past release, or a material threat of a release into structures on the property or in the ground, groundwater, or surface water of the property. Most of the RECs for this project are depicted in **Waste Management Figure 1.** The RECs for the proposed project site include: five former underground storage tanks (USTs), unidentified concrete structures, a farm equipment wash pad, a former PO fertilizing manufacturing facility, outdoor and indoor tailings piles of raw materials used by PO, PO East Sump, and a number of locations with stained surface soil. (HECA 2012e, Appendix L).

The results of the preliminary soil sampling and analytical testing indicate that there are elevated concentrations of petroleum hydrocarbons and other contaminants affected by previous site activities on a former wash area immediately north of the HECA site. There is soil staining in various areas on the project site. The soil staining is likely to be caused by handling of fuel, lubricating oils, and pesticides. Residual contaminants at the site include organochlorine pesticides, dieldrin, endrin, and endosulfan (HECA 2012e, page 5.13-3).

Soil samples taken at the site indicate that concentrations of the pesticides dieldrin, endrin, and endosulfan exceed the Regional Water Quality Control Board (RWQCB) Environmental Screening Levels, but did not exceed the California Human Health Screening Levels (CHHSLs)[2] (HECA 2012e, page 5.13-3). Staff is concerned that hazardous substances are located on the proposed project site. The Department of Toxic Substances Control (DTSC) has indicated that additional site characterization is required to further define the level of contamination at the proposed site. Staff will not defer mitigation and must ensure that there is no potential for construction workers and onsite industrial workers to be exposed to contaminated surface and subsurface soils, which could result in adverse health effects. The project owner must enter into an Agreement with DTSC for the purpose of fully characterizing and if necessary remediating the site property so that it is in the appropriate condition to allow for future use. In addition based on the type of agreement with DTSC the applicant should conduct the necessary site characterization to determine if site remediation is needed and if so what the scope of remediation would be prior to the FSA.

Provided the applicant can satisfactorily characterize site conditions and develop the scope of remediation needed prior to completion of the FSA staff would also recommend that the project owner develop a Soils Management Plan (SMP) describing the procedures that would be followed during construction and operation at the site. The plan would be designed to protect workers from potential adverse reactions to The objective of the SMP is to describe the procedures that would be followed during the soil disturbances so workers can be protected from adverse reactions to any soil contamination that may be encountered. Staff proposes Condition of Certification **WASTE-1** to ensure the applicant has procedures in place to properly handle and dispose of contaminated soil. The scope of the SMP would be limited to activities involving the excavation, characterization, management, reuse and/or disposal of soils at this site. The SMP would cover the following issues:

- Land use history, including description and locations of known contamination.
- A listing and description of institutional controls, such as the County's excavation ordinance and other local, state, and federal regulations and laws that would apply to HECA.
- Names and positions of individuals involved with soils management and their specific role.
- An earthwork schedule.
- A description of protocols for the investigation and evaluation of historically related chemicals such as total petroleum hydrocarbons (TPH) and previously unidentified contamination that may be encountered, including any temporary and permanent controls that may be required to reduce exposure to onsite workers, visitors and the public.

---

[2] CHHSLs were developed as a tool to assist in the evaluation of contaminated sites for potential adverse threats to human health. The soil and soil gas CHHSLs are modeled after the U.S. EPA Region IX PRGs. The primary difference between the CHHSLs and PRGs is the use of CAL/EPA specific "toxicity factor" (estimates of a chemical's toxicity to humans) in development, when available, rather than toxicity factors published by U.S. EPA.

- Requirements for site-specific Health and Safety Plans (HSPs) to be prepared by all contractors at HECA.
- Hazardous waste determination and disposal procedures for known and previously unidentified contamination.
- Requirements for site specific techniques at the site to minimize dust, manage stockpiles, run-on and run-off controls, waste disposal procedures, etc.
- Copies of relevant permits or closures from regulatory agencies

The SMP would include engineering controls, Health and Safety Plans, earthwork schedules and list of responsible staff. Staff is requiring Condition of Certification **WASTE-1** to provide protective measures as needed. These measures include soil removal, refined or enhanced airborne dust mitigation measures currently proposed in the **Air Quality** section of this document so as to better control emissions of fugitive dust containing hazardous wastes (such as increased watering frequency, use of a chemical “wetting agent”, continuously covering stockpiled soils), workers wearing personal protective equipment for short durations, and a combination of all three measures. The implementation of refined and enhanced dust suppression measures and using personal protective equipment can be implemented immediately.

In the event that agricultural chemicals or other contaminants are detected at levels that are considered hazardous, then soil removal or other remediation methods are proposed by staff in Condition of Certification **WASTE-1, WASTE-2,** and **WASTE-3**. Proposed conditions **WASTE-2** and **WASTE-3** would require the project owner to further characterize and remediate the site if other conditions are found during site preparation. These proposed conditions would ensure that any chemicals occurring in hazardous concentrations would be appropriately mitigated in accordance with applicable LORS.

The Elk Hills Oil Field (NPR-1) is an oil-producing field owned by Occidental of Elk Hills, Inc (Oxy). The facility was formerly owned by the United States Department of Energy (DOE) and Chevron Oil Company. DOE sold its interest in the NPR-1 to Occidental Petroleum in 1997. The NPR-1 occupies approximately 47,985 acres or 75 square miles. As a result of the land transfer to Occidental, California Department of Toxic Substances Control (DTSC) entered into an Agreement for Site Assessment (ASA) with DOE and completed a Resource Conservation and Recovery Act (RCRA) Facility Assessment (RFA) of NPR-1 in 1998. DOE agreed to head up an environmental and human health risk assessment of the entire site with remediation to address the effects of past practices at the site.

The working arrangement with DTSC began with an ASA starting in 1997. Three amendments have been made to the ASA, the last of which was for a work plan for the assessment of 131 Areas of Concern (AOCs). The AOCs consist of both small and large areas of contamination. The work was stalled for seven years. On December 23, 2008, DOE and DTSC signed a Corrective Action Consent Agreement to complete the work in December, 2011 and early 2012. DOE representatives submitted numerous Pre-Decisional Project Approach documents. The documents Include an "overview of the planned approach to achieve site closure" for each of the approximate 131 AOCs (DTSC ENVIROSTOR Occidental of Elk Hills (80001254).

To ensure that contamination is not spread at the EHOF and that construction workers are not exposed to hazardous materials as a result of project related activities, safety procedures should be developed and implemented for the construction of the project. All federal, state and local statutes and regulations must be complied with, and DTSC, DOE, and Oxy employees and contractors must be made aware of areas of concern/contamination. Staff recommends DTSC adopt and implement **Mitigation Measure WASTE-1**. **Mitigation Measure Waste-1** would require OEHI to keep DOE and DTSC informed of construction areas and implement all appropriate and applicable safety measures to limit exposure to hazardous materials.

Project Linear Alignment

The crops grown around the HECA 2012 project potable water line, process water line, transmission lines and natural gas lines are located in areas that have crops very similar to linears associated with the 2009 amended HECA project. Typical crops grown in the area include alfalfa, cotton, onion dry, pistachio, sugar beet, and wheat. URS obtained available crop information from Kern County Department of Agriculture and Measurements Standards to identify past crops for the years 1998 to 2008.There are over 95 pesticides used on the various crops around the project linears (URS 2010k Data Response 38). Cliff Smith California Department of Pesticide Regulation, Pesticide Programs Division, Enforcement Branch confirmed that the pesticides currently used in the area and on the list provided by Kern County are non-toxic.

Refined or enhanced airborne dust mitigation measures currently proposed in the **Air Quality** section of this document so as to better control emissions of fugitive dust containing pesticides and/or hazardous wastes (such as increased watering frequency, use of a chemical “wetting agent”, continuously covering stockpiled soils), workers wearing personal protective equipment for short durations, and a combination of these measures will help to protect construction workers. For further analysis of impacts from airborne dust and protection of public health see the **Air Quality** section of this document.

Construction Impacts and Mitigation

Site preparation, construction, and startup of the proposed power plant and associated facilities would take approximately 42 months and would generate 3,177 cubic yards of solid nonhazardous and hazardous waste (HECA 2012e, Table 5.13-21). Staff was not provided a breakdown of types and quantities of nonhazardous waste that will be generated from the OEHI component to confirm that the project will not have an impact on Kern County. This data would be needed for staff to complete assessment of potential impacts.

Nonhazardous Wastes

The applicant has indicated that non-hazardous wastes would be recycled to the extent possible and nonrecyclable wastes would be collected by a licensed hauler and disposed of in a solid waste disposal facility, pursuant to Title 14, CCR, Section 17200 et seq.

The California Department of Resources Recycling and Recovery (now CalRecycle formerly California Integrated Waste Management Board (CIWMB)) is responsible for recycling, waste reduction, and product reuse programs in California. Officially known as the Department of Resources Recycling and Recovery, CalRecycle also promotes innovation in technology to encourage economic and environmental sustainability. Under the administration of CalRecycle the Integrated Waste Management Act requires jurisdictions such as Kern County to divert 50 percent of their waste from landfill disposal. Jurisdictions select and implement the combination of waste prevention, reuse, recycling, and composting programs that best meet the needs of their community while achieving the diversion requirements of the Act. SB 1016 (Stats. 2008, ch. 343) introduced a per capita disposal measurement system that measures the 50 percent diversion requirement using a disposal measurement equivalent. The 2008 California Green Building Standards Code Requires all construction projects to develop a recycling plan to divert and/or recycle at least 50 percent of waste generated during construction, (CalGreen Building Standards Code Section 708 construction Waste Reduction, Disposal and Recycling).

Adoption of Condition of Certification **WASTE-4** would facilitate proper management of project construction wastes. Condition of Certification **WASTE-4** requires the project owner to develop and implement a Construction Waste Management Plan. The plan would identify the type, volume, and waste disposal and recycling methods to be used during construction of the facility. Staff believes that compliance with the proposed condition of certification would also assist the applicant’s compliance with the CalGreen Building Code requirements. Staff believes this condition of certification would ensure construction wastes would be handled and disposed of in accordance with applicable LORS.

Nonhazardous liquid wastes would also be generated during construction, including sanitary wastes, dust suppression and stormwater drainage, and equipment wash and test water. Sanitary wastes would be collected in portable, self-contained chemical toilets and pumped periodically for disposal at an appropriate facility. Potentially contaminated equipment wash and/or test water would be contained at designated areas, tested to determine if hazardous, and either discharged to the storm water retention basin (if nonhazardous) or transported to an appropriate treatment/disposal facility. Please see the **Soil and Water Resources** section of this document for more information on the management of project wastewater.

Hazardous Wastes

Hazardous wastes that would likely be generated during construction of the HECA project include solvents, waste paint, oil absorbents, used oil, oily rags, batteries, cleaning wastes, spent welding materials, and empty hazardous material containers (HECA 2012e, Table 5.13-2).

The total volume of liquid hazardous wastes generated during construction is estimated to be approximately four million gallons (including sanitary waste). All liquid hazardous waste would be considered for recycling. Liquids not suitable for recycling would be taken to a suitable Treatment, Storage or Disposal Facility for disposal.
Both the construction contractor and the project owner/operator could be considered the generators of hazardous wastes at the site during the construction period. Because hazardous waste generator status is determined by site, the project owner would be required to obtain a unique hazardous waste generator identification number for the site prior to starting construction, pursuant to proposed Condition of Certification **WASTE-5**. Wastes would be accumulated on site for less than 90 days and then properly manifested, and transported to and disposed of at a permitted hazardous waste management facility by licensed hazardous waste collection and disposal companies.

Staff has reviewed the proposed waste management methods described in the Application for Certification (HECA 2012e, Table 5.13-2), and in the responses to data requests, and concludes that project construction wastes would be managed in accordance with all applicable LORS. Absent any unusual circumstances, staff considers project compliance with LORS during construction to be sufficient to ensure that no significant impacts would occur as a result of construction-related project waste management activities. To facilitate continuous project compliance with LORS during construction, staff proposes Condition of Certification **WASTE-6**, requiring the project owner to notify the CPM if and when the owner becomes aware of any HECA project waste management-related enforcement action being initiated or taken by a regulatory agency. Along with the notification, the project owner must also describe how the violation would be corrected and include a timeline for completion of the correction. In the event that construction excavation, grading, or trenching activities for the proposed project encounter potentially contaminated soils, specific waste handling, disposal, or other precautions may be necessary pursuant to hazardous waste management LORS. Staff also believes that proposed conditions of certification **WASTE-2** and **WASTE-3** would be adequate to address any soil contamination contingency that may be encountered during construction of the project and would further support compliance with LORS.

Operation Impacts and Mitigation

The proposed HECA project would generate 14,983 cubic yards per year (not including gasification solids) of nonhazardous and hazardous solid waste under normal operating conditions. Table 5.13-3 of the project AFC gives a summary of the anticipated operation waste streams, estimated waste volumes and generation frequency, and management methods proposed.

Nonhazardous Solid Wastes

Nonhazardous solid wastes generated during HECA project operation, excluding gasification waste, could include routine maintenance wastes (such as used air filters, scrap metal, and plastics) and concentrated process waste (salt cake from the Zero Liquid Discharge system (ZLD) and spent carbon monoxide (CO) oxidation catalysts from the air pollutant emissions control equipment), as well as domestic/sanitary and office wastes (such as office paper, newsprint, aluminum cans, glass, and septic system sludge) (HECA 2012e, Table 5.13-3).

Page 4.16-8 of Volume II of the amended AFC states that 4,000 tons per year of solid waste is disposed into solid waste landfills from EHOF during operation. The project owner does not anticipate a significant increase of solid (nonhazardous) waste generated from the OEHI component. Staff was not provided a breakdown of types and quantities of nonhazardous waste that will be generated from the OEHI component to confirm that the project will not have an impact. This information is needed for staff to complete assessment of potential impacts.

Each city, county, or regional agency with a CalRecycle-approved planning document (such as a Source Reduction and Recycling Element (SRRE) or a countywide regional agency Integrated Waste Management Plan) must submit an annual report to CalRecycle summarizing its progress in reducing solid waste as required by Public Resource Code (PCR) Section 41821. Kern County provides CalRecycle with an SRRE and an Integrated Waste Management Plan (IWMP). The SRRE sets forth a jurisdiction's basic strategy for management of solid waste generated within its borders, with emphasis on implementation of the SRRE.

Before operations can begin, the project owner should be required to develop and implement an Operation Waste Management Plan pursuant to proposed Condition of Certification **WASTE-7**. This would facilitate proper management of project operation wastes by requiring the applicant to identify the type and volume of waste, and waste disposal and recycling methods to be used, during operation of the facility. If nonhazardous waste is exported out of the state of California the applicant should be required to provide reports pursuant to Title 14, California Code of Regulations, Section 18808.9. A public contract hauler who exports solid waste from California shall provide the agency in which the waste originated with the total tons of solid waste exported from each jurisdiction of origin. Reporting in accordance with the proposed operation waste management plan would also provide the necessary information for Kern County to demonstrate compliance with IWMP as discussed above.

Liquid Wastes

Liquid wastes generated during operations include wastewater from the cooling tower blowdown, raw water treatment, gasifier condensate wastewater, sour water stripper, the Acid Gas Removal unit, and the Urea plant. Treatment and disposal of waste water is addressed in the **Soil and Water Resources** section of this document.

Hazardous Wastes

The project owner/operator would be considered the generator of hazardous wastes at the site during HECA operations. Therefore, the project owner’s unique hazardous waste generator identification number, obtained prior to construction in accordance with proposed Condition of Certification **WASTE-5**, would be retained and used for hazardous waste generated during facility operation.

Hazardous solid wastes that may be generated during routine project operation include oil filters and oily rags, spent Selective Catalytic Reduction (SCR) and oxidation catalysts, waste paint and empty containers, as well as universal wastes (batteries, fluorescent light tubes, and similar items) (HECA 2012e, Table 5.13-3). Should any HECA operations waste management-related enforcement action be taken or initiated by a regulatory agency, the project owner would be required by proposed Condition of Certification **WASTE-6** to notify the CPM whenever the owner becomes aware of any such action.

Staff has not been provided a breakdown of types and quantities of hazardous waste that will be generated from the OEHI project to confirm that the project will not have an impact. This information is needed for staff to complete assessment of potential impacts.

In addition, spills and unauthorized releases of hazardous materials or hazardous wastes may generate contaminated soils or cleanup materials that may require management and disposal as hazardous waste. Proper hazardous material handling and good housekeeping practices would help keep spill wastes to a minimum. However, to ensure proper cleanup and management of any contaminated soils or waste materials generated from hazardous materials spills, staff proposes Condition of Certification **WASTE-10**, which requires the project owner/operator to document, clean up, and properly manage and dispose of wastes from any hazardous materials spills or releases in accordance with all applicable federal, state, and local requirements.

The hazardous wastes would be temporarily stored on site, transported off site by licensed hazardous waste haulers, and recycled or disposed of at authorized disposal facilities in accordance with established standards applicable to generators of hazardous waste (Title 22, CCR, §66262.10 et seq.). Should any operations waste management-related enforcement action related to disposal of the gasification solids be taken or initiated by a regulatory agency, the project owner would be required by proposed Condition of Certification **WASTE-6** to notify the CPM whenever the owner becomes aware of any such action and provide information on how the violation(s) causing the enforcement action would be corrected.

Gasification Solids

The project would gasify petroleum coke (petcoke) or blends of petcoke and coal, as needed, to produce hydrogen-rich fuel for a combustion turbine operating in a combined cycle mode to produce electricity and sequester carbon dioxide in the EHOF. The blend of feedstock was based on the maximum performance guarantee the manufacturer provided HECA which is 25 percent petcoke and 75 percent coal (URS 2013 tn: 69172). Petcoke is a carbonaceous solid derived from the refining of heavy crude oils. The project would generate approximately 306,000 tons (271,584 cubic yards)[3] of gasification solids per year (HECA 2012e, Table 5.13-3). As proposed by the applicant, the gasification solids would either be sold or reused, or be disposed of as nonhazardous waste ((HEI 2009c, page 2-24).

The project owner suggests in the AFC that the gasification solids produced from the feedstock are excluded from hazardous waste regulations and requirements, per the exclusions in applicable federal and California regulations and requirements, (i.e., Title 40 of the Code of Federal Regulations (40 CFR) Section 261.4(b) (7) (ii) (F), and California regulations 22 CCR Section 66261.4(b) (5) (A). Kern County has indicated that although this exclusion applies they would still require the applicant to test and properly characterize the HECA project gasification solids prior to disposal in a Class III (solid/nonhazardous waste) landfill. The gasification solids generated at the HECA facility would be collected and accumulated on a concrete pad until transported. The facility would be covered with a roof and partial siding. The gasification solids handling system is described in **Data Responses A108, A109, A110, A111, A112, A113, and A114** (HECA 2012p).

The HECA project owner cannot conclusively demonstrate the nonhazardous nature of the HECA gasification solids. The project owner does expect the gasification solids to be nonhazardous based on available information from existing Integrated Gasification Combined Cycle (IGCC) facilities. The Applicant conducted a literature search to compile data on the composition and leachability of existing gasification solids. This information was then compared against Toxic Characteristic Leaching Procedure TCLP (federal) standards/thresholds. (Refer to **Waste Management Table 2**) The applicant provided data on four plants. Only one plant was located in California and that plant no longer exists. The applicant has proposed to provide information on the gasification solids characteristics after research has been conducted on similar facilities located in Japan. Staff requests that this information be provided prior to issuance of the FSA/FEIS.

[3] The tons of gasification waste numbers reflect the use of limestone fluxant.

The federal TCLP and California Waste Extraction Test (WET) are test methods used by the U.S. EPA and the California Department of Toxic Substances Control (DTSC) to determine whether a waste is a toxic hazardous waste (40 CFR Part 261). The purpose of the leaching tests is to obtain aqueous phase concentrations of constituents which are released from solids when placed in a land disposal unit. The tests are similar in that they both simulate what happens to waste in a landfill setting with simulated landfill leachates, and list chemical concentration thresholds (http://ccelearn.csus.edu/wasteclass/mod6/mod_05.html). The applicant states on page 5.13-12 of the HECA amended AFC that similar gasification wastes from the IGCC facilities outside of California have been determined to be nonhazardous based on federal leachate tests. The applicant has not determined the toxicity of the gasification waste using the California WET test. The main differences between TCLP and WET are in both the laboratory analysis methods used and the regulated chemicals that are tested. The California WET protocol is considered more aggressive than the federal method.[4] Therefore, given the more stringent California WET testing methods the concentrations of the constituents tested in **Waste Management Table 2** likely would have been higher and maybe exceed some California regulatory thresholds.

[4] A comparison between the Federal and California leachate testing protocol is summarized from information presented on the California Department of Toxic Substances Control web site (DTSC, 2010) as follows:
• The federal TCLP method (U.S. Environmental Protection Agency Method 1311) involves an 18-hour extraction (plus or minus 2 hours) with an acetate buffer solution. The ratio of extraction solution to sample is 20-to-1. The test simulates contaminant leaching of waste materials that are disposed with municipal solid waste in a landfill.
• The California WET protocol involves a 48-hour extraction with a citrate buffer solution (except for chromium-VI, for which the extraction solution is deionized water). The ratio of extraction solution to sample is 10-to-1 (URS Data Response 218, http://ccelearn.csus.edu/wasteclass/mod6/mod_05.html).

The final disposition of the gasification waste as either a Class I (hazardous) or Class III (non-hazardous) waste should be determined using the source of coal and petcoke and processing methods proposed for HECA operation prior to project construction so a strategy for management of the waste can be developed. Depending on the characterization of the waste there could be different potentially significant impacts related to the volume of waste and how it can be disposed. These impacts are further discussed below under impacts on existing waste disposal facilities. The testing can also be used to identify whether it is possible to reuse as a nonhazardous waste in commercial applications (e.g. cement products, soil amendment, etc.). Staff has also received a comment letter from Kern County (Kern County 2013d) expressing their concern about the characterization of the waste. They have requested that prior to acceptance of residual material from HECA at any public landfill, the project applicant is required to supply the Kern County Waste Management Department (KCWMD) a characterization of the waste for chemical and physical characteristics, and secure written approval from the Director of the KCWMD to ensure compatibility with landfill operations and fee schedules. Mitsubishi will operate a gasification pilot in Japan. Staff believes the results of these tests should be submitted prior to completion of the FSA so there is preliminary indication of whether the waste will be hazardous or non-hazardous. This will in turn affect what disposal options are available and whether there may be a market for the waste. This information is needed to evaluate what mitigation would be appropriate for the potential impacts.

If adequate preliminary characterization of the gasification solids can be conducted prior to the FSA staff would recommend the applicant be required to comply with Condition of Certification **WASTE-8,** which requires that the project owner perform ongoing tests to classify the waste and determine the appropriate method of disposal whenever there are any variations in source of fuel supply or changes in the percentages of fuel sources used during operation. This condition would also require that the applicant ensure there continues to be: 1) No impact to local landfills, 2) an ongoing market for the waste, 3) and they can continue to comply with Kern County and California state waste disposal requirements.

In rare cases, the zero liquid discharge (ZLD) sludge/solids could contain concentrations of chemicals that could be hazardous, depending on water quality and cooling system operation. To ensure proper disposal of the ZLD solids, staff proposes Condition of Certification **WASTE-9,** which requires that the project owner perform the appropriate tests to classify the waste and determine the appropriate method of disposal. All nonhazardous wastes would be recycled to the greatest extent possible and nonrecyclable wastes would be collected by a licensed hauler and disposed in a Class II solid waste disposal facility, in accordance with Title 14, California Code of Regulations.

Impact on Existing Waste Disposal Facilities

Nonhazardous Solid Wastes

The HECA project during operation would generate an extremely high volume of waste because of the gasification process. If the waste is generated or disposed in Kern County, the County's State-mandated diversion rates would be exceeded and the County would incur financial penalties from the State (CalRecycle) and increased costs for improvements made to local landfills. The project could dispose of 306,000 tons (271,584 cubic yards) per year of gasification solids and approximately an additional 15,000 tons (14,983 cubic yards) per year of miscellaneous operational waste in a Class III landfill (HECA 2012e, Table 5.13-3). The project owner proposes to reuse, reclaim or dispose of the gasification wastes in a landfill. The applicant is anticipating that the gasification waste would be classified as non-hazardous. **Waste Management Table 3** identifies four nonhazardous (Class III) and one Class II (designated)[5] waste disposal facilities located in Kern County that could potentially take the nonhazardous construction and operation wastes generated by the project. The remaining capacity for the four Class III landfill facilities combined is over 60 million cubic yards. The maximum amount of nonhazardous waste generated from project construction and operation (including gasification solids), 271,584 cubic yards (306,000 tons) assuming none is reused or recycled, would consume almost ten percent of the remaining landfill capacity of the Kern County Class III landfills during the life of the project.

Waste Management Table 3
Kern County Class III Landfills

Solid Recycling/Waste Disposal Site	Title 23 Class	Permitted Throughput (Daily Tonnage)	Permitted Capacity	Remaining Capacity	Estimated Closure Date
Taft Sanitary Landfill (Solid Waste Facility)[1]	Class III	419 tons per day	8.8 million cubic yards	6.7 million cubic yards	2123
Bakersfield Metropolitan Sanitary Landfill[1] Facility	Class III	4.5 thousand tons per day	53 million cubic yards	35 million cubic yards	2038
Shafter-Wasco Sanitary Landfil[1]	Class III	888 tons per day	11,6 million cubic yards	7.9 million cubic yards	2027
U.S. Borax, Inc Refuse Waste Pile[1]	Class III	443 tons per	8.5 million cubic yards	1.0 million cubic yards	2023
McKitrick Waste Treatment Site	Class II	1.2 thousand tons per day	2.1 million cubic yards	84.1 thousand cubic yards	2029
Chemical Waste Management Kettleman Hills Landfill	Class I	400 trucks per day	10.7 million cubic yards	<100 thousand cubic yards	2022

Sources: HECA AFC Table 5.13-1 and http://www.calrecycle.ca.gov/SWFacilities/Directory/Search.aspx
[1] Kern county owned public solid waste facilities. http://www.kerncountywaste.com/landfills-transfer-stations-bin-sites/landfills

[5] Class II landfills allow disposal of designated wastes determined by the Regional Water Quality Control Board (RWQCB) to be nonhazardous wastes, but which may contain soluble pollutants that could be released in concentrations exceeding applicable water quality objectives and could cause degradation of waters of the state. (Scott Walker and Robert Anderson)

Staff concludes that if the gasification waste is indeed determined to be nonhazardous as anticipated by the applicant, there could be a significant impact on Kern County or other nearby landfills. Prior to the FSA the applicant should submit the Japanese pilot project's gasification waste test results to staff, using the California Waste Extraction Test (WET) protocol. The WET test is more stringent than the federal TCLP and will be the test used once HECA is in operation. The applicant would also provide a draft Gasification Waste Diversion Plan (GWDP) in accordance with Condition of Certification **WASTE-8** that will outline the project's recycling, disposal and exportation strategies provided the preliminary waste characterization can be completed and demonstrate adequate mitigation strategies for disposal and marketing of the waste can be developed. If this is the case then staff would recommend the applicant be required to comply with condition of certification **WASTE-8** which requires that the project owner perform ongoing tests to classify the waste and determine the appropriate method of disposal whenever there are any variations in source of fuel supply or changes in the percentages of fuel sources used during operation. This condition would also require that the applicant ensure there continues to be: 1) No impact to local landfills, 2) an ongoing market for the waste, 3) and they can continue to comply with Kern County and California state waste disposal requirements
The KCWMD operates and owns several public solid waste facilities (See **Waste Management Table 3**). KCWMD is requesting that the HECA waste stream, including gasification waste if non-hazardous, be subdivided between several facilities to reduce the potential impacts to any one Kern County facility (Kern County 2013d). It may also be necessary for some of the waste to be transported out of the county or state.

The California Integrated Waste Management Act (Public Resources Code section 40000 et seq.) originally required all California cities, counties and approved regional solid waste management agencies responsible for enacting plans and implementing programs to divert 25 percent of their waste by 1995, 50 percent by 2000, and 75 percent by 2020 (http://www.calrecycle.ca.gov/). SB 1016 (Stats. 2008, ch. 343) introduced a per capita disposal measurement system that measures the 50 percent diversion requirement using a disposal measurement equivalent. SB 1016 uses a jurisdiction's population (or in some cases employment) and its disposal as reported by disposal facilities. Kern County's unincorporated jurisdiction's per capita disposal equivalent to a 50 percent diversion rate was set at 7.6 pounds (lbs)/person/day. Kern County's actual disposal rate for the unincorporated area is 5.7 lbs/person/day. The amount of waste generated and disposed of by the HECA project would increase the County's disposal rate by 48.5 percent, thus placing Kern County in potential non-compliance with mandated recycling goals (see **Waste Management Table 4**).

Waste Management Table 4
Disposal Rate (SB 1016)

Kern County (disposal cap)	7.6 lbs/person/day
Kern County (actual)	5.7 lbs/person/day
HECA Project (estimated generation)	5.36 lbs/person/day
HECA plus Kern County	11.56 lbs/person/day
Reference Kern County letter to Board of Supervisor, February 26, 2013	

To avoid regulatory non-compliance KCWMD and staff recommend the applicant undertake one or more of the following strategies:

- Recycle or reuse residual wastes as a beneficial use.

- Dispose of material and receive confirmation from CalRecycle that the waste material cannot be recycled and have Cal Recycle concurrence that the waste can be adjusted out of the jurisdictional reporting as disposal.
- Seek/receive legislative or regulatory exemption (Kern County 2013d).

Staff recommends condition of certification **WASTE-8**, which would require the applicant to identify how the waste can be disposed of and whether there are diversion methods that can be used to identify what the appropriate strategy would be for Kern County to maintain compliance with Public Resources Code section 40000 et seq.

Recycle/Reuse

Staff recommends recycling or reuse of the gasification solids to the greatest extent possible. Data Response A123 suggests that the applicant would complete and submit a white paper to the county on the reuse of the gasification solids (URS 2013, tn: 69339)[6]. HECA November 2009 Data Responses 28 and 115 discussed possible industries that would use the gasification solids, the list included: ready-mix concrete, cement manufacturing, aggregate application, Portland Cement Concrete or a sand-blasting application (November 2009). The data responses did not provide any indication or letters of commitment showing there is a market for the solids and how much would be used for any of the identified purposes.

The California Department of Transportation (Caltrans) could possibly provide potential mitigation for the 246,016 cubic yards of gasification solids. The Caltrans Cement Sub-Group of the California Climate Action Team (CAT) state on their website that Supplementary Cementitious Materials (SCMs) can reduce greenhouse gas (GHG) emissions. Common SCMs in use include slag, fly ash, silica fume, and calcined clay. Using two or more SCMs together with Portland cement is referred to as a ternary cement mix. Proper use of ternary mixes comprised of fly ash and slag can produce better quality concrete. Many of these mixes are being used for construction of the Bay Bridge project, but the fly ash and slag are being imported because of lack of domestic sources. Caltrans encourages the use of SCMs in Portland Cement Concrete (PCC). Staff addresses SCM in Data Requests A215, A216 and A217. The applicant has indicated the solids may not be useable for SCM because of the chemical composition. Staff believes it is premature to make this determination since there is no data on the specific chemical composition of the SCM. Staff believes a final determination of the use of the solids for SCM should be made once the applicant has completed testing. The physical and chemical characteristics of the gasification solids could determine whether the solid may be used as a SCM. The applicant should provide information on the chemical and physical properties of the gasification solids from the Mitsubishi pilot plant prior to the FSA to confirm if the solids are hazardous or non-hazardous. Staff points out that the final composition of the waste cannot be determined until the project is operational due to the potential variability of the fuel sources and petcoke to coal ratio during the operation of HECA. Staff needs the data from the test facility to further evaluate whether it is adequate to depend on for use as a starting point for analysis of potential impacts during future operating scenarios. Staff has also proposed Condition of Certification WASTE-8 which would also

[6] There are a number of waste management data requests related to waste diversion, Data Responses, A114, A115, and A116) to the reuse of the gasification solids. URS 2009j –URS/D. Shileikis (TN: 54054) Applicant's responses to CEC Data Requests Set 1, dated 11/11/09. Submitted to CEC/Docket Unit on 11/12/09.

require the applicant to conduct ongoing testing provided it can be shown impacts can be mitigated using result s of the initial testing.

Exportation of waste

The project owner also submitted the option of waste from the project being disposed out of state. Nonhazardous gasification solids that are not beneficially used would be transported by truck or rail to a Subtitle D solid waste disposal facility. The project owner anticipates using the following facilities when landfill disposal of the solids is required (HECA 2012p, Data Response A122):

- Clean Harbors Sawyer Landfill, USEPA ID: NDD000351270 in North Dakota.
- ECDC Environmental, L.C. Class V Landfill Permit 9433R1 in Utah.

There would be no impacts to the landfills located in North Dakota and Utah. Staff spoke with Steve Tillotson, Assistant Director, North Dakota Department of Health, Division of Waste Management and he stated that 277,000 tons per year of waste imported into North Dakota would not cause an impact the State or the Clean Harbors Sawyer landfill (Tillotson 2013). The ECDC Environmental solid waste landfill located in East Carbon Utah is located on 2,500 acres of land and has 382 million cubic yards of capacity. The landfill permit is renewed every ten years (Bohn 2013). The States of Utah and North Dakota confirmed that both would use 40 CFR§261.4(b): Exclusions: Solid Wastes which are Not Hazardous Wastes (7) ((ii) (F) Coal gasification to dispose of the gasification solids into solid waste (nonhazardous) landfills.

Although, the project owner proposes out-of-state disposal as an option the exported tonnage is applied to Kern County's waste disposal totals. Below is a quote from Melissa Vargas of CalRecycle (Vargas, 2013b):

> "…Even if it is a private business that is paying someone to haul its waste or if it is the private business itself self-hauling and in either circumstance they are hauling it from the point of generation and not from a solid waste facility, then they are involved in solid waste enterprise and solid waste handling. The rules still apply that they must report the exported tonnage and identify the jurisdiction of origin.
>
> Below are excerpts that address the definition of Disposal and the relationship with export tonnages.
>
> Definitions
> •"Disposal" means all solid waste from all sources within California jurisdiction boundaries, transported by all types of haulers (including self-haul) to Board-permitted disposal or transformation facilities.
> • "Disposal" also means: (1) all out-of-state solid waste from all sources, imported to Board-permitted disposal or transformation facilities, and (2) all solid waste originating from all sources within California jurisdiction boundaries and exported out of state.
>
> There could be several implications if we did not capture wastes exported, which include, but are not limited too:
>
> 1. CalRecycle could not effectively determine a Target or Annual pounds per person per day as it is based on disposal;

2. CalRecycle could not effectively determine if the wastes disposed contain recyclables material that could be diverted vs. disposed and ensure viability of markets;
3. CalRecycle staff would have a difficult time assessing programs;
4. Wastes exported vs. utilizing local landfills could impact financial viability of a City or County's programs and financial responsibility for landfill closure plans; and so on.

The following webpage provides information that addresses out-of-state waste disposal and includes the regulatory references: http://www.calrecycle.ca.gov/lgcentral/basics/DispRept.htm

Also, here is a link to the Regulations http://www.calrecycle.ca.gov/Laws/Regulations/Title14/ch9a92b.htm"

Staff believes the exportation of waste may be a viable means of waste diversion or disposal but the role it would play in maintaining compliance with Kern County waste diversion and volume requirements is currently uncertain. Staff recommends the applicant provide additional characterization information based on Mitsubishi gasifier currently operating in order to provide a better understanding of the potential options available for this project. Staff will discuss this issue further in the FSA/FEIS.

Hazardous Wastes

Less than 54 cubic yards of hazardous waste would be generated during the 42 month construction of the HECA facility and disposed of in a Class I Landfill. Hazardous wastes generated during operation would be 277 cubic yards per year. The applicant proposes to recycle these wastes to the extent possible and practical. Section 5.13 of the project AFC provides information on treatment, storage, or disposal facilities (TSDFs); landfills; recycling facilities; and transfer stations that could be used to manage project wastes. Any wastes that cannot be recycled would be transported off site to a permitted TSDF or landfill.

The Clean Harbors Buttonwillow Landfill in Kern County and the Chemical Waste Management Kettleman Hills Landfill in Kings County have approximately 10 million cubic yards of remaining hazardous waste disposal capacity at these landfills, with at least 30 years remaining in their operating lifetimes (HECA 2012e, Table 5.13-2).

Given the availability of recycling facilities for high volume hazardous wastes such as used oil and solvents, along with the remaining capacity available at Class I disposal facilities, staff concludes that the volume of hazardous waste requiring off-site disposal from the HECA project, as proposed by the applicant, would be far less than staff's threshold of significance if the gasification solids are determined to be non-hazardous. Under those circumstances, the proposed project would not significantly impact the capacity or remaining life of the available Class I waste facilities. However, although the applicant states in the AFC that similar gasification wastes from IGCC facilities outside of California have been determined to be nonhazardous based on federal leachate tests, it has not been demonstrated that the gasification waste from the proposed project would be found to be nonhazardous based on California's leachate testing protocol.

If the gasification solids are determined to be hazardous and all or most of the waste generated would need to be disposed of in Class I landfill facilities, the project could potentially pose a very significant impact to California Class I landfill capacity: The maximum annual gasification waste from the project would be 246,016 cubic yards and the annual production of other hazardous waste from the project would be approximately 277 cubic yards, for a potential total annual production of 246,516 cubic yards of hazardous wastes. Multiplying this annual amount by the twenty five year life of the project, the total impact to Class I facilities would be 6,162,900 cubic yards which is approximately 61percent of the existing 10 million cubic yard land fill capacity, far exceeding staff's criterion of 10 percent.

The final disposition of the gasification waste as either a Class I (hazardous) or Class III (non-hazardous) waste, and its possible reuse as a nonhazardous waste in commercial applications (e.g. cement products, soil amendment, etc.), should be determined by sampling and characterization, and by evaluating market potential. As discussed above, to ensure proper reuse or disposal of the gasification solids, staff needs the results of waste characterization tests from the Mitsubishi facility in Japan to evaluate whether the solids waste will be considered hazardous and if there are disposal methods that would ensure there are no impacts to local landfill capacity.

Diversion Program

The County has recommended the HECA project owner be required to compensate Kern County by paying a fee in addition to the gate/tipping fee for disposal. The money would be deposited in a Diversion Mitigation Reserve Account. The money from the Diversion Mitigation Reserve Account would fund Kern County diversion programs. The proposed fees are outlined in **Waste Management Table 5**:

Waste Management Table 5
Diversion Program Mitigation

Cost (dollars)	Tons per day
30	0 – 100 tons per day
50	101 – 200 per day
75	Greater than 200 tons per day

HECA has not responded to this request and it is unknown if the applicant would be willing to participate in the proposed program. Staff believes this program and its suitability as mitigation should be further discussed at a workshop prior to publication of the Final Staff Assessment and could be further defined in the GWDP recommended in Condition of Certification **WASTE-8**. Staff also notes that this program is intended for mitigation only if the waste is found to be nonhazardous.

CUMULATIVE IMPACTS AND MITIGATION

The California Environmental Quality Act (CEQA) Guidelines (Cal. Code Regs., Title 14 Section 15355) define cumulative effects as "two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts."

The Elk Hill Oil Field Legacy Waste Relocation is a project that would be considered with the OEHI CO_2 EOR and HECA wastes to determine possible cumulative impacts. The Department of Energy (DOE) has entered into a Corrective Action Consent Agreement with the Department of Toxic Substances Control (DTSC) for corrective measures for protection of the environmental and public health regarding the clean-up and/or remediation of several “legacy waste sites” within the former NPR-1 or the Elk Hills Oil Field (DTSC 2013). Prior to 1987, wastes were disposed of at several of the “legacy waste sites” throughout the EHOF. As a part of the Consent Agreement, the DOE proposes the relocation of previously disposed wastes from these sites to permitted Kern County facilities. This relocation is expected to begin in 2013 and continue through 2015 (Kern 2013). **Waste Management Table 6** lists the quantities and estimated dates of removal of waste from the EHOF legacy sites.

Waste Management Table 6
Elk Hill Oil Field Legacy Waste Relocation

Area of Concern	Date of Use	Waste Class	Weight (tons)	Estimated date of removal
60	1977-1987	Class II/III	4,500 -6,000	2013
65	1977-1987	Class II/III	18,500 to 25,000	2014/2015
95	1977 through 1987	Class II/III	45,000 to 50,000	2014/2015
104	Prior 1984	Class II/III	150	2013
108	Prior 1984	Class II/III	2,550	2013
109	Prior 1984	Class II/III	4,050	2013
98	1915-1940	Class II/III	150	2013

KCWMD staff is conferring with CalRecycle to verify that the NPR-1(Elk Hills Oil Field) relocated wastes should qualify for a modification from Jurisdictional Disposal Reporting Accounting. Furthermore, Statute (PRC sections 41031-41033, 41331-41333), Regulation (14 CCR sections 18722 et seq. and 18800 et seq.), and CalRecycle Policy allow for reporting yearly disposal tonnage modifications. The KCWMD staff proposes that the wastes relocated as a result of the DOE Consent Agreement should not be subject to the annual Disposal Reporting Accounting methods because these wastes were originally disposed of prior to 1987, and are being relocated for proper and safe disposal (Kern 2013). The relocation of the NPR-1 legacy waste, approximately 586,000 cubic yards, would use less than two percent of Kern County remaining landfill capacity. Also, if CalRecyle would allow a modification to the Kern County Jurisdictions Disposal Accounting, the County would not be affected by relocation of the legacy waste.

As proposed, the amount of nonhazardous and hazardous wastes generated during construction and operation of HECA and OEHI CO_2 EOR would add to the total quantity of waste generated in the region and State of California. The waste management impacts of the proposed project, in combination with past, present and reasonably foreseeable projects in the area would be cumulatively considerable The project has the potential to consume as much as ten percent of Kern County’s Class III landfill capacity. The large quantity of waste would significantly impact Kern County landfills and possibly compromise the county’s compliance with Public Resources Code section 40000 et seq and implementing regulations.

Condition of certification **WASTE-7** and **WASTE-8** would require the applicant to develop and implement an operation waste management plan and GWDP that would address waste diversion goals and identify appropriate waste disposal methods for HECA. These conditions would require the applicant to take all the necessary steps to ensure they mitigate any potential significant impacts.

Staff points out that some of the methods of waste disposal and how they are counted towards Kern County's waste diversion goals and per capita limit may require findings from Cal Recycle. Kern County could petition Cal Recycle to acknowledge that the waste material cannot be recycled and concur that the waste can be adjusted out of the jurisdictional reporting as disposal. Or Kern County may be required to seek and receive legislative or regulatory exemption for the jurisdictions disposal accounting.

Staff also recommends Kern County adopt and implement Mitigation Measure **WASTE - 2** for the OEHI EOR component which would require OEHI to consult with Kern County to develop a waste management and diversion plan that would ensure the county can maintain state compliance and mitigate potentially significant cumulative impacts from disposal of EHOF wastes and legacy waste sites.

COMPLIANCE WITH LORS

Energy Commission staff concludes that the proposed HECA project would comply with all applicable LORS regulating the management of hazardous and nonhazardous wastes during both facility construction and operation. The applicant would be required to recycle and/or dispose of hazardous and nonhazardous wastes at facilities licensed or otherwise approved to accept the wastes. Because hazardous wastes would be produced during both project construction and operation, HECA would be required to obtain a hazardous waste generator identification number from U.S. EPA. HECA would also be required to properly store, package, and label all hazardous waste; use only approved transporters; prepare hazardous waste manifests; keep detailed records; and appropriately train employees, in accordance with state and federal hazardous waste management requirements.

DOE'S FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the Applicant for the HECA Project. The Applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

RESPONSE TO PUBLIC AND AGENCY COMMENTS

Staff received comments from Kern County and the Department of Toxic Substances Control (DTSC). DTSC reviewed the HECA AFC, the Phase I ESA, and the Phase II ESA and determined that the proposed project site requires additional characterization and the project would require a Voluntary Cleanup Agreement (VCA) with DTSC for possible remediation of the proposed project site (DTSC 2013b).

The KCWMD determined that Kern County's State-mandated diversion rates would be substantially impacted due to the high volume of HECA project gasification solid waste. The amount of waste generated from the HECA facility would result in a significant increase in per capita disposal and reduce the diversion and recycling rate below the 50 percent State-mandate. KCWMD provided comments to the Kern County Board of Supervisors which outlined potential impacts and proposed mitigation for the HECA project.

Staff has proposed conditions of certification **WASTE-1**, **WASTE-2**, **WASTE-3**, **WASTE-4**, **WASTE-7** and **WASTE-8** to address site contamination, waste reporting requirements, and constituent test requirements.

CONCLUSIONS

Although the management of the nonhazardous and hazardous waste generated during construction and operation of HECA would comply with applicable waste management laws, ordinances, regulations, and standards provided that the measures proposed in the AFC and staff's proposed conditions of certification are implemented, HECA as currently proposed will cause a significant waste management impacts to Kern County. The project will produce a significant amount of operational waste and push Kern County into non compliance according to AB939 and SB1016.

To help ensure and facilitate ongoing project compliance with LORS, staff proposes conditions of certification **WASTE-1** through **10.** These conditions would require the project owner to do all of the following:

- Ensure that existing waste on the project site is identified and characterized, and that any contamination identified is remediated as necessary, with appropriate professional and regulatory agency oversight (**WASTE-1**, **2**, and **3**).
- Obtain a hazardous waste generator identification number (**WASTE-5**).
- Prepare Construction Waste Management and Operation Waste Management Plans detailing the types and volumes of wastes to be generated and how wastes would be managed, recycled, and/or disposed of after generation (**WASTE-4** and **7**).
- Report any waste management-related LORS enforcement actions and how violations would be corrected (**WASTE-6**).
- Ensure proper disposal of the gasification solids and ZLD salt cake (**WASTE-8** and **WASTE-9)**.

- **WASTE-7 and 8 a**re de**s**igned to decrease the project's impacts of waste disposal of the gasification solids on Kern County landfill capacity.
- Ensure that all spills or releases of hazardous substances are reported and cleaned-up in accordance with all applicable federal, state, and local requirements (**WASTE-10)**.

Existing conditions at the HECA project site include areas where prior site uses may have resulted in releases of hazardous substances or soil contamination. To ensure that the project site is investigated and remediated as necessary and to reduce any impacts from prior or future hazardous substance or hazardous waste releases at the site to a level of less than significant, staff proposes conditions of certification **WASTE-1**, **2**, **3**, **4**, **5** and **6**. These conditions would require the project owner to ensure that the project site is investigated and remediated as necessary; demonstrate that project wastes are managed properly; and ensure that any future spills or releases of hazardous substances or wastes are properly reported, cleaned-up, and remediated as necessary. Therefore, staff concludes that construction and operation of the proposed HECA project would not result in contamination or releases of hazardous substances that would pose a substantial risk to human health or the environment.

Regarding impacts of project wastes on existing waste disposal facilities, staff uses a waste volume threshold equal to ten (10) percent of a disposal facility's remaining capacity to determine if the impact from disposal of project wastes at a particular facility would be significant. The existing available capacity for the four Class III landfills that may be used to manage nonhazardous project wastes exceeds 56 million cubic yards. The HECA Project could pose a significant impact and could place the Kern County in jeopardy of non-compliance with mandated recycling goals. Conditions of Certification **WASTE-8**, **9** and **10** are proposed to decrease this impact.

As discussed in the **Socioeconomic Resources** section, the minority population in the six-mile buffer of the project site constitutes an environmental justice population as defined by Environmental Justice: Guidance under the National Environmental Policy Act. Staff has identified a significant adverse direct and cumulative impact resulting from the operation of the proposed project, but the impact does not significantly or adversely affect the identified environmental justice community. The direct and cumulative impact affects Kern County in regards to compliance with Public Resources Code section 40000 et seq. Therefore, there is no **WASTE MANAGEMENT** environmental justice issues related to this project and no environmental justice populations would be significantly, adversely, or disproportionately impacted.

OUTSTANDING INFORMATION REQUIRED FOR COMPLETION OF THE FSA/FEIS

1. Staff was not provided a breakdown of types and quantities of nonhazardous and hazardous waste that will be generated from the OEHI component of HECA to confirm that the project will not have an impact on Kern County landfills. This data would be needed for staff to complete an assessment of potential impacts

Staff needs the results of waste characterization tests in accordance with to Title 22, California Code of Regulations, Division 4.5, section 66262.10 on coal and petcoke mixes using the Mitsubishi gasifier in Japan using processing methods representative of those to be used for project operation. The purpose of the testing is to determine whether the gasification solids would be hazardous or non-hazardous. This information is needed to further evaluate how the waste can be disposed of and whether it is feasible to market the solids for other uses. The information should include a description of the waste stream, an evaluation of where the residual material is suitable for disposal, identification of facilities that would accept the volume of waste generated, a letter from the facility demonstrating they would accept the waste, and evidence the disposal of the waste would be in compliance with Kern County waste disposal requirements. If the project owner proposes to market the solids for use as Supplementary Cementitious Materials or other purposes, then a detailed report indicating what uses can be marketed and letters of intent from prospective purchases should be included.

2. The project owner should enter into an Agreement with DTSC for the purpose of fully characterizing and if necessary remediating the site property so that it is in the appropriate condition to allow for future use. In addition based on the type of agreement with DTSC the applicant should conduct the necessary site characterization to determine if site remediation is needed and if so what the scope of remediation would be prior to the FSA.

3. Staff needs information on additional waste streams that would result from the addition of the limestone fluxant such as total tons and cubic yards. The applicant shall also provide information on the increased amount of gasification solids in tons and cubic yards.

PROPOSED CONDITIONS OF CERTIFICATION

WASTE-1 The project owner shall prepare and submit to the CPM a Soils Management Plan (SMP) prior to any earthwork. The SMP must be prepared by a California Registered Geologist or a California Registered Civil Engineer with sufficient experience in hazardous waste management. The SMP shall be updated as needed to reflect changes in laws, regulations or site conditions. An SMP summary report, which includes all analytical data and other findings, must be submitted once the earthwork has been completed. Topics covered by the SMP shall include, but not be limited to:

- Land use history, including description and locations of known contamination.
- The nature and extent of previous investigations and remediation at the site.
- The nature and extent of unremediated areas at HECA.
- A listing and description of institutional controls, such as the County's excavation ordinance and other local, state, and federal regulations and laws that would apply to HECA.
- Names and positions of individuals involved with soils management and their specific role.

- An earthwork schedule.
- A description of protocols for the investigation and evaluation of historically related chemicals such as DDE and previously unidentified contamination that may be potentially encountered, including any temporary and permanent controls that may be required to reduce exposure to onsite workers, visitors and the public.
- Requirements for site-specific Health and Safety Plans (HSPs) to be prepared by all contractors at HECA. The HSP should be prepared by a Certified Industrial Hygienist and would protect onsite workers by including engineering controls, personal protective equipment, monitoring, and security to prevent unauthorized entry and to reduce construction related hazards. The HSP should address the possibility of encountering subsurface hazards including hazardous waste contamination and include procedures to protect workers and the public.
- Hazardous waste determination and disposal procedures for known and previously unidentified contamination.
- Requirements for site specific techniques at the site to minimize dust, manage stockpiles, run-on and run-off controls, waste disposal procedures, etc.
- Copies of relevant permits or closures from regulatory agencies.

Verification: At least 45 days prior to any earthwork, the project owner shall submit the SMP to the CPM for review and approval. The SMP shall also be submitted to the Sacramento office of the California Department of Toxic substances Control (DTSC) for review and comment. All earthworks at the site shall be based on the SMP. A SMP summary shall be submitted to CPM and DTSC within 25 days of completion of any earthwork.

WASTE-2 The project owner shall hire an experienced and qualified Professional Engineer or Professional Geologist with experience in remedial investigation and feasibility studies, which shall be available for consultation during site construction, excavation, and grading activities.

The Professional Engineer or Professional Geologist shall be given full authority by the project owner to oversee any earth moving activities that have the potential to disturb contaminated soil.

Verification: At least 30 days prior to the start of site mobilization, the project owner shall submit the resume showing the required experience to the CPM for review and approval.

WASTE-3 If potentially contaminated soil is identified during site construction, excavation, or grading at either the proposed site or along linear facilities, as evidenced by discoloration, odor, detection by handheld instruments, or other signs, the Professional Engineer or Professional Geologist shall inspect the site, determine the need for sampling to confirm the nature and extent of contamination, and provide a written report to the project owner, representatives of DTSC, and the CPM stating the recommended course of action.

The Professional Engineer or Professional Geologist shall have the authority to temporarily suspend construction activity at that location for the protection of workers or the public when the nature or extent of contamination warrants such suspension in the judgment of the Professional Engineer or Professional Geologist. If, in the opinion of the Professional Engineer or Professional Geologist, significant remediation may be required, the project owner shall contact the CPM and representatives of the Department of Toxic Substances Control for guidance and possible oversight.

Verification: The project owner shall submit any final reports filed by the Professional Engineer or Professional Geologist to the CPM within 5 days of applicant's receipt of reports. The project owner shall notify the CPM within 24 hours of any orders issued to halt construction.

WASTE-4 The project owner shall prepare a Construction Waste Management Plan for all wastes generated during construction of the facility, and shall submit the plan to the CPM for review and approval. The plan shall contain, at a minimum, the following:

- a description of all construction waste streams, including projections of frequency, amounts generated, and hazard classifications;
- management methods to be used for each waste stream, including temporary on-site storage, housekeeping and best management practices to be employed, treatment methods and companies providing treatment services, waste testing methods to assure correct classification, methods of transportation, disposal requirements and sites, and recycling and waste minimization/source reduction plans;
- a method for collecting weigh tickets or other methods for verifying the volume of transported and or location of waste disposal; and,
- a method for reporting to demonstrate project compliance with construction waste diversion requirements of 50 percent pursuant to the CalGreen Code Section 708 construction Waste Reduction, Disposal and Recycling.

Verification: The project owner shall submit the Construction Waste Management Plan to Kern County for review and the CPM for review and approval no less than 30 days prior to the initiation of construction activities at the site.

WASTE-5 The project owner shall obtain a hazardous waste generator identification number from the United States Environmental Protection Agency prior to generating any hazardous waste during construction and operations.

Verification: The project owner shall keep a copy of the identification number on file at the project site and provide documentation of the hazardous waste generation and notification and receipt of the number to the CPM in the next scheduled Monthly Compliance Report after receipt of the number. Submittal of the notification and issued number documentation to the CPM is only needed once unless there is a change in ownership, operation, waste generation, or waste characteristics that requires a new notification to USEPA. Documentation of any new or revised hazardous waste generation notifications or changes in identification number shall be provided to the CPM in the next scheduled compliance report.

WASTE-6 Upon notification of any impending waste management-related enforcement action related to project site activities by any local, state, or federal authority, the project owner shall notify the CPM of any such action taken or proposed against the project itself, or against any waste hauler or disposal facility or treatment operator with which the owner contracts for the project, and describe the owner's response to the impending action or if a violation has been found, how the violation would be corrected.

Verification: The project owner shall notify the CPM in writing within 10 days of receiving written notice from authorities of an impending enforcement action. The CPM shall notify the project owner of any changes that would be required in the way project-related wastes are managed as a result of a finalized action against the project.

WASTE-7 The project owner shall submit an Operation Waste Management Plan to the Compliance Project manager (CPM) for review and approval. The plan shall contain, at a minimum, the following:

- A detailed description of all operation and maintenance waste streams, including projections of amounts to be generated, frequency of generation, and waste hazard classifications;
- Management methods to be used for each waste stream, including temporary on-site storage, housekeeping and best management practices to be employed, treatment methods and companies providing treatment services, waste testing methods to assure correct classification, methods of transportation, disposal requirements and sites, and recycling and waste minimization/source reduction plans;
- Information and summary records of conversations with the local CUPA and DTSC regarding any waste management requirements necessary for project activities. Copies of all required waste management permits, notices, and/or authorizations shall be included in the plan and updated as necessary;
- A section incorporating the Gasification Waste Diversion Plan;
- A detailed description of how facility wastes would be managed, and any contingency plans to be employed, in the event of an unplanned closure or planned temporary facility closure; and
- A detailed description of how facility wastes would be managed and disposed of upon closure of the facility.

Verification: The project owner shall submit the Operation Waste Management Plan to the CPM for approval no less than 30 days prior to the start of project operation. The project owner shall submit any required revisions to the CPM within 20 days of notification from the CPM that revisions are necessary. The project owner shall also document in each Annual Compliance Report the actual volume of wastes generated and the waste management methods used during the year; provide a comparison of the actual waste generation and management methods used to those proposed in the original Operation Waste Management Plan; and update the Operation Waste Management Plan as necessary to address current waste generation and management practices.

WASTE-8 During project operation the project owner shall periodically conduct waste characterization tests in accordance with Title 22, California Code of Regulations, Division 4.5, section 66262.10 on all coal and petcoke mixes being used for operation. The purpose of the testing is to determine whether the gasification solids would be hazardous or non-hazardous and if there is a change in characteristics when the source of coal or petcoke changes or the percentages used for power generation are changed. This information would also be used to develop a Gasification Waste Diversion Plan (GWDP) that would identify how and where the wastes would be disposed and whether it is feasible to market the solids for other uses. The GWDP would be submitted to Kern County for review and comment and the CPM for review and approval. The GWDP shall include a description of the waste stream, an evaluation of where the residual material is suitable for disposal, identification of facilities that would accept the volume of waste generated, a letter from the facility demonstrating they would accept the waste, and evidence the disposal of the waste would be in compliance with Kern County waste disposal requirements. If the project owner proposes to market the solids for use as Supplementary Cementitious Materials or other purposes, then a detailed report indicating what uses can be marketed and letters of intent from prospective purchases should be included. The test results, and method and location of gasification solid disposal shall also be reported in the Annual Compliance Report required in Condition of Certification **WASTE-7.**

Verification: The project owner shall provide to the CPM 60 days prior to operation for review and approval a report detailing the general and chemical characteristics of the gasification solids after test runs of the plant with the planned fuel mixture have been completed. The project owner shall also provide an initial GWDP developed based on data from preliminary waste characterization tests and a preliminary plan for solids disposal and marketing based on these test results. The project owner shall provide to the CPM 60 days prior to a change in the fuel mixture or fuel source, a plan showing the proposed changes and a discussion of the anticipated changes in character of the waste solids and any new information that may be available indicating there would be no significant change in the waste character for CPM review and approval. The project owner shall provide to the CPM within 30 days a report summarizing the results of waste characterization tests and indicate whether they can continue to be disposed of as indicated in the GWDP or whether the GWDP should be updated to address new information. If the GWDP must be updated a draft GWDP shall be submitted to the CPM for review within 60 days of notification by the CPM.

WASTE-9 The project owner shall ensure that the Zero Liquid Discharge (ZLD) salt cake is tested pursuant to Title 22, California Code of Regulations, Division 4.5, section 66262.10 and report the findings to the CPM. The handling, testing, and disposal methods for sludge shall be identified in the Operation Waste Management Plan required in Condition of Certification **WASTE-7**.

Verification: The project shall report the results of ZLD salt cake testing to the CPM within seven days of sampling. If two consecutive tests show that the salt cake is non-hazardous, the project owner may apply to the CPM to discontinue testing. The test results and method and location of ZLD salt cake shall also be reported in the Annual Compliance Report required in Condition of Certification **WASTE-7**.

WASTE-10 The project owner shall ensure that all accidental spills or unauthorized releases of hazardous substances, hazardous materials, or hazardous waste are documented and remediated, and that wastes generated from the accidental spills and unauthorized releases are properly managed and disposed of in accordance with all applicable federal, state, and local requirements.

Verification: The project owner shall document management of all accidental spills and unauthorized releases of hazardous substances, hazardous materials, and hazardous wastes that occur on the project property or related linear facilities. The documentation shall include, at a minimum, the following information: location of release; date and time of release; reason for release; volume released; how release was managed and material cleaned up; amount of contaminated soil and/or cleanup wastes generated; if the release was reported; to whom the release was reported; release corrective action and cleanup requirements placed by regulating agencies; level of cleanup achieved and actions taken to prevent a similar release or spill; and disposition of any hazardous wastes and/or contaminated soils and materials that may have been generated by the release. A copy of the accidental spill or unauthorized release documentation shall be provided to the Compliance Project manager (CPM) within 30 days of the date the release was discovered.

RECOMMENDED MITIGATION MEASURES

The applicant will work with DTSC to implement recommended **Waste Mitigation Measure 1.**

WASTE-1 OEHI shall keep DOE and DTSC informed of construction areas and implement all appropriate and applicable safety measures and LORS to limit employee and contractor exposure to hazardous materials.

The applicant will work with Kern County to implement **Waste Mitigation Measure-2**.

WASTE-2 The OEHI EOR project owner shall consult with Kern County to develop a waste management and diversion plan that would ensure the county can maintain state compliance and mitigate potentially significant cumulative impacts from EHOR legacy landfills.

WATER SUPPLY

Mike Conway, PG, John Fio, and Steve Deverel, PG

SUMMARY OF CONCLUSIONS

Staff is supportive of projects that use degraded water supplies. The Buena Vista Water Storage District (BVWSD) service area is known to be impacted by shallow, and in some cases, saline ground water. Removal of water within the district that has limited use, or may improve crop productivity, would be supported by staff for use in power plant cooling.

Staff was unable to obtain geologic reports that were prepared for Buena Vista Water Storage District (BVWSD) specifically to evaluate the impact of the proposed water supply. Much of the data that staff had sought was relied upon to produce the original Application for Certification (AFC) Hydrogen Energy California (08-AFC-8), however this data is still relevant to the current proceeding (08-AFC-8A) because the proposed project's water supply has not changed significantly. Staff Data Request 103, dated October 12, 2009, states, "Please provide a copy of the completed document, or most recent draft, of the following report: "An Evaluation of the Geology, Hydrology, Well Placements and Potential Impacts of the Buena Vista Water Storage District's proposed Brackish Groundwater Remediation Project", prepared by Sierra Scientific Services, Bakersfield, California, dated 2009." BVWSD has indicated in their Final Environmental Impact Report for the Brackish Groundwater Remediation Program (BGRP) that this and other supporting reports provide the scientific basis for development of the proposed water supply through the BGRP. The Kern Water Bank Authority, Sierra Club, and the California Department of Water Resources have also independently inquired about this report as well and have not received a copy that we are aware of. Without these reports or other substantial data, staff could not evaluate how BVWSD and the applicant analyzed the potential impacts and feasibility of the proposed water supply. Since these reports were not made available, staff conducted an independent assessment.

Staff conducted a workshop on February 20, 2013, to discuss the preliminary results of the independent assessment of the proposed project water supply. Staff expended a considerable amount of time and effort analyzing the available information and repeatedly requesting the additional information to substantiate the applicant's conclusions related to water supply impacts. Staff's conclusions are presented below. At the workshop BVWSD indicated they have additional data that was not considered in staff's analysis. They offered to provide additional information and requested staff reanalyze the potential project impacts. BVWSD indicated some data is confidential and requested that staff work directly with BVWSD to obtain the data and ensure it is protected in accordance with state law. Staff agreed and transmitted data requests to BVWSD on March 21, 2013. Staff has not received the data or met with BVWSD since the workshop and is awaiting the data for further analysis in a revised staff assessment. Much of the analysis presented below is the same or similar to that presented in the draft preliminary staff assessment at the workshop.

On March 19, 2013, BVWSD also submitted a detailed comment letter on the technical merits of the draft preliminary analysis. Many of the comments relied on interpretation of data that is not available to staff. Staff will address these comments in a future revision of the staff assessment once the data has been received.

Based on a preliminary assessment of the proposed Hydrogen Energy California (HECA) project, the California Energy Commission (Energy Commission) staff preliminarily concludes that development of the project's proposed industrial water supply could result in the following without further analysis:

1. ***The project pumping could result in well interference and lower water levels in neighboring wells.***
   The applicant utilized a three-dimensional numerical groundwater-flow model and superposition to simulate the proposed well field and quantify water level drawdown due to project pumping. The applicant's model simulated drawdown values at select well locations that range from -0.7 to 12.0 feet; drawdown less than zero indicate that as a result of simulated recharge water levels increase during the 25-year simulation period. However, staff believes the model incorrectly includes simulated recharge, ignores potentially relevant boundaries, and may use inappropriate parameter values. Staff modifications to correct and test the model increased simulated drawdown. A worst-case simulation showed that drawdowns range between 5.1 and 34.2 feet.

   Staff employed a significance threshold of 15-feet for well interference. Simulated drawdown by the applicant's model did not exceed the threshold at any well locations considered. However, simulated drawdown by the modified model (no-flow boundary added and no recharge) exceeded the threshold at one location. Additional model tests conducted by staff indicate the drawdown threshold was exceeded at one location using the above staff-modified model with reduced storativity (0.007), and the threshold was exceeded at 13 well locations using the staff-modified model with reduced storativity and increased anisotropy. These results indicate there is uncertainty in the magnitude and scope of potential well interference due to uncertainty in hydrogeologic conditions.

2. ***The proposed industrial supply wells may induce the inflow of relatively poor quality groundwater into a zone of relatively higher water quality within the water-supply aquifer beneath the Buttonwillow Service Area.***
   Staff cannot verify that the project's proposed well configuration protects water quality beneath the Buttonwillow Service Area. The proposed industrial supply wells may induce the inflow of relatively poor quality groundwater into a zone of relatively higher water quality within the water-supply aquifer beneath the Buttonwillow Service Area. The depth to the base of freshwater beneath the well field is about 700 feet, and up-coning of the underlying salt water is a potentially important factor affecting inflow of salt into the pumped zone. The applicant's model indicates a substantial proportion of extracted groundwater (58-percent) likely would originate at depths below the proposed extraction wells. The staff-modified model with reduced storativity and increased anisotropy simulates a lesser proportion (15-percent). For example, assuming a minimum salinity for brackish groundwater of 2,000 mg/L, the staff-modified groundwater-flow model results suggest a new salt load in this up-coning that may be 15,400 tons per year. Because the underlying salt water has a different composition from the overlying groundwater, the up-coning may potentially

increase TDS concentrations in the local water supply aquifer and shift the water from a calcium-sulfate to sodium-chloride dominated water.

Staff provides this data to show that the quantification of the proposed water quality benefit to the region from the BGRP must include a budget that shows the proportions of water sources from the reportedly higher salt loads beneath the wells.

3. ***The project's pumping could exacerbate overdraft in the Kern County subbasin.***
   Observed water levels in wells spanning the period 1974-2001 show a statistically significant upward trend at the 95 percent confidence level. The significant upward trends range from 0.28 feet per year (ft/yr) to 1.27 ft/yr. The average trend suggests the annual increase in groundwater storage beneath Buena Vista Water Storage District's Buttonwillow Service Area ranged from about 4,600 to 6,100 AF/yr (assumed specific yield values ranging from 0.15 to 0.20, respectively). The geometric mean storativity from local aquifer test results (0.007) is substantially lower than the applicant's assumed specific yield, and estimated groundwater storage changes may therefore be considerably less than 4,600 to 6,100 AF/yr. The planned well field extraction rate (7,500 AF/yr) may therefore exceed the annual storage increase characterized by historical water level trends.

4. ***The project pumping could reverse local water level increases and increase the threat to the California Aqueduct from subsidence.***
   If the proposed well field extraction indeed exacerbates overdraft in the Kern County subbasin, staff's analysis indicates it could also exacerbate subsidence in areas near the California Aqueduct. There is no historical evidence for subsidence in the Buttonwillow Service Area or immediate vicinity of the proposed well field. However, the Buttonwillow Service Area is located adjacent to two major historic subsiding areas in the southern San Joaquin Valley. Observed Buttonwillow Service Area groundwater level data indicate water levels have increased on average since 1970; however if pumping causes these trends to reverse and water levels decline below historical lows it could increase the risk of land surface subsidence.

5. ***The project use of the proposed water supply may not be consistent with Energy Commission and other state water policies.***
   Staff conducted several methods of analysis to estimate the expected TDS concentrations in water produced by extraction wells operating in the proposed well field. The results indicated an expected concentration range from 945 mg/L to 3,730 mg/L. This range in concentrations suggests water of sufficient quality for other beneficial uses may be produced during pumping from the proposed well field. Staff notes that the proposed power plant would use water at an extremely high rate, primarily for evaporative cooling. Staff also cannot verify that the proposed groundwater for use is the worst water quality available, or that the use satisfies state and Energy Commission policies regarding the use and conservation of water resources. Staff is therefore unable to verify that the proposed groundwater pumping for industrial cooling is reasonable.

   Alternative water supplies have not been adequately evaluated by the applicant. In staff Data Request 97 dated October 12, 2009, staff initially introduced this issue. Staff issued 11 Data Requests on November 12, 2010, again inquiring about water supply and alternatives. In a staff Issues ID Report from July 10, 2012 staff reiterated that water supply alternatives that appear to be feasible are sources of shallow, degraded groundwater to the north of the proposed well field, other well field construction and pumping configurations, or surplus water from the Elk Hills oil field operation. These or other alternatives should be evaluated in detail to ensure there is no other environmentally desirable or economically feasible supply.

6. ***Staff cannot verify a persistent source of saline water flowing eastward towards the Buttonwillow Service Area.***
   The applicant contends that the source of saline water impacting the district originates in the Temblor Range west of the Buttonwillow Service Area. Staff cannot verify a persistent source of saline water flowing eastward. Though waters of elevated salt concentrations exist in the Buttonwillow Service Area, its source cannot be verified. Staff shows for example how significant the contribution of more saline water beneath the well could be relative to water from the west. Local agricultural management practices also have significant influence on groundwater quality, which make determination of the source of salts additionally difficult. Geologic depositional environment may also have influence on the character of the soil and groundwater in the area. Staff considers the identification of the source of salts an important piece of the foundation of a remediation program. A 25-year or longer remediation pumping program should adequately identify the location, mass, and mobility of a contaminant source, not just its assumed present location.

7. ***Applicant dismisses potentially feasible water alternatives because proposed use is so high.***
   An extremely high water demand of the proposed project is cited by the applicant as reason to eliminate many otherwise feasible alternative supplies. Water alternatives dismissed by the applicant such as municipal wastewater from Bakersfield, oil field wastewater, or BVWSD Target Area A water, were eliminated because they can't supply the proposed project's entire water supply. However it is unreasonable to dismiss all of these options when any one of them could provide up to 50 percent of the project's water needs.

   In light of the project potential impacts to water resources, alternative water supplies should be considered. A high water use scenario should not preclude consideration of alternate water sources.

UNRESOLVED ISSUES

INDUSTRIAL WATER SUPPLY

A fundamental requirement for a power plant licensed by the Energy Commission is to demonstrate that the proposed water use is reasonable relative to current technology and regional and state water needs. In essence, staff believes that a power plant must demonstrate that its use constitutes the least amount of the most degraded source available.

The project's most significant unresolved issue in terms of the industrial water supply is a failure to demonstrate that the project uses the least amount of the worst quality water available. Furthermore, seemingly reasonable alternative water supplies are not given rigorous consideration. For example, BVWSD's Final Environmental Impact Report (FEIR) describes that the second phase of their proposed Brackish Groundwater Remediation Program (BGRP) could provide up to 4,500 AF/y of brackish groundwater. The water source is shallow groundwater that is already problem water and impacting crop type and yield. Accordingly, this alternative source is worthy of consideration for at least some portion of industrial supply water for the HECA plant. In light of this potentially superior alternative, staff expects a more thorough analysis of its viability. Staff will prepare an independent analysis of the feasibility of using additional sources of water produced by the BGRP, in addition to the proposed supply.

The applicant has also neglected to adequately consider a dry-cooled project alternative. As stated in this analysis, in some cases the impact to water resources may be proportional to the volume pumped, and likewise, any decrease in water use could contribute to a lessening of the impact, proportional to the decrease. It is reasonable to consider dry cooling to reduce the potential project's water consumption, even if it would not reduce such consumption to zero. Dry cooling has the potential to: a) reduce project water demand to roughly 17-percent of the currently proposed amount, and thereby b) reduce water costs by approximately $70,000,000 over a 25-year period.

Applicant responses to staff inquiries about dry cooling, including Data Response 203, January 2013, rely on references that don't reflect the current state of power plant development n California, and do not consider project and site specific conditions. Since the data responses have been inadequate for staff to complete an analysis of the feasibility of dry-cooling, staff will prepare an independent analysis for the Final Staff Assessment.

As discussed above, the project's current industrial supply well field could create three significant impacts.

1. The project's pumping could exacerbate overdraft in the Kern County subbasin.
2. The project's pumping could potentially induce a significant proportion of degraded water to move into the local water-supply aquifer, further degrading local water supplies.
3. The project's pumping could also reverse local water level increases and increase the threat to the California Aqueduct from subsidence.

Staff has provided preliminary conditions of certification that can be used to mitigate potential impacts from basin overdraft, well interference, and subsidence. However, these conditions are only applicable if it can be shown through further analysis that potential groundwater quality impacts identified herein are not a concern. In addition, given staff's current conclusions, a more rigorous analysis of alternatives must be conducted to show there is no other economically feasible and environmentally desirable water supply available consistent with Energy Commission and other state water policy.

INTRODUCTION

This section of the Preliminary Staff Assessment (PSA) analyzes potential impacts to water resources from the construction and operation of the Hydrogen Energy California

(HECA) project. Where the potential of a significant impact is identified, staff proposes mitigation to reduce the significance of the impact and, as appropriate, recommends conditions of certification.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS (LORS)

The following federal, state, and local environmental LORS were established for the HECA project and similar facilities to ensure the best and appropriate use and management of water resources. Additionally, the requirements of these LORS are specifically intended to protect human health and the environment. The potential for project compliance with these LORS is a major component of staff's determination regarding the significance and acceptability of the HECA project with respect to the use and management of water resources.

Water Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Federal LORS	
-	-
State LORS	
California Constitution, Article 10, Section 2, and California Water Code (CWC), Section 100	These laws require that the water resources of the state be put to beneficial use to the fullest extent possible and that the waste, unreasonable use or unreasonable method of use of water be prevented. The laws also require that conservation of such water be exercised with a view to the reasonable and beneficial use of the water in the interest of the people and for the public welfare.
CWC, Division 7, Section 13000 et seq. — Porter-Cologne Water Quality Control Act	The Porter-Cologne Water Quality Control Act (Porter-Cologne) was established to protect the water quality and beneficial uses of waters of the state. The law gives broad authority to the State Water Resources Control Board (SWRCB) and nine Regional Water Quality Control Boards (RWQCBs) to establish water quality standards and discharge prohibitions, issue waste discharge requirements, and implement provisions of the federal Clean Water Act. Under Porter-Cologne, "waters of the state" include both surface and groundwaters.
CWC, Sections 13240, 13241, 13242, 13243, & Water Quality Control Plan for the Sacramento and San Joaquin River Basin – Region 5 (Basin Plan)	The Basin Plan establishes the beneficial use designations and water quality objectives for surface water and groundwater in the Central Valley Region. It also describes implementation plans and measures necessary to achieve standards and ensure compliance with both regional and statewide water quality plans and policies; and acts as the comprehensive water quality planning document for the Central Valley Region.
CWC, Section 13550	This section of Porter-Cologne establishes that the use of potable domestic water for non-potable uses (including industrial use) is a waste or an unreasonable use of the water if recycled water is available and meets the following conditions: the quality and quantity of the reclaimed water are suitable for the use; the cost is reasonable; the use is not detrimental to public health; and the use will not impact

	downstream users or biological resources.
CWC, Sections 231 and 13700 et seq.	Section 231 and Division 7, Chapter 10 of the Water Code establish the authority for development and implementation of minimum water well standards for the state. Minimum standards for the construction and destruction of water wells are established in Bulletins 74-81 and 74-90, California Well Standards, by the California Department of Water Resources (DWR). A well completion report must be filed with DWR for each well that is constructed, reworked, or destroyed.
Title 17, California Code of Regulations (CCR), Division 1, Chapter 5	This chapter of the CCR addresses the requirements for backflow prevention and cross connections of potable and non-potable water lines.
Title 22 , CCR, Division 4 — Environmental Health	Title 22, Division 4 is implemented by the California Department of Public Health (CDPH) (formerly known as the California Department of Health Services). The regulations address requirements for drinking water standards, water treatment and operator certification, and water recycling criteria. Section 64431 establishes the public drinking water maximum contaminant levels (MCLs), including an MCL for nitrate of 45 mg/L (equivalent to 10 mg/L for nitrate as nitrogen). Section 64449 establishes secondary drinking water standards, including a recommended total dissolved solids (TDS) level of 500 mg/l, with an upper limit of 1,000 mg/l, and a short term level of 1,500 mg/l. Article 3 also requires monitoring of potable water wells defined as non-transient, non-community water systems (serving 25 people of more for more than six months).
The Safe Drinking Water and Toxic Enforcement Act of 1986, Health and Safety Code 25241.5	Prohibits discharge of chemicals known to cause cancer or reproductive toxicity into drinking water sources.
Local LORS	
Kern County General Plan-Land Use Element: Resource Goals, Objectives, and Policies Policy LU 1.4.5	Ensures that an adequate water supply is available for industrial uses.
State Policies and Guidance	
State Water Resources Control Board Resolution No. 68-16	The “Antidegradation Policy” mandates that: 1) existing high quality waters of the state are maintained until it is demonstrated that any change in quality will be consistent with maximum benefit to the people of the state, will not unreasonably affect present and anticipated beneficial uses, and will not result in waste quality less than adopted policies; and 2) requires that any activity which produces or may produce a waste or increased volume or concentration of waste and which discharges or proposes to discharge to existing high quality waters, must meet WDRs which will result in the best practicable treatment or control of the discharge necessary to assure that: a) a pollution or nuisance will not occur and b) the highest water quality consistent with maximum benefit to the people of the state will be maintained.

SWRCB Resolution No. 75-58 — Water Quality Control Policy on the Use and Disposal of Inland Waters Used for Power Plant Cooling (adopted June 19, 1975).	This SWRCB policy specifically addresses the use of inland waters for power plant cooling. The policy states that fresh inland waters should only be used for power plant cooling if other sources or other methods of cooling would be environmentally undesirable or economically unsound. The policy establishes a general hierarchy for cooling water whereby the lowest quality water reasonably available is to be utilized for evaporative cooling processes. It also includes cooling water discharge prohibitions.
SWRCB Resolution No. 88-63 —Sources of Drinking Water Policy (Revised by Resolution 2006-0008)	This policy states that all surface and groundwaters of the state are considered to be suitable, or potentially suitable, for municipal or domestic water supply, and should be designated as such by the RWQCBs, with the exception of certain waters (such as contaminated sources or process wastewaters), or waters that exceed 3,000 mg/L total dissolved solids (TDS).
State Water Resources Control Board Resolution No. 2005-0006	Adopts the concept of sustainability as a core value for State Water Board programs and directs its incorporation in all future policies, guidelines, and regulatory actions.
The 2003 California Energy Commission *Integrated Energy Policy Report (IEPR)*	The *2003 IEPR* was developed and adopted pursuant to Public Resources Code sections 25301 and 25302. It includes a water and wastewater policy stating that the Energy Commission will approve the use of fresh water for cooling purposes by power plants it licenses only where alternative water supply sources and alternative cooling technologies are shown to be "environmentally undesirable" or "economically unsound." In addition, the policy states that the Energy Commission will also require that zero-liquid discharge technologies be used to manage project wastewater unless such technologies are shown to be "environmentally undesirable" or "economically unsound."

PROPOSED PROJECT

SETTING AND EXISTING CONDITIONS

The proposed Hydrogen Energy California (HECA) project would be constructed on a 453-acre site located seven miles west of Bakersfield and a mile and half northwest of Tupman, western Kern County. The site is contained within Section 10 of Township 30 South, Range 24 East. The site is also just north of the West Side/Outlet Canal, the Kern River Flood Control Channel, and the California Aqueduct. Agriculture is the primary land use at the site and local vicinity; onions, cotton, and alfalfa are currently being cultivated on the proposed project site. The project site is approximately 285 feet above mean sea level (amsl) (HECA 2012b).

The proposed project would require extensive construction and groundwater pumping in close proximity to the California Aqueduct. The proposed power plant would be built within 0.5 miles of the aqueduct and the proposed groundwater supply would be pumped within approximately 2 miles of the aqueduct. The California Aqueduct is a significant conveyance component of the State Water Project (SWP) managed by the California Department of Water Resources, which begins at the Sacramento-San

Joaquin River Delta and continues south through the Central Valley, over the Tehachapi Mountains, and into southern California. The State Water Project provides a water supply for up to 23 million Californians and up to 755,000 acres of irrigated agriculture and is a vital water supply for many southern Californians. This analysis pays particular attention to impacts to the California Aqueduct (HECA 2012b).

The HECA project would be built along the west side of the San Joaquin Valley river basin, contained between the Coast Ranges to the west, the Emigdio and Tehachapi Mountains to the south, and the Sierra Nevada to the East. The proposed site is approximately two miles north of the Elk Hills oil field, the location of proposed carbon dioxide injection related to the project. The Elk Hills form the surface expression of an anticline composed of gravel and mudstone (HECA 2012b).

The site is located within the Kern County groundwater subbasin of the San Joaquin Valley Basin. The subbasin covers almost 2,000,000 acres within Kern County. Two main water units exist within the Kern County subbasin, the Plio-Pleistocene Tulare Formation and the overlying Pleistocene alluvium/stream deposits. Within the Kern County subbasin further hydrogeologic subunits are defined based on geologic structures that create some degree of separation that is not fully understood. The proposed process water supply would be drawn from and used within the Buttonwillow subbasin. The site is located along the course of the old Kern River. The site is uniquely situated along the axis of the Kern County subbasin and is underlain by 600-700 feet of interbedded alluvial deposits (BVW 2010a). The inferred subbasins in the region are shown in **Water Figure 1**.

Surface water flow is northward from the terminal drainage basin. The proposed project site is north of both the Kern and Buena Vista ephemeral lakebeds and is in the Tulare Hydrologic Unit. Surface water in the southern portion of the subbasin discharges toward the north, toward Goose Lake lakebed via various drainage canals.

The Central Valley climate is semi-arid, creating hot dry summers and mild winters. Average daily summer temperatures recorded between 1937 and 2006 range between the 70s and 80s, while average daily winter temperatures range between the 40s and 50s. Average annual precipitation during the same period was 6.23 inches (HECA 2012b).

Local Water Management

Both the proposed power plant and proposed water supply wells are located within the Buena Vista Water Storage District (BVWSD) service area. The district contains two sub-service areas within it, the Buttonwillow Service area which is approximately 46,600 acres and the Maples Service Area which is approximately 5,000 acres. Approximately 45,000 acres of the district is developed and 35,000 acres of district land are farmed annually for field and row crops. **Water Figure 1** shows the location of the service areas (FEIR 2009). The project site is within the Buttonwillow Service Area.

BVWSD manages supply and demand within the district which has been recorded during the period 1970 through 2007 (BVW 2010a). The district relies on groundwater and various surface water deliveries to supply its customers. The district's most significant supply is provided by a Kern River entitlement dating back to 1888, known as the Miller-Haggen Agreement. As a second-point interest (State Water Rights Board Decision D 1196 defines First, Second, and Lower Service Areas, or interests) to the Kern River water supply, the BVWSD is entitled to about 158,000 AF/y. The district also has a contract with the Kern County Water Agency (KCWA) to receive 21,300 AF/y from the State Water Project (SWP). In years when it is available, the district also has a surplus entitlement of 3,750 AF/y. The district also receives Central Valley Project water from the Friant-Kern Canal water to supplement its entitlements (BVW 2010a).

KCWA is one of 29 SWP contractors. The KCWA was created in 1961 by the State Legislature and is the designated SWP contracting entity for local water districts in Kern County. KCWA is involved with various banking and recovery operations and also provides some flood control services. KCWA has contracts with 13 member agencies including Belridge Water Storage District, Berrenda Mesa Water Storage District, BVWSD, Cawelo Water District, Henry Miller Water District, Kern Delta Water District, Lost Hills Water District, Rosedale-Rio Bravo Water Storage District, Semitropic Water Storage District, Tehachapi-Cummings County Water District, Tejon-Castaic Water District, West Kern Water District, and Wheeler Ridge-Maricopa Water Storage District (KCWA 2010). The BVWSD is bounded by and operates in conjunction with these numerous water districts and agencies in the southern San Joaquin Valley as shown in **Water Figure 1**. The BVWSD is able to exchange its Kern River entitlements for other KCWA members' SWP water, due to the BVWSD's close proximity to the California Aqueduct (BVW 2010a). The BVWSD receives its SWP water from five turnouts along the California Aqueduct. The turnouts provide a direct, gravity-fed connection to the district's distribution system.

The Belridge Water Storage District (BWSD) is located immediately west of BVWSD's Buttonwillow Service Area. The 92,000 acre district has 121,508 acre-feet of SWP firm entitlement. The district is highly invested in pumping water from the California Aqueduct; aqueduct water is pumped from a canal altitude of 300 feet amsl uphill to an elevation of 500' amsl using up to 14,000 horsepower. The BWSD also participates in banking projects within Kern County, but extracts very little groundwater from beneath its district boundaries (BVW 2010a).

The West Kern Water District (WKWD) serves a population of approximately 25,000 people within a 250 square mile area located along the western border of Kern County. The WKWD supplies its customers with groundwater pumped from eight wells within the district. Current water demand is approximately 20,000 AF/y (BVW 2010a).

The Semitropic Water Storage District (SWSD) is located immediately east of the BVWSD. SWSD serves 300 customers located within 220,000 acres. The district also offers groundwater banking and storage services for various water districts in Kern County, Southern California, and the Bay Area. SWSD currently banks 700,000 acre-feet of water and has a capacity to bank 2.15 million acre-feet of water (SWSD 2010).

The Rosedale-Rio Bravo Water Storage District (RRBWSD) is located immediately southeast of the BVWSD. The RRBWSD spans approximately 43,000 acres and serves approximately 33,400 acres of cropland and 6,000 acres of urban area (USBR 2009).

The Kern Water Bank Authority (KWBA) owns about 20,500 acres located along the Kern River and directly southeast of the BVWSD. Similar to the BVWSD, the KWBA receives its water supply from the Kern River, the Friant-Kern Canal, and the California Aqueduct. The KWBA includes 80 supply wells, which have the capacity to recover 240,000 AF/y. The primary purpose of the water bank is to recharge, store, and recover water for the benefit of those participating in the program. The KWBA is a Joint Powers Authority, formed in 1995. Participants in the management of the water bank include Dudley Ridge Water District, Kern County Water Agency, Improvement District 4, Semitropic Water Storage District, Tejon-Castaic Water District, Westside Mutual Water Company, and Wheeler Ridge-Maricopa Water Storage District (KWB 2010).

Kern Water Bank (KWB) facilities are also located southeast of BVWSD. The KWB was formed in 1995 to manage banking facilities previously operated by DWR. The KWB has the capacity to store up to 1,000,000 acre-feet and extract up to 240,000 acre-feet per year. The facilities are jointly managed by Dudley Ridge Water District, KCWA (Improvement District 4), SWSD, Tejon-Castaic Water District, Westside Mutual Water Company, and Wheeler Ridge-Maricopa Water Storage District (BVW 2010a).

Water purveyors in the Kern County subbasin are engaged in joint groundwater management agreements. The interconnectivity of hydrogeological subunits within the greater Kern County subbasin requires a joint interest in protecting the shared groundwater resource. For instance, the Memorandum of Understanding (MOU) Regarding Operation and Monitoring of the BVWSD Groundwater Banking Program (2002) reflects the interest of many of the local water districts to safely manage groundwater in the Kern County subbasin. The districts that are party to the MOU include: BVWSD, Semitropic Water Storage District, Henry Miller Water District, Kern County Water Agency, Kern Delta Water District, Kern Water Bank Authority, Rosedale-Rio Bravo Water Storage District, and West Kern Water District. This agreement is hereafter referred to as MOU #1 (BVW 2010a).

Staff is aware of another agreement titled Memorandum of Understanding Regarding Operation and Monitoring of the Semitropic Groundwater Banking Project, signed September 14, 1994. The agreement was entered into by the following: Semitropic Improvement District of Semitropic Water Storage District, North Kern Water Storage District, Shafter Wasco Irrigation District, Southern San Joaquin Municipal Utility District, Shafter Wasco Irrigation District, Southern San Joaquin Municipal Utility District, Buena Vista Water Storage District, and Rosedale-Rio Bravo Water Storage District. This agreement is hereafter referred to as MOU #2 (BVW 2010a).

BVWSD is also engaged in two banking and recovery programs with their immediate neighbors. In 1983 BVWSD entered an agreement with the West Kern Water District and in 2002 with the Rosedale-Rio Bravo Water Storage District.

PROJECT DESCRIPTION

The proposed project would use a blend of coal and petroleum coke to produce hydrogen, which would then be used to fuel a combined cycle turbine. This 431-gross-megawatt (MW) plant would provide up to 300 MW of baseload power to the grid. The gasification block would capture 90 percent of raw syngas carbon, which would be transported to the Elk Hills 3 miles to the south, via pipeline, where it would be used to facilitate carbon dioxide enhanced oil recovery (CO_2-EOR).

Process water would be supplied by the Buena Vista Water Storage District (BVWSD) and would be delivered from a new well field that would be installed 15 miles northwest of the project site. The summary of Proposed Water Transfer Terms (HECA 2012b, Appendix N) shows BVWSD would supply HECA with up to 7,500 acre-feet per year (AF/y) of water with a concentration of total dissolved solids (TDS) ranging from 1,000 to 4,000 mg/L. The use of this water supply would allow the BVWSD to implement one of the primary components of their Brackish Groundwater Remediation Plan (HECA 2012b). HECA will fund development of this component of BVWSD's program and turn it over to BVWSD to own and operate.

Water for construction and potable uses would be supplied by the WKWD located south of the project. Seven miles of pipeline would be constructed to deliver water from the district. Horizontal directional drilling (HDD) would be necessary to route the pipeline beneath the Outlet Canal, the Kern River Flood Control Channel (KRFCC), and the California Aqueduct (HECA 2012b).

Project construction milestones have been affected by delays in the application process. The projected milestones below are based upon an approximately 7-month delay from those projected proposed by the applicant in the May 2, 2012, AFC (Vol. I, page 2-11):

- Commencement of preconstruction, and construction activities: January 2014
- Completion of construction: September 2017
- Commencement of commercial operation of HECA: April 2018

Project Water Supply

West Kern Water District, Construction and Domestic Supply

Potable water needs during operation would be supplied by groundwater from WKWD. Average potable water use would be approximately 1,800 gallons per day (gpd), but could be as high as 2,750 gpd. The average potable water demand would be equal to 2.0 AF/y. The project would provide potable water for up to 200 full-time employees (HECA 2012b).

Construction water would also be supplied by WKWD by pipeline and truck. Average construction water use would be approximately 5,340 gpd and maximum use would be approximately 12,000 gpd. Total use over the 42 months of construction would be about 46 AF, about 12 AF/y (HECA 2012b).

Buena Vista Water Storage District, Industrial Supply

The proposed project would use an annual average of about 6.6 million gallons of groundwater per day and up to 7.4 million gallons per day (gpd) in summer for industrial purposes. This is equivalent to an average water use of 7,420 acre-feet per year (AF/y). BVWSD would supply up to 7,500 AF/y to HECA as detailed in the will-serve letter (HECA 2012b). About 0.5 million gpd of the supply would be necessary to create high-quality demineralized water for a gasifier and boiler make-up water. All of the proposed industrial supply water would be supplied by the BVWSD and treated as necessary by HECA.

The projected annual use by HECA is presented in **Water Table 2** below.

Water Table 2
Expected Industrial Use

	Supplier	Average Use Rate (gpd)	Average Use Rate (AF/y)	Maximum Use Rate (gpd)
Industrial Water (total)	BVWSD	6,624,000	7,420	7,416,000

Source: HECA 2012b

Beneath the proposed well field, TDS concentrations in well water samples range from 1,000 to 4,000 mg/L. The TDS concentrations in groundwater reportedly decrease toward the east, where groundwater for agricultural supply increases. West of the proposed well field, groundwater is believed to be relatively high in salinity and of low quality due to the influence of alluvium originating from the Coast Range marine rocks. The BVWSD therefore envisions extraction wells located near the western district boundary to intercept the high TDS groundwater originating in the Coast Range alluvium while inducing the westward migration of relatively low TDS groundwater from the east. The desired outcome of well field operation is therefore an overall improvement in groundwater quality beneath BVWSD areas located east of the well field.

BVWSD does not currently have the capacity for the proposed groundwater pumping or conveyance facilities necessary to implement the BGRP and would construct pumping and conveyance facilities specifically for HECA. No other potential users of this supply are identified in BVWSD's Final Environmental Impact Report (FEIR) for the BGRP (BVW 2010a). The purpose of the BGRP program would be to remediate shallow perched and brackish groundwater that has adversely impacted plant growth and crop yield within the district. The program would seek to operate two strategic pump zones called Target Area A (north of 7^{th} Standard Road) and Target Area B (mostly south of 7^{th} Standard Road), as shown on **Water Figure 2**. The portion of the district south of 7th Standard Road is underlain by groundwater having total dissolved solids (TDS) concentrations ranging from 700 to 4,000 mg/L (Target Area B), whereas areas to the north are underlain by ground water with concentrations ranging from 1,000 to 5,000 mg/L (Target Area A). Combined extraction of the BGRP could total up to 12,000 AFY (BVW 2010a).

The BGRP Target Area A would include 40 shallow, low-flow extraction wells in a grid pattern in the northern half of the district where water stands at two to ten feet below the ground surface. The goal in this target area is to lower the water table and improve cropland productivity. The FEIR identifies no potential users for this water. This water is identified as having TDS concentrations between 1,000 and 5,000 mg/L (BVW 2010a). Though not a proposed source of groundwater for HECA, Target Area A is described as a source of brackish water that may supply up to 4,500 AF/y to the BGRP.

The HECA project would receive water from Target Area B. Target Area B is located along the west-central edge of the district. Up to ten wells are planned to extract groundwater from between 200 to 700 feet below the ground surface (the zone of brackish water with TDS concentrations between 700 and 4,000 mg/L). The water quality produced by the extraction wells is expected to be a mix of relatively high TDS water originating west of the well field and low TDS water originating east of the well field. The strategic locations of the proposed wells are intended to reduce the lateral recharge from the west from moving further eastward into the district (BVW 2010a).

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

This section provides an evaluation of the expected direct, indirect, and cumulative impacts to soil and water resources that could be caused by construction, operation, and maintenance of HECA. Staff's analysis consists of a description of the potentially significant impact, gathering data related to construction and operation of the project, then reaching a conclusion to determine whether or not the project presents a potentially significant impact. If staff determines there is a significant impact, then staff evaluates the applicants' proposed mitigation for sufficiency and staff may or may not recommend additional or entirely different mitigation measures that are potentially more effective than those proposed by the applicant. Mitigation is designed to reduce the effects of potentially significant HECA impacts to a level that is less than significant. The determination of significance for potential impacts to soil and water resources is discussed below.

METHOD FOR DETERMINING SIGNIFICANCE OF IMPACTS

This document analyzes the project's impacts pursuant to both the National Environmental Policy Act (NEPA) and CEQA. The two statutes are similar in their requirements concerning analysis of a project's impacts. Therefore, unless otherwise noted, staff's use of, and reference to, CEQA criteria and guidelines also encompasses and satisfies NEPA requirements for this environmental document.

This section provides an evaluation of the expected direct, indirect, and cumulative impacts to water supply that would be caused by construction, operation, and maintenance of the project. Staff's analysis of potential impacts consists of a description of the potential effect, an analysis of the relevant facts, and application of the threshold criteria for significance to the facts. If mitigation is warranted, staff provides a summary of the applicant's proposed mitigation and a discussion of the adequacy of the proposed mitigation. If necessary, staff presents additional or alternative mitigation measures and refers to specific conditions of certification related to a potential impact and the required mitigation. Mitigation is designed to reduce the effects of potential significant project impacts to a level that is less than significant.

Staff evaluated the potential of the project's proposed water use to cause a substantial depletion or degradation of groundwater resources, including beneficial uses. Staff considered compliance with the LORS and policies presented in **Water Table 1** and whether there would be a significant California Environmental Quality Act (CEQA) impact. Compliance with LORS and policies includes the Energy Commission's and

State Water Resources Control Board's policy against using freshwater for power plant cooling unless other sources or other methods of cooling would be environmentally undesirable or economically unsound. A discussion of the applicable policies is contained in the "Water Use LORS and State Policy Guidance" subsection of this PSA section.

To evaluate if significant CEQA impacts to water resources would occur, the following criteria were used. Where a potentially significant impact was identified, staff or the applicant proposed mitigation to reduce the impacts to less than significant or reduce to the extent possible.

a. Would the project substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume (deplete groundwater storage).
b. Would the project contribute to any lowering of groundwater levels and impact the production rate of pre-existing wells to a level which would not support existing or planned uses for which permits have been granted or cause physical damage to the well?
c. Would the project contribute to any lowering of the groundwater levels such that protected species or habitats are affected?
d. Would the project cause substantial degradation to surface water or groundwater quality?

STAFF ANALYSIS OF INDUSTRIAL WATER SUPPLY

Applicant Groundwater-Flow Model Construction

The applicant utilized a three-dimensional numerical groundwater-flow model to simulate well interference (drawdown) and delineate the pumping zone of influence (ZOI). The model is based on MODFLOW (McDonald&Harbaugh1988); MODFLOW is a widely accepted model code that has been verified to produce numerically stable solutions (Anderson&Woessner1991).

Numerical groundwater-flow modeling involves first developing a conceptual model of the physical system and then applying a mathematical model to quantitatively represent it. The conceptual model is a clear, qualitative description of the natural system and its operation including water sources (recharge), flow directions, and groundwater sinks (discharge). The mathematical model utilizes equations to simulate the physical processes described by the conceptual model. The potential complexity of processes and variety of boundary conditions typically require numerical procedures to determine an approximate solution to the mathematical groundwater-flow equations.

In applying models to real world groundwater-flow systems, errors can potentially arise from the following sources:

- Numerical deficiencies from errors associated with the equation solvers. These errors introduce problems with computational accuracy and precision.

- Conceptual deficiencies (i.e., erroneous basin geometry, incorrect boundary conditions, neglecting important processes, including inappropriate processes, and so forth).
- Inadequate representation of water transmitting and storage properties (parameterization) and incorrectly specified stresses (the magnitude, timing, and spatial distribution of water inflow [recharge] and outflow [pumpage]).

The most common modeling errors are attributed to conceptual deficiencies and inadequate/poorly defined parameterization and stresses. Key model assumptions and construction specifics are listed below, followed by modifications staff deemed necessary to improve the model's representation of the real-world groundwater system.

- The model simulates a 25-year period. Each year comprises two stress periods. One stress period is 75 days in length, and simulates the two and one-half month period that recharge occurs due to seepage from irrigation ditches and the canal system, and the second stress period is 290 days in length to simulate the remainder of the year when recharge does not occur. Pumpage is simulated during both stress periods to represent continuous pumpage 365 days of the year. These stress periods sufficiently represent temporal changes in water use within the model area as a result of the proposed project. However, staff disagreed with simulating recharge in this model application and provide their reasons in the section "Applicant's Modeling Approach."
- The model represents a 10,000 square mile area, which is considerably larger than the proposed project area and intended to minimize boundary effects on the simulation results. Head-dependent flow conditions specified at its boundaries are employed to further minimize boundary effects and approximate an aquifer of infinite extent. Staff concluded this approach is too generalized for this application, and the results likely minimize water level changes due to project pumping. Staff recommended changes to the model are discussed below in "Staff Recommended Changes to Model Construction."
- The model is a rectangular grid appropriately utilizing cell sizes that range from 20 x 20 feet in the vicinity of the proposed pumping wells to 2,500 x 2,500 feet at the most distant model boundaries. By definition, the simulated groundwater level changes in each model cell represent the average groundwater level change within the area represented by the cell.
- In the vertical direction, three model layers represent the aquifer. The simulated water table and pumping wells are located in layer 1 (270 feet thick saturated interval), and deeper aquifer conditions are represented by layer 2 (300 feet thick saturated interval) and layer 3 (2,000 feet thick saturated interval). The approach assumes that the constant parameter values specified for each layer adequately represent vertical variations in water transmitting and storage properties.
- The modeled hydraulic conductivity value is 42.8 ft/d and reasonably close to the median effective conductivity value of 47.6 ft/d determined from 7 aquifer tests reported by URS (2010a). Horizontal hydraulic conductivity is therefore likely appropriately specified in the model. The modeled vertical conductivity is assumed to be 30 times smaller than the horizontal conductivity. No measured vertical conductivity values are available from which to confirm this value, nor is

geologic data summarized and discussed to relate the assumed vertical conductivity and observed vertical variations in relatively coarse- and fine-grained deposits that occur within the modeled depth intervals that range from 270 to 2,000 feet in thickness. For example, a previous San Joaquin Valley modeling effort suggested that fine-grained deposits could reduce the effective vertical conductivity represented by relatively thick model layers. Hence, the effective vertical hydraulic conductivity may be lower than represented in the model. Staff therefore recommended a more complete assessment to include potential uncertainty in model results due to the assumed vertical conductivity. The recommended analysis is discussed below in the subsequent section “Staff Recommended Changes to Model Construction.”

- The modeled specific yield and specific storage values are 0.18 and $5.5x10^{-5}$ per ft, respectively. However, aquifer test results reported by URS (2010a) indicate a geometric mean storativity of 0.007. The actual water level decrease due to simulated pumpage from the model layer 1 depth interval may therefore be substantially greater than modeled. Staff recommended a more complete assessment to include potential uncertainty due to the specified storage parameter. The recommended analysis is discussed below in the subsequent section “Staff Recommended Changes to Model Construction.”
- The model simulations are assumed to converge when the residuals in hydraulic head and volumetric fluxes meet the user’s specified criteria. The recommended error criterion for groundwater levels should be one to two orders of magnitude smaller than the accuracy level desired, and the error in the water balance is ideally less than 0.1 percent (Anderson&Woessner1991). The model simulations reviewed by staff appropriately employed a water level closure criterion of 0.01-foot and resulted in typical mass balance errors less than 0.01 percent.
- Groundwater pumpage is the sole discharge simulated from the aquifer. The model appropriately simulates a continuous annual pumping rate of 7,500 AF/yr distributed evenly between three wells. All of the pumpage occurs in model layer 1.
- Recharge is the primary simulated inflow to the aquifer. Recharge is simulated to “off-set project pumping”, and 7,500 AF/yr of recharge is simulated as occurring within 18,750 acres around the extraction wells. The simulated recharge is assumed to occur during a 75-day period each year. Staff disagreed with the need to simulate recharge in this model application, and the recommended changes to simulated recharge are discussed below in the subsequent section “Review of Applicant’s Modeling Approach.”

Staff Recommended Changes to Model Construction

Staff disagrees with several of the hydrologic conditions and assumptions utilized to construct the groundwater-flow model as follows:

- The model domain ignores the contact between water-bearing alluvium and the essentially non-water bearing marine rocks of the Coast Ranges. The contact between alluvium and rock is located approximately six miles west of the proposed well field. Accordingly, a zero- or no-flow boundary is needed approximately 6 miles west of the well field.

- Hydrogeologic subbasin boundaries are reportedly located about 5 to almost 17 miles north and south of the proposed well field, respectively. These boundaries are defined by structural highs due to folding or faulting, and may isolate, at least partially, the hydrogeologic subbasin in which the simulated well field is located (the Buttonwillow subbasin) from other parts of the southern San Joaquin Valley groundwater basin (URS2009). Hence, the three remaining model boundaries could conceivably also be re-located and changed to no-flow boundaries to correspond to the Buttonwillow subbasin boundaries.
- Head-dependent flow conditions were reportedly specified at the boundaries of the active model domain to minimize boundary effects and approximate an aquifer of infinite extent. However, the model files provided by the applicant (Confidential May 12, 2010 transmittal of model files from Liz Elliot, URS) specified head-dependent flow conditions in model layer 1 only. Employing head-dependent flow conditions can be an acceptable approach for minimizing boundary effects, however there must be a physical reason for utilizing different boundary conditions in the other model layers. Furthermore, because head-dependent boundaries can add or remove significant quantities of groundwater to or from the model domain, the results should be inspected to confirm boundary conditions do not significantly influence model results.
- Specific yield is a measure of the volume of water drained from saturated unconfined aquifer material under the force of gravity per unit surface area and unit change in water table elevation. The applicant assumed the 270-feet thick pumped aquifer simulated by the model is unconfined, and the model assigned a specific yield value of 0.18 to pumped aquifer represented by model layer 1. The aquifer test results reported by URS (2010a) suggest however that the pumped aquifer is not unconfined but rather may be semi-confined.

  The URS (2010a) aquifer tests were conducted on wells screened at depths corresponding to model layer 1 and the upper portion of model layer 2. The aquifer test results indicate a geometric mean storativity of 0.007. Storativity is a measure of the volume of water released by compression of the aquifer structure and expansion of the water in response to the decline in pressure in a confined or semi-confined aquifer. The storativity of 0.007 is about 25 times smaller than the modeled specific yield (0.18), and is indicative of semi-confined aquifer conditions. The model therefore inappropriately represents the entire upper 270 feet of saturated sediment as an unconfined aquifer, and as a result likely under-estimates the water level decline caused by groundwater extractions that occur at depths below the water table.

  Additional information is needed to identify the thickness of the unconfined water table aquifer, which based on URS (2010a) aquifer test results occurs at depths less than 270 feet. This information can be utilized to separate the existing model layer 1 into two layers. The new layer 1, which will be less than 270 feet thick, can represent the upper unconfined depth interval of the aquifer and utilize the specific yield value of 0.18. The new, underlying layer 2 can be assigned the remaining thickness of the original layer 1 and represents the semi-confined aquifer characterized by the reported storativity value of 0.007.

- In the absence of reliable information to complete these necessary model layer refinements, a simpler approach assigns the reported storativity (0.007) to the entire depth interval represented by layer 1. This simpler approach is limited because less water is available from storage than if the unconfined portion of the aquifer were explicitly modeled. Hence, the model results from this simpler approach will likely over-estimate the water level decline caused by groundwater extractions and therefore provides conservative estimates of groundwater impacts. In the absence of reliable information to delineate the unconfined and confined portions of the aquifer, the simpler approach is therefore preferred.
- The model assumes vertical conductivity is 30 times smaller than horizontal conductivity, which may be too low relative to actual conditions and model layer thicknesses. URS (2009) tested model sensitivity to vertical conductivity and reported that the extent of simulated drawdown increases as the modeled vertical conductivity decreases. However, the modeled vertical conductivity is the net effect of all the sediment beds within the entire depth interval represented by the model layer. Aquifer testing and model calibration results reported by Belitz and others (1993) for Coast Range and Sierran alluvium suggest that intermittent clay deposits can reduce the modeled vertical conductivity relative to horizontal conductivity by a factor of more than 1,000. Unless data from boreholes located in the well field and adjacent areas show an absence of clay deposits within the relatively thick depth intervals represented by the model layers, staff recommends addressing the potential influence of fine-grained beds on the modeled vertical conductivity. In the absence of more detailed information, staff recommends revising the anisotropy[1] in the model to 1,000 to consider uncertainty in vertical conductivity across the relatively thick model layers.

Review of Applicant's Modeling Approach

The applicant appropriately employed "superposition" to simulate the proposed well field operation. Superposition solves a complex problem using an incremental and additive approach. The principal constraint to using superposition is that the mathematical equation describing the groundwater problem – both within the model domain and the boundary conditions – must be linear.[2] In this application, the complex problem is the prediction of groundwater level changes in the basin, and superposition is employed to determine the incremental drawdown due solely to pumping for proposed power plant water use.

[1] Anisotropy in hydrogeologic terms refers to a matrix of earth materials with differing hydraulic conductivity in different directions. It is typically measured or compared in the horizontal and vertical directions and expressed as a ratio of horizontal to vertical conductivity, or H:V. It is an important parameter for estimation of effects on groundwater flow because the presence of fine grained deposits like clay in sedimentary deposits can significantly reduce the rate of vertical flow compared to horizontal flow in sand and gravel deposits.

[2] Some of the mathematical equations that describe groundwater flow are linear – others are not. The equations utilized to describe unconfined groundwater-flow are not linear, but when the saturated interval is thick relative to the water level changes considered it is common practice to assume the unconfined system behaves approximately linearly. As a rule of thumb, superposition can be applied if the basin-wide drawdown of the unconfined aquifer is 10 percent or less of the saturated interval (Reilly&Others1987).

In practice, in a superposition model, the specified initial head distribution and boundary conditions are defined in terms of relative changes rather than actual observed values. Initial heads within the model domain are specified as all being equal. Fixed-head boundaries use water levels specified equal to initial groundwater levels so that the initial hydraulic gradient along the boundary is zero. Constant-flux boundaries are specified as no-flow (zero-flux) boundaries corresponding to no net change in flow. Specified pumpage represents the incremental increase in the pumping rate relative to existing or background pumpage, and specified recharge represents the incremental increase in recharge relative to existing or background recharge rates.

In applying superposition to analyze the proposed well field, the applicant simulated a pumping rate of 7,500 AF/yr. The simulated pumping rate represents an incremental increase in groundwater extraction above background groundwater production within the Buttonwillow Service Area. Similarly, the applicant simulated a recharge rate of 7,500 AF/y to represent an incremental increase in recharge within the Buttonwillow Service Area. The simulated water levels and fluxes therefore represent the incremental changes in groundwater conditions resulting from these increases in pumping and recharge. The model results are relative to background groundwater conditions, and actual changes would be the combined sum of the incremental changes due to the project and background conditions.

Simulated recharge (7,500 AF/y) applied by the applicant represents an incremental increase in recharge above typical annual recharge rates in the Buttonwillow Service Area. Typically, recharge rates in the project setting are supplied by applied water and/or seepage losses from drainage ditches and canals. Accordingly, the 7,500 AF/y increase in recharge must correspond to an increase in water deliveries and applied water, a 7,500 AF/y reduction in existing annual water consumption, or a similar decrease in annual drainage discharge. An increase in water deliveries in the Buttonwillow Service Area must correspond with a decrease in water deliveries in another part of the BVWSD. Furthermore, the applicant's analysis does not consider potential downstream impacts resulting from the reduction in ditch and canal flows that would occur if these sources provided the necessary increase in seepage. Because the source of the "new" water for the recharge increase was not identified as part of the project description, staff concluded recharge is incorrectly specified in the model.

Model Results

Well Interference

Consumptive use of water from wells within a groundwater basin may contribute to lower water levels at other well locations (well interference). The groundwater-flow model was employed to simulate the water level drawdown at existing wells due to pumping from the proposed well field.

Well interference is considered significant if water level changes in and around an existing well appreciably affects its ability to meet its intended use. Reductions in well yield can occur as the static or pumping water levels decrease. The maximum theoretical well yield can be defined as the maximum pumping rate supplied by a well without lowering the water level below the pump intake (Freeze&Cherry1979). Typically, pump intakes are located near the top of the screened interval because it is desirable to keep the well screen submerged as this minimizes chemical clogging and physical deterioration of the well screen (Driscoll1995).

Water Table 3 summarizes available well completion data from well driller reports (well logs) and water level data records obtained from the California Department of Water Resources. On average, wells are almost 450 feet deep and the top of the well screens are located almost 200 feet below land surface. See **Water Figure 3** for general locations of wells.

Water Table 3
Available Well Completion Data from Well Driller Reports (Well Logs)
And Water Level Data Records

Map number	Well Depth	Top of perforation	Bottom of perforation	Water level (amsl)	Date

Drawdown Impacts

Staff analyzed the potential for water level declines that could result in wells that neighbor the proposed project wells. Staff determined that a predicted 15-foot drawdown would constitute a significant impact. As shown in the "**Increased Cost of Pumping**" section below, a 15-foot decline could result in a 25% increase in the cost of pumping. The analysis below explains the specific treatment and potential impacts to local receptors. Staff utilized the applicant's model to simulate projected water level changes owing to 25-years of project pumping. Simulated drawdown contours resulting from use of the applicant's model are mapped in **Water Figure 4**, and simulated drawdown at select well locations is summarized in **Water Table 3** (see **Water Figure 3** for well locations corresponding to the map numbers listed in **Water Table 3**). The simulated drawdown values using the applicant's model ranged from -0.7 to 12.0 feet; drawdown less than zero indicates that as a result of simulated recharge the model predicts water levels will increase during the 25-year simulation period.

The simulated drawdown contours from staff's modified model (no-flow boundary added and no recharge) are shown in **Water Figure 5.** The results indicate greater drawdown over a generally larger area than simulated by the applicant's model. The simulated drawdown in the staff modified model ranged from 2.2 to 15.8 feet, representing an average increase of more than 3 feet relative to the applicant's model. The maximum drawdown (15.8 feet) exceeds the well interference threshold by almost 1 foot at one well (the well is located within the boundaries of the proposed well field area and identified by Map ID 6 in **Water Figure 3**).

Simulated drawdown in **Water Table 4** represents the water level changes due solely to project well field operation. Actual water level changes and volumetric fluxes will be the net result of multiple recharge and discharge processes occurring in the basin and can therefore be quite different from the model results. For example, the simulated drawdown in the well identified by Map ID 50 is 3.8 feet, indicating that 25-years after well field start-up the water level in this well will be 3.8 feet lower than without the well field (no project conditions).

Minimum	-0.7	2.2	3.5	5.1

Staff performed additional model testing which showed simulated drawdown extracted by the proposed well field is sensitive to assumed aquifer conditions. Utilizing the reported representative storativity (0.007) increased the magnitude and extent of simulated drawdown (**Water Figure 6**), and on average simulated drawdown increased by almost five feet relative to the applicant's model results (**Water Table 4**). The maximum simulated drawdown increased from 12.0 to 17.3 feet, but the 15-feet threshold was exceeded at only one location.

Increasing the applicant's simulated anisotropy from 30 to 1,000 further increased the magnitude and extent of simulated drawdown (**Water Figure 7)**. On average, simulated drawdown increased by almost 11 feet relative to the applicant's model (**Water Table 4**). The maximum simulated drawdown increased from 12.0 to 34.2 feet, and the 15-feet threshold was exceeded at 13 locations (an increase of 12 wells).

Increased Cost of Pumping

If the total hydraulic head in neighboring domestic wells is lowered, then well yield would be reduced and an increase in pumping cost is expected. Pumping costs can be estimated with the following equation:

$C = 0.746Qhc / 3960e_pe_m$

Where

C = total cost per hour
Q = pump rate (gpm)
h = total head (ft)
c = cost per kWh
e_p= pump efficiency
e_m = motor efficiency

Staff estimated potential increases in pump cost incurred by an owner (pumping 10 gpm) experiencing a 15-foot decline in water levels using a pump (e_p) and motor (e_m) efficiency of 80-percent (0.80) and a cost for energy equal to $0.16 per kWh. Using these values, pumping costs could increase by about 25 percent. Staff believes that the decrease in well yield that would result in a 25 percent increase in pumping costs is a significant impact. Staff proposes Condition of Certification **WATER-1** which would require the monitoring of local domestic wells to determine if project-induced water level decline is observed. Staff also proposes Condition of Certification **WATER-2** which provides a method for calculating the reimbursement necessary to offset costs from decreased well yield. This condition utilizes an equation similar to Equation 3 above, but applied to a particular well under its own set of unique circumstances.

Groundwater Quality Impacts

Staff could find no specific provision or policy used by BVWSD to identify what constitutes a water quality impact from pumping such as that proposed for the project. Staff used the RWQCB Basin Plan beneficial uses for groundwater designated in this area and considered whether the pumping would degrade water quality such that it could not be used for the identified beneficial uses. The suitability of water for use as irrigation water becomes marginal where TDS reaches concentrations of 2,000 ppm. As described by Dr. L.D. Doneen in 1954 (Doneen, 1954), reiterated by DWR in various Water Quality Investigations, and promulgated in the Water Control Plan for the Tulare Lake Basin (RWQCB, 2004), water that exceeds electrical conductivity levels of 3,000 micromhos per centimeter and TDS levels of 2,000 mg/L has limited suitability for irrigation use (**Water Table 5**).

Water Table 5
Irrigation Water Suitabilities

Irrigation use	Electrical Conductivity (mhos/cm @ 25°C)	TDS (mg/L)
Suitable/Class I	0 - 1,500	< 700
Marginal/Class II	1,500 - 3,000	700 - 2,000
Inferior/Class III	> 3,000	> 2,000

Source: Doneen, 1954; Tulare Lake Basin Plan, RWQCB, 2004

The HECA project proposes to receive groundwater from BGRP Target Area B. The water underlying Target Area B contains TDS at concentrations between 1,000 mg/L and 4,000 mg/L. The will-serve letter signed by Hydrogen Energy and BVWSD states that the water supply for HECA would vary between 1,000 mg/L to 4,000 mg/L, with an average of 2,000 mg/L. This water is described by BVWSD as having few uses and also as being the cause of low crop yield and low crop quality within the district. However, specific studies of crops of pistachios from western San Joaquin Valley indicate no adverse impacts to crop or yield at salinities even greater than 3,000 mg/L TDS (Fergusson et al., 2002). This same claim is made by HECA intervenor and residents, Association of Irritated Residents (AIR), that states the water proposed for use by the project is suitable for pistachios (AIRe). They believe groundwater of this quality should be protected for such agricultural use.

Staff used a TDS concentration of 2,000 mg/L as a threshold for comparison with background or baseline conditions where the primary beneficial use is irrigation. Where project pumping could cause TDS concentrations to exceed 2,000 mg/L staff believes there is potential for a significant impact. See staff's discussion of project-related water quality changes below. Where background TDS concentration is greater than 2,000 mg/L staff considered whether the groundwater may reasonably be considered a potential drinking water supply that should be protected in accordance with SWRCB drinking water policy. This policy requires, among other things, that a water source with TDS concentrations less than 3,000 mg/L should be protected as a potential drinking water supply. Where project pumping would cause TDS concentration increases beyond 2,000 mg/L staff concludes this would also be a significant impact for potential use as a drinking water supply. Where background TDS concentrations are greater than 3,000 mg/L staff believes that pumping would not impact reasonable beneficial uses.

In the Buttonwillow Service Area, the pumped groundwater zone as indicated by the average depth to the top of the perforations in water supply wells is about 200 feet below land surface (**Water Table 2**). Well water sample results from the period 1961-2006 and composite 1970-2007 TDS concentrations contours (BVWSD2009) for deep wells are mapped in **Water Figure 8**. Five deep wells have posted values that are greater than the TDS concentrations depicted by the contours. Four of these five wells are located in the central part of the Buttonwillow Service Area or to the east and in the Semitropic Water Storage District. Over half of the remaining wells have posted TDS concentrations that are less than the values depicted by the contours. The remaining posted well concentrations generally agree with the contours. There doesn't appear to be an identifiable spatial pattern in the differences between well concentrations and the reported contours, and the contours may be considered an unbiased but only approximate representation of the spatial variability in groundwater quality.

Well water sample results and summer 2001 TDS concentrations contours (BVWSD2009) for deep wells are mapped in **Water Figure 9**. Most well water samples had TDS concentrations either less than or similar to the TDS concentrations contours. The sample results generally agree with the contours in the area south of Highway 58 where TDS concentrations are relatively low. In the central part of the Buttonwillow Service Area and near the proposed well field, all but two of the well water samples have lower TDS concentrations than indicated by the contour values (the two exceptions are the 4,300 mg/L sample from the well located on the 2,000 mg/L contour, and 1,400 mg/L sample from the well located east of the 1,000 mg/L contour). In the northern part of the Buttonwillow Service area, there appears to be little agreement between well water sample results and TDS concentrations contours.

In the northern part of the Buttonwillow Service Area, shallow “perched”[3] groundwater and elevated TDS concentrations have reportedly adversely impacted plant growth and crop yields. **Water Figure 10** shows 2008 TDS concentrations contours reported by BVWSD (2009) and the results from shallow well-water samples collected in the northerly area. The posted well sample results are generally higher than the TDS concentrations depicted by the contours. One exception is the DWR data value of 537 mg/L from a well of unknown depth located near the intersection of I-5 and Highway 46. In the southern half of the area represented by the contours, the posted values are either consistent or lower than the contours. The three lower posted values are located between the West Side and Main Drain canals and range from 389 to 828 mg/L, whereas the contours indicate concentrations range from between 2,000 and 4,000 mg/L. Two of the three samples (389 and 828 mg/L) are from wells of unknown depth, and therefore may represent deep groundwater. These samples were collected and analyzed more than 50-years ago (DWR1961), and present-day TDS concentrations at these locations may be different than at the time of sampling.

In 1986, the USGS collected TDS and stable isotope data (deuterium and oxygen-18) which indicated greater TDS concentrations in the northern area likely reflect concentration increases due to evaporation from the shallow water table. The evaporation process adds kinetic separation to the deuterium and oxygen-18 species causing increased enrichment resulting in a characteristic evaporative trend line. **Water Figure 11** shows the deuterium and oxygen-18 compositions (expressed in the “δ” notation) for the 1986 USGS sample locations shown in **Water Figure 12** (the deep well samples plotted in **Water Figure 11** were discussed previously under the heading “TDS Concentrations in the “Deep” Pumped Groundwater Zone”). The shallow well data points plot on an evaporative trend line with a shallower slope than the meteoric water line discussed in Craig (1961), and the posted TDS concentrations indicate the more isotopically enriched Buttonwillow Service Area water samples generally have the greater TDS concentrations.

---

[3] A perched water-table is a special case of an unconfined aquifer whereby the perched groundwater is separated from the underlying main groundwater system by low permeability strata and an underlying unsaturated zone. In the Buttonwillow Service Area, it is uncertain whether an unsaturated zone exists between the shallow water table and main (pumped) groundwater zone.

The evaporative trend line is described by the equation $\delta D = 4.6 \times \delta^{18}O - 31.5$ and is comparable with previous isotope studies from the San Joaquin Valley (Deverel& Fujii1988; Deverel&Gallanthine1989) and other arid areas (e.g. Gat&Isaar1974; Fontes&Gonfiantini1967). **Water Figure 13** shows that correlation between TDS concentrations and isotope composition ($\delta^{18}O$) and calculations indicate the correlation is statistically significantly ($r^2 = 0.47$, $p < 0.05$). Deverel&Fujii1988 and Deverel&Gallanthine1989 found similar correlations between groundwater salinity and isotopic enrichment in the San Joaquin Valley.

Evaporation from the water table is likely ongoing in parts of the Buttonwillow Service Area where shallow groundwater conditions are prevalent. Moreover, the shallow geologic deposits in the area are fine-grained and hydraulic conductivity is low. In the area where the depth to groundwater is ten feet or less, the soils range in texture from clay to clay loam (USDANRDC2008). These soil textures are similar to shallow groundwater areas in the San Joaquin Valley described by Fio&Deverel1991 and Deverel&Fio1991, where they determined groundwater velocities are low (ten feet per year or less). Hence, we expect present-day TDS concentrations to be similar to those measured by the USGS in 1986, which is corroborated by the general agreement between 1986 sample results and BVWSD-reported 2008 TDS concentrations contours (**Water Figure 10**). In 2002, HydroFocus re-sampled shallow groundwater wells located north of BVWSD and in the area between Firebaugh and Kettleman City. The wells were originally sampled in 1984 (Deverel1984), and comparisons between results confirmed that groundwater quality changes were insignificant even though the two sampling events were separated by more than 20 years (HydroFocus2006).

The TDS concentrations in groundwater beneath the Buttonwillow Service Area vary with depth. For example, URS (2010a and 2010b) analyzed water samples and conducted down-hole specific conductance logging in seven wells. They concluded from the well water sample results that groundwater beneath the proposed well field is relatively higher in TDS concentrations and dominated by sodium and chloride ions, whereas samples from wells located further east are dominated by calcium and sulfate ions. Down-hole specific conductance logging suggested vertical stratification of groundwater salinity at some locations, and high salinity water in discrete zones.

When an aquifer is pumped by partially penetrating wells, upward movement of deeper groundwater to the well screens can occur (herein referred to as “up-coning”). In the San Joaquin Valley, saline (brackish) groundwater of sodium chloride water type reportedly underlies the base of the pumped groundwater zone (Page1973). **Water Figure 14** conceptually illustrates up-coning of brackish groundwater to variable depth pumping wells; the timing and quantity of up-coning groundwater is determined by the spatial distribution of active wells, their depths, the magnitude and timing of pumping, and the actual TDS concentration contrasts in groundwater with depth.

Beneath the Buttonwillow Service Area, Page (1973) mapped the depths to brackish groundwater (defined as groundwater having dissolved solids concentrations greater than about 2,000 mg/L) as generally ranging from less than 500 feet in the north to more than 700 feet in the south (**Water Figure 12**). These depths correspond to the bottom third of model layer 2 and upper 200 feet of model layer 3. Hence, simulated up-coning from model layer 3 can contribute to or replace the volume of extracted groundwater originating as inflow from below the well screens. The applicant and staff-modified models simulated proportional contributions of inflow from beneath the well screens that range from 58- to 63-percent of the extracted volume of groundwater, respectively (the volume of inflow from beneath the well screens divided by the annual pumping rate as reported in **Water Figure 15**). In additional model tests completed by staff, simulated inflow from beneath the well ranged from 64-percent (**Water Figure 16**) to 15-percent (**Water Figure 17**).

During the 25-year simulation period, not all up-coning is extracted by the partially penetrating wells.[4] Rather, the up-coning groundwater that remains replaces the relatively shallower groundwater that was extracted by the wells; a portion of the water extracted from the zone influenced by the pumping well (the ZOI) is replaced by up-coning from beneath the well screens (simulated up-coning in the staff-modified model as reported in **Water Figure 15**).

The applicant model did not show any flow induced from beneath 600 feet depth (upward flow from layer 3), unlike each of staff's model runs (**Water Figure 15, 16, 17**). In staff's modified, reduced storativity, and high anisotropy model, water from model layer 3 (below 600 feet depth) moved upward into model layer 2 (between 300 and 600 feet below land surface). The simulated annual flux rates, in AF/y year, are 2,101; 5,666; and 5,454; respectively. Each of these scenarios could represent an additional salt load to the aquifer system that is induced by project pumping but not accounted for in the applicant's model. Assuming the minimum salinity of the up-coning water is 2,000 mg/L, as much as 15,400 tons of salt could be induced to flow upwards from greater depths of the aquifer. Staff acknowledges that if the up-coning water is equal in quality to the water being pumped, there may be no net degradation. However, if the source of degraded water is beneath the "fresh" water at a depth between 500 and 700 feet, pumping which results in up-coning may be more likely to degrade the local aquifer than to improve it. The applicant's mis-application of "recharge" to their groundwater model likely resulted in a low estimate (zero) estimate of up-coning water. This potential source of salt was not analyzed by the applicant, but should be considered prior to concluding a benefit to water quality in the aquifer.

The concentrations of total dissolved solids are reportedly greater west of the well field. The quality of the water extracted by the well field is therefore determined by the spatial distribution of groundwater-flow paths and associated volumetric fluxes into the wells, which delineate the shape and extent of the ZOI. Staff did not calculate the net salt loading created under each of the different pumping/model scenario's, but notes that any quantification of the project's benefit to salt loads in the aquifer would require budgeting of water sources from the west and all other sources affected by the well field pumping. As staff has pointed out there is limited data to show what the source of salts is in the proposed pumping area. This salt loading may also contribute to a shift from calcium-sulfate to sodium-chloride dominated water, and an increase in TDS concentrations within the ZOI. This change in water quality could result in significant impacts to other reasonable beneficial uses.

[4] Staff utilized the post-processor MODPATH (Pollock1994) to delineate the pumping ZOI for the proposed well field, and the post-processor ZONEBUDGET (Harbaugh1990) to extract the simulated average annual volumetric water fluxes (volumetric water budget).

After 25-years of pumping, the applicant's model results indicate groundwater beneath about 1,400 acres will be extracted by the proposed well field. Most of this water (58-percent) comes from beneath the 300 feet deep well screens, and lesser volumes are contributed by horizontal inflow (34-percent), direct recharge (7-percent) and storage (1-percent). The proposed extraction wells remove substantially more horizontal inflow originating east of the well field (22-percent) relative to the assumed low quality water that originates west of the well field (12-percent).

The staff-modified model (no-flow boundary added and no recharge) simulates a slightly smaller pumping ZOI (1,300 acres). An even greater proportion of extracted groundwater (63-percent) is from beneath the well screens. The proportional contribution of horizontal inflow increases slightly to 36-percent (a net increase of 2-percent), and the remaining water extracted is removed from storage (1-percent); there is no recharge. Although the magnitude of inflow from the east decreases by about 20 AF/yr, its proportional contribution to the water extracted from the aquifer is the same (22-percent). Inflow from the west increases more than 120 AF/yr, and its proportional contribution to the pumpage increases from 12- to 14-percent.

Staff performed additional model testing which showed water quality extracted by the proposed well field is sensitive to assumed aquifer conditions. Utilizing the reported representative storativity (0.007) staff found the simulated pumping ZOI area has limited sensitivity to the change in storage coefficient because most of the groundwater extracted comes from beneath the well screens. The simulated pumping ZOI area mapped in **Water Figure 16** is 1,350 acres and only about 50 acres less than simulated by the applicant's model. The proportional contribution of water extracted from below the well screens increased slightly from 63- to 64-percent, and the relative contributions of horizontal flows originating east and west of the well field remained approximately the same.

Increasing the anisotropy substantially increased the pumping ZOI area from 1,350 acres to almost 3,100 acres (**Water Figure 17**). The proportional contribution of water extracted from below the well screens decreased dramatically from 58- to 15-percent, and the contribution from horizontal inflow increased from 34- to 85-percent; most of the horizontal inflow (53-percent) originates east of the well field and a lesser proportion (31-percent) originates west of the well field.

Estimated TDS Concentrations for Industrial Supply

Staff estimated the range in expected TDS concentrations in water produced by the proposed well field. Staff utilized well water sample results, reported TDS concentrations contours (1970-2007 composite contours and 2001 summer contours), and the 25-year pumping ZOI simulated by the applicant's model (URS2009). Staff utilized the ZOI from the applicant's model because there were negligible differences between the applicant and staff-modified models' ZOIs using a lower value for storativity (0.007). Furthermore, although the ZOI area for the staff-modified model increased following an increase in simulated anisotropy (**Water Figure 17**); it did not encroach into areas with additional sampling locations. The TDS concentration data and ZOI are mapped in **Water Figure 18**, and the estimated TDS concentrations based on several different approaches, are summarized below in **Water Table 6**.

Water Table 6
Estimated TDS Concentrations in Water Produced by the Proposed Well Field

ZOI sub-zone	Proportion of ZOI Area (percentage)	Well Field Concentration Estimates			
		1 (mg/L)	2 (mg/L)	3 (mg/L)	4 (mg/L)
A	16.8	1,930	780	2,000	3,000
B	16.5	1,930	399	2,000	3,000
C	18.8	1,930	2,400	2,500	3,000
D	16.2	1,930	2,900	3,000	3,000
E	13.9	1,930	2,030	3,000	3,000
F	17.8	1,930	1,160	2,500	3,000
Mixing Model Results		**1,930**	**1,606**	**2,484**	**3,000**

Approach 1: Representative ZOI quality based on median well water sample concentration.
Approach 2: Representative ZOI quality based on well water sample concentrations in six sub-zones.
Approach 3: Representative ZOI quality based on 1970-2007 composite TDS concentration contours and six sub-zones.
Approach 4. Representative ZOI quality based on summer 2001 TDS concentration contours and six sub-zones.

In the first approach, staff utilized the median observed TDS concentrations from one shallow well sample (1,930 mg/L), three deep well samples (399 to 2,900 mg/L), and one sample from a well of unknown depth (389 mg/L); all the sample locations are located within the simulated ZOI (**Water Figure 18**). The representative TDS concentration of groundwater extracted by the well field using the first approach (median concentration of the five samples) is 1,930 mg/L.

In the second approach, staff considered observed spatial variability in TDS concentrations and assigned a representative concentration to each ZOI sub-zone. The observed concentrations ranged from 389 to 2,900 mg/L (standard deviation of about 70-percent), and the contributing areas represented by the sub-zones range from 14- to 18-percent of the total ZOI area. The representative groundwater concentrations in sub-zones B, C, D and F were selected based on the water samples from wells located within the respective sub-zones (399, 2,400, 2,900, and 1,160 mg/L, respectively); the representative TDS concentration for groundwater in sub-zone F (1,160 mg/L) was estimated from the average of two samples located in the sub-zone (389 and 1,930 mg/L). No samples are located within sub-zones A and E. For sub-zone A, staff assumed a representative TDS concentration equal to the average of the representative concentrations in adjacent sub-zones B and F (780 mg/L). Similarly, the representative TDS concentration in sub-zone E is assumed equal to the average of the concentrations representing adjacent sub-zones D and F (2,030 mg/L).

Assuming the above TDS concentration estimates are representative for groundwater beneath the ZOI sub-zones, the expected composite TDS concentration in water produced by the well field was equal to the area-weighted average of each sub-zone concentration (almost 1,610 mg/L). If sample concentrations vary as much as 70-percent (the standard deviation of the sample results), the estimated TDS concentration in water produced by the well field ranged from 945 to 2,730 mg/L (calculations not shown in **Water Table 6**).

In the third approach, staff utilized TDS concentrations estimated from the composite 1970-2007 contours. The contours indicate a representative concentration of 2,000 mg/L beneath sub-zones A and B. The TDS concentration contours beneath sub-zones C and F range from 2,000 to 3,000 mg/L; hence, we assigned a representative TDS concentration of 2,500 mg/L to these two sub-zones. Sub-zones D and E are generally both located west of the 3,000 mg/L contour, and we assigned representative TDS concentrations beneath these two sub-zones equal to 3,000 mg/L. Assuming these TDS concentrations are representative for groundwater beneath the ZOI sub-zones extracted by the wells, the expected composite TDS concentration in water produced by the well field was equal to the area-weighted average of each sub-zone concentration (about 2,480 mg/L). After varying the contour concentrations by 50-percent of the contour intervals, the estimated TDS concentration in water produced by the well field ranged from 1,000 to 3,730 mg/L (calculations not shown in **Water Table 6**).

In the fourth approach, staff utilized summer 2001 contours which indicate TDS concentrations in groundwater beneath the well field are equal to 3,000 mg/L (**Water Figure 12**). Although observed TDS concentrations in samples from wells located west of the well field are spatially variable and less than 3,000 mg/L, we conservatively assumed TDS concentrations beneath the entire ZOI everywhere equal to 3,000 mg/L. The expected composite TDS concentration in water produced by the well field calculated by this fourth approach is equal to 3,000 mg/L. If the contour concentrations are varied by 50-percent of the contour interval, the estimated TDS concentration in water produced by the well field ranges from 2,500 to 3,500 mg/L (calculations not shown in **Water Table 5**).

Depending on the approach employed, the expected TDS concentrations in water produced by extraction wells operating in the proposed well field area could range from a minimum of about 945 mg/L to a maximum of 3,730 mg/L. This range in concentrations suggests the proposed groundwater supply is not sufficiently degraded such that it can’t be used for agricultural purposes and possibly as a drinking water supply.

Factors Affecting TDS Concentrations in Water from Proposed Well Field

Spatial variability in TDS concentrations in groundwater and the three-dimensional movement of groundwater to extraction wells contribute to uncertainty in the estimated water quality produced by the proposed well field. Observed well water concentrations are limited in number and represent variable sampling dates and well depths. Additionally, extraction wells can intercept groundwater moving both horizontally toward the proposed partially penetrating well screens and upward moving water originating from depths below the well screens.

There are only five samples from wells located within the simulated pumping ZOI, collected over a period of about 50 years (**Water Figure 18**). One of the samples is from a well of unknown depth (389 mg/L). The samples with the lowest TDS concentrations (389 and 399 mg/L) were collected in 1961; whereas the more recent samples collected in 2010 represent different locations and have substantially greater TDS concentrations.

At a workshop on February 20, 2013, staff discussed the results of the preliminary water supply analysis that raised questions about BVWSD's BGRP. At the workshop BVWSD indicated they had additional information that was not considered in staff's analysis. BVWSD requested that staff provide data requests indicating what data they would need to reevaluate the preliminary results and agree to maintain the confidentiality of information that may be submitted by BVWSD. Staff agreed but has not yet received responses to the data requests. Information provided by the district may improve staff's understanding of water quality in the district. Staff expects some new information to be incorporated in future iterations of this analysis, but will proceed with an independent analysis of impacts and alternatives if such information is not forthcoming.

Changes in Water Level and Storage

Many agricultural wells exist within the Buttonwillow Service Area, and a number of wells are monitored for water level and water quality data. Water level data for 64 wells obtained from California Department of Water Resources Water Data Library[5] were assembled and analyzed to identify trends and estimate average annual historical changes in groundwater storage.

In general, water levels were measured semiannually although most records were incomplete. For most years, the water levels were measured during the winter and fall, but in other years the data were collected in the spring and fall. Staff created a subset of 19 wells with at least 35 water level measurements each, spanning the period 1974-2001 (**Water Figure 19**). This subset includes the greatest number of wells with the longest period of over-lapping records and well locations that are spatially distributed across most of the Buttonwillow Service Area.

The Mann-Kendal test and Sen's slope estimator were calculated to determine significant water level trends. The data from most wells (14 of the 19 total wells) show a statistically significant upward trend at the 95 percent confidence level (**Water Table 7**). The significant upward trends range from 0.28 feet per year (ft/yr) to 1.27 ft/yr (average and median trend of 0.68 and 0.64 ft/yr, respectively).
Annual changes in groundwater storage (ΔS) were estimated using the calculated trends and the following equation:

$$\Delta S = A \cdot Sy \cdot \frac{\Delta H}{t}\text{; where,}$$

A is the area of the Buttonwillow Service Area (reported at about 45,000 acres);

Sy is the specific yield (assumed values ranging from 0.15 to 0.20); and,

$\frac{\Delta H}{t}$ is the calculated annual water level trend represented by the Sen's slope estimator (in ft/yr).

The average trend of 0.68 ft/yr indicates the annual increase in groundwater storage ranges from about 4,600 to 6,100 AF/yr (calculated using specific yield values ranging

[5] www.water.ca.gov/waterdatalibrary

from 0.15 to 0.20, respectively)[6]. The planned well field extraction rate (7,500 AF/yr) exceeds the average annual storage change during 1974 through 2001. Staff also reviewed aquifer testing results reported by URS to evaluate site specific conditions and found the data (2010a) indicate a geometric mean storativity of 0.007. Therefore, if this storativity value were representative for the area it would result in an even lower calculated 1974-2001 storage increase. These estimates suggest project pumping may have a larger impact to groundwater storage beneath the BVWSD than assumed by the applicant, and the proposed project pumping (7,500 AFY) likely exceeds the historical annual volume of water contributing to storage beneath the BVWSD. The consumption of stored groundwater will result in long-term water level declines beneath the BVWSD.

Water Table 7
Water Level Trends in Buttonwillow Service Area Wells

Map ID[a]	**Trend** (ft/yr)		
	alpha = 0.05		
	Years	Number of records	Observed
63	1974-2001	45	0.59

Average (significant trends)	---	---	0.68
Average (all trends)	---	---	0.56

a) Well locations and map ID numbers are shown in **Water Figure 7**.

The district's willingness to provide 7,500 AF/y may be unreasonable considering groundwater levels are declining in the Kern County subbasin. The KCWA budget for 1970 through 1998 indicates a negative change in storage of 325,000 AF/y. Over approximately the same time period, the storage change beneath the Buttonwillow Service Area (BSA) estimated from observed water level trends was positive and between 4,600 and 6,100 AF/y. Staff views this increase in storage as definite positive influence on basin storage during a period of significant and widespread storage decline in the Kern County subbasin. However if the proposed project pumping created a negative change in storage within the BSA, this would compound deficits in a basin that has experienced a perpetual decline in groundwater storage.

[6] 45,000 acres x 0.68 foot per year x 0.15 = 4,590 acre-feet per year;
45,000 acres x 0.68 foot per year x 0.20 = 6,120 acre-feet per year.

Project pumping and increased groundwater consumption could cause water level declines and reduce groundwater storage. Staff believes a consumptive use offset could be appropriate mitigation for this potential impact. Staff also believes a suite of possible methods could be implemented to offset project pumping such as developing alternative supplies or funding water conservation programs. The Kern County subbasin has a very high annual extraction rate and many groundwater users. The potential for achieving a water savings in this basin is therefore very good. Much of the basin's water use is non-uniformly metered and accounted for, further increasing the odds for funding a water savings program. These mitigation methods may include retirement of agricultural lands and irrigation efficiency improvement programs, such as micro-sprinkler or drip irrigation, drainage improvements, or tail water reuse. Utilizing other technologies such as dry cooling could also reduce water needed for industrial processes. Staff recommends adoption of Condition of Certification **WATER-3**, which requires the project owner to develop and implement a Water Supply Plan prior to project construction and provide water use offset within the Kern County subbasin that is equal to project pumping, thereby ensuring no new net increase in groundwater consumption. Staff will provide additional analysis concerning the various options for offsetting water use in the FSA/FEIS.

To ensure that the water use analyzed is consistent with that used by the proposed project, staff proposes Condition of Certification **WATER-4**. This condition would limit project pumping to an average of 7,500 acre-feet per year for project operations. Furthermore, this condition requires that water use is metered and reported consistent with these limitations. Staff also proposes Condition of Certification **WATER-5** to ensure that project wells are constructed to state standards.

Subsidence

Declining groundwater levels can cause dewatering and compaction of fine-grained sediment beds resulting in subsidence of the land surface. Hydrocompaction of moisture deficient deposits above the water table (shallow or near-surface subsidence), fluid withdrawal from oil and gas fields, and tectonic movement also contribute to land subsidence. In the San Joaquin Valley, aquifer-system compaction due to water-level decline and near-surface hydrocompaction are the primary causes of historical subsidence. Aquifer–system compaction could resume if groundwater consumption by the project caused water levels to decline below previous water-level lows.

The Buttonwillow Service Area is located adjacent to two major historic subsiding areas in the southern San Joaquin Valley; the Tulare-Wasco area to the northeast and Arvin-Maricopa area to the southeast. **Water Figure 20** shows lines of equal land subsidence mapped in these areas (Ireland&Others1984). They concluded that during the period 1926 to 1970, land surface declines in the Tulare-Wasco area ranged from a maximum of 12 feet near Pixley to a minimum of 2 feet near Wasco. In the Arvin-Maricopa area the land surface declines ranged from less than 1 foot to more than 9 feet. The primary cause of subsidence was declining groundwater levels in the confined zone due to the proliferation of wells and groundwater consumption for agricultural operations. In 1998, DWR concluded that about 1-foot of subsidence occurred since 1970 along a 29-mile reach of the California Aqueduct in an area west of Wasco and the Buttonwillow Service Area (Swanson1998).

Since 1994, the Department of Water Resources has operated an extensometer located about 17 miles southeast of the proposed well field. Details of extensometer construction were not available. **Water Figure 21** shows the measured aquifer compaction and expansion from 1994 to 2009. The water levels in the extensometer well and another nearby well (state well identification number of 29S24E11R001M) show declining groundwater levels since 2001. Groundwater levels reported for 2009 appear to be at their lowest since the start of the data record in 1983. We employed the Mann-Kendal test for trend and the Sen's slope estimator to determine the observed subsidence during this period was statistically significant and the downward trend at the 95% confidence level was 0.001 ft per year.

There is no historical evidence for subsidence in the Buttonwillow Service Area or immediate vicinity of the proposed well field. Statistical analyses of groundwater level data from wells located in the Buttonwillow Service Area indicate statistically significant upward water level trends since 1974 that range from 0.28 ft/yr to 1.27 ft/yr. These upward trends indicate groundwater storage increased on average during the 1974 through 2001 period (**Water Figure 19**). If these water level trends reverse, and water levels decline below historical lows, project groundwater use could contribute to an increased risk of land surface subsidence in the Buttonwillow Service Area. As discussed above in 'Changes in Water Level and Storage' the proposed use of 7,500 AF/y may have a larger impact to groundwater storage beneath the BVWSD than assumed by the applicant, and the proposed project pumping likely exceeds the current annual volume of water contributing to storage beneath the BVWSD. The consumption of stored groundwater will result in long-term water level declines beneath the BVWSD that could lead to subsidence. Staff is concerned that given the proximity to the California aqueduct and historic occurrence of subsidence during extensive groundwater use, there may be potential for significant impacts in the region from project pumping.

Given past and current groundwater pumping in the basin, subsidence could be occurring and project pumping could exacerbate subsidence rates and magnitude. It is unclear however, if subsidence is occurring on or near the proposed well field and whether any resources or structures could be affected by subsidence. Due to the uncertainty related to conditions at the project site, staff recommends that survey monuments be installed and monitoring stations established for assessment of long term changes that may occur as a result of subsidence due to groundwater pumping in the area. Staff also recommends the applicant be required to develop an action plan for mitigation of impacts based on analysis of monitoring station data. Staff recommends the project owner be required to implement Condition of Certification **WATER-6** to monitor and mitigate any potential impacts associated with ground subsidence due to project groundwater pumping. If intermediary measures in the adopted plan do not sufficiently address impacts resulting from subsidence, this condition would require the project to modify or cease pumping until the impacts can be addressed.

Construction and Drinking Water

The proposed project would be supplied with construction water and potable water during operations by either West Kern Water District (WKWD) or existing onsite wells. If delivered from WKWD, water would be delivered through a 1-mile pipeline that runs west to the project site. The onsite supply options would be to obtain supply water from one of the two alternative onsite wells, the Ackerman well or the Alternative B well. Maximum use from either supply would be up to 12 AF/y. A summary of average and maximum use rates for construction and potable water is summarized below in **Water Table 8**.

Water Table 8
Water Supply Quantities

	Supplier	Average Use (gpd)	Max Use (AF/y)	Maximum Use (gpd)
Construction Water	Onsite/WKWD	11,800	12	24,000
Potable Water (Operations)	WKWD	1,800	2	2,700

Source: AFC 2012, Table 5.14-8

Using the transmissivity (116,000 gal/day/foot) and storage coefficient (0.007) from the applicant's aquifer test (URS 2010j, Table 4), staff used the Theis equation to conservatively estimate impacts from pumping groundwater from construction. The average use rate during construction is expected to be 11,800 gpd. Over the construction period, pumping would result in less than a tenth of a foot of drawdown at a distance of 500 feet from the well. Based on this analysis staff concludes that the volume of water required for both construction and potable water would have no significant impact on local wells and aquifer storage.

Similar to the project's proposed use of groundwater within the BVWSD, use of groundwater from the WKWD would contribute to cumulative overdraft of the Kern County subbasin. The project's use of water for construction and domestic uses should be offset by the replacement of water in the basin. Staff proposes Condition of Certification **WATER-3** to mitigate for the proposed project's contribution to overdraft. Staff also proposes **WATER-4** which would limit construction water use to 12 AF/y.

CUMULATIVE IMPACT ANALYSIS

A project may result in a significant adverse cumulative impact where its effects are cumulatively considerable. "Cumulatively considerable" means that the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of reasonably foreseeable future projects (California Code of Regulations, Title 14, section 15130).

The HECA project would be located within the Kern County subbasin, which would be the groundwater unit across which a cumulative impact from the project should be analyzed. Due to the large extent of the Kern County subbasin it is difficult to assess the extent of foreseeable projects that could impact the groundwater balance. However, the available basin budget analyses reviewed by staff indicate that uses within the Kern County subbasin may already exceed supply. The project's potential incremental impact would be additive and cumulatively considerable. If the Kern County subbasin is in a state of overdraft, the proposed project's pumping would contribute to the water storage deficit. Though BVWSD's contribution to the Kern County subbasin is currently positive, the use of 7,500 AF/y of water by the project can potentially exacerbate overdraft conditions in the Kern County subbasin and create a significant adverse impact. Staff recommends adoption of Condition of Certification **WATER-3**, which requires the project owner to develop and implement a Water Supply Plan prior to project construction and provide water use offset within the Kern County subbasin that is equal to project pumping, thereby mitigating for any cumulative impact to the water balance of the Kern County subbasin.

WATER SUPPLY ALTERNATIVES

The AFC contained a number of water use alternatives, but failed to consider dry cooling. Dry cooling is worthy of consideration for at least the two following reasons:

- The proposed project could be the most water intensive power plant in California.
- The proposed project has the potential to create significant impacts to water resources.

The applicant states that dry cooling is infeasible in Data Response A203 by stating:

- Capital cost differential of approximately $20-30 million
- Reduced power output of between 20 to 40 megawatts
- Overall total cost impact of about $50 million

Staff has not yet been able validate or deny the applicant's statement about the infeasibility of the dry cooling alternative, but notes that the following factors do not appear to have been considered by the applicant:

- The energy required to move 7,500 acre-feet per year, 15 miles, and about 30 feet upgradient.
- The untreated water cost of $3,375,000 per year, or $84,375,000 over a 25-year period
- Cost of treating 7,500 acre-feet per year with zero liquid discharge (ZLD) technology.
- Disposal of ZLD solids that may be generated if untreated process water contains high concentrations of total dissolved solids.

As stated in previous sections of this analysis, the Kern County subbasin is in overdraft. The proposed pumping does not provide any obvious benefit to local landowners or their water supply. The quality of water produced by the proposed well field may not be sufficiently degraded to justify power plant use. As also stated in this analysis, in some cases the impact to water resources may be proportional to the volume pumped, and likewise, any decrease in water use could contribute to a lessening of the impact, proportional to the decrease. It is therefore reasonable to consider dry cooling to reduce the potential project's water consumption. Dry cooling has the potential to create the following benefits:

- Reduce project water demand to roughly 10-percent of the currently proposed amount, which could result in a cost savings of approximately $75,937,500 over a 25-year period.
- Energy savings over a 25-year period from reduced water transport.
- Significantly reduce the contribution to overdraft in the Kern County subbasin.
- Reduce project-induced drawdown in local water wells in an area that has been identified as an Environmental Justice population.
- Reduce potential for inducing lower quality water to the pumping field aquifer area.
- Reduce potential for impacts to the California Aqueduct from subsidence.

Given staff's current conclusions regarding impacts to basin overdraft and groundwater quality, and consistency with the water policy, staff believes dry cooling should seriously be considered as an alternative to the project's current water use proposal. Staff intends to provide a more detailed analysis of this alternative technology in the FSA/FEIS.

A number of alternative water supplies for the proposed HECA project are provided within Section 6.0 (Alternatives) of the AFC (2008), Revised AFC (2009), and Amended AFC (2012). Based upon the water supply alternatives identified above within the subsection entitled **ALTERNATIVES CONSIDERED WITHIN THE APPLICATION FOR CERTIFICATION**, the following alternatives have been eliminated from further consideration by the applicant, but not necessarily by staff:

- <u>Ocean Water Alternative</u>. The proposed HECA project site is approximately 75-miles from the Pacific Ocean. Although this supply is virtually limitless and desalination technology is successfully proven, the capital cost for transporting, treating, and disposing of this option is high, exceeding $500 million (HECA 2012e, Section 6.0, p. 6-24). Upon review, staff has determined that constructing a pipeline this distance would result in increased environmental impacts compared to those of the proposed HECA project. Additionally, Energy Commission and other state agency directives are eliminating use of ocean water for power plant cooling. Based upon these factors, an ocean water supply alternative is considered infeasible and is, therefore, eliminated from further consideration.
- <u>Ocean Discharge Alternative</u>. Identical to that discussed above for an ocean water supply alternative, staff has determined that constructing a pipeline this distance would result in increased environmental impacts compared to those of the proposed HECA project. While it is assumed this alternative would capture water prior to being discharged to the ocean, it would result in a decrease to ocean water inflow and be inconsistent with overall Energy Commission and other State agency directives toward eliminating use of ocean water for power plant cooling. Based upon these factors, an ocean discharge alternative is considered infeasible and is, therefore, eliminated from further consideration.
- <u>Brackish Water - Industrial Wastewater</u>**.** The project applicant has indicated that producers of industrial wastewater are willing to provide this water to the proposed HECA project (HECA 2012e, Section 6.0, p. 6-25). However, they are reluctant to guarantee specific quantities of future water supply (HECA 2012e, Section 6.0, p. 6-

25). Additionally, the proposed HECA project applicant estimated the capital cost to construct a water plant to process this raw water supply could be $200 million and could result in a nearly 15 MW additional parasitic load over use of brackish groundwater (HECA 2012e, Section 6.0, p. 6-25). The proposed HECA project applicant has indicated that these capital and operating costs are substantial and deem this alternative infeasible.

The thermal treatment technology would produce a concentrated brine waste stream (HECA 2012e, Section 6.0, p. 6-25). Based upon water quality data already obtained, it is possible that this reject stream will have constituents at sufficient levels to trigger classification of the brine waste stream as hazardous waste (HECA 2012e, Section 6.0, p. 6-25). This waste generation could conflict with the intent of the proposed HECA project design to minimize the production of hazardous waste to the extent feasible (HECA 2012e, Section 6.0, p. 6-25).

In summary, the applicant has indicated that although oilfield-produced water appears to be technologically possible as a water supply to the proposed HECA project, it is not the preferred option, due to availability, environmental, waste disposal, and cost considerations (HECA 2012e, Section 6.0, p. 6-25).

Staff's independent review of this alternative has likewise determined that this alternative is technologically feasible. Appendix A of the AFC states, "Total dissolved solids concentrations can be as high as 5,000 parts per million (ppm)." Water of this quality would likely comply with the Energy Commission's Water Policy. This option would also be less energy intensive for water transport to the site. The HECA site is down gradient and approximately 3 miles from the Elk Hills oil field, whereas the site is uphill and 15 miles from the proposed well fields. The difference in cost of getting water to the site between the two options may be substantial.

Even though 7,500 acre-feet per year may not be available from the oil field, some lesser amount may be feasible. Staff is still seeking information about the amounts of water available from local oil fields. In addition it is not clear to staff whether a significant volume of hazardous waste would be generated. The brine can often be managed such that the concentrations are kept below the threshold values. Further analysis may show that given disposal options currently available it may be a viable alternative.

- <u>Brackish Water – Semitropic Water District</u>. The project applicant has indicated that Semitropic Water District was unable to verify the water supply quantity and composition and, therefore, unable to provide a firm water supply commitment for the proposed HECA project (HECA 2012e, Section 6.0, p. 6-24). Staff independent review of this alternative has not been able to validate the applicant's statements in the AFC. At this time, staff cannot eliminate this alternative.
- <u>Inland Wastewater – Municipal Effluent Alternative</u>. Currently, the city of Bakersfield is selling its treated effluent to local farmers for irrigation purposes. They do not have excess capacity outside of existing contracts, which could supply the proposed HECA project with its total water needs (HECA 2012e, Section 6.0, p. 6-27). This provider does have some excess production (approximately 1 million gallons per day), which is expected to increase prior to proposed HECA project start-up. This growth rate is estimated at approximately 0.25 million gallons per day (mgd) per year, resulting in another 1 mgd available by 2014.

This amount is insufficient to supply all of the HECA project needs (6.624 mgd), and would have to be augmented by an additional water supply (HECA 2012e, Section 6.0, p. 6-27). Based upon staff's preliminary review of this factor, a Municipal Wastewater Effluent Alternative option is considered infeasible to meet all of the proposed project needs, but cannot be eliminated because this source could supply a substantial portion of the needs. Staff experience also suggests the contracts with farmers may not be firm and a recycled water provider will often prefer contracting with an industrial facility that will use the supply on a consistent and reliable basis. If the proposed project were to use some proportion from this source, the level of potential impacts to water resources from the proposed project could be reduced. This is particularly true, when compared to the current use of the supply for agriculture which has a high return flow, because it is possible there is increased salt load to the aquifer where the water is applied. Such potential salt loading would not be consistent with current state policy. Consumptive use at a power plant would generally be a preferred alternative. Furthermore, this option for the water source would likely comply with the Energy Commission's water policy and state policy that encourages the use of reclaimed water for power plant cooling.

- Inland Wastewater – Agricultural Wastewater Alternative. Agricultural wastewater (i.e., tile drainage) is excess water from irrigation practices. This wastewater is not available in sufficient quantities in the vicinity of the proposed HECA project site, nor is it sufficiently reliable for use at the proposed HECA project due to water quality variability (HECA 2012e, Section 6.0, p. 6-27).

  Based upon staff independent review of this alternative, an agricultural wastewater supply alternative option is considered potentially feasible and cannot be eliminated from further consideration. The amount available from the Buena Vista Water Storage District's Target Area A is 4,500 acre-feet per year, which is insufficient to supply all of the HECA project needs (6.624 mgd), but could be augmented by an additional water supply (HECA 2012e, Section 6.0, p. 6-27). This volume may also be sufficient to meet the needs for the alternative where there is no fertilizer facility included. If the proposed project were to use some proportion from this source, the level of potential impacts to water resources from the proposed project could be reduced. Furthermore, this option for the water source would likely comply with the Energy Commission's water policy and state policy that encourage the use of reclaimed water for power plant cooling.

- Other Inland Waters – State Water Project Alternative. Water supply from the State Water Project was evaluated in comparison to the proposed HECA project brackish groundwater supplier (BVWSD). The aqueduct located directly south of the proposed HECA site delivers State Water Project water. However, the proposed HECA project would not receive an allocation for the use of freshwater from the State Water Project (HECA 2012e, Section 6.0, p. 6-27).

  The use of fresh water for power plant cooling is discouraged through state guidance and policy. This factor, when considered with the fact that no specific allocation is identified, makes the State Water Project water supply alternative infeasible. This alternative is therefore eliminated from further consideration.

- Other Inland Waters – Fresh Groundwater Alternative. Water supply from inland groundwater was evaluated in comparison to the proposed HECA project brackish groundwater supplier (BVWSD). Given the availability of other viable sources of water, use of this freshwater supply would be inconsistent with the California Water Policy (HECA 2012e, Section 6.0, p. 6-27).

The use of fresh water for power plant cooling is discouraged through state guidance and policy. This factor, when considered with the fact that no specific allocation is identified, makes the fresh groundwater alternative water supply infeasible. This alternative is therefore eliminated from further consideration.

- Other Inland Waters – Municipal Water Supply Alternative. Water supply from inland municipal water suppliers was evaluated in comparison to the proposed HECA project brackish groundwater supplier (BVWSD). Given the availability of other viable sources of water, use of this water supply would be inconsistent with the California Water Policy (HECA 2012e, Section 6.0, p. 6-28).

  The use of fresh water for power plant cooling is discouraged through state guidance and policy. This factor, when considered with the fact that no specific allocation is identified, makes the State Water Project water supply alternative infeasible. This alternative is therefore eliminated from further consideration.

COMPLIANCE WITH LORS

WATER USE LORS AND STATE POLICY AND GUIDANCE

The Energy Commission has at least four sources for statements of policy relating to water use in California applicable to power plants. They are the California Constitution, the Warren-Alquist Act, the Commission's restatement of the state's water policy in the 2003 Integrated Energy Policy Report ("IEPR"), and the State Water Resources Control Board ("SWRCB" or "Board") resolutions (in particular Resolutions 75-58 and 88-63).

California Constitution

Article X, section 2 prohibits the waste or unreasonable use, including unreasonable method of use, of water, and it requires all water users to conserve and reuse available water supplies to the maximum extent possible (Cal. Const., art. X, § 2). Groundwater is subject to reasonable use (*Katz v. Walkinshaw* (1903) 141 Cal. 116).

Warren-Alquist Act

Section 25008 of the Energy Commission's enabling statutes echoes the Constitutional concern, by promoting "all feasible means" of water conservation and "all feasible uses" of alternative water supply sources (Pub. Resources Code § 25008).

Integrated Energy Policy Report

In the 2003 Integrated Energy Policy Report (IEPR or Report), the Energy Commission reiterated certain principles from SWRCB's Resolution 75-58, discussed below, and clarified how they would be used to discourage use of fresh water for cooling power plants under the Commission's jurisdiction. The report states that the Commission will approve the use of fresh water for cooling purposes only where alternative water supply sources or alternative cooling technologies are shown to be ''environmentally undesirable" or "economically unsound" (IEPR (2003), p. 41). In the report, the

Commission interpreted "environmentally undesirable" as equivalent to a "significant adverse environmental impact" under CEQA, and "economically unsound" as meaning "economically or otherwise infeasible," also under CEQA (IEPR, p. 41). CEQA and the Commission's siting regulations define feasible as "capable of being accomplished in a successful manner within a reasonable amount of time," taking into account economic and other factors (Cal. Code Regs., tit. 14, § 15364; tit. 20, § 1702, subd. (f)). At the time of publication in 2003, dry cooling was already feasible for three projects—two in operation and one just permitted (IEPR, p. 39).

The report also notes California's exploding population, estimated to reach more than 47 million by 2020, a population that will continue to use "increasing quantities of fresh water at rates that cannot be sustained" (IEPR, p. 39).

State Water Resources Control Board Resolutions

The SWRCB not only considers quantity of water in its resolutions, but also the quality of water. In 1975, the Board adopted the *Water Quality Control Policy on the Use and Disposal of Inland Waters Used for Power Plant Cooling* (Resolution 75-58). In it, the Board encourages the use of wastewater for power plant cooling. It also determined that water with a TDS concentration of 1,000 mg/L or less should be considered fresh water (Resolution 75-58). One express purpose of that resolution was to "keep the consumptive use of fresh water for power plant cooling to that *minimally essential*" for the welfare of the state (*Ibid*; emphasis added).

In 1988, the Board determined that water with TDS concentrations of 3,000 mg/L or less should be protected for, and considered as, potential supplies for municipal or domestic use unless otherwise designated by one of the Regional Water Quality Control Boards (Resolution 88-63).

NOTEWORTHY PUBLIC BENEFITS

Staff has not identified any noteworthy public benefits of the proposed project that are associated with water resources.

DOE'S FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the applicant for the HECA project. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

What is HECA's definition of brackish water in mg/L of dissolved salts. What is the level of salts in the proposed brackish water? Is there a guarantee that water below a certain level of salts will not be used by HECA for process water?	Please see the "Groundwater Quality Impacts" section for further analysis.
2.2	**Kern County Farm Bureau**	**July 12, 2012**	I am here to advise you of our initial concerns on the impacts the proposed hydrogen energy project would have on agriculture and those who live on and work the land in the Buttonwillow community. Specifically; "Disruption to local water delivery infrastructure,"	Staff analyzed well interference that could be caused by project pumping and identified mitigation for any potential impacts in Condition of Certification WATER-1 and -2.
2.3	**Chris Romanin i**	**July 12, 2012**	What if the unforeseen happens…. a problem with their pipes, an earthquake, an accident, or an unknown that has not been regulated yet, or something else. Our ground water will be contaminated. Contaminated water is impossible to correct.	Staff would require that all hazardous material/ contaminants are handled appropriately according to the law. Please see the **Hazardous Materials** and **Waste Management** sections for details about material handling and containment requirements.
3.1	**Marjorie Bell**	**July 26, 2012**	In addition, the HECA plant will use "brackish" water (huge quantities of it) as a coolant on the theory that there are huge quantities to be had in this valley. As one farmer said at the hearing, slightly brackish water can be used on certain crops,	Staff acknowledges that the water proposed for use may be acceptable irrigation water for some farmers in the district. Staff provides some discussion in this analysis that explains these uses. Others have also questioned the available volume of "brackish" water available for

Cmnt 1	From	Date	COMMENT TOPIC **Government Agencies**	RESPONSE
			especially when mixed with fresh water. This isn't necessarily waste water we are talking about. It is water already being used successfully for crops. And what will happen when the brackish water is gone? The plant will then begin to use fresh water, which is currently in diminished supply because of a drought that may well continue into the next century.	project use. The staff analysis shows that water of different qualities could be blended by the proposed wells to produce the water supply. The degree of blending that would occur is difficult to quantify. The applicant also has yet to identify the source of the lower quality waters in the district and it is therefore difficult to evaluate the quantity that may be available.
3.2	**Kendell Heck**	**July 27, 2012**	I live right down the road from HECA. I'm afraid for my air, water, traffic, and those tall smoke stacks are terrible.	Please see the above analysis of potential impacts to water resources. Staff is awaiting additional data to complete analysis for potential impacts of the proposed water supply. Where appropriate staff has identified mitigation measures to ensure there would be no impacts to other water users in the basin. Please continue to provide comments that articulate your concerns.
3.3	**Richard and Jan Wolfe**	**July 30, 2012**	We also have drilled our own water well. The new plant will also be pulling from the same water table. If this causes the water table to lower too much, we may have to re-drill our water well deeper. Who's gonna pay for that? We sure can't afford it!	The project owner would be required to mitigate for an impact like this through a payment to the well owner. Condition of Certification WATER-1 would require the applicant to reimburse local well owners for this impact.
3.4	**Cindy Stiles**	**August 3, 2012**	I believe the promise of jobs for our county has blinded the local officials to the negative impact this factory will have: more-brackish ground water to irrigate our crops (this will negatively impact crop yield);	Staff is examining these issues closely. Please review sections of the Preliminary Staff Assessment that address your concerns.

Cmnt 1	From	Date	COMMENT TOPIC Government Agencies	RESPONSE
3.5	**Debbie Shepher d**	**August 3, 2012**	Water: Define brackish water and is it going to be long term? What impact is this going to have on the water table? Who or what is going to control how much water the plant uses?	The term brackish has different definitions depending on who defines it. Staff described some of the uses for water of different quality in this analysis. Generally staff believe brackish should be used to define water with limited beneficial uses due to a high salt concentration. Staff analyzed and described the potential water level lowering that could result from this project in this analysis. The amount of water that would be used by the project would be regulated through Condition of Certification WATER-4.
3.6	**Trudy Douglas**	**Septemb er 21, 2012**	The HECA coal powered chemical factory will put 520 tons of pollution and particulates into the air a year and use 6.6 million gallons of water a day. These are issues that we must examine closely but, the CEC seems not to be interested in helping us to do so.	Staff is examining these issues closely. Please review sections of the Preliminary Staff Assessment that address your concerns.

STAFF CONCLUSIONS

Staff evaluated the reasonableness of water use using multiple sources of guidance. Ultimately, staff attempts to uphold Article X, Section II of the California Constitution which states that water shall not be wasted. In the context of power plant water use, this equates to the “least of the worst,” which means a project should demonstrate that it uses the least amount of the poorest quality water available.

The project proposes to use up to 7,500 AF/y, which is significantly more water per megawatt than other recently licensed projects. Staff understands that approximately 30 percent of the proposed water use would go to the gasification process, but even then the projected water use required produce up to 300 MW net is inordinately high.

Presumably at the time of the original AFC (July, 2008), the applicant also considered the pumping in the context of SWRCB Resolution 75-58 which states that water with TDS above 1,000 mg/L might be a preferential source for power plant cooling. Furthermore, staff does not agree that the proposed pumping would constitute reclamation. Water below 2,000 mg/L TDS would certainly not qualify as significantly degraded (**Water Table 5)**, based on data that indicates this water is not only suitable for agriculture, but widely used in the region for this purpose. Water between 2,000 and 3,000 mg/L TDS could generally be considered degraded in terms of agriculture supply, which is the region's primary use, but would still be a source worthy of protection for potential domestic supply (SWRCB, Resolution 88-63).

Recent studies and intervenors that farm in the area point out that the water supply is still beneficial for irrigation of crops grown in the district and should be protected for those purposes. A source worthy of protection, is at the very least, not degraded enough to justify reclamation but still subject to reasonable use. The applicant's belief that the project could reclaim portions of the BVWSD may be true, but staff would not label pumping as a reclamation activity when there may be other reasonable beneficial uses of a supply with TDS concentration of 2,000 to 3,000 mg/L. Staff can only support the use of groundwater greater than 3,000 mg/L for cooling, given the high volume required for this project and the need to be consistent with using "the least of the worst". Staff's estimate that the project's water use would likely range from a minimum of about 945 mg/L to a maximum of 3,730 mg/L in TDS concentrations using the limited groundwater quality data available suggests it is likely the proposed pumping would not produce a sufficiently degraded supply.

As stated in this analysis, the district's willingness to provide 7,500 AF/y to the project may be unreasonable considering that the Kern County subbasin is in overdraft and considering that the district average water level increase is not as high as 7,500 AF/y. The KCWA budget for 1970 through 1998 indicates a negative change in storage of 325,000 AF/y. This indicates that the Kern County subbasin was in overdraft during that period and is likely still in overdraft. Over approximately the same time period, the storage change beneath the Buttonwillow Service Area (BSA) estimated from observed water level trends was positive and between 4,600 and 6,100 AF/y. Staff views this increase in storage as a positive influence on basin storage during a period of significant and widespread storage decline in the Kern County subbasin. However if the proposed project pumping created a negative change in storage within the BSA, this would compound deficits in a basin that appears to be in overdraft.

The proposed use would appear more reasonable if it were able to achieve multiple benefits. For instance, if the project was supplied with water from a remediation project the use of water within the Kern County subbasin would be more reasonable. The current location would supply a large volume of groundwater of an unsure quality, TDS concentrations between 1,000 mg/L and 4,000 mg/L. Assuming the worst case scenario, where the supply is closer to 1,000 mg/L, the project may have no quantifiable benefit other than providing an industrial water supply. However if the project were to pump shallow groundwater from the northern Buttonwillow Service Area, which is a known regional issue, it is much more likely that the project could at least lower the shallow groundwater table beneath the root zone and perhaps also remove water with no other beneficial uses. BVWSD's FEIR states that the district is interested in pumping water from their Target Area A, which has a shallow groundwater problem and is available in sufficient quantity to supply a significant portion of the project needs.

STAFF'S PROPOSED AREAS OF FURTHER REVIEW

Staff believes that other well configurations or locations could more effectively capture poor quality water or water with no other beneficial uses. If the project's pumping were able to better induce horizontal flow, particularly flow from the east, it is more likely that pumping could remove brackish water from the local aquifer. Staff believes this effect could be accomplished by a couple of distinct changes in the pumping strategy.

- As described in this analysis and in the BVWSD FEIR, the northern portion of the district appears to contain low quality water at shallower depths. This water is detrimental to agriculture and should be removed from the crop root zone. In their FEIR, BVWSD identifies the intent to develop brackish groundwater remediation in the northern BSA and produce up to 4,500 AF/y, in addition to the supply allocated for HECA. Staff believes this opportunity provides a much greater potential for meeting the proposed objectives of remediation and power plant cooling supply. Supply wells located in BVWSD's northern BSA are more likely to remediate agricultural lands and produce a consistent poor quality supply.
- The applicant has not sufficiently evaluated alternative water sources that may better satisfy water policy concerns. The Revised Application for Certification contains a brief description of the alternative water supplies considered for the project. The description of the alternative, agricultural wastewater, is very brief and general. BVWSD's Water Balance (FIER, 2009) indicates that surface outflow from the agriculture-dominated district may be significant. Staff is also aware that BVWSD is exploring methods for treatment and options for reuse of agricultural drainage, see "Low-pressure RO membrane desalination of agricultural drainage water," published in Desalination in 2003. Staff also notes approximately 12,000 to 15,000 acres of the Buttonwillow Service Area located north of the proposed well field is affected by a shallow water table. Use of this alternative water supply by HECA could provide dual benefits of root zone salt balance and improved soil aeration in the affected area.
- Staff is interested in learning more about the proposed well field and potential water quality that may be produced from it. Additional wells may provide useful information about how water quality varies with depth at the proposed well field site and also may help provide clarity in future discussions on water policy and potential impacts.
- Water alternatives dismissed by the applicant such as municipal wastewater from Bakersfield, oil field wastewater, or BVWSD Target Area A water, were eliminated because they can't supply the proposed project's entire water supply. However it is unreasonable to dismiss all of these options when any one of them could provide up to 50 percent of the project's water needs.

- The applicant has also neglected to adequately consider a dry-cooled project alternative. As stated in this analysis, in some cases the impact to water resources may be proportional to the volume pumped, and likewise, any decrease in water use could contribute to a lessening of the impact, proportional to the decrease. It is reasonable to consider dry cooling to reduce the potential project's water consumption. Dry cooling has the potential to: a) reduce project water demand to roughly 17-percent of the currently proposed amount, and thereby b) reduce untreated water costs by approximately $70,000,000 over a 25-year period.

ENVIRONMENTAL ANALYSIS OF CO_2 INJECTION

This section of the PSA/DEIS analyzes potential impacts to water resources from the construction and operation of the Occidental of Elk Hills, Inc. (OEHI) CO_2 Enhanced Oil Recovery component(OEHI). Where the potential of a significant impact is identified, staff proposes mitigation to reduce the significance of the impact and, as appropriate, recommended conditions of certification.

PROPOSED PROJECT DESCRIPTION

Occidental of Elk Hills, Inc. (OEHI) is proposing to extend the life of the Enhanced Oil Recovery (EOR) operations at their Elk Hills, California site by utilizing carbon dioxide (CO_2) to facilitate oil production from its Elk Hills Unit operations. The OEHI component would require carbon dioxide produced by the proposed Hydrogen Energy California (HECA) project. The HECA project would be located approximately three miles north of the Elk Hills Unit and will generate CO_2 from an Integrated Gasification Combined Cycle (IGCC) power plant. HECA would utilize technology capable of capturing over 90 percent of the CO_2 produced during facility operations. This 2.6 million tons per year of CO_2 would be compressed and delivered via a new 12-inch diameter pipeline to OEHI's EOR processing facility. Approximately 0.4 million tons per year would not be sequestered but used in fertilizer production.

The source of non-potable water for the proposed project is the Tulare aquifer. The project site is located within the Kern County subbasin of the San Joaquin Valley groundwater basin. The depth to groundwater ranges from 380 feet to as much as 780 feet below the surface. The groundwater has both artificial and natural sources. The artificial sources are from injection of produced water. The natural source of groundwater recharge is likely from the Temblor Range to the west. The Tulare aquifer is an exempt aquifer within the Elk Hills and currently accepts produced water from oil production activities at the Elk Hills oil field. The groundwater in the Tulare aquifer is highly mineralized and generally poor quality. Total dissolved solids concentrations can be as high as 5,000 parts per million (ppm) (AFC, 2012).

Project Water Supply

The project proposes the use of five existing make-up water wells with the permitted capacity of producing 50,000 barrels of water per day each. OEHI anticipates that approximately 10,000 barrels of water for each well per day will be produced to support the project. There are no other pre-existing wells located nearby that could be affected by OEHI's proposed use of the five groundwater production wells such that production rates of other wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted. The OEHI component would therefore not substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level that would have the potential to adversely affect other existing or planned uses of the Tulare Aquifer. This is a less than significant impact.

No local well owners are known to rely on the aquifer in this area for a domestic or agricultural supply. No well owners would therefore be impacted by water level lowering as a result of the proposed project pumping. Impacts resulting from the project's water use would be less than significant. Staff does not propose any mitigation for the project's water use. OEHI's water use would not result in any potential impacts due to subsidence.

Staff reviewed the EOR component of this project for its potential impact to underground sources of drinking water (USDW). Geologic sequestration of CO_2 through well injection meets the definition of "underground injection" in section 1421(d)(1) of the Safe Drinking Water Act (SDWA). The EPA has authority for underground injection under the SDWA Underground Injection Control (UIC) program. In California, the EPA granted primacy to DOGGR to regulate Class II injection wells which includes wells used for enhanced oil recovery but not carbon capture and sequestration. Also pertinent to sequestration is Public Resources Code, Section 3106, which requires DOGGR to supervise the drilling, operation, maintenance, and abandonment of all wells drilled in California for the purpose of injecting fluids for stimulating oil or gas recovery. To meet the requirements of the SDWA, OEHI is obtaining a UIC permit through DOGGR to protect underground sources of drinking water from potential impacts related to the enhanced oil recovery injection operations. For more information on the proposed injection wells, please see the **Carbon Sequestration and Greenhouse Gas Emissions** section of this PSA/DEIS. Potential impacts related to subsidence from this project component are also discussed in this section.

PROPOSED CONDITIONS OF CERTIFICATION

Staff has provided preliminary conditions of certification that could be used to mitigate potential impacts from basin overdraft, well interference, and subsidence. However, these conditions are only applicable if it can be shown through further analysis that potential groundwater quality impacts identified herein are not a concern. In addition, given staff's current conclusions, a more rigorous analysis of alternatives must be conducted to show there is no other economically feasible and environmentally desirable water supply available. Staff is currently researching water supply alternatives and expects to release its conclusions and recommendations in the Final Staff Assessment.

WATER LEVEL MONITORING FOR IMPACTS TO NEIGHBORING WELLS

WATER –1: The project owner shall submit a Groundwater Level Monitoring, Mitigation, and Reporting Plan to the CPM for review and approval in advance of construction activities and prior to the operation of onsite groundwater supply wells. The Groundwater Level Monitoring, Mitigation, and Reporting Plan shall provide detailed methodology for monitoring background and site and off-site groundwater levels. The monitoring period shall include pre-operation and project operation. The plan shall establish pre-well-construction groundwater level trends that can be quantitatively compared against predicted trends near the project pumping wells and near potentially impacted receptors.

A. Prior to Project Construction

1. A well reconnaissance shall be conducted to investigate and document the condition of existing water supply wells located within 3 miles of the project site, provided that access is granted by the well owners. The reconnaissance shall include sending notices by registered mail to all property owners within a 3 mile radius of the project area, shall identify the owner of each well, and shall include the location, depth, screened interval, pump depth, static water level, pumping water level, and capacity of each well, The plan should include, as feasible, agreements from the owner of each well approving monitoring activities.
2. Monitor to establish pre-installation conditions. The monitoring plan and network of monitoring wells shall make use of existing and new monitoring wells installed by the project owner. All monitoring wells shall be installed to a depth that matches the depth of the project pumping wells. A plan for design and construction of any new monitoring wells and how they will be effective in evaluating project pumping impacts on domestic well owners shall be submitted to the CPM for review and approval prior to installation and monitoring.

   The projected area of groundwater drawdown shall be refined on an annual basis during project construction and every year during project operations using the data acquired through implementation of this condition.
3. As access allows, measure groundwater levels from the off-site and on-site wells within the network and background wells to provide initial groundwater levels for pre-project trend analysis. Assess the significance of an apparent trend and estimate the magnitude of that trend using the Kendall test for trend (Kendall and Kendall, 1980) and the Sen’s slope estimator (Sen, 1968).

B. During Construction:

1. Collect water levels from wells within the monitoring network on a monthly basis throughout the construction period and at the end of the construction period. Perform statistical trend analysis for water levels. Assess the significance of an apparent trend and estimate the magnitude of that trend using the Kendall test for trend (Kendall and Kendall, 1980) and the Sen's slope estimator (Sen, 1968).

C. During Operation:

1. On a monthly basis for the first year of operation and quarterly thereafter for the life of the project, collect water level measurements from wells identified in the groundwater monitoring program to evaluate operational influence from the project. Operational parameters (i.e., pumping rate) of the water supply wells shall be monitored.
2. On an annual basis, perform statistical trend analysis of water level data and compare to predicted water level declines due to project pumping. Analysis of the significance of an apparent trend shall be determined and the magnitude of that trend estimated. Assess the significance of an apparent trend and estimate the magnitude of that trend using the Kendall test for trend (Kendall and Kendall, 1980) and the Sen's slope estimator (Sen, 1968).
3. If water levels have been lowered more than 15 feet below preconstruction levels at the nearest determined neighboring well, and monitoring data provided by the project owner show these water level changes are different from background trends and are caused by project pumping, then the project owner shall provide mitigation to the impacted well owner(s). Mitigation shall be provided to the impacted well owners that experience 15 feet or more of project-induced drawdown if the CPM's inspection of the well monitoring data confirms changes to water levels and water level trends relative to measured pre-project water levels, and the well (private owner's well in question) yield or performance has been significantly affected by project pumping. The type and extent of mitigation shall be determined by the amount of water level decline induced by the project, the type of impact, and site specific well construction and water use characteristics. If an impact is determined to be caused by drawdown from more than one source, the level of mitigation provided shall be proportional to the amount of drawdown induced by the project relative to other sources. In order to be eligible, a well owner must provide documentation of the well location and construction, including pump intake depth, and that the well was constructed and usable before project pumping was initiated. The mitigation of impacts shall be determined as follows:
    a. If project pumping has lowered water levels by 15 feet or more and increased pumping lifts, increased energy costs shall be calculated. Payment or reimbursement for the increased costs shall be provided at the option of the affected well owner on an

annual basis. In the absence of specific electrical use data supplied by the well owner, the project owner shall use **WATER-2** to calculate increased energy costs.

b. If groundwater monitoring data indicate project pumping has lowered water levels below the top of the well screen, and the well yield is shown to have decreased by 10 percent or more of the pre-project average seasonal yield, compensation shall be provided for the diagnosis and maintenance to treat and remove encrustation from the well screen. Reimbursement shall be provided at an amount equal to the customary local cost of performing the necessary diagnosis and maintenance for well screen encrustation. Should the well yield reductions be recurring, the project owner shall provide payment or reimbursement for periodic maintenance throughout the life of the project. If with treatment the well yield is incapable of meeting 110 percent of the well owner's maximum daily demand, dry season demand, or annual demand, the well owner should be compensated by reimbursement or well replacement as described under Condition 3.c.

c. If project pumping has lowered water levels to significantly impact well yield so that it can no longer meet its intended purpose, causes the well to go dry, or causes casing collapse, payment or reimbursement of an amount equal to the cost of deepening or replacing the well shall be provided to accommodate these effects. Payment or reimbursement shall be at an amount equal to the customary local cost of deepening the existing well or constructing a new well of comparable design and yield (only deeper). The demand for water, which determines the required well yield, shall be determined on a per well basis using well owner interviews and field verification of property conditions and water requirements compiled as part of the pre-project well reconnaissance. Well yield shall be considered significantly impacted if it is incapable of meeting 110% of the well owner's maximum daily demand, dry-season demand, or annual demand – assuming the pre-project well yield documented by the initial well reconnaissance met or exceeded these yield levels.

d. The project owner shall notify any owners of the impacted wells within one month of the CPM approval of the compensation analysis for increased energy costs.

e. Pump lowering – In the event that groundwater is lowered as a result of project pumping to an extent where pumps are exposed but well screens remain submerged, the pumps shall be lowered to maintain production in the well. The project owner shall reimburse the impacted well owner for the costs associated with lowering pumps.

f. Deepening of wells – If the groundwater is lowered enough as a result of project pumping that well screens and/or pump intakes are exposed, and pump lowering is not an option, such affected wells shall be deepened or new wells constructed. The project owner shall reimburse the impacted well owner for all costs associated with deepening existing wells or constructing new wells.

4. Groundwater elevations shall be measured throughout the life of the project at least twice per year, and reported to the CPM.
5. If mitigation includes monetary compensation, the project owner shall provide documentation to the CPM that compensation payments have been made by March 31 of each year of project operation or, if lump-sum payments are made, payment is made by March 31 following the first year of operation only. Within 30 days after compensation is paid, the project owner shall submit to the CPM a compliance report describing compensation for increased energy costs necessary to comply with the provisions of this condition.
6. At the end of every subsequent five-year monitoring period, the collected data shall be evaluated by the CPM who will determine if the sampling frequency should be revised or eliminated.
7. During the life of the project, the project owner shall provide to the CPM all monitoring reports, complaints, studies and other relevant data within 10 days of being received by the project owner.

Verification: The project owner shall do all of the following:

- At least 60 days prior to operation of the site groundwater supply wells, the project owner shall submit to the CPM a comprehensive report presenting all the data and information required in item A. 1. above. The project owner shall submit to the CPM a report showing the results of the well reconnaissance, conditions of existing wells that will be used to evaluate potential project pumping impacts, and all calculations, assumptions, well logs, and reports made in development of the report data and interpretations.
- At least 180 days prior to project construction the project owner shall submit a plan showing the proposed design and construction of the new monitoring well network and existing wells that will be used to evaluate potential impacts to domestic well owners. The plan will include well design and installation methods.
- During project construction, the project owner shall submit to the CPM quarterly reports presenting all the data and information required in item B above. The quarterly reports shall be provided 30 days following the end of the quarter. The project owner shall also submit to the CPM all calculations and assumptions made in development of the report data and interpretations.
- No later than March 31 of each year of construction or 60 days prior to project operation, the project owner shall provide to the CPM for review and approval, documentation showing that any mitigation to private well owners during project

construction was satisfied, based on the requirements of the property owner as determined by the CPM.

- During project operation, the project owner shall submit to the CPM applicable quarterly, semi-annual and annual reports presenting all the data and information required in item C above. Quarterly reports shall be submitted to the CPM 30 days following the end of the quarter. The fourth quarter report shall serve as the annual report and shall be provided on January 31 in the following year. The project owner shall submit to the CPM all calculations and assumptions made in development of report data and interpretations, calculations, and assumptions used in development of any reports.

After the first five year operational and monitoring period, the project owner shall submit a 5-year monitoring report to the CPM that includes all monitoring data collected and a summary of the findings. The CPM will determine if the water level measurements and sampling frequencies should be revised.

GROUNDWATER PUMPING COST CALCULATION

WATER-2: Where it is determined that the project owner shall reimburse a private well owner for increased energy costs identified as a result of analysis performed in Condition of Certification **WATER-1,** the project owner shall calculate the compensation owed to any owner of an impacted well as described below.

Increased cost for energy =	change in lift/total system head x total energy consumption x costs/unit of energy

Where:

change in lift (ft) =	calculated change in water level in the well resulting from project
total system head (ft) =	elevation head + discharge pressure head
elevation head (ft) =	difference in elevation between wellhead discharge pressure gauge and water level in well during pumping.
discharge pressure head (ft) =	pressure at wellhead discharge gauge (psi) X 2.31

The project owner shall submit to the CPM for review and approval the documentation showing which well owners must be compensated for increased energy costs and that the proposed amounts are sufficient compensation to comply with the provisions of this condition.

- Any reimbursements (either lump sum or annual) to impacted well owners shall be only to those well owners whose wells were in service within six months of the Commission decision and within a 3-mile radius of the project site.
- The project owner shall notify all owners of the impacted wells within one month of the CPM approval of the compensation analysis for increased energy costs.
- Compensation shall be provided on either a one-time lump-sum basis, or on an annual basis, as described below.

Annual Compensation: Compensation provided on an annual basis shall be calculated prospectively for each year by estimating energy costs that will be incurred to provide the additional lift required as a result of the project. With the permission of the impacted well owner, the project owner shall provide energy meters for each well or well field affected by the project. The impacted well owner, to receive compensation, must provide documentation of energy consumption in the form of meter readings or other verification of fuel consumption. For each year after the first year of operation, the project owner shall include an adjustment for any deviations between projected and actual energy costs for the previous calendar year.

One-Time Lump-Sum Compensation: Compensation provided on a one-time lump-sum basis shall be based on a well-interference analysis, assuming the maximum project-pumping rate of 7,500 acre-feet per year. Compensation associated with increased pumping lift for the life of the project shall be estimated as a lump sum payment as follows:

- The current cost of energy to the affected party considering time of use or tiers of energy cost applicable to the party's billing of electricity from the utility providing electric service, or a reasonable equivalent if the party independently generates their electricity;
- An annual inflation factor for energy cost of 3 percent; and
- A net present value determination assuming a term of 30 years and a discount rate of 9 percent.

Verification: The project owner shall do all of the following:

1. No later than 30 days after CPM approval of the well drawdown analysis, the project owner shall submit to the CPM for review and approval all documentation and calculations describing necessary compensation for energy costs associated with additional lift requirements.
2. The project owner shall submit to the CPM all calculations, along with any letters signed by the well owners indicating agreement with the calculations, and the name and phone numbers of those well owners that do not agree with the calculations. Compensation payments shall be made by March 31 of each year of project operation or, if lump-sum payment is selected, payment shall be made by March 31 of the first year of operation only. Within 30 days after compensation is paid, the project owner shall submit to the CPM a compliance report describing compensation for increased energy costs necessary to comply with the provisions of this condition.

CONSTRUCTION AND OPERATIONS WATER USE

WATER-4: The proposed project's use of groundwater for all construction activities shall not exceed 12 acre-feet per year of construction. The proposed project's use of groundwater for all operations and domestic use activities shall not exceed 7,500 acre-feet per year or the reduced volume that may be identified as a result of the alternatives analysis.

Prior to the use of groundwater for construction, the project owner shall install and maintain metering devices as part of the water supply and distribution system to document project water use and to monitor and record in gallons per month the total volume(s) of water supplied to the project from this water source. The metering devices shall be of an adequate design for the intended use and shall be operational for the life of the project. Metering devices shall be calibrated and maintained in accordance with the manufacturer's recommended procedures and schedule.

Verification: Beginning six (6) months after the start of construction, the project owner shall prepare a semi-annual summary report of the amount of water used for construction purposes. The summary shall include the monthly water usage in gallons. The report shall also include photographs and documentation showing the type of meter selected and installed condition.

The project owner shall prepare an annual summary report, which shall include daily usage, monthly range and monthly average of daily water usage in gallons per day, and total water used on a monthly and annual basis in acre-feet by source. For years subsequent to the initial year of operation, the annual summary report shall also include the yearly range and yearly average water use by source. For calculating the total water use, the term "year" shall correspond to the date established for the annual compliance report submittal. The report shall also include reports on meter calibration and maintenance, and document that the meter is in working order.

PROJECT GROUNDWATER WELLS

WATER-5 Pre-Well Installation. The project owner proposes to construct and operate groundwater production wells that will produce water from the Kern County Subbasin. The project owner shall ensure that the wells are completed in accordance with all applicable state and local water well construction permits and requirements. Prior to initiation of well construction activities, the project owner shall submit for review and comment a well construction packet to the Kern County Environmental Health Services Department and fees normally required for the county's well permit, with copies to the CPM for review and approval. The project shall not construct a well or extract and use groundwater until the CPM provides approval to construct and operate the well.

POST-WELL INSTALLATION. The project owner shall provide documentation to the CPM that the well has been properly completed. In accordance with California's Water Code section 13754, the driller of the well shall submit to the DWR a Well Completion Report for each well installed. The project owner shall ensure the Well Completion reports are submitted. The project owner shall ensure compliance with all county water well standards and requirements for the life of the wells and shall provide the CPM with two (2) copies each of all monitoring or other reports required for compliance with the Kern County Environmental Health Services Department water well standards and operation requirements, as well as any changes made to the operation of the well.

Verification: The Project owner shall do all of the following:

A. No later than sixty (60) days prior to the construction of the onsite groundwater production wells, the project owner shall submit to the CPM for review and approval a copy of the water well construction packet submitted to the Kern County Environmental Health Services Department.

B. No later than thirty (30) days prior to the construction of the onsite groundwater production wells, the project owner shall submit a copy of written concurrence received from the Kern County Environmental Health Services Department that the proposed well construction activities comply with all county well requirements and meet the requirements established by the county's water well permit program.

C. No later than sixty (60) days after installation of each well at the project site, the project owner shall ensure that the well driller submits a Well Completion Report to the DWR with a copy provided to the CPM. The project owner shall submit to the CPM, together with the Well Completion Report, a copy of well drilling logs, water quality analyses, and any inspection reports.

D. During well construction and for the operational life of the well, the project owner shall submit two (2) copies each to the CPM of any proposed well construction or operation permit changes within ten (10) days of submittal to or receipt from the Kern County Environmental Health Services Department.

E. No later than fifteen (15) days after completion of the onsite groundwater production wells, the project owner shall submit proof of well completion documentation to the CPM, and the CVRWQCB that well drilling activities were conducted in compliance with Title 23, California Code of Regulations, Chapter 15, Discharges of Hazardous Wastes to Land, (23 CCR, sections 2510 et seq.) requirements and that any onsite drilling sumps used for project drilling activities were removed in compliance with 23 CCR section 2511(c).

GROUND SUBSIDENCE MONITORING AND ACTION PLAN

WATER–6 The project owner shall construct one monument monitoring station per production well or a minimum of three stations to measure potential inelastic subsidence that may affect structures near the proposed production wells, including the California Aqueduct. The project owner shall:

A. Prepare and submit a Subsidence Monitoring Plan (SMP), including all calculations and assumptions. The plan shall include the following elements:

1. Construction diagrams of the proposed monument monitoring stations including size and description, planned depth, measuring points, and protection measures;
2. Map depicting locations (minimum of three) of the planned monument monitoring stations;
3. Monitoring program that includes monitoring frequency and reporting format.

B. Prepare annual reports commencing three (3) months following commencement of groundwater production during construction and operations. The reports shall include presentation and interpretation of the data collected including comparison to the requirements and actions taken to comply with the elements developed in Item C.

C. Prepare a Mitigation Action Plan that details the following:

1. How subsidence shall not be allowed to damage existing structures either on or off the site or alter the appearance or use of the structure;
2. How to avoid subsidence that may alter natural drainage patterns or permit the formation of lakes;
3. If any subsidence violates (a) or (b), the project owner shall investigate the need to immediately modify or cease pumping for project operations until the cause is interpreted and subsidence caused by project pumping abates and the structures and/or drainage patterns are stabilized and corrected.

The project owner shall submit the Ground Subsidence Monitoring and Action Plan, prepared by an Engineering Geologist or Geotechnical Engineer registered in the State of California, thirty (30) days prior to the start of extraction of groundwater for construction or operation.

Verification: The project owner shall do all of the following:

1. At least thirty (30) days prior to project construction, the project owner shall submit to the CPM a comprehensive report presenting all the data and information required in item A above.
2. During project construction and operations, the project owner shall submit to the CPM quarterly reports presenting all the data and information required in item B above.
3. The project owner shall submit to the CPM all calculations and assumptions made in development of the report data and interpretations.

After the first five (5) years of the monitoring period, the project owner shall submit a 5-year monitoring report to the CPM that includes all monitoring data collected and provides a summary of the findings. The CPM shall determine if the Ground Subsidence Monitoring and Action Plan frequencies should be revised, based on project-related consolidation around the well field, when and if it is detected.

WORKER SAFETY AND FIRE PROTECTION

Alvin Greenberg, Ph.D.

SUMMARY OF CONCLUSIONS

Staff concludes that if the applicant for the proposed Hydrogen Energy California project (HECA) will provide project construction safety and health, project operations and maintenance safety and health plans and programs, and fire protection plans and programs as required by proposed Conditions of Certification **WORKER SAFETY-1,** through **-11**, the project would incorporate sufficient measures to both ensure adequate levels of industrial safety and fire protection and comply with applicable laws, ordinances, regulations, and standards (LORS). These proposed conditions of certification ensure that these programs would be reviewed by the appropriate agencies and approved by the Energy Commission compliance project manager before they are implemented. The conditions also require verification that the proposed plans adequately ensure worker safety and fire protection and comply with applicable LORS.

The proposed HECA project is a complex industrial facility similar in scope to a small refinery. The proposed project includes many chemical processes such as reactor vessels, storage vessels, treatment units, piping, valves, and flanges as well as transfer and transport facilities which would, if considered separately, each constitute a stand-alone industrial plant. The project proposes to use, store, create, and transport large volumes of several highly toxic hazardous materials. Furthermore, in addition to the actual facilities owned and operated by Hydrogen Energy California, this Preliminary Staff Assessment/Draft Environmental Impact Statement (PSA/DEIS) also includes an environmental review of the high-pressure CO_2 pipeline and enhanced oil recovery and carbon sequestration facility to be owned and operated by Occidental of Elk Hills, Inc.

The different processes and large volumes of hazardous materials that would be utilized at the proposed facility and described in this PSA/DEIS have the potential to pose significant threats to worker safety and also pose a serious threat of fire and/or explosion. These processes include the following:

1. A coal/petroleum coke gasification plant;
2. An air separation unit producing liquid oxygen and liquid nitrogen;
3. A syngas scrubber, sour shift, low-temperature gas cooling, sour water treatment facility;
4. A mercury removal unit;
5. An acid gas removal (Rectisol process) unit;
6. An ammonia synthesis unit that produces and includes anhydrous ammonia storage;
7. A urea unit;
8. A urea pastillation unit;
9. A urea pastille handling and transfer unit;
10. A urea ammonium nitrate complex that produces nitric acid, ammonium nitrate, and urea;

11. A sulfur recovery unit;

12. A 13-mile natural gas pipeline;

13. A 3-mile pressurized CO_2 pipeline;

14. An enhanced oil recovery (EOR) facility;

15. Additional storage of large volumes of hazardous materials including:

    a. sodium hydroxide

    b. sodium hypochlorite

    c. diesel fuel

    d. gasoline during construction

The presence of these complex chemical processes -- specifically the larger gasification process, sulfur recovery process, and anhydrous ammonia production and storage that would consist of large amounts of hazardous materials in closed tanks and piping at elevated temperature and pressure – could potentially pose significant risks to workers and have the potential to cause explosions and fires if not managed properly. Staff has not encountered such a complex power generation facility in the history of the Energy Commission and the Kern County Fire Department states it has not either. In order to properly review and assess the potential worker safety and fire protection issues, staff spent considerable time evaluating the entire process and even visited a similar gasification facility in Polk County, Florida. As a result of staff's efforts to understand the processes and the risks involved, staff determined that all of these processes must be managed and monitored in greater detail than usual and that a significant potential for accidents that would impact workers exists. Also, due to the complex nature of the project and numerous industrial processes that use highly combustible or flammable materials, coupled with the remote location in an area served by the Kern County Fire Department, staff found that a significant direct impact, as well as a cumulative impact, on the Kern County Fire department would exist but that these impacts can be mitigated with the adoption of proposed Conditions of Certification **WORKER SAFETY-8** and **-9**.

Also, as discussed in the **Introduction** section of the PSA, this document analyzes the project's impacts pursuant to both the National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA). The two statutes are similar in their requirements concerning analysis of a project's impacts. Therefore, unless otherwise noted, staff's use of, and reference to, CEQA criteria and guidelines also encompasses and satisfies NEPA requirements for this environmental document.

INTRODUCTION

Worker safety and fire protection are regulated through federal, state, and local LORS. Industrial workers at the facility both operate equipment and handle hazardous materials daily, and could face hazards resulting in accidents and serious injury. Protection measures are employed to eliminate or reduce these hazards or minimize their risk through special training, protective equipment, and procedural controls.

The purpose of this Preliminary Staff Assessment/Draft Environmental Impact Statement (PSA/DEIS) is to assess the worker safety and fire protection measures proposed by the HECA applicant, determine whether the applicant has proposed adequate measures, and for staff to propose additional measures to:

- Comply with applicable safety LORS;
- Protect workers during the construction and operation of the facility;
- Protect against fire; and
- Provide adequate emergency response procedures.

The original AFC (08-AFC-8) was filed with the Energy Commission on July 31, 2008; and a Revised AFC was submitted in 2009 to reflect a change of the project site to an alternative location. In 2011, Hydrogen Energy California, LLC, (HECA) was acquired from the previous owners by SCS Energy California, LLC. On May 2, 2012, SCS Energy, LLC, submitted an Amended Application for Certification (08-AFC-8A) reflecting several changes to the original project design.

The new Amended Application for Certification (AFC) has been assigned a separate distinguishing docket number, 08-AFC-8A. The Amended AFC for the project supersedes and replaces all previous submissions, and incorporates all relevant information from the previous versions of the HECA proceedings. The applicant intends to construct and operate an integrated gasification combined cycle (IGCC) power generating facility called Hydrogen Energy California (HECA).

The proposed HECA project would gasify a mixture of western coal and petroleum coke from California refineries to produce hydrogen to fuel a combustion turbine operating in combined-cycle mode. The amended project incorporates a proposed manufacturing complex that would produce urea in both liquid and pellet form, and other byproducts for agricultural uses.

For power generation, a Mitsubishi Heavy Industries MHI 501GAC® CT combustion turbine has been selected. The combined cycle power block would generate approximately 405 MW of gross power and would provide about 300-megawatts of electricity to the grid. The gasification block would also capture carbon from the raw syngas (the direct end of the gasification process) at steady-state operation, which would be transported to a custody transfer point at the Elk Hills Oil Field for CO_2 enhanced oil recovery (EOR) and sequestration. Due to the complex gasification and sequestration process, there is a larger than usual parasitic electrical load.

Highlights of the project include:

- The Amended HECA facility proposes to operate with 25 percent petroleum coke from California refineries blended with 75 percent western bituminous coal. Transportation of coal to the project would be by either a truck route, or via an alternative rail spur proposed to be built and owned by the applicant.
- The feedstock (coal and petroleum coke) would be gasified to produce a synthesis gas (syngas) that would be processed and purified to produce a hydrogen-rich gas, which would be used to fuel the combustion turbine for electric power generation and provide supplemental fuel to the heat recovery steam generator (HRSG) that

produces steam from the combustion turbine exhaust heat. At least 90 percent of the carbon in the raw syngas would be captured in a high-purity carbon dioxide stream during steady-state operation, and would be sold to Occidental Petroleum, compressed and transported by pipeline off-site to the nearby Elk Hills Oil Field for injection into deep underground oil reservoirs for enhanced oil recovery (EOR) and sequestration.

- State-of-the-art emission controls are included in the design.
- Zero Liquid Discharge technology is used in the project design for process and waste water.
- Liquid oxygen and nitrogen are produced in the air separation unit, and supplied to the gasification unit, the combustion turbine, sulfur recovery unit and other process components of HECA.

Some notable project changes are proposed in the Amended AFC, including the following:

- Mitsubishi Heavy Industries (MHI) oxygen-blown dry feed gasification technology has been selected.
- A MHI 501GAC® Combustion Turbine and Steam Turbine has been selected.
- A new, integrated manufacturing complex (IMC) will produce approximately 1 million tons per year of low-carbon nitrogen-based products, including urea ammonium nitrate and anhydrous ammonia, to be used in agriculture.

HECA proposes to use two alternatives for transporting coal to the project site:

Alternative 1, Rail Transportation: An approximately 5-mile new industrial railroad spur would connect the project site to the existing San Joaquin Valley Railroad, Buttonwillow railroad line, north of the project site. This railroad spur would also be used to transport some IMC products to customers.

Alternative 2, Truck Transportation: Truck transport would be via existing roads from an existing coal transloading facility northeast of the project site. The truck route distance is approximately 27 miles.

The routes of the natural gas pipeline, potable water pipeline, and electrical transmission have been refined as follows:

- An approximately 13-mile new natural gas pipeline will interconnect with an existing Pacific Gas and Electric Company (PG&E) natural gas pipeline located north of the project site.
- Potable water will be delivered via an approximately 1-mile pipeline from a new West Kern Water District potable water production site east of the project site.
- An approximately 2-mile electrical transmission line will interconnect with a future PG&E switching station east of the project site.

If approved, construction of the project is proposed by the applicant to begin 2013 or 2014, with completion of construction in 2017, and commencement of commercial operation by the end of 2017. However, it is highly likely that the construction would start, if approved by the commission, sometime in 2014 and commencement of commercial operations occur sometime in 2018 or 2019.

Worker Safety and Fire Protection Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable Law	Description
Federal	
29 U.S. Code sections 651 et seq (Occupational Safety and Health Act of 1970)	This Act mandates safety requirements in the workplace, with the purpose of "[assuring] so far as possible every working man and woman in the nation safe and healthful working conditions and to preserve our human resources" (29 USC § 651).
29 CFR sections 1910.1 to 1910.1500 (Occupational Safety and Health Administration Safety and Health Regulations)	These sections define the procedures for promulgating regulations and conducting inspections to implement and enforce safety and health procedures to protect workers, particularly in the industrial sector.
29 CFR sections 1952.170 to 1952.175	These sections provide federal approval of California's plan for enforcement of its own safety and health requirements, in lieu of most of the federal requirements found in 29 CFR §1910.1 to 1910.1500.
State	
8 CCR all applicable sections (Cal/OSHA regulations)	Requires that all employers follow these regulations as they pertain to the work involved. This includes regulations pertaining to safety matters during the construction, commissioning, and operation of power plants, as well as safety around electrical components, fire safety, and hazardous materials usage, storage, and handling.
24 CCR section 3, et seq.	Incorporates the current edition of the International Building Code.
Health and Safety Code sections 25500 to 25541	Requires a Hazardous Materials Business plan detailing emergency response plans for hazardous materials emergencies at a facility.
Local (or locally enforced)	
2010 Edition of California Fire Code (24 CCR Part 9)	The fire code contains general provisions for fire safety, including road and building access, water supplies, fire protection and life safety systems, fire-resistive construction, storage of combustible materials, exits and emergency escapes, and fire alarm systems. It is based on the 2009 edition of the International Fire Code.
Title 24, California Code of Regulations (24 CCR § 3, et seq.)	The California Building Code comprises 11 parts containing building design and construction requirements as they relate to fire, life, and structural safety. It incorporates current editions of the International Building Code, including the electrical, mechanical, energy, and fire codes applicable to the project.

NFPA Standards And Standard 850	NFPA is a professional organization that adopts fire protection standards and guidelines for industry, government, and fire departments. NFPA 850 addresses fire protection at power plants.
Kern County Fire Code Chapter 17.32 of the Code of Building Regulations	Kern County adopted and enforces the 2006 edition of the International Fire Code.
Kern County Zoning Ordinance, Development Standards section 19.80.030.	Contains safety setbacks required by the Kern County Fire Department.

SETTING

Fire support services to the site will be under the jurisdiction of the Kern County Fire Department (KCFD). KCFD fire Station 25 is 7 miles from the project site, located at 100 Mirasol Avenue, Buttonwillow, California, and would be the first responder to an emergency at the HECA facility with a three-person crew and one type-2 fire engine and one 4WD fire patrol vehicle. The response time from first notification would be no more than 15 minutes. The next station that would respond is located in McKittrick (station 24) and it has the same staffing and equipment. The response time to the HECA site from first notification would be ~25-30 minutes. The third in line for response to the HECA site would be station 53 located on Highway 53 east of I-5. This station is proposed for re-location west of I-5 with an addition of a helipad. The fourth station that would respond is station 21 located in Taft and this includes a ladder company. All four stations are continuously staffed with three personnel per shift.

In Kern County, hazardous materials permits and spills are handled and investigated by the KCFD. Kern County firefighters receive specialized training to address emergency responses to industrial hazards, and response would come from the same facilities as for fire services response. If ever needed, a specialized hazardous materials response team would come from 3000 Landco Drive, Bakersfield, CA with a response time of approximately 50 minutes.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

METHOD AND THRESHOLD FOR DETERMINING SIGNIFICANCE

Two issues are assessed in **Worker Safety and Fire Protection**:

1. The potential for impacts on the safety of workers during demolition, construction, and operation activities; and

2. Fire prevention/protection, emergency medical response, and hazardous materials spill response during construction and operations.

Staff's worker safety analysis is essentially a LORS conformity review and if all LORS are followed, workers will be adequately protected. Thus, the standard for staff's review and determination is whether the applicant has demonstrated adequate knowledge of, and commitment to, implementation of all pertinent and relevant Cal-OSHA standards.

Staff reviews and evaluates the on-site fire-fighting systems proposed by the applicant, as well as the time needed for off-site local fire departments to respond to a fire, medical, or hazardous material emergency at the HECA site. If on-site systems do not follow established codes and industry standards, staff recommends additional measures. Staff reviews local fire department capabilities and response times, and interviews local fire officials to determine if they feel they are adequately staffed, and equipped to respond to the needs of a power plant. Staff then determines if the presence of the power plant would cause a significant impact on a local fire department. If it does, staff will recommend that the applicant mitigate this impact by providing additional resources to the fire department.

DIRECT/INDIRECT IMPACTS AND MITIGATION

Worker Safety

Industrial environments are potentially dangerous during both construction and operation. Workers at the proposed project will be exposed to loud noises, moving equipment, trenches, and confined space entry and egress. Workers may sustain falls, trips, burns, lacerations, and other injuries. They may be exposed to falling equipment or structures, chemical spills, hazardous waste, fires, explosions, and electrical sparks or electrocution. It is important that HECA has well-defined policies and procedures, training, and hazard recognition and control to minimize these hazards and protect workers. If the facility complies with all LORS, workers will be adequately protected from health and safety hazards.

A Safety and Health Program will be prepared by the applicant to minimize worker hazards during construction and operation of the project. "Safety and Health Program," for staff, refers to measures that will be taken to ensure compliance with the applicable LORS during the construction and operation of the project.

Construction Safety and Health Program

The project includes the construction and operation of a power plant that includes a petroleum coke (pet coke) and coal gasification unit with all its associated hazardous chemical separation and fuel handling systems along with several industrial operations that make urea ammonia nitrate fertilizer (UAN) and liquid sulfur for shipment off-site for distribution and commercial sale. Although workers would be exposed to hazards typical of construction of an industrial facility and gas-fired power plant, workers would be exposed to hazards during operations that could be described as anything but typical.

Construction safety orders are published at Title 8 of the California Code of Regulations, section 1502 et seq. These requirements are promulgated by Cal/OSHA and apply to the construction phase of the project. The construction safety and health program will include the following:

- Construction injury and illness prevention program (8 CCR § 1509);

- Construction fire prevention plan (8 CCR § 1920);
- Personal protective equipment program (8 CCR §§ 1514 - 1522); and
- Emergency action program and plan.

Additional programs under General Industry Safety Orders (8 CCR §§ 3200 to 6184), Electrical Safety Orders (8 CCR §§2299 to 2974) and Unfired Pressure Vessel Safety Orders (8 CCR §§ 450 to 544) will include:

- Electrical safety program;
- Motor vehicle and heavy equipment safety program;
- Forklift operation program;
- Excavation/trenching program;
- Fall protection program;
- Scaffolding/ladder safety program;
- Articulating boom platforms program;
- Crane and material handling program;
- Housekeeping and material handling and storage program;
- Respiratory protection program;
- Employee exposure monitoring program;
- Hand and portable power tool safety program;
- Hearing conservation program;
- Back injury prevention program;
- Hazard communication program;
- Heat and cold stress monitoring and control program;
- Pressure vessel and pipeline safety program;
- Hazardous waste program;
- Hot work safety program;
- Permit-required confined space entry program; and
- Demolition procedure (if applicable).

The AFC includes adequate outlines for each of the above programs (HECA 2012e, section 5.7.2.1). The applicant also provided information on the proposed Construction/Commissioning Fire Protection Plan (HECA 2012e, sections 5.7.2.1 and 2.9.12). Prior to the project's start of construction, detailed programs and plans will be provided pursuant to Condition of Certification **WORKER SAFETY-1**.

Operations and Maintenance Safety and Health Program

Prior to the start-up of HECA, an operations and maintenance safety and health program will be prepared. This program will include the following programs and plans:

- Injury and illness prevention program (8 CCR § 3203);
- Fire prevention program (8 CCR § 3221);
- Personal protective equipment program (8 CCR §§ 3401 to 3411); and
- Emergency action plan (8 CCR § 3220).

In addition, the requirements under General Industry Safety Orders (8 CCR §§ 3200 to 6184), Electrical Safety Orders (8 CCR §§2299 to 2974) and Unfired Pressure Vessel Safety Orders (8 CCR §§ 450 to 544) will apply to this project. Written safety programs for HECA, which the applicant will develop, will ensure compliance with those requirements.

The AFC includes adequate outlines for an operations injury and illness prevention program, an emergency action plan, a fire prevention program, and a personal protective equipment program (HECA 2012e, section 5.7.2.3). Prior to operation of HECA, all detailed programs and plans will be provided pursuant to Condition of Certification **WORKER SAFETY-2**.

Safety and Health Program Elements

As mentioned above, the applicant provided the proposed outlines for both a Construction Safety and Health Program and an Operations Safety and Health Program. The measures in these plans are derived from applicable sections of state and federal law. The major items required in both safety and health programs are as follows:

Injury and Illness Prevention Program (IIPP)

The IIPP will include the following components (HECA 2012e, section 5.7.2.3):

- Identify persons with the authority and responsibility for implementing the program;
- Establish the safety and health policy of the plan;
- Define work rules and safe work practices for work activities;
- Establish a system for ensuring that employees comply with safe and healthy work practices;
- Establish a system to facilitate employer-employee communication;
- Develop procedures for identifying and evaluating workplace hazards and establish necessary program(s);
- Establish methods for correcting unhealthy/unsafe conditions in a timely manner;
- Determine and establish training and instruction requirements and programs;
- Specify safety procedures; and
- Provide training and instruction.

Fire Prevention Plan

The California Code of Regulations requires an operations fire prevention plan (8 CCR § 3221). The AFC outlines a proposed fire prevention plan that is acceptable to staff (HECA 2012e, section 5.7.2.10). The plan will include the following:

- Determine general program requirements;
- Determine fire hazard inventory, including ignition sources and mitigation;
- Develop good housekeeping practices and proper materials storage;
- Establish employee alarms and/or communication system(s);
- Provide portable fire extinguishers at appropriate site locations;
- Locate fixed firefighting equipment in suitable areas;
- Specify fire control requirements and procedures;
- Establish proper flammable and combustible liquid storage facilities;
- Identify the location and use of flammable and combustible liquids;
- Provide proper dispensing and determine disposal requirements for flammable liquids;
- Establish and determine training and instruction requirements and programs; and
- Identify contacts for information on plan contents.

Staff proposes that the applicant submit a final fire prevention plan to the California Energy Commission compliance project manager (CPM) for review and approval and to the KCFD for review and comment to satisfy proposed conditions of certification **WORKER SAFETY-1** and **WORKER SAFETY-2**.

Personal Protective Equipment Program

California regulations require personal protective equipment (PPE) and first aid supplies whenever hazards in the environment, or from chemicals or mechanical irritants, could cause injury or impair bodily function through absorption, inhalation, or physical contact (8 CCR sections 3380 to 3400). The HECA operational environment will require PPE (HECA 2012e, section 5.7.2.6).

All safety equipment must meet National Institute of Safety and Health (NIOSH) or American National Standards Institute (ANSI) standards and will carry markings, numbers, or certificates of approval. Respirators must meet NIOSH and Cal/OSHA standards. Each employee must be provided with the following information about protective clothing and equipment:

- Proper use, maintenance, and storage;
- When protective clothing and equipment are used;
- Benefits and limitations; and
- When and how protective clothing and equipment are replaced.

The PPE program ensures that employers comply with applicable requirements for PPE and provides employees with the information and training necessary to protect them from potential hazards in the workplace, and will be required as per proposed Conditions of Certification **WORKER SAFETY-1** and **-2**.

Emergency Action Plan

California regulations require an emergency action plan (8 CCR § 3220). The AFC contains a satisfactory outline for an emergency action plan (HECA 2012e, section 5.7.2.2 and Tables 5.7-5).

The outline describes the following features:

- Establishes emergency procedures for the protection of personnel, equipment, the environment, and materials;
- Identifies fire and emergency reporting procedures;
- Determines response actions for accidents involving personnel and/or property;
- Develops response and reporting requirements for bomb threats;
- Specifies site assembly and emergency evacuation route procedures;
- Defines natural disaster responses (for example, earthquakes, high winds, and flooding);
- Establishes reporting and notification procedures for emergencies (including on-site, off-site, local authorities, and/or state jurisdictions);
- Determines alarm and communication systems needed for specific operations;
- Includes a spill response, prevention, and countermeasure (SPCC) plan;
- Identifies emergency personnel (response team) responsibilities and notification roster;
- Specifies emergency response equipment and strategic locations; and
- Establishes and determines training and instruction requirements and programs.

An emergency action plan will be required as per proposed Conditions of Certification **WORKER SAFETY-1 and -2**

Written Safety Program

In addition to the specific plans listed above, additional LORS called “safe work practices” apply to the project. Both the construction and operations safety programs will address safe work practices in a variety of programs. The components of these programs include, but are not limited to, the programs found under the heading “Construction Safety and Health Program” in this staff assessment.

In addition, the project owner would be required to provide personnel protective equipment and exposure monitoring for workers involved in activities where contaminated soil and/or contaminated groundwater exist, per staff’s proposed Conditions of Certification **WORKER SAFETY-1** and**-2**.

These proposed conditions of certification ensure that workers are properly protected from any hazardous wastes presently at the site.

Safety Training Programs

Employees will be trained in the safe work practices described in the above-referenced safety programs.

Additional Mitigation Measures

Protecting construction workers from injury and disease is one of the greatest challenges today in occupational safety and health. The following facts are reported by NIOSH:

- More than seven million persons work in the construction industry, representing six percent of the labor force. Approximately 1.5 million of these workers are self-employed;
- Of approximately 600,000 construction companies, 90 percent employ fewer than 20 workers. Few have formal safety and health programs;
- From 1980-1993, an average of 1,079 construction workers were killed on the job each year, with more fatal injuries than any other industry;
- Falls caused 3,859 construction worker fatalities, or 25.6 percent of the total, between 1980 and 1993;
- 15 percent of workers' compensation costs are spent on construction-related injuries;
- Ensuring safety and health in construction is a complex task involving short-term work sites, changing hazards, and multiple operations and crews working in close proximity to one another;
- In 1990, Congress directed NIOSH to conduct research and training to reduce diseases and injury among construction workers in the United States. Under this mandate, NIOSH funds both intramural and extramural research projects.

The hazards associated with the construction industry are well documented. These hazards increase in complexity in the multi-employer worksites typical of large, complex industrial projects such as the proposed HECA project. In order to reduce and/or eliminate these hazards, it has become standard industry practice to hire a construction safety supervisor to ensure a safe and healthful environment for all workers. This has been evident in the audits of power plants recently conducted by the staff. The Federal Occupational Safety and Health Administration (OSHA) has also entered into strategic alliances with several professional and trade organizations to promote and recognize safety professionals trained as construction safety supervisors, construction health and safety officers, and other professional designations. The goal of these partnerships is to encourage construction subcontractors to improve their safety and health performance; to assist them in striving to eliminate the four major construction hazards (falls, electrical, caught in/between, and struck-by hazards) that account for the majority of fatalities and injuries in this industry and have been the focus of targeted OSHA inspections; to prevent serious accidents in the construction industry through implementation of enhanced safety and health programs and increased employee training; and to recognize subcontractors that have exemplary safety and health programs.

There are no OSHA or Cal-OSHA requirements that an employer hire or provide for a construction safety officer. OSHA and Cal-OSHA regulations do, however, require that safety be provided by an employer and the term “Competent Person” appears in many OSHA and Cal-OSHA standards, documents, and directives. A “Competent Person” is defined by OSHA as an individual who, by way of training and/or experience, is knowledgeable of standards, is capable of identifying workplace hazards relating to the specific operations, is designated by the employer, and has authority to take appropriate action. Therefore, in order to meet the intent of the OSHA standard to provide for a safe workplace during power plant construction, staff proposes Condition of Certification **WORKER SAFETY-3,** which would require the project owner to designate and provide for a project site construction safety supervisor.

As discussed above, the hazards associated with the construction industry are well documented. These hazards increase in complexity in the multi-employer worksites typical of large, complex industrial projects like a coal gasification power plant, a UAN production plant, a sulfur plant, and with the storage of large amounts of hazardous materials such as anhydrous ammonia, methanol, cryogenic liquids, and nitric acid.

When project owners have failed to recognize and control safety hazards and there is inadequate monitoring of compliance with occupational safety and health regulations, accidents, fires, and a worker death have occurred. Safety problems have been documented by Energy Commission staff in safety audits conducted since 2005 at several power plants under construction. The findings of the audits include, but are not limited to, safety oversights like:

- Lack of posted confined-space warning placards/signs;
- Confusing and/or inadequate electrical and machinery lockout/tagout permitting and procedures;
- Confusing and/or inappropriate procedures for handing over lockout/tagout and confined space permits from the construction team to the commissioning team, and then to operations;
- Dangerous placement of hydraulic elevated platforms under one another;
- Inappropriate placement of fire extinguishers near hot work;
- Dangerous placement of numerous power cords in standing water on the site, increasing the risk of electrocution;
- Inappropriate and unsecured placement of above-ground natural gas pipelines inside the facility, but too close to the perimeter fence; and
- Lack of adequate employee or contractor written training programs that address the proper procedures to follow in the event of the discovery of suspicious packages or objects either onsite or offsite.

In order to reduce and/or eliminate these hazards, it is necessary for the Energy Commission to require a professional Safety Monitor on-site to track compliance with

Cal-OSHA regulations and periodically audit safety compliance during construction, commissioning, and the hand-over to the operations staff. These requirements are outlined in Condition of Certification **WORKER SAFETY-4**. A Safety Monitor, hired by the project owner but reporting to the chief building official (CBO) and the compliance project manager (CPM), will serve as an extra set of eyes to ensure that safety procedures and practices are fully implemented during construction at all power plants certified by the Energy Commission. During audits conducted by staff, most site safety professionals welcomed the audit team and actively engaged them in questions about the team's findings and recommendations. These safety professionals recognized that safety requires continuous vigilance and that the presence of an independent audit team provides a "fresh perspective" of the site.

In addition, because of the complexity of this project, staff recommends an additional safety measure found in proposed condition **WORKER SAFETY-10** that would require the project owner to ensure that during commissioning and operations, at least one person would be on the site at all times (24 hours/day, 7 days/week) who was knowledgeable of and dedicated to safety, security, and fire protection.

Valley Fever (Coccidioidomycosis)

Coccidioidomycosis or "Valley Fever" (VF) is primarily encountered in southwestern states, particularly in Arizona and California. It is caused by inhaling the spores of the fungus Coccidioides immitis (*c.immitis)*, which are released from the soil during soil disturbance (e.g., during construction activities) or wind erosion. The disease usually affects the lungs and can have potentially severe consequences, especially in at-risk individuals such as the elderly, pregnant women, and people with compromised immune systems.

A February 2013 outbreak of Valley Fever affecting at least 28 workers at a photovoltaic solar plant in eastern San Luis Obispo County, along with an increase in inmates at two San Joaquin Valley prisons coming down with the disease, has sparked renewed interest and concern. (The California Department of Public Health, Cal-OSHA, and San Luis Obispo County are investigating that outbreak.) The Centers for Disease Control and Prevention says the total number of Valley Fever cases nationwide rose by nearly 900 percent from 1998 to 2011. Researchers don't have a good explanation for the dramatic increase even when accounting for growing populations throughout the Southwest, although when soil is dry and it is windy, more spores are likely to become airborne in endemic areas, according to Dr. Gil Chavez, Deputy Director of the Center for Infectious Diseases at the California Department of Public Health.

Trenching, excavation, and construction workers are often the most exposed population. Treatment usually includes rest and antifungal medications. No effective vaccine currently exists for Valley Fever. VF is endemic to the San Joaquin Valley in California, which presumably gave this disease its common name. Kern County, located at the southern end of the San Joaquin Valley, is where Valley Fever occurs most frequently (Valley Fever Vaccine Project of the Americas 2010; KCDPH 2008). Depending on the particular year, either Tulare or Fresno county have the second highest rates of VF.

In 1991, 1,200 cases of VF were reported to the California Department of Health Services (CDHS) compared with an annual average of 428 cases per year for the period of 1981 to 1990. In 1992, 4,516 cases were reported in California and 4,137 cases in 1993. Seventy percent of VF cases were reported from Kern County (CDC 1994; Flaherman 2007; CDHS 2010).

A 2004 CDC report found that the number of reported cases of coccidioidomycosis in the U.S. increased by 32 percent during 2003-2004, with the majority of these cases occurring in California and Arizona. The report attributed these increases to changes in land use, demographics, and climate in endemic areas, although certain cases might be attributable to increased physician awareness and testing (CDC 2006).

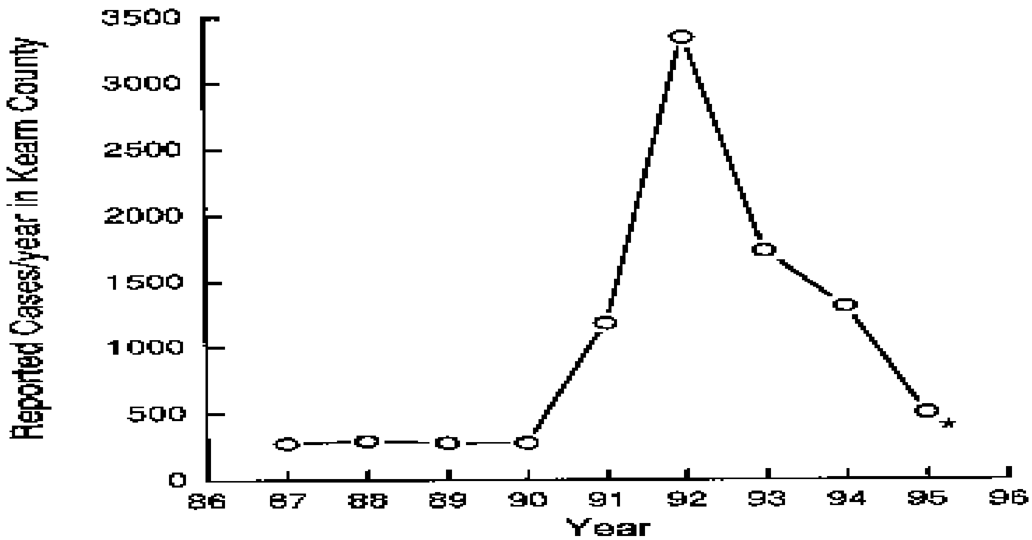
Number of Coccidioidomycosis Cases Identified by Serologic Testing at the Kern County Public Health Laboratory between 1986 and 1996*



*Source: CDC 2006, Figure 4

According to the CDC Morbidity and Mortality Weekly Report of February 2009, incidences of valley fever have increased steadily in Arizona and California in the past decade. Cases of coccidioidomycosis averaged about 2.5 per 100,000 population annually from 1995 to 2000 and increased to 8.0 per 100,000 population between 2000 and 2006 (incident rates tripled). In 2007 there was a slight drop in cases, but the rate was still the highest it has been since 1995. The report identified Kern County as having the highest incidence rates (150.0 cases per 100,000 population), and non-Hispanic blacks having the highest hospitalization rates (7.5 per 100,000 population). In addition, between the years 2000 and 2006, the number of valley fever related hospitalizations climbed from 1.8 to 4.3 per 100,000 population (611 cases in 2000 to 1,587 cases in 2006) and then decreased to 1,368 cases in 2007 (3.6 per 100,000 population). Overall in California, during 2000-2007, a total of 752 (8.7 percent) of the 8,657 persons hospitalized for coccidioidomycosis died (CDC 2009).

A 2007 study published in the Emerging Infectious Diseases journal of the Center for Disease Control and Prevention (CDC), found the frequency of hospitalization for coccidioidomycosis in the entire state of California to be 3.7 per 100,000 residents per year for the period between 1997 and 2002 (see Table 1 below). There were 417 deaths from VF in California in those years, resulting in a mortality rate of 2.1 per 1 million California residents annually. The data shows that Kern County had the highest total number and highest frequency of hospitalizations (Flaherman 2007).

Worker Safety Table 1
Hospitalizations for Coccidioidomycosis, California, 1997 – 2002*

Category	Total hospitalizations	Total person-years (× 10^6)	Frequency of hospitalization**	Frequency of hospitalization for coccidioidal meningitis**
Total	7,457	203.0	3.67	0.657
Year				
1997	1,269	32.5	3.90	0.706
1998	1,144	32.9	3.50	0.706
1999	1,167	33.4	3.5	0.61
2000	1,100	34.0	3.23	0.62
2001	1,291	34.7	3.7	0.58
2002	1,486	35.3	4.2	0.71
Highest incidence counties				
Kern	1,700	3.97	42.8	
Tulare	479	2.21	21.7	
Kings	133	0.77	17.4	
San Luis Obispo	170	1.48	11.5

**Per 100,000 residents per year

A 1996 paper that tried to explain the sudden increase in Coccidioidomycosis cases that began in the early 90s found that the San Joaquin Valley in California has the largest population of C. immitis, which is found to be distributed unevenly in the soil and seems to be concentrated around animal burrows and ancient Indian burial sites. It is usually found 4 to 12 inches below the surface of the soil (CDC 2006). The paper also reported that incidences of coccidioidomycosis vary with the seasons; with highest rates in late summer and early fall when the soil is dry and the crops are harvested. Dust storms are frequently followed by outbreaks of coccidioidomycosis (CDC 2006). A modeling attempt to establish the relationship between fluctuations in VF incident rates and weather conditions in Kern County found that there is only a weak connection between weather and VF cases (weather patterns correlate with up to 4% of outbreaks). The study concluded that the factors that cause fluctuations in VF cases are not weather-related but rather biological and anthropogenic (i.e. human activities, primarily construction on previously undisturbed soil) (Talamantes 2007).

Data from the Kern County Department of Public Health (KCDPH) on the period between 1995 and 2008 shows that VF cases increased in Kern County during the early 1990’s, decreased during the late 1990’s, increased again between 2000 and 2005, and have been declining slightly in the last several years. The majority of VF cases are recorded in the Bakersfield area where 50 to 70 percent of all Kern County VF cases occur. Delano, Lamont, and Taft have the next highest recorded incidences of VF.

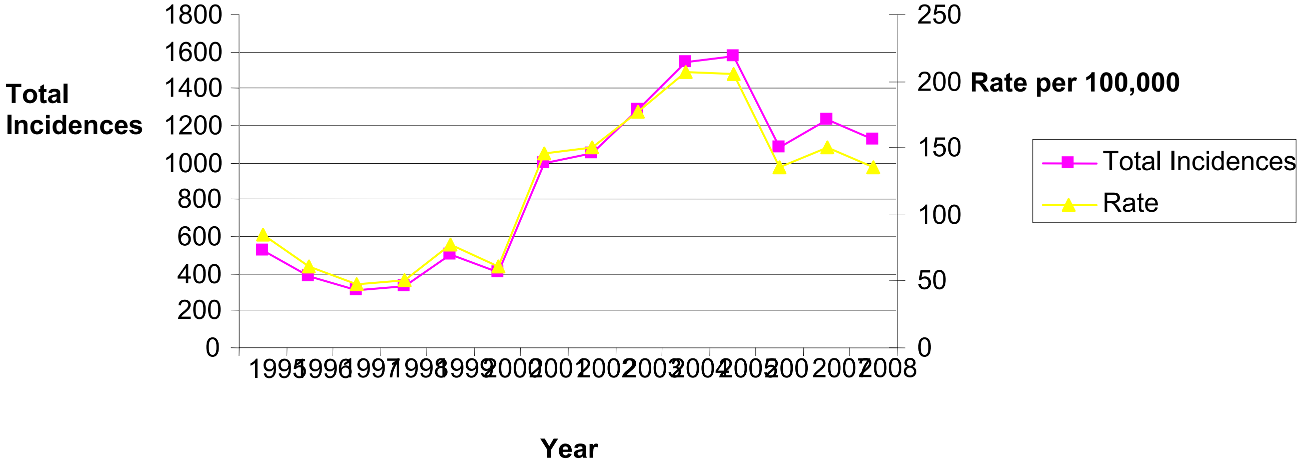
Worker Safety Figure 3
VF Cases in Kern County 1995 - 2008*



*Source: KCDPH 2008, Figure 2

During a phone conversation with Dr. Michael MacLean of the Kings County Health Department, he noted that according to his experience and of those who study VF, it is very hard to find the fungus in soil that was previously farmed and irrigated, which greatly reduces the risk of infection resulting from disturbance of farmed lands (MacLean 2009). This does not apply to previously undisturbed lands where excavation, grading, and construction may correlate with increases in VF cases. Dr. MacLean feels that with the current state of knowledge, we can only speculate on the causes and trends influencing VF cases and he does not feel that construction activities are necessarily the cause of VF outbreaks (KCEHS 2009).

Valley Fever is spread through the air. If soil containing the fungus is disturbed by construction, natural disasters, or wind, the fungal spores get into the air where people can breathe in the spores. The disease is not spread from person to person. Occupational or recreational exposure to dust is an important consideration. Agricultural workers, construction workers, or others (such as archeologists) who dig in the soil in the disease-endemic area of the Central Valley are at the highest risk for the disease (CDC 2006; CDHS 2010). The risk for disseminated coccidioidomycosis is much higher among some ethnic groups, particularly African-Americans and Filipinos. In these ethnic groups, the risk for disseminated coccidioidomycosis is tenfold that of the general population (CDC 2006).

A VF website claims that most cases of valley fever do not require treatment. Even though 30-60% of the population in areas where the disease is highly prevalent - such as in the southern San Joaquin Valley of California - have positive skin tests indicating previous infection, most were unaware of ever having had valley fever ("Valley Fever Vaccine Project of the Americas" 2010).

Worker Safety Table 4
Disease Forms

CATEGORIES	NOTES
Asymptomatic	• Occurs in about 50% of patients
Acute Symptomatic	• Pulmonary syndrome that combines cough, chest pain, shortness of breath, fever, and fatigue. • Diffuse pneumonia affects immunosuppressed individuals • Skin manifestations include fine papular rash, erythema nodosum, and erythema multiforme • Occasional migratory arthralgias and fever
Chronic Pulmonary	• Affects between 5 to 10% of infected individuals • Usually presents as pulmonary nodules or peripheral thin-walled cavities
Extrapulmonary/Disseminated Varieties	
Chronic skin disease	• Keratotic and verrucose ulcers or subcutaneous fluctuant abscesses
Joints / Bones	• Severe synovitis and effusion that may affect knees, wrists, feet, ankles, and/or pelvis • Lytic lesions commonly affecting the axial skeleton
Meningeal Disease	• The most feared complication • Presenting with classic meningeal symptoms and signs • Hydrocephalus is a frequent complication
Others	• May affect virtually any organ, including thyroid, GI tract, adrenal glands, genitourinary tract, pericardium, peritoneum

Given the available scientific and medical literature on Valley Fever, it is difficult for staff to assess the potential for VF to impact workers during construction and operation of the proposed HECA facility with a reasonable degree of accuracy but given the scientific evidence to date, it is possible that the soils at the HECA site contain *c.immitis*. Furthermore, the higher number of cases reported in Kern County and recently in nearby San Luis Obispo County also indicate that the project site may have an elevated risk for exposure. To minimize potential exposure of workers and also the public to coccidioidomycosis during soil excavation and grading, extensive wetting of the soil prior to and during construction activities should be employed and dust masks should be worn at certain times during these activities. The dust (PM10) control measures found in the **Air Quality** section of this PSA/DEIS should be strictly adhered to in order to adequately reduce the risk of contracting VF to less than significant. Towards that, Energy Commission staff proposes Condition of Certification **WORKER SAFETY-7** which would require that the dust control measures found in proposed Conditions **AQ-SC3** and **AQ-SC4** be supplemented with additional requirements including the monitoring of airborne dust (PM_{10}) to ensure that dust control methods are effective.

Fire Hazards

During construction and operation of the proposed HECA there is the potential for small fires, major fires, and even explosions. Electrical sparks, combustion of fuel oil, hydraulic fluid, mineral oil, insulating fluid, or flammable liquids, explosions, and overheated equipment at the sulfur recovery unit, anhydrous ammonia storage tanks, the nitric acid storage tank, the gasifier, the UAN production plant, or the methanol storage tank, may cause small or large fires. Major fires in areas without or even with automatic fire detection and suppression systems are likely to occur at a facility that contains so many flammable liquids in such large volumes. A review of incidents at similar industrial sites is provided in the **Hazardous Materials Management** section of this PSA/DEIS. The list of accidents is illuminating and serves as a basis for precautions to be taken. Even fires and explosions due to the accidental rupture or failure of a natural gas pipeline can occur. Because of the complexity of this project, staff has determined that additional fire prevention and suppression methods are required in order to be in compliance with all LORS and has proposed a condition of certification to ensure additional protection from all fire hazards. These additional methods include the use of foam and more in-depth review of fire protection plans, as discussed below. Adoption of mitigation as described in proposed **WORKER SAFETY-8** would provide the KCFD with the resources it needs to effect these additional protections.

Staff reviewed the information provided in the AFC and contacted the KCFD to determine if available fire protection services and equipment would adequately protect workers, and to further determine the project's impact on fire protection services in the area. Staff met with the Kern County Fire Chief, Fire Marshall, and a Battalion Chief and toured all four fire stations that would respond to an emergency at the proposed project site. As a result of this meeting and tour, staff found that the HECA project would create direct and cumulative significant impacts on the KCFD but that these impacts could be mitigated to a less than significant level. Although the project will rely on both onsite fire protection systems and local fire protection services as described in the AFC (HECA 2012e, section 5.7.2.10), additional equipment and manpower is needed by the KCFD in order to adequately respond to a fire, rescue, hazardous material spill, or medical emergency and also not severely draw-down resources of the department thus leaving large areas of Kern County unprotected.

Emergency response will first be provided by crews for KCFD station 25 located in Buttonwillow. The station is staffed at all times with three firefighters (three shifts) and has one type-2 fire engine and one 4WD fire patrol vehicle. Staff drove the route to the project site at normal speed and found the roads narrow but suitable. According to the KCFD, the response time to the site from first notification at the fire station would be between 7 and 15 minutes. The next station that would respond is located in McKittrick (station 24) and it has the same staffing and equipment. The response time to the HECA site from first notification would be ~ 25-30 minutes. The third in line for response to the HECA site would be station 53 located on Highway 53 east of I-5. This station is proposed for re-location west of I-5 with an addition of a helipad. The fourth station that would respond is station 21 located in Taft. In addition to having one type-2 fire engine and one 4WD fire patrol vehicle, this station has a ladder truck (essential for fighting elevated fires and for rescue at elevations), six firefighters and a Battalion Chief.

Emergency Medical response (EMS) is provided by the KCFD. All firefighters are trained EMTs and a paramedic is located approximately one hour from the HECA site. Private ambulance service is available in both Buttonwillow and Taft.

First response to a hazardous materials spill is also provided by the KCFD and all firefighters are trained as HazMat Technicians.

The onsite fire protection system provides the first line of defense for small fires. In the event of a major fire, fire support services by trained firefighters and equipment for a sustained response would be provided by the KCFD.

Construction

During construction, the applicant has stated that portable fire extinguishers and small hose lines will be located and maintained throughout the site and some fixed firefighting equipment will be made available as soon as possible. Safety procedures and training will also be implemented (HECA 2012e, section 5.7.2.1). KCFD Station #25 in Buttonwillow will provide fire protection backup for larger fires that cannot be extinguished using the project's portable suppression equipment. The applicant intends to place into operation the permanent fire water loop and hydrants as soon as possible after construction begins (HECA 2012e, page 5.7-5) and staff encourages this action. However, staff believes that a firm date for the placement of a fire water loop is appropriate and thus proposes Condition of Certification **WORKER SAFETY-11** that would require placement of the fire water loop on the site not later than six months prior to the start of commissioning.

Operation

The information in the AFC indicates that the project intends to meet the fire protection and suppression requirements of the California Fire Code, all applicable recommended NFPA standards (including Standard 850, which addresses fire protection at electric generating plants), and all Cal-OSHA requirements. Fire suppression elements in the proposed plant will include both fixed and portable fire extinguishing systems. A dedicated supply of potable water will be stored on-site and will serve the fire loops, hydrants, sprinkler, and deluge systems. These will be placed in appropriate locations as per the California Fire Code and NFPA 850 (HECA 2012e, sections 2.5.11.1 and

2.5.11.2). In addition, fire-fighting foam equipment will be deployed near the methanol storage tanks and an automatic CO_2 extinguishing apparatus will be installed at the combustion turbine enclosure. The fire water loop pressure will be maintained by an electric jockey pump and back-up emergency diesel pump. Automatic fire suppression systems will be placed inside the control room, rack room, and the fire pump enclosure.

In addition to the fixed fire protection system, smoke detectors, flame detectors, high-temperature detectors, appropriate class of service portable extinguishers, and fire hydrants would be located throughout the facility at code-approved intervals. These systems are standard requirements of the fire code and NFPA. Staff has determined that they will ensure adequate fire protection.

The applicant would be required by Conditions of Certification **WORKER SAFETY-1** and**-2** to provide a final and more refined fire protection and prevention program to both staff and the KCFD prior to the construction and operation of the project for review in order to confirm the adequacy of proposed fire protection measures.

In conversations with the applicant, staff has been assured that the KCFD will have at least three secure access points though the perimeter fence into the facility. Both the California Fire Code (24 CCR Part 9, chapter 5, section 503.1.2) and NFPA require more than one access point for emergency responders. Therefore, staff proposes Condition of Certification **WORKER SAFETY-6** that would require the project owner to provide at least three secure access points to the site (one on each of the west, north, and east sides) for emergency vehicles and to equip these access gates with an acceptable entry system or keypad for fire department personnel to open the gate. As per staff's proposed condition addressing site security, the use of chains and padlocks to secure gates is prohibited (see the **Hazardous Materials Management** section of this PSA/DEIS, proposed condition **HAZ-7**).

Staff has discussed mitigation with the Kern County Fire Department and has received a list of needed capital and personnel improvements through the Kern County Planning Department (Kern County 2013b). The KCFD has requested that nine specific mitigation measures in the form of equipment and personnel be provided to mitigate direct and cumulative impacts on the fire department. The nine specific mitigation measures requested are summarized here:

1. Provide a fire-fighting foam pumper/tender.
2. Provide a fire protection specialist to be hired by the KCFD during the plan review process.
3. Purchase a plot of land for the relocation of KCFD station 53 and a helipad.
4. Provide 50% of the costs of a KCFD fire prevention inspector during the construction phase.
5. Provide the costs of training the crews at five fire stations who would respond to emergencies at the facility.
6. Purchase for the KCFD a fire rescue truck and a rotator crane to assist in vehicular accidents within Kern County.

7. Provide air monitoring equipment to the KCFD that will monitor multiple toxic gases.
8. Provide funds for six fire engineer positions needed to operate the foam pumper/tender.
9. Contribute annual funds to help maintain the reverse 9-1-1 system.

Staff has reviewed all the requests by the KCFD and had independently arrived at the same opinion for some of the requested mitigation. Staff has asked the KCFD to provide cost estimates of each suggested mitigation measure, but to-date, the county has provided some but not all those costs. However, staff is able to rely on its experience with other fire jurisdictions and propose a level of funding that is a reasonable estimate of what is required. Therefore, to address the direct incremental and cumulative impacts on the KCFD and to ensure that emergency response for fires, spills, rescue, and EMS are adequate, staff proposes Condition of Certification **WORKER SAFETY-8** which would require a one-time initial funding in the amount of $2,000,000 for capital improvements and other costs and $850,000 annually for operations and maintenance. The annual amount, however, would be off-set by the amount of property taxes paid each year by the HECA facility that would go to the Kern County Fire Department. Staff has learned that the usual and customary level of property taxes to be paid each year by an industrial facility that would go to the KCFD would be 10 percent of the total property taxes paid (personal communication with Kern County Fire Marshal Benny Wofford, April 2, 2013). In addition to the receipt of a certain portion of the annual property taxes, the KCFD has a fee schedule for plan review, permits, and inspections. However, since the initial one-time funding amount proposed by staff would cover the costs of these activities during construction and commissioning (a fire protection specialist for the plan review process and a fire prevention inspector during construction), it is expected that fees would not also be charged during this period. During operations, staff proposes that any usual and customary inspection fees charged by the KCFD be paid by the project owner.

Staff bases its proposed mitigation on several factors. First, the complexity of the proposed HECA facility, the use and storage of vast amounts of flammable and combustible materials, the relatively remote location, and the size of the industrial environment, all dictate the need for the following efforts to be undertaken by the KCFD:

1. Complex plan reviews;
2. Frequent hazmat and fire inspections;
3. Emergency Response including medical, fire, rescue, and hazardous materials incidents.

Second, standard fire department responses for a fire and for a hazmat spill include response from two fire stations and at least three fire fighters from each station. To fight a fire inside a structure, the KCFD must adhere to standard operating procedures and Cal-OSHA regulations that require “two men in”, “two men out”. Thus, a response of three fire fighters from one station would not allow fire fighters to attack a fire from within a structure or conduct a rescue. Confined space and collapsed trench rescues would also be problematic with only three fire fighters (although they could be accomplished as per Cal-OSHA requirements of “two in and one out”). Therefore, no matter what size the fire or how many workers are initially in need of rescue, the KCFD would dispatch engines from at least two fire stations so that at a minimum, six firefighters are sent to the scene. The issue of “draw-down” becomes a concern if two or more fire stations are dispatched to the HECA site. The community cannot be left without fire response and thus crews from other KCFD stations would be dispatched to cover the areas vacated by those going to aid at the HECA facility. Because of the very serious threat of escalation from a small incident to a much larger incident at the HECA facility, dispatch from more stations will be the rule rather than the exception and draw-down would occur more rapidly.

Third, it is very important to note that the HECA facility would be located in an area that has a rather harsh environment in the summer months. The ability of a fire fighter to perform duties while wearing a turn-out coat, heavy boots, and a respirator (self contained breathing apparatus) is limited under the best of circumstances. If conducting a rescue or fighting a fire that necessitates use of a respirator, the high-temperatures of the Tupman area (often approaching and exceeding 100° F), severely limits a fire fighter’s ability to perform the duties to 15 minutes at a time. This severe time restriction necessitates the mobilization of more fire fighters to respond to the emergency and hence more draw-down occurs.

Fourth, the KCFD lacks the specialized fire-fighting and rescue equipment (foam tender and rescue truck with a crane) and training to respond to emergencies at such a facility which does not now exist in California. Towards that, additional training is required and staff proposes **WORKER SAFETY-9** to require joint training with the HECA staff and the KCFD at least every two years.

All of the above necessitates a build-up of the KCFD’s ability to respond to the proposed facility. Staff has reviewed costs of equipment and fire fighters’ salaries (plus benefits) in other jurisdictions and arrived at an estimate of funds needed to provide necessary mitigation. The total amount is reflected in proposed condition **WORKER SAFETY-8**.

Emergency Medical Services Response

As described above, EMS is provided by the KCFD from several stations. All firefighters are trained EMTs and a paramedic is located approximately one hour from the HECA site. Private ambulance service is available in both Buttonwillow and Taft and medical air services are available by contract. However, the issue of increased vehicular (truck and tanker truck) activity on the roads and highways of Kern County going to and from the facility will undoubtedly increase the risk of vehicular accidents involving life-threatening injuries. The applicant has estimated that a total in excess of 36,000 single trips into and out of the facility will occur each year. The KCFD has noted that this significant increase in vehicle trips (mostly via truck and tanker trucks) will cause a significant impact on the EMS and rescue capability of the KCFD. Staff concurs with this opinion and supports mitigation to address this impact as described in number 6 above.

A statewide survey was conducted by staff and staff has determined that the potential for both work-related and non-work related heart attacks exists at power plants. In fact, staff’s research on the frequency of EMS response to gas-fired power plants shows that many of the responses for cardiac emergencies involved non-work related incidents, including visitors. The need for prompt response within a few minutes is well documented in the medical literature. Staff believes that the quickest medical intervention can only be achieved with the use of an on-site defibrillator often called an Automatic External Defibrillator or AED; the response from an off-site provider would take longer regardless of the provider location. This fact is also well documented and serves as the basis for many private and public locations including airports, factories, and government buildings, all of which maintain on-site cardiac defibrillation devices. Therefore, staff concludes that with the availability of modern cost-effective AED devices, it is proper in a power plant environment to maintain these devices on-site in order to treat cardiac arrythmias resulting from industrial accidents or other non-work related causes. Therefore, an additional condition of certification, **WORKER SAFETY-5**, is proposed so that a portable AED will be located on site, and workers trained in its use.

ENHANCED OIL RECOVERY FACILITY (EOR)

The Enhanced Oil Recovery (EOR) project at Occidental of Elk Hills, Inc. (OEHI) is located approximately four miles south of the proposed HECA project (OXY 2012). Carbon dioxide would be a byproduct at HECA and is proposed to be compressed and delivered by pipeline to the EOR project where it would be injected into the oil wells to help in the recovery of naturally trapped oil. The project is expected to result in the sequestration of approximately three (3) million tons of CO_2 per year during the demonstration phase. This rate of sequestration would also be required for the operational life of the power plant due to the requirements of California law (SB 1368) and the value created by the use of the CO_2 for EOR. The captured CO_2 would be compressed and transported via pipeline to the Elk Hills Oil Field. The CO_2 would enhance domestic oil production, contributing to the nation's energy security. An additional small amount of the CO_2 produced by the facility would be used to manufacture urea.

The EOR process involves the injection and reinjection of CO_2 to reduce the viscosity and enhance other properties of trapped oil in order to facilitate its flow through the reservoir, improving extraction. During EOR operations, the pore space left by the extracted oil is occupied by the injected CO_2, sequestering it in the geologic formation. EOR operations would be monitored to ensure that the injected CO_2 remains within the formation.

Staff met with the environmental and security personnel for Occidental Elk Hills, Inc. and reviewed the hazardous materials that would be used and stored at the EOR site and discussed fire protection measures. The OEHI property is protected by a private fire brigade with a mutual response agreement with the Kern County Fire Department. During construction and operations at the EOR facility, the site would have flow, pressure, and temperature monitoring devices, fire detection system sensing flame, leak detection sensing petroleum products, and have available a fire water supply tank of 1.5 million gallons. The CO_2 pipeline would for the most part be located underground and security at the two parts above ground where valve boxes exist would be surrounded by chain-link fence and since CO2 does not present a fire hazard, no fire detection or suppression equipment is required.

Staff concludes that given the on-site fire detection and suppression systems and the presence of a private fire brigade, emergency response to the EOR site for spills or fire would not have a significant impact on the Kern County Fire Department. Since mitigation is proposed to reduce the impacts on the KCFD from the HECA project site to an insignificant level, enhancements of the capabilities of the KCFD would also enhance response to the EOR site and therefore no additional conditions or mitigation is required.

CUMULATIVE IMPACTS AND MITIGATION

Staff reviewed what impacts the construction and operation of HECA could have on the fire and emergency service capabilities of the KCFD. Staff has identified both direct and cumulative impacts and mitigation to reduce those impacts to a level of less than significant. Staff's proposed Conditions of Certification **WORKER SAFETY-8** and **9** address both individual direct and cumulative impacts.

COMPLIANCE WITH LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

Staff concludes that if all proposed conditions were adopted and implemented, the construction and operation of the HECA project would be in compliance with all applicable laws, ordinances, regulations, and standards (LORS) regarding long-term and short-term project impacts in the area of worker safety and fire protection.

RESPONSE TO AGENCY AND PUBLIC COMMENTS

Comment: AIR (Association of Irritated Residents) provided a status report and data requests in a document dated November 2, 2012 (TN #68076). Residents asked about the dangers of anhydrous ammonia and if it is deadly. Several asked for more information on the possibility of accidents or releases at the project resulting in fatalities in nearby residents or workers (emphasis added), and accidents involving trucks transporting hazardous materials. They asked specifically how safe is it for someone to live or work nearby if there is a release of CO_2 or anhydrous ammonia, and are there other hazardous gases that might be released and cause harm. There was additional concern expressed regarding the potential for materials on-site to cause explosions and what impact that would have on the neighboring area. A question was raised as to whether the chemical factory will produce ammonium nitrate fertilizer and in what quantity and what security will HECA provide for storage and shipping of ammonium nitrate.

Response: Staff assessed these issues and its response can be seen in this section of the PSA/DEIS above and in the section addressing Hazardous Materials Management. In addition to the laws and regulations that must be followed by the project owner should this facility be licensed and built, staff has proposed seven conditions of certification that would, if adopted, increase the level of safety to workers. Worker safety plans would be prepared and reviewed and approved before workers would arrive on the site for either construction or operations.

Comment: The Kern County Fire Department has provided comments through the Kern County Planning Department (Kern County 2013b) and has requested that nine specific mitigation measures in the form of equipment and personnel be provided to mitigate direct and cumulative impacts on the fire department. The nine specific mitigation measures requested are summarized above.

Response: Staff considered all these issues and proposes mitigation as found in proposed condition **WORKER SAFETY-8** and ***9.***

CONCLUSIONS

Staff concludes that if the applicant for the proposed HECA project will provide project construction safety and health programs and project operations and maintenance safety and health programs, as required by Conditions of Certification **WORKER SAFETY -1**, and **-2**; and complies with the requirements of Conditions of Certification **WORKER SAFETY-3** through**-11**, HECA would incorporate sufficient measures to ensure adequate levels of industrial safety and fire protection and comply with applicable LORS. Staff also concludes that the proposed project would have significant impacts on local fire protection services but that implementation of staff's proposed conditions would reduce those impacts to less than significant.

DOE'S FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the applicant for HECA. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

PROPOSED CONDITIONS OF CERTIFICATION

WORKER SAFETY-1 The project owner shall submit to the compliance project manager (CPM) a copy of the Project Construction Safety and Health Program containing the following:

- A Construction Personal Protective Equipment Program;
- A Construction Exposure Monitoring Program;
- A Construction Injury and Illness Prevention Program;
- A Construction Emergency Action Plan; and
- A Construction Fire Prevention Plan.

The Personal Protective Equipment Program, the Exposure Monitoring Program, and the Injury and Illness Prevention Program shall be submitted to the CPM for review and approval concerning compliance of the program with all applicable safety orders. The Construction Emergency Action Plan and the Fire Prevention Plan shall be submitted to the Kern County Fire Department for review and comment prior to submittal to the CPM for approval.

Verification: At least thirty (30) days prior to the start of construction, the project owner shall submit to the CPM for review and approval a copy of the Project Construction Safety and Health Program. The project owner shall provide a copy of a letter to the CPM from the Kern County Fire Department stating the Fire Department's comments on the Construction Fire Prevention Plan and Emergency Action Plan.

WORKER SAFETY-2 The project owner shall submit to the CPM a copy of the Project Operations and Maintenance Safety and Health Program containing the following:

- An Operation Injury and Illness Prevention Plan;
- An Emergency Action Plan;
- Hazardous Materials Management Program;
- Fire Prevention Program (8 CCR § 3221); and;
- Personal Protective Equipment Program (8 CCR §§ 3401-3411).

The Operation Injury and Illness Prevention Plan, Emergency Action Plan, and Personal Protective Equipment Program shall be submitted to the CPM for review and approval concerning compliance of the program with all applicable Safety Orders. The Operation Fire Prevention Plan and the Emergency Action Plan shall also be submitted to the Kern County Fire Department for review and comment.

Verification: At least thirty (30) days prior to the start of first-fire or commissioning, the project owner shall submit to the CPM for approval a copy of the Project Operations and Maintenance Safety and Health Program. The project owner shall provide a copy of a letter to the CPM from the Kern County Fire Department stating the Fire Department's comments on the Operations Fire Prevention Plan and Emergency Action Plan.

WORKER SAFETY-3 The project owner shall provide a site Construction Safety Supervisor (CSS) who, by way of training and/or experience, is knowledgeable of power plant construction activities and relevant laws, ordinances, regulations, and standards, is capable of identifying workplace hazards relating to the construction activities, and has authority to take appropriate action to assure compliance and mitigate hazards. The CSS shall:

- Have over-all authority for coordination and implementation of all occupational safety and health practices, policies, and programs;
- Assure that the safety program for the project complies with Cal/OSHA and federal regulations related to power plant projects;
- Assure that all construction and commissioning workers and supervisors receive adequate safety training;
- Complete accident and safety-related incident investigations, emergency response reports for injuries, and inform the CPM of safety-related incidents; and

- Assure that all the plans identified in Worker Safety 1 and 2 are implemented.

Verification: At least thirty (30) days prior to the start of site mobilization, the project owner shall submit to the CPM the name and contact information for the Construction Safety Supervisor (CSS). The contact information of any replacement (CSS) shall be submitted to the CPM within one business day.

The CSS shall submit in the Monthly Compliance Report a monthly safety inspection report to include:

- Record of all employees trained for that month (all records shall be kept on site for the duration of the project);
- Summary report of safety management actions and safety-related incidents that occurred during the month;
- Report of any continuing or unresolved situations and incidents that may pose danger to life or health; and
- Report of accidents and injuries that occurred during the month.

WORKER SAFETY-4 The project owner shall make payments to the Chief Building Official (CBO) for the services of a Safety Monitor based upon a reasonable fee schedule to be negotiated between the project owner and the CBO. Those services shall be in addition to other work performed by the CBO. The Safety Monitor shall be selected by and report directly to the CBO, and shall be responsible for verifying that the Construction Safety Supervisor, as required in Worker Safety 3, implements all appropriate Cal/OSHA and Commission safety requirements. The Safety Monitor shall conduct on-site (including linear facilities) safety inspections at intervals necessary to fulfill those responsibilities.

Verification: At least thirty (30) days prior to the start of construction, the project owner shall provide proof of its agreement to fund the Safety Monitor services to the CPM for review and approval.

WORKER SAFETY-5 The project owner shall ensure that a portable automatic external defibrillator (AED) is located on site during construction and operations and shall implement a program to ensure that workers are properly trained in its use and that the equipment is properly maintained and functioning at all times. During construction and commissioning, the following persons shall be trained in its use and shall be on-site whenever the workers that they supervise are on-site: the Construction Project Manager or delegate, the Construction Safety Supervisor or delegate, and all shift foremen. During operations, all power plant employees shall be trained in its use. The training program shall be submitted to the CPM for review and approval.

Verification: At least thirty (30) days prior to the start of site mobilization the project owner shall submit to the CPM proof that a portable AED exists on site and a copy of the training and maintenance program for review and approval.

WORKER SAFETY-6 The project owner shall identify and provide at least three secure access points for emergency personnel to enter the site. These access points and the method of gate operation shall be submitted to the Kern County Fire Department for review and comment and to the CPM for review and approval.

Verification: At least sixty (60) days prior to the start of site mobilization, the project owner shall submit to the Kern County Fire Department and the CPM preliminary plans showing the location of at least three secure access points to the site and a description of how the gates will be opened by the fire department. At least thirty (30) days prior to the start of site mobilization, the project owner shall submit final plans to the CPM for review and approval. The final plan submittal shall also include a letter containing comments from the Kern County Fire Department or a statement that no comments were received.

WORKER SAFETY-7 The project owner shall develop and implement an enhanced Dust Control Plan that includes the requirements described in **AQ-SC3** and additionally requires:

i) site worker use of dust masks (NIOSH N-95 or better) whenever visible dust is present;

ii) implementation of enhanced dust control methods (increased frequency of watering, use of dust suppression chemicals, etc. consistent with **AQ-SC4**) immediately whenever visible dust comes from or onto the site

iii) no downwind PM_{10} ambient concentrations to increase more than 50 micrograms per cubic meter above upwind concentrations as determined by simultaneous upwind and downwind sampling. High-volume particulate matter samplers or other EPA-approved equivalent method(s) for PM_{10} monitoring shall be used. Samplers shall be:

a. Operated, maintained, and calibrated in accordance with 40 Code of Federal Regulations (CFR), Part 50, Appendix J, or appropriate EPA-published documents for EPA-approved equivalent methods(s) for PM_{10} sampling;

b. Reasonably placed upwind and downwind of the large operation based on prevailing wind direction and as close to the property line as feasible, such that other sources of fugitive dust between the sampler and the property line are minimized; and

c. Operated during active operations.

Verification: At least 60 days prior to the commencement of site mobilization, the enhanced Dust Control Plan shall be provided to the CPM for review and approval.

WORKER SAFETY-8 The project owner shall on the date of site mobilization, as mitigation for direct and cumulative impacts, make a one-time payment of $2,000,000 to the Kern County Fire Department for capital improvements. Also as mitigation, the project owner shall make an annual payment of

$850,000 for operations and maintenance commencing with the date of start of site mobilization and continuing annually thereafter on the anniversary until the final date of power plant decommissioning. The annual amount shall be off-set by the amount of property taxes paid each year by the HECA facility that would go to the Kern County Fire Department.

Verification: At least sixty (30) days prior to the start of site mobilization the project owner shall provide to the CPM documentation that the one-time capital improvement payment of $2,000,000 and the first annual payment of $850,000 have been paid to the KCFD, and shall also provide a statement in the Annual Compliance Report that subsequent annual payments (less the share of property taxes paid that go to the KCFD) have been made.

WORKER SAFETY-9 The project owner shall participate in joint training exercises with the Kern County Fire Department (KCFD) every two years.

Verification: At least 10 days prior to the start of commissioning, the project owner shall submit to the CPM proof that a joint training program with the KCFD is established. In the annual compliance report to the CPM, the project owner shall include the date, list of participants, training protocol, and location of the joint training.

WORKER SAFETY-10 The project owner shall ensure that during commissioning and operation, there shall be at least one person on site at all times (24 hours/day, 7 days/week) who shall be knowledgeable of and dedicated to safety, security, and fire protection.

Verification: At least 10 days prior to the start of commissioning, the project owner shall submit to the CPM proof that a competent person has been retained and will be on the site at all times. In the annual compliance report to the CPM, the project owner shall verify that the person was present.

WORKER SAFETY-11 The project owner shall place into operation the permanent fire water loop and hydrants as soon as possible after construction begins but in any event not later than six months (180 days) days prior to the start of commissioning.

Verification: At least six months (180 days) prior to the start of commissioning, the project owner shall submit to the CPM proof that the permanent fire water loop and hydrants have been built on-site, tested, and has received code approval from the CBO and review and comment from the KCFD.

ENGINEERING ASSESSMENT

FACILITY DESIGN

Shahab Khoshmashrab

SUMMARY OF CONCLUSIONS

The California Energy Commission staff concludes that the design, construction, and eventual closure of the project and its linear facilities would likely comply with applicable engineering laws, ordinances, regulations and standards. The proposed conditions of certification, below, would ensure compliance with these laws, ordinances, regulations and standards.

INTRODUCTION

Facility design encompasses the civil, structural, mechanical, and electrical engineering design of the Hydrogen Energy California (HECA) project. The HECA project would consist of the feedstock handling block, fuel gasification block, syngas conditioning system, power generation block, fertilizer production complex, air separation unit, CO_2 transmission system, and enhanced oil recovery system. The purpose of this analysis is to:

- Verify that the laws, ordinances, regulations and standards (LORS) that apply to the engineering design and construction of the project have been identified;
- Verify that both the project and its ancillary facilities are sufficiently described, including proposed design criteria and analysis methods, in order to provide reasonable assurance that the project will be designed and constructed in accordance with all applicable engineering LORS, in a manner that also ensures the public health and safety;
- Determine whether special design features should be considered during final design to address conditions unique to the site which could influence public health and safety; and
- Describe the design review and construction inspection process and establish the conditions of certification used to monitor and ensure compliance with the engineering LORS, in addition to any special design requirements.

Subjects discussed in this analysis include:

- Identification of the engineering LORS that apply to facility design;
- Evaluation of the applicant’s proposed design criteria, including identification of criteria essential to public health and safety;
- Proposed modifications and additions to the application for certification (AFC) necessary for compliance with applicable engineering LORS; and
- Conditions of certification proposed by staff to ensure that the project will be designed and constructed to ensure public health and safety and comply with all applicable engineering LORS.

LAWS, ORDINANCES, REGULATIONS AND STANDARDS (LORS)

Lists of LORS applicable to each engineering discipline (civil, structural, mechanical, and electrical) are described in the AFC (HECA 2012, AFC Appendix D). Key LORS are listed in **Facility Design Table 1,** below:

Facility Design Table 1
Key Engineering Laws, Ordinances, Regulations and Standards (LORS)

Applicable LORS	Description
Federal	Title 29 Code of Federal Regulations (CFR), Part 1910, Occupational Safety and Health standards
State	2010 (or the latest edition in effect) California Building Standards Code (CBSC) (also known as Title 24, California Code of Regulations)
Local	Kern County regulations and ordinances
General	American National Standards Institute (ANSI) American Society of Mechanical Engineers (ASME) American Welding Society (AWS) American Society for Testing and Materials (ASTM)

The following conditions of certification require the project to comply with the California Building Standards Code and Kern County regulations and ordinances to ensure that the project would be built to applicable engineering codes and ensure public health and safety.

For the project to be built in a manner that would ensure public health and safety and operational integrity of project equipment, the LORS listed above in **Facility Design Table 1** under the “**General**” heading, must also be met by the project. The LORS listed under this heading are only some of the key engineering standards applicable to the project; for a comprehensive list of engineering LORS, please see AFC Appendix D.

SETTING

HECA would be built on an approximately 453-acre site located in Kern County, California. For more information on the site and its related project description, please see the **Project Description** section of this document. Additional engineering design details are contained in the AFC, Appendix D (HECA 2012).

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The purpose of this analysis is to ensure that the project would be built to applicable engineering codes and ensure public health and safety. This analysis further verifies that applicable engineering LORS have been identified and that the project and its ancillary facilities have been described in adequate detail. It also evaluates the applicant’s proposed design criteria, describes the design review and construction inspection process, and establishes conditions of certification that would monitor and ensure compliance with engineering LORS and any other special design requirements. These conditions allow both the California Energy Commission (Energy Commission) compliance project manager (CPM) and the applicant to adopt a compliance monitoring program that will verify compliance with these LORS.

SITE PREPARATION AND DEVELOPMENT

Staff has evaluated the proposed design criteria for grading, flood protection, erosion control, site drainage, and site access, in addition to the criteria for designing and constructing linear support facilities such as natural gas and electric transmission interconnections. The applicant proposes the use of accepted industry standards (see HECA 2012, Appendix D, for a representative list of applicable industry standards), design practices, and construction methods in preparing and developing the site. Staff concludes that this project, including its linear facilities, would most likely comply with all applicable site preparation LORS. To ensure compliance, staff proposes the conditions of certification listed below and in the **Geology and Paleontology** section of this document.

MAJOR STRUCTURES, SYSTEMS, AND EQUIPMENT

Major structures, systems, and equipment are structures and their associated components or equipment that are necessary for power production, costly or time consuming to repair or replace, are used for the storage, containment, or handling of hazardous or toxic materials, or could become potential health and safety hazards if not constructed according to applicable engineering LORS.

HECA will be designed and constructed to the 2010 California Building Standards Code (CBSC), also known as Title 24, California Code of Regulations, which encompasses the California Building Code (CBC), California Building Standards Administrative Code, California Electrical Code, California Mechanical Code, California Plumbing Code, California Energy Code, California Fire Code, California Code for Building Conservation, California Reference Standards Code, and other applicable codes and standards in effect when the design and construction of the project actually begin. If the initial designs are submitted to the chief building official (CBO) for review and approval after the update to the 2010 CBSC takes effect, the 2010 CBSC provisions shall be replaced with the updated provisions.

Certain structures in a power plant may be required, under the CBC, to undergo dynamic lateral force (structural) analysis; others may be designed using the simpler static analysis procedure. In order to ensure that structures are analyzed according to their appropriate lateral force procedure, staff has included condition of certification **STRUC-1**, below, which, in part, requires the project CBO's review and approval of the owner's proposed lateral force procedures before construction begins.

PROJECT QUALITY PROCEDURES

The applicant describes a quality program intended to inspire confidence that its systems and components will be designed, fabricated, stored, transported, installed, and tested in accordance with all appropriate power plant technical codes and standards (HECA 2012, AFC § 3.12.6, Appendix D). Compliance with design requirements will be verified through specific inspections and audits. Implementation of this quality assurance/quality control (QA/QC) program will ensure that HECA is actually designed, procured, fabricated, and installed as described in this analysis.

COMPLIANCE MONITORING

Under Section 104.1 of the 2010 CBC, the CBO is authorized and directed to enforce all provisions of the CBC. The Energy Commission itself serves as the building official, and has the responsibility to enforce the code, for all of the energy facilities it certifies. In addition, the Energy Commission has the power to interpret the CBC and adopt and enforce both rules and supplemental regulations that clarify application of the CBC's provisions.

The Energy Commission's design review and construction inspection process conforms to CBC requirements and ensures that all facility design conditions of certification are met. As provided by Section 103.3 of the 2010 CBC, the Energy Commission appoints experts to perform design review and construction inspections and act as delegate CBOs on behalf of the Energy Commission. These delegates may include the local building official and/or independent consultants hired to provide technical expertise that is not provided by the local official alone. The applicant, through permit fees provided by the CBC, pays the cost of these reviews and inspections. While building permits in addition to Energy Commission certification are not required for this project, the applicant pays in lieu of CBC permit fees to cover the costs of these reviews and inspections.

Engineering and compliance staff will invite Kern County or a third-party engineering consultant to act as CBO for this project. When an entity has been assigned CBO duties, Energy Commission staff will complete a memorandum of understanding (MOU) with that entity to outline both its roles and responsibilities and those of its subcontractors and delegates.

Staff has developed proposed conditions of certification to ensure for protection of public health and safety and compliance with engineering design LORS. Some of these conditions address the roles, responsibilities, and qualifications of the engineers who will design and build the proposed project (conditions of certification **GEN-1** through **GEN-8**). These engineers must be registered in California and sign and stamp every submittal of design plans, calculations, and specifications submitted to the CBO. These conditions require that every element of the project's construction (subject to CBO review and approval) be approved by the CBO before it is performed. They also require that qualified special inspectors perform or oversee special inspections required by all applicable LORS.

While the Energy Commission and delegate CBO have the authority to allow some flexibility in scheduling construction activities, these conditions are written so that no element of construction (of permanent facilities subject to CBO review and approval) which could be difficult to reverse or correct can proceed without prior CBO approval. Elements of construction that are not difficult to reverse may proceed without approval of the plans. The applicant bears the responsibility to fully modify construction elements in order to comply with all design changes resulting from the CBO's subsequent plan review and approval process.

FACILITY CLOSURE

The removal of a facility from service (decommissioning) when it reaches the end of its useful life ranges from “mothballing,” to the removal of all equipment and appurtenant facilities and subsequent restoration of the site. Future conditions that could affect decommissioning are largely unknown at this time.

In order to ensure that decommissioning will be completed in a manner that is environmentally sound, safe, and protects the public health and safety, the applicant shall submit to the Energy Commission for review and approval a contingency plan for unplanned closure prior to project operations, and a decommissioning plan before the project’s decommissioning begins. The plan shall include a discussion of:

- Proposed decommissioning activities for the project and all appurtenant facilities that were constructed as part of the project;
- All applicable LORS, local/regional plans, and proof of adherence to those applicable LORS and local/regional plans;
- The activities necessary to restore the site if the plan requires removal of all equipment and appurtenant facilities; and
- Decommissioning alternatives other than complete site restoration.

Satisfying the above requirements should serve as adequate protection, even in the unlikely event that the project is abandoned. Staff has proposed general conditions (see **Compliance Conditions**) to ensure that these measures are included in the Facility Closure Plan.

DOE’S FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the applicant for HECA. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

CONCLUSIONS AND RECOMMENDATIONS

1. The laws, ordinances, regulations and standards (LORS) identified in the AFC and supporting documents directly apply to the project.

2. Staff has evaluated the proposed engineering LORS, design criteria, and design methods in the record, and concludes that the design, construction, and eventual closure of the project will likely comply with applicable engineering LORS.

3. The proposed conditions of certification will ensure that HECA is designed and constructed in accordance with applicable engineering LORS. This will be

accomplished through design review, plan checking, and field inspections that will be performed by the CBO or other Energy Commission delegate. Staff will audit the CBO to ensure satisfactory performance.

4. Though future conditions that could affect decommissioning are largely unknown at this time, it can reasonably be concluded that if the project owner submits a decommissioning plan as required in the **Compliance Conditions** portion of this document prior to decommissioning, decommissioning procedures will comply with all applicable engineering LORS.

Energy Commission staff recommends that:

1. The proposed conditions of certification be adopted to ensure that the project is designed and constructed in a manner that protects the public health and safety and complies with all applicable engineering LORS;

2. The project be designed and built to the 2010 CBSC (or successor standards, if in effect when initial project engineering designs are submitted for review); and

3. The CBO reviews the final designs, checks plans, and performs field inspections during construction. Energy Commission staff shall audit and monitor the CBO to ensure satisfactory performance.

Under the No-Action Alternative, DOE would not provide financial assistance to the Applicant for the HECA Project. The Applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

CONDITIONS OF CERTIFICATION

GEN-1 The project owner shall design, construct, and inspect the project in accordance with the 2010 California Building Standards Code (CBSC), also known as Title 24, California Code of Regulations, which encompasses the California Building Code (CBC), California Building Standards Administrative Code, California Electrical Code, California Mechanical Code, California Plumbing Code, California Energy Code, California Fire Code, California Code for Building Conservation, California Reference Standards Code, and all other applicable engineering LORS (including the applicable Kern County engineering LORS) in effect at the time initial design plans are submitted to the CBO for review and approval (the CBSC in effect is the edition that has been adopted by the California Building Standards Commission and published at least 180 days previously). The project owner shall ensure that all the provisions of the above applicable codes are enforced during the construction, addition, alteration, moving, demolition, repair, or maintenance of the completed facility. All transmission facilities (lines, switchyards, switching stations and substations) are covered in the conditions of certification in the **Transmission System Engineering** section of this document.

In the event that the initial engineering designs are submitted to the CBO when the successor to the 2010 CBSC is in effect, the 2010 CBSC provisions shall be replaced with the applicable successor provisions. Where, in any specific case, different sections of the code specify different materials, methods of construction or other requirements, the most restrictive shall govern. Where there is a conflict between a general requirement and a specific requirement, the specific requirement shall govern.

The project owner shall ensure that all contracts with contractors, subcontractors, and suppliers clearly specify that all work performed and materials supplied comply with the codes listed above.

Verification: Within 30 days following receipt of the certificate of occupancy for any increment of construction, the project owner shall submit to the CPM a statement of verification, signed by the responsible design engineer, attesting that all designs, construction, installation, and inspection requirements of the applicable LORS and the Energy Commission's decision have been met in the area of facility design for that increment of construction. The project owner shall provide the CPM a copy of the certificate of occupancy within 30 days of receipt from the CBO.

Once the certificate of occupancy has been issued for any portion(s) of the completed facility, the project owner shall inform the CPM at least 30 days prior to any construction, addition, alteration, moving, demolition, repair, or maintenance to be performed on that portion(s) of the completed facility, if it requires CBO approval for compliance with the above codes. The CPM will then determine if the CBO needs to approve the work.

GEN-2 Before submitting the initial engineering designs for CBO review, the project owner shall furnish the CPM and the CBO with a schedule of facility design submittals, and master drawings and master specifications list. The master drawings and master specifications list shall contain a list of proposed submittal packages of designs, calculations, and specifications for major structures, systems, and equipment. Major structures, systems, and equipment are structures and their associated components or equipment that are necessary for power production, costly or time consuming to repair or replace, are used for the storage, containment, or handling of hazardous or toxic materials, or could become potential health and safety hazards if not constructed according to applicable engineering LORS. The schedule shall contain the date of each submittal to the CBO. To facilitate audits by Energy Commission staff, the project owner shall provide specific packages to the CPM upon request.

Verification: At least 60 days (or a project owner- and CBO-approved alternative time frame) prior to the start of rough grading, the project owner shall submit to the CBO and to the CPM the schedule, and the master drawings and master specifications list of documents to be submitted to the CBO for review and approval. These documents shall be the pertinent design documents for the major structures, systems, and equipment defined above in Condition of Certification **GEN-2**. Major structures and equipment shall be added to or deleted from the list only with CPM approval. The project owner shall provide schedule updates in the monthly compliance report.

GEN-3 The project owner shall make payments to the CBO for design review, plan checks, and construction inspections, based upon a reasonable fee schedule to be negotiated between the project owner and the CBO. These fees may be consistent with the fees listed in the 2010 CBC, adjusted for inflation and other appropriate adjustments; may be based on the value of the facilities reviewed; may be based on hourly rates; or may be otherwise agreed upon by the project owner and the CBO.

Verification: The project owner shall make the required payments to the CBO in accordance with the agreement between the project owner and the CBO. The project owner shall send a copy of the CBO's receipt of payment to the CPM in the next monthly compliance report indicating that applicable fees have been paid.

GEN-4 Prior to the start of rough grading, the project owner shall assign a California-registered architect, or a structural or civil engineer, as the resident engineer (RE) in charge of the project. All transmission facilities (lines, switchyards, switching stations, and substations) are addressed in the conditions of certification in the **Transmission System Engineering** section of this document.

The RE may delegate responsibility for portions of the project to other registered engineers. Registered mechanical and electrical engineers may be delegated responsibility for mechanical and electrical portions of the project, respectively. A project may be divided into parts, provided that each part is clearly defined as a distinct unit. Separate assignments of general responsibility may be made for each designated part.

The RE shall:

1. Monitor progress of construction work requiring CBO design review and inspection to ensure compliance with LORS;
2. Ensure that construction of all facilities subject to CBO design review and inspection conforms in every material respect to applicable LORS, these conditions of certification, approved plans, and specifications;
3. Prepare documents to initiate changes in approved drawings and specifications when either directed by the project owner or as required by the conditions of the project;
4. Be responsible for providing project inspectors and testing agencies with complete and up-to-date sets of stamped drawings, plans, specifications, and any other required documents;
5. Be responsible for the timely submittal of construction progress reports to the CBO from the project inspectors, the contractor, and other engineers who have been delegated responsibility for portions of the project; and

6. Be responsible for notifying the CBO of corrective action or the disposition of items noted on laboratory reports or other tests when they do not conform to approved plans and specifications.

The resident engineer (or his delegate) must be located at the project site, or be available at the project site within a reasonable period of time, during any hours in which construction takes place.

The RE shall have the authority to halt construction and to require changes or remedial work if the work does not meet requirements.

If the RE or the delegated engineers are reassigned or replaced, the project owner shall submit the name, qualifications and registration number of the newly assigned engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer.

<u>Verification:</u> At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of rough grading, the project owner shall submit to the CBO, for review and approval, the resume and registration number of the RE and any other delegated engineers assigned to the project. The project owner shall notify the CPM of the CBO's approvals of the RE and other delegated engineer(s) within five days of the approval.

If the RE or the delegated engineer(s) is subsequently reassigned or replaced, the project owner has five days to submit the resume and registration number of the newly assigned engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer within five days of the approval.

GEN-5 Prior to the start of rough grading, the project owner shall assign at least one of each of the following California registered engineers to the project: a civil engineer; a soils, geotechnical, or civil engineer experienced and knowledgeable in the practice of soils engineering; and an engineering geologist. Prior to the start of construction, the project owner shall assign at least one of each of the following California registered engineers to the project: a design engineer who is either a structural engineer or a civil engineer fully competent and proficient in the design of power plant structures and equipment supports; a mechanical engineer; and an electrical engineer. (California Business and Professions Code section 6704 et seq., and sections 6730, 6731 and 6736 require state registration to practice as a civil engineer or structural engineer in California). All transmission facilities (lines, switchyards, switching stations, and substations) are handled in the conditions of certification in the **Transmission System Engineering** section of this document.

The tasks performed by the civil, mechanical, electrical, or design engineers may be divided between two or more engineers, as long as each engineer is responsible for a particular segment of the project (for example, proposed earthwork, civil structures, power plant structures, equipment support). No segment of the project shall have more than one responsible engineer. The transmission line may be the responsibility of a separate California registered electrical engineer.

The project owner shall submit, to the CBO for review and approval, the names, qualifications, and registration numbers of all responsible engineers assigned to the project.

If any one of the designated responsible engineers is subsequently reassigned or replaced, the project owner shall submit the name, qualifications and registration number of the newly assigned responsible engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer.

A. The civil engineer shall:
   1. Review the foundation investigations, geotechnical, or soils reports prepared by the soils engineer, the geotechnical engineer, or by a civil engineer experienced and knowledgeable in the practice of soils engineering;
   2. Design (or be responsible for the design of), stamp, and sign all plans, calculations, and specifications for proposed site work, civil works, and related facilities requiring design review and inspection by the CBO. At a minimum, these include: grading, site preparation, excavation, compaction, construction of secondary containment, foundations, erosion and sedimentation control structures, drainage facilities, underground utilities, culverts, site access roads and sanitary sewer systems; and
   3. Provide consultation to the RE during the construction phase of the project and recommend changes in the design of the civil works facilities and changes to the construction procedures.

B. The soils engineer, geotechnical engineer, or civil engineer experienced and knowledgeable in the practice of soils engineering, shall:
   1. Review all the engineering geology reports;
   2. Prepare the foundation investigations, geotechnical, or soils reports containing field exploration reports, laboratory tests, and engineering analysis detailing the nature and extent of the soils that could be susceptible to liquefaction, rapid settlement or collapse when saturated under load;
   3. Be present, as required, during site grading and earthwork to provide consultation and monitor compliance with requirements set forth in the 2010 CBC (depending on the site conditions, this may be the responsibility of either the soils engineer, the engineering geologist, or both); and
   4. Recommend field changes to the civil engineer and RE.

This engineer shall be authorized to halt earthwork and to require changes if site conditions are unsafe or do not conform to the predicted conditions used as the basis for design of earthwork or foundations.

C. The engineering geologist shall:

1. Review all the engineering geology reports and prepare a final soils grading report; and
2. Be present, as required, during site grading and earthwork to provide consultation and monitor compliance with the requirements set forth in the 2010 CBC (depending on the site conditions, this may be the responsibility of either the soils engineer, the engineering geologist, or both).

D. The design engineer shall:

1. Be directly responsible for the design of the proposed structures and equipment supports;
2. Provide consultation to the RE during design and construction of the project;
3. Monitor construction progress to ensure compliance with engineering LORS;
4. Evaluate and recommend necessary changes in design; and
5. Prepare and sign all major building plans, specifications, and calculations.

E. The mechanical engineer shall be responsible for, and sign and stamp a statement with, each mechanical submittal to the CBO, stating that the proposed final design plans, specifications, and calculations conform to all of the mechanical engineering design requirements set forth in the Energy Commission's decision.

F. The electrical engineer shall:

1. Be responsible for the electrical design of the project; and
2. Sign and stamp electrical design drawings, plans, specifications, and calculations.

<u>Verification:</u> At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of rough grading, the project owner shall submit to the CBO for review and approval, resumes and registration numbers of the responsible civil engineer, soils (geotechnical) engineer and engineering geologist assigned to the project.

At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of construction, the project owner shall submit to the CBO for review and approval, resumes and registration numbers of the responsible design engineer, mechanical engineer, and electrical engineer assigned to the project.

The project owner shall notify the CPM of the CBO's approvals of the responsible engineers within five days of the approval.

If the designated responsible engineer is subsequently reassigned or replaced, the project owner has five days in which to submit the resume and registration number of the newly assigned engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer within five days of the approval.

GEN-6 Prior to the start of an activity requiring special inspection, including prefabricated assemblies, the project owner shall assign to the project, qualified and certified special inspector(s) who shall be responsible for the special inspections required by the 2010 CBC. All transmission facilities (lines, switchyards, switching stations, and substations) are handled in conditions of certification in the **Transmission System Engineering** section of this document.

A certified weld inspector, certified by the American Welding Society (AWS), and/or American Society of Mechanical Engineers (ASME) as applicable, shall inspect welding performed on-site requiring special inspection (including structural, piping, tanks and pressure vessels).

The special inspector shall:

1. Be a qualified person who shall demonstrate competence, to the satisfaction of the CBO, for inspection of the particular type of construction requiring special or continuous inspection;
2. Inspect the work assigned for conformance with the approved design drawings and specifications;
3. Furnish inspection reports to the CBO and RE. All discrepancies shall be brought to the immediate attention of the RE for correction, then, if uncorrected, to the CBO and the CPM for corrective action; and
4. Submit a final signed report to the RE, CBO, and CPM, stating whether the work requiring special inspection was, to the best of the inspector's knowledge, in conformance with the approved plans, specifications, and other provisions of the applicable edition of the CBC.

<u>Verification:</u> At least 15 days (or project owner- and CBO-approved alternative time frame) prior to the start of an activity requiring special inspection, the project owner shall submit to the CBO for review and approval, with a copy to the CPM, the name(s) and qualifications of the certified weld inspector(s), or other certified special inspector(s) assigned to the project to perform one or more of the duties set forth above. The project owner shall also submit to the CPM a copy of the CBO's approval of the qualifications of all special inspectors in the next monthly compliance report.

If the special inspector is subsequently reassigned or replaced, the project owner has five days in which to submit the name and qualifications of the newly assigned special inspector to the CBO for approval. The project owner shall notify the CPM of the CBO's approval of the newly assigned inspector within five days of the approval.

GEN-7 If any discrepancy in design and/or construction is discovered in any engineering work that has undergone CBO design review and approval, the project owner shall document the discrepancy and recommend required corrective actions. The discrepancy documentation shall be submitted to the CBO for review and approval. The discrepancy documentation shall reference this condition of certification and, if appropriate, applicable sections of the CBC and/or other LORS.

Verification: The project owner shall transmit a copy of the CBO's approval of any corrective action taken to resolve a discrepancy to the CPM in the next monthly compliance report. If any corrective action is disapproved, the project owner shall advise the CPM, within five days, of the reason for disapproval and the revised corrective action to obtain CBO's approval.

GEN-8 The project owner shall obtain the CBO's final approval of all completed work that has undergone CBO design review and approval. The project owner shall request the CBO to inspect the completed structure and review the submitted documents. The project owner shall notify the CPM after obtaining the CBO's final approval. The project owner shall retain one set of approved engineering plans, specifications, and calculations (including all approved changes) at the project site or at another accessible location during the operating life of the project. Electronic copies of the approved plans, specifications, calculations, and marked-up as-builts shall be provided to the CBO for retention by the CPM.

Verification: Within 15 days of the completion of any work, the project owner shall submit to the CBO, with a copy to the CPM, in the next monthly compliance report, (a) a written notice that the completed work is ready for final inspection, and (b) a signed statement that the work conforms to the final approved plans. After storing the final approved engineering plans, specifications, and calculations described above, the project owner shall submit to the CPM a letter stating both that the above documents have been stored and the storage location of those documents.

Within 90 days of the completion of construction, the project owner shall provide to the CBO three sets of electronic copies of the above documents at the project owner's expense. These are to be provided in the form of "read only" (Adobe .pdf 6.0 or newer version) files, with restricted (password-protected) printing privileges, on archive quality compact discs.

CIVIL-1 The project owner shall submit to the CBO for review and approval the following:

1. Design of the proposed drainage structures and the grading plan;
2. An erosion and sedimentation control plan;
3. A construction storm water pollution prevention plan (SWPPP);
4. Related calculations and specifications, signed and stamped by the responsible civil engineer; and

5. Soils, geotechnical, or foundation investigations reports required by the 2010 CBC.

Verification: At least 15 days (or project owner- and CBO-approved alternative time frame) prior to the start of site grading the project owner shall submit the documents described above to the CBO for design review and approval. In the next monthly compliance report following the CBO's approval, the project owner shall submit a written statement certifying that the documents have been approved by the CBO.

CIVIL-2 The resident engineer shall, if appropriate, stop all earthwork and construction in the affected areas when the responsible soils engineer, geotechnical engineer, or the civil engineer experienced and knowledgeable in the practice of soils engineering identifies unforeseen adverse soil or geologic conditions. The project owner shall submit modified plans, specifications, and calculations to the CBO based on these new conditions. The project owner shall obtain approval from the CBO before resuming earthwork and construction in the affected area.

Verification: The project owner shall notify the CPM within 24 hours, when earthwork and construction is stopped as a result of unforeseen adverse geologic/soil conditions. Within 24 hours of the CBO's approval to resume earthwork and construction in the affected areas, the project owner shall provide to the CPM a copy of the CBO's approval.

CIVIL-3 The project owner shall perform inspections in accordance with the 2010 CBC. All plant site-grading operations, for which a grading permit is required, shall be subject to inspection by the CBO.

If, in the course of inspection, it is discovered that the work is not being performed in accordance with the approved plans, the discrepancies shall be reported immediately to the resident engineer, the CBO, and the CPM. The project owner shall prepare a written report, with copies to the CBO and the CPM, detailing all discrepancies, non-compliance items, and the proposed corrective action.

Verification: Within five days of the discovery of any discrepancies, the resident engineer shall transmit to the CBO and the CPM a non-conformance report (NCR), and the proposed corrective action for review and approval. Within five days of resolution of the NCR, the project owner shall submit the details of the corrective action to the CBO and the CPM. A list of NCRs, for the reporting month, shall also be included in the following monthly compliance report.

CIVIL-4 After completion of finished grading and erosion and sedimentation control and drainage work, the project owner shall obtain the CBO's approval of the final grading plans (including final changes) for the erosion and sedimentation control work. The civil engineer shall state that the work within his/her area of responsibility was done in accordance with the final approved plans.

Verification: Within 30 days (or project owner- and CBO-approved alternative time frame) of the completion of the erosion and sediment control mitigation and drainage work, the project owner shall submit to the CBO, for review and approval, the final grading plans (including final changes) and the responsible civil engineer's signed statement that the installation of the facilities and all erosion control measures were completed in accordance with the final approved combined grading plans, and that the facilities are adequate for their intended purposes, along with a copy of the transmittal letter to the CPM. The project owner shall submit a copy of the CBO's approval to the CPM in the next monthly compliance report.

STRUC-1 Prior to the start of any increment of construction, the project owner shall submit plans, calculations and other supporting documentation to the CBO for design review and acceptance for all project structures and equipment identified in the CBO-approved master drawing and master specifications lists. The design plans and calculations shall include the lateral force procedures and details as well as vertical calculations.

Construction of any structure or component shall not begin until the CBO has approved the lateral force procedures to be employed in designing that structure or component.

The project owner shall:

1. Obtain approval from the CBO of lateral force procedures proposed for project structures;
2. Obtain approval from the CBO for the final design plans, specifications, calculations, soils reports, and applicable quality control procedures. If there are conflicting requirements, the more stringent shall govern (for example, highest loads, or lowest allowable stresses shall govern). All plans, calculations, and specifications for foundations that support structures shall be filed concurrently with the structure plans, calculations, and specifications;
3. Submit to the CBO the required number of copies of the structural plans, specifications, calculations, and other required documents of the designated major structures prior to the start of on-site fabrication and installation of each structure, equipment support, or foundation;
4. Ensure that the final plans, calculations, and specifications clearly reflect the inclusion of approved criteria, assumptions, and methods used to develop the design. The final designs, plans, calculations, and specifications shall be signed and stamped by the responsible design engineer; and
5. Submit to the CBO the responsible design engineer's signed statement that the final design plans conform to applicable LORS.

Verification: At least 60 days (or project owner- and CBO-approved alternative time frame) prior to the start of any increment of construction of any structure or component listed in the CBO-approved master drawing and master specifications list, the project owner shall submit to the CBO the above final design plans, specifications and calculations, with a copy of the transmittal letter to the CPM.

The project owner shall submit to the CPM, in the next monthly compliance report, a copy of a statement from the CBO that the proposed structural plans, specifications, and calculations have been approved and comply with the requirements set forth in applicable engineering LORS.

STRUC-2 The project owner shall submit to the CBO the required number of sets of the following documents related to work that has undergone CBO design review and approval:

1. Concrete cylinder strength test reports (including date of testing, date sample taken, design concrete strength, tested cylinder strength, age of test, type and size of sample, location and quantity of concrete placement from which sample was taken, and mix design designation and parameters);
2. Concrete pour sign-off sheets;
3. Bolt torque inspection reports (including location of test, date, bolt size, and recorded torques);
4. Field weld inspection reports (including type of weld, location of weld, inspection of non-destructive testing (NDT) procedure and results, welder qualifications, certifications, qualified procedure description or number (ref: AWS); and
5. Reports covering other structural activities requiring special inspections shall be in accordance with the 2010 CBC.

Verification: If a discrepancy is discovered in any of the above data, the project owner shall, within five days, prepare and submit an NCR describing the nature of the discrepancies and the proposed corrective action to the CBO, with a copy of the transmittal letter to the CPM. The NCR shall reference the condition(s) of certification and the applicable CBC chapter and section. Within five days of resolution of the NCR, the project owner shall submit a copy of the corrective action to the CBO and the CPM.

The project owner shall transmit a copy of the CBO's approval or disapproval of the corrective action to the CPM within 15 days. If disapproved, the project owner shall advise the CPM, within five days, the reason for disapproval, and the revised corrective action to obtain CBO's approval.

STRUC-3 The project owner shall submit to the CBO design changes to the final plans required by the 2010 CBC, including the revised drawings, specifications, calculations, and a complete description of, and supporting rationale for, the proposed changes, and shall give to the CBO prior notice of the intended filing.

Verification: On a schedule suitable to the CBO, the project owner shall notify the CBO of the intended filing of design changes, and shall submit the required number of sets of revised drawings and the required number of copies of the other above-mentioned documents to the CBO, with a copy of the transmittal letter to the CPM. The project owner shall notify the CPM, via the monthly compliance report, when the CBO has approved the revised plans.

STRUC-4 Tanks and vessels containing quantities of toxic or hazardous materials exceeding amounts specified in the 2010 CBC shall, at a minimum, be designed to comply with the requirements of that chapter.

Verification: At least 30 days (or project owner- and CBO-approved alternate time frame) prior to the start of installation of the tanks or vessels containing the above specified quantities of toxic or hazardous materials, the project owner shall submit to the CBO for design review and approval final design plans, specifications, and calculations, including a copy of the signed and stamped engineer's certification.

The project owner shall send copies of the CBO approvals of plan checks to the CPM in the following monthly compliance report. The project owner shall also transmit a copy of the CBO's inspection approvals to the CPM in the monthly compliance report following completion of any inspection.

MECH-1 The project owner shall submit, for CBO design review and approval, the proposed final design, specifications and calculations for each plant major piping and plumbing system listed in the CBO-approved master drawing and master specifications list. The submittal shall also include the applicable QA/QC procedures. Upon completion of construction of any such major piping or plumbing system, the project owner shall request the CBO's inspection approval of that construction.

The responsible mechanical engineer shall stamp and sign all plans, drawings, and calculations for the major piping and plumbing systems, subject to CBO design review and approval, and submit a signed statement to the CBO when the proposed piping and plumbing systems have been designed, fabricated, and installed in accordance with all of the applicable laws, ordinances, regulations and industry standards, which may include, but are not limited to:

- American National Standards Institute (ANSI) B31.1 (Power Piping Code);
- ANSI B31.2 (Fuel Gas Piping Code);
- ANSI B31.3 (Chemical Plant and Petroleum Refinery Piping Code);
- ANSI B31.8 (Gas Transmission and Distribution Piping Code);
- NACE R.P. 0169-83;
- NACE R.P. 0187-87;
- NFPA 56;
- Title 24, California Code of Regulations, Part 5 (California Plumbing Code);
- Title 24, California Code of Regulations, Part 6 (California Energy Code, for building energy conservation systems and temperature control and ventilation systems);
- Title 24, California Code of Regulations, Part 2 (California Building Code); and

- Kern County codes.

  The CBO may deputize inspectors to carry out the functions of the code enforcement agency.

Verification: At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of any increment of major piping or plumbing construction listed in the CBO-approved master drawing and master specifications list, the project owner shall submit to the CBO for design review and approval the final plans, specifications, and calculations, including a copy of the signed and stamped statement from the responsible mechanical engineer certifying compliance with applicable LORS, and shall send the CPM a copy of the transmittal letter in the next monthly compliance report.

The project owner shall transmit to the CPM, in the monthly compliance report following completion of any inspection, a copy of the transmittal letter conveying the CBO's inspection approvals.

MECH-2 For all pressure vessels installed in the plant, the project owner shall submit to the CBO and California Occupational Safety and Health Administration (Cal-OSHA), prior to operation, the code certification papers and other documents required by applicable LORS. Upon completion of the installation of any pressure vessel, the project owner shall request the appropriate CBO and/or Cal-OSHA inspection of that installation.

The project owner shall:

1. Ensure that all boilers and fired and unfired pressure vessels are designed, fabricated, and installed in accordance with the appropriate section of the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code, or other applicable code. Vendor certification, with identification of applicable code, shall be submitted for prefabricated vessels and tanks; and
2. Have the responsible design engineer submit a statement to the CBO that the proposed final design plans, specifications, and calculations conform to all of the requirements set forth in the appropriate ASME Boiler and Pressure Vessel Code or other applicable codes.

Verification: At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of on-site fabrication or installation of any pressure vessel, the project owner shall submit to the CBO for design review and approval, the above listed documents, including a copy of the signed and stamped engineer's certification, with a copy of the transmittal letter to the CPM.

The project owner shall transmit to the CPM, in the monthly compliance report following completion of any inspection, a copy of the transmittal letter conveying the CBO's and/or Cal-OSHA inspection approvals.

MECH-3 The project owner shall submit to the CBO for design review and approval the design plans, specifications, calculations, and quality control procedures for any heating, ventilating, air conditioning (HVAC) or refrigeration system.

Packaged HVAC systems, where used, shall be identified with the appropriate manufacturer's data sheets.

The project owner shall design and install all HVAC and refrigeration systems within buildings and related structures in accordance with the CBC and other applicable codes. Upon completion of any increment of construction, the project owner shall request the CBO's inspection and approval of that construction. The final plans, specifications and calculations shall include approved criteria, assumptions, and methods used to develop the design. In addition, the responsible mechanical engineer shall sign and stamp all plans, drawings and calculations and submit a signed statement to the CBO that the proposed final design plans, specifications and calculations conform with the applicable LORS.

Verification: At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of construction of any HVAC or refrigeration system, the project owner shall submit to the CBO the required HVAC and refrigeration calculations, plans, and specifications, including a copy of the signed and stamped statement from the responsible mechanical engineer certifying compliance with the CBC and other applicable codes, with a copy of the transmittal letter to the CPM.

ELEC-1 Prior to the start of any increment of electrical construction for all electrical equipment and systems 110 Volts or higher (see a representative list, below) the project owner shall submit, for CBO design review and approval, the proposed final design, specifications, and calculations. Upon approval, the above listed plans, together with design changes and design change notices, shall remain on the site or at another accessible location for the operating life of the project. The project owner shall request that the CBO inspect the installation to ensure compliance with the requirements of applicable LORS. All transmission facilities (lines, switchyards, switching stations, and substations) are handled in conditions of certification in the **Transmission System Engineering** section of this document.

A. Final plant design plans shall include:

1. one-line diagram for the 13.8 kV, 4.16 kV and 480 V systems;
2. system grounding drawings;
3. lightning protection system; and
4. hazard area classification plan.

B. Final plant calculations must establish:

1. short-circuit ratings of plant equipment;
2. ampacity of feeder cables;
3. voltage drop in feeder cables;
4. system grounding requirements;

5. coordination study calculations for fuses, circuit breakers and protective relay settings for the 13.8 kV, 4.16 kV and 480 V systems;
6. system grounding requirements;
7. lighting energy calculations; and
8. 110 volt system design calculations and submittals showing feeder sizing, transformer and panel load confirmation, fixture schedules and layout plans.

C. The following activities shall be reported to the CPM in the monthly compliance report:

1. Receipt or delay of major electrical equipment;
2. Testing or energization of major electrical equipment; and
3. A signed statement by the registered electrical engineer certifying that the proposed final design plans and specifications conform to requirements set forth in the Energy Commission decision.

Verification: At least 30 days (or project owner- and CBO-approved alternative time frame) prior to the start of each increment of electrical construction, the project owner shall submit to the CBO for design review and approval the above listed documents. The project owner shall include in this submittal a copy of the signed and stamped statement from the responsible electrical engineer attesting compliance with the applicable LORS, and shall send the CPM a copy of the transmittal letter in the next monthly compliance report.

HECA 2012 – Hydrogen California LLC, 08-AFC-8A. Amended Application for Certification, Volumes 1, 2, and 3 dated May 02, 2012. Submitted to CEC/Docket Unit on May 02, 2012.

GEOLOGY AND PALEONTOLOGY

Casey Weaver, C.E.G.

SUMMARY OF CONCLUSIONS

The proposed Hydrogen Energy California (HECA) project is located in an active geologic area of the southern Great Valley geomorphic province in western Kern County, California. Because of its geologic setting, the site could be subject to moderate to high levels of earthquake-related ground shaking. Significant thicknesses of expansive clay soils are also present at the surface. The effects of strong ground shaking and expansive soils must be mitigated, to the extent practical, through structural designs required by the California Building Code (CBC 2010) and the project geotechnical report. CBC 2010 requires that structures be designed to resist seismic stresses from ground acceleration and, to a lesser extent, liquefaction potential. The design-level geotechnical investigation required for the project by the CBC, proposed Condition of Certification **GEO- 1** in this section and Conditions of Certification **GEN-1**, **GEN-5** and **CIVIL-1**, presented in the **Facility Design** section of this document, address standard engineering design recommendations for mitigation of seismic shaking and adverse site soil conditions.

There are no known viable geologic or mineralogical resources at the site, with the exception of the oil and gas fields of the Naval Petroleum Reserve. Paleontological resources have been documented regionally within Quaternary alluvium and Tertiary Tulare Formation, similar to deposits that underlie the project site. Numerous new fossil localities were discovered by the applicant during cursory field explorations at the proposed plant site. Potential impacts would be mitigated through worker training and monitoring by qualified paleontologists, as required by Conditions of Certification, **PAL-1** through **PAL-7**.

The proposed Occidental of Elk Hills, Inc., (OEHI) component of HECA is located in the Elk Hills Oil Field (EHOF). The EHOF is located near the southwestern edge of the San Joaquin Valley, approximately 25 miles southwest of the city of Bakersfield in Kern County, California. The EHOF is located on the topographic expression of the northwest trending linear Elk Hills Anticline. The Elk Hills Anticline is a large compound fold structure approximately 17 miles long and over 7 miles wide. Because of its geologic setting, the site could be subject to moderate to high levels of earthquake-related ground shaking. The effects of strong ground shaking must be mitigated, to the extent practical, through structural designs required by the California Building Code (CBC 2010) and the project geotechnical report. CBC 2010 requires that structures be designed to resist seismic stresses from ground acceleration and, to a lesser extent, liquefaction potential. The design-level geotechnical investigation required for the project by the CBC, and recommended mitigation measures **OEHI GEO- 1** in this section and recommended mitigation measures **GEN-1**, **GEN-5** and **CIVIL-1**, presented in the **Facility Design** section of this document, address standard engineering design recommendations for mitigation of seismic shaking and adverse site soil conditions.

Regarding viable geologic or mineralogical resources at the site, the site is underlain by the oil and natural gas fields of the Naval Petroleum Reserve. Active oil and gas production is ongoing at the project site.

The applicant assessed domestic mines within the Western United States capable of providing the quantity and quality of required solid feedstocks. Coal sourced from New Mexico, Utah, and Colorado was among the analyzed alternatives. Based on these alternatives the project currently plans to use Western sub-bituminous coal from New Mexico.

The applicant has not selected a limestone supplier yet, but it is anticipated that fluxant would be shipped from a distribution center in Riverside, California.

Paleontological resources have been documented regionally within Quaternary alluvium and Tertiary Tulare Formation, similar to deposits that underlie the project site. Potential impacts could be mitigated through worker training and monitoring by qualified paleontologists, as presented in the recommended mitigation measures **OEHI PAL-1** through **OEHI PAL-7**.

Based on the information summarized above, Energy Commission staff believes that the potential adverse cumulative impacts to project facilities from geologic hazards during its design life, if any, would be less than significant. Similarly, staff believes the potential adverse cumulative impacts to potential geologic, mineralogic, and paleontologic resources from the construction, operation, and closure of the proposed project, if any, would be less than significant. It is staff's opinion that the proposed HECA can be designed and constructed in accordance with all applicable laws, ordinances, regulations, and standards (LORS), and in a manner that both protects environmental quality and assures public safety.

INTRODUCTION

Hydrogen Energy California, LLC, (HECA) is proposing an integrated gasification combined cycle (IGCC) polygeneration project (HECA or Project). The Project would gasify a fuel blend of 75 percent coal and 25 percent petroleum coke (petcoke) to produce synthesis gas (syngas). Syngas produced via gasification would be purified to hydrogen-rich fuel, and the project proposes to generate between 405 and 431 MW gross or an average of 416MW gross electrical power and between 151 to 266 MW net after accounting for onsite auxiliary power loads in a combined-cycle power block, low-carbon, nitrogen-based products in an integrated manufacturing complex, and carbon dioxide (CO_2) for use in enhanced oil recovery (EOR). CO_2 from HECA would be transported by pipeline for use in EOR in the adjacent Elk Hills Oil Field (EHOF), which is owned and operated by Occidental of Elk Hills, Inc. (OEHI). The EOR process results in sequestration (storage) of the CO_2. This introduction provides brief descriptions of both HECA and the OEHI component.

Terms used throughout this section are defined as follows:

- **Project or HECA.** The HECA IGCC electrical generation facility, low-carbon nitrogen based products manufacturing complex, and associated equipment and processes, including its linear facilities.

- **Project Site or HECA Project Site.** The 453-acre parcel of land on which the HECA IGCC electrical generation facility, low-carbon nitrogen-based products manufacturing complex, and associated equipment and processes (excluding off-site portions of linear facilities), would be located.
- **OEHI Component.** The use of CO_2 for EOR at the EHOF and resulting sequestration, including the CO_2 pipeline, EOR processing facility, and associated equipment.
- **OEHI Component Site.** The portion of land within the EHOF on which the OEHI Component would be located and where the CO_2 produced by HECA would be used for EOR and resulting sequestration**.**
- **Controlled Area.** The 653 acres of land adjacent to the Project Site over which HECA would control access and future land uses.

The various project elements of the combined project are discussed below:

HECA Project Site
The HECA project includes a 453-acre parcel of land on which the HECA IGCC electrical generation facility, low-carbon nitrogen-based products manufacturing complex, and associated equipment and processes.

HECA Project Linear Facilities
The HECA project includes the following linear facilities, which extend off the HECA project site:

- **Electrical transmission line.** An approximately 2-mile-long electrical transmission line would interconnect the Project to a future Pacific Gas and Electric Company (PG&E) switching station east of the Project Site.
- **Natural gas supply pipeline.** An approximately 13-mile-long natural gas interconnection would be made with PG&E natural gas pipelines located north of the Project Site.
- **Water supply pipelines and wells.** An approximately 15-mile-long process water supply line and up to five new groundwater wells would be installed by the Buena Vista Water Storage District (BVWSD) to supply brackish groundwater from northwest of the Project Site. An approximately 1-mile-long water supply line from the West Kern Water District (WKWD) east of the Project Site would provide potable water.
- **Coal transportation.** HECA is considering two alternatives for transporting coal to the Project Site:
  - **Alternative 1, rail transportation.** An approximately 5-mile-long new industrial railroad spur that would connect the Project Site to the existing San Joaquin Valley Railroad (SJVRR) Buttonwillow railroad line, north of the Project Site. This railroad spur would also be used to transport some HECA products to market.
  - **Alternative 2, truck transportation.** An approximately 27-mile-long truck transport route via existing roads from an existing coal transloading facility northeast of the Project Site.

OEHI Component

OEHI would be installing the CO_2 pipeline from the Project Site to the EHOF, as well as installing the EOR Processing Facility, including any associated wells and pipelines needed in the EHOF for CO_2 EOR and sequestration. The following is a brief description of the OEHI component:

- — **CO_2 EOR Processing Facility.** The CO_2 EOR Processing Facility and 13 satellites are expected to occupy approximately 136 acres within the EHOF. The facility would use 720 producing and injection wells: 570 existing wells and 150 new well installations. Approximately 652 miles of new pipeline would also be installed in the EHOF.
- — **CO_2 pipeline.** An approximately 3-mile-long 12" diameter CO_2 pipeline would transfer the CO_2 from the HECA Project Site south to the OEHI CO_2 EOR Processing Facility.

The OEHI component does not fall under the jurisdiction of the Energy Commission. However it is considered part of the whole of the HECA project. Therefore, its effect on the environment is also analyzed in this document.

Occidental of Elk Hills, Inc. (OEHI) is proposing to extend the life of the enhanced oil recovery (EOR) operations by utilizing carbon dioxide (CO_2) to facilitate oil production from its Elk Hills Oil Field (EHOF) operations. This is known as the OEHI CO_2 EOR project. The carbon dioxide used by OEHI would be sourced from HECA. HECA would be located approximately four miles north of the EHOF and would generate CO_2 from an integrated gasification combined cycle (IGCC) power plant. HECA would utilize technology capable of capturing over 90 percent of the CO_2 produced during HECA facility operations. This CO_2 would be compressed and delivered via pipeline to OEHI's EOR Processing Facility. The OEHI CO_2 EOR component is expected to receive an annual average rate of 107 million standard cubic feet per day (mmscfd) of CO_2 (approximately 2.6 million tons per year). The planned injection process would be reviewed as a part of the OEHI permitting process with Department of Conservation, Division of Oil, Gas and Geothermal Resources (DOGGR). During all phases of this project, OEHI must comply with Underground Injection Control (UIC) Class II regulations enforced by DOGGR.

CO_2 from HECA would be transported via pipeline to the EOR Processing Facility, at which point the CO_2 would be distributed to CO_2 injection wells placed in a geometric pattern designed to optimize the recovery of oil from the reservoir.

For each injection well there may be three or more nearby production wells where produced fluids are pumped to the surface and then transported by pipeline in a closed loop system to a centralized collection and processing facility. Typically, these wells are arranged in a consistent geometrical pattern with an injection well in the center and production wells on the perimeter. For example, in a five spot pattern, there would be four production wells on the four corners of a square geometric pattern, with a single injection well in the center of the pattern. The pattern of injection and production wells may change over time, and is typically based on predictive computer simulations that model reservoir performance based on reservoir characterization and historical operations.

At the surface, the recovered fluids would be transferred to a separator at the EOR Processing Facility where the oil, water, and natural gas would be separated. The natural gas would contain CO_2 as the injected gas begins to break through at the production wells. Separated natural gas would enter a pipeline for transport to the existing gas processing facility in Section 35R of the EHOF where it is combined and processed with other produced gas from the field for sale to customers. The CO_2 would be separated from the produced natural gas and CO_2 would then be recompressed for reinjection along with CO_2 purchased from HECA to further optimize the CO_2 EOR process.

In the section provided below, Energy Commission staff discusses the potential impacts of HECA development on geologic, mineralogic, and paleontologic resources as well as impacts on the proposed HECA site from potential geologic hazards. Staff's objective is to identify resources that could be significantly adversely affected, evaluate the potential of the project construction and operation to significantly impact the resources and provide mitigation measures as necessary to ensure that there would be no significant adverse impacts to geological and paleontological resources during the project construction, operation, and closure and to ensure that operation of the plant would not expose occupants to high-probability geologic hazards. A brief geological and paleontological overview is provided. The section concludes with staff's proposed conditions of certification - *i.e.*, monitoring and mitigation measures that, if implemented, would reduce any project impacts to geologic, mineralogic, and paleontologic resources or threat from geologic hazards to less than significant levels.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

Applicable laws, ordinances, regulations, and standards (LORS) are listed in the application for certification (AFC) (HEI 2008c). The following briefly describes the current LORS for both geologic hazards and resources and mineralogic and paleontologic resources.

Geology and Paleontology Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable Law	Description
Federal	The proposed project is not located on federal land. There are no federal LORS for geologic hazards and resources for this site.
State	
California Building Code (2010)	The California Building Code (CBC 2010) includes a series of standards that are used in project investigation, design, and construction (including seismicity, grading and erosion control). The CBC has adopted provisions in the International Building Code (IBC, 2009).

Applicable Law	Description
Alquist-Priolo Earthquake Fault Zoning Act, Public Resources Code (PRC), section 2621–2630	Mitigates against surface fault rupture of known active faults beneath occupied structures. Requires disclosure to potential buyers of existing real estate and a 50-foot setback for new occupied buildings. No portions of the site and proposed ancillary facilities are located within designated Alquist-Priolo Earthquake Fault Zones (EFZ).
The Seismic Hazards Mapping Act, PRC Section 2690–2699	Areas are identified that are subject to the effects of strong ground shaking, such as liquefaction, landslides, tsunamis, and seiches.
Applicable Standard (General)	**Description**
PRC, Chapter 1.7, sections 5097.5 and 30244	Regulates removal of paleontological resources from state lands, defines unauthorized removal of fossil resources as a misdemeanor, and requires mitigation of disturbed sites.
Warren-Alquist Act, PRC, sections 25527 and 25550.5(i)	The Warren-Alquist Act requires the Energy Commission to "give the greatest consideration to the need for protecting areas of critical environmental concern, including, but not limited to, unique and irreplaceable scientific, scenic, and educational wildlife habitats; unique historical, archaeological, and cultural sites…" With respect to paleontologic resources, the Energy Commission relies on guidelines from the Society for Vertebrate Paleontology.
Society for Vertebrate Paleontology (SVP), 1995	The "Measures for Assessment and Mitigation of Adverse Impacts to Non-Renewable Paleontological Resources: Standard Procedures" is a set of procedures and standards for assessing and mitigating impacts to vertebrate paleontological resources. The measures were adopted in October 1995 by the SVP, a national organization of professional scientists.
Bureau of Land Management (BLM) Instructional Memorandum 2008-009	Provides up-to-date methodologies for assessing paleontological sensitivity and management guidelines for paleontological resources on lands managed by the Bureau of Land Management. Staff also uses this methodology for non BLM lands as it provides a more detailed categorization of paleontological sensitivity than what is provided by SVP.
Local	
Kern County General Plan	The Kern County General Plan contains policies, goals, and implementation measures that address physical and environmental constraints, seismic hazards and landslides and, in areas of known paleontological resources, addresses the preservation of these resources where feasible.

To simplify the understanding of this Geology and Paleontology analysis, this section is broken into a discussion of HECA followed by a discussion of the OEHI Component

HECA SETTING

HECA would be constructed on 453 acres of privately owned land located approximately 7 miles west of the western border of the city of Bakersfield and 1.5 miles northwest of the unincorporated community of Tupman in west-central Kern County, California (**Geology and Paleontology Figure 1**). The proposed project site is currently used for irrigated agricultural production.

HECA would be a base load power generating facility that proposes to generate between 405 and 431 MW gross or an average of 416MW gross electrical power and between 151 to 266 MW net after accounting for onsite auxiliary power loads. Ancillary facilities would include a 13-mile natural gas pipeline, a 2-mile above-ground electrical transmission connection to the existing PG&E electrical grid west of the site, a 15-mile brackish water process supply pipeline, a 1-mile-long potable water supply pipeline, and a 3-mile-long carbon dioxide pipeline. Other onsite improvements would include a process water treatment plant, a petroleum coke (petcoke)/coal gasification facility, control and administrative buildings, a zero liquid discharge system for treatment of process water, and various smaller outbuildings and facilities. Carbon dioxide produced by petcoke and/or coal gasification would be compressed and pumped to the nearby Elk Hills petroleum production field for enhancing oil recovery and ultimate sequestration (HEI 2008c).

REGIONAL SETTING

The proposed HECA site is located in the southern San Joaquin Valley, which is part of the Great Valley geomorphic province of California (**Geology and Paleontology Figure 2**). The Great Valley is approximately 400 miles long and 60 miles wide, bounded on the north by low-lying hills; on the northeast by the volcanic plateau of the Cascade Range; on the west by the Coast Ranges; on the east by the Sierra Nevada; and on the south by the Coast Ranges and the Tehachapi Mountains. The northern one-third of the Great valley is known as the Sacramento Valley, whereas the southern two-thirds is known as the San Joaquin Valley. The boundary between the two sub-basins is located at the confluence of the Sacramento and San Joaquin Rivers in the delta area near Suisun Bay and the city of Stockton (USGS 1986). The Great Valley is characterized by dissected uplands, and relatively undeformed low alluvial plains and fans, river flood plains and channels, and lake bottoms. In the late Cenozoic era much of the San Joaquin Valley was occupied by shallow brackish and freshwater lakes. Much of the valley fill alluvium is underlain by marine and non-marine sedimentary rocks and crystalline basement which have undergone anticlinal and synclinal folding and faulting related to regional tectonism. Major oil fields, pooled in antiformal structures associated with this regional tectonic activity, have been developed in the southern portion of the San Joaquin Valley.

PROJECT SITE DESCRIPTION

The proposed HECA site would consist of land that has been extensively disturbed by agricultural activities for at least the past 50 years. Elevations on the property range from roughly 282 to 291 feet above mean sea level (msl). Located at approximately 35.33 degrees north latitude by 119.39 degrees west longitude, the majority of the proposed project site is in Section 10, Township 34 South, Range 24 East of the Mount Diablo Baseline and Meridian in western Kern County, near the city of Bakersfield. The 453-acre site is approximately 2.25 miles west and one mile south of the intersection of Interstate 5 and Bellevue Road.

The proposed project site lies on the northeastern flank of the Elk Hills anticline, a structural fold which is part of a series of fold and thrust complexes that mark the southern boundary of the Great Valley geomorphic province **(Geology and Paleontology Figure 2)**. Surface soils are composed of Quaternary (Holocene) age alluvial gravel and sand deposits of the Kern River Valley (Dibblee 2005a; URS 2009a) (**Geology and Paleontology Figure 3)**. Alluvium, shed from the Elk Hills southwest of the HECA site, is likely interbedded with fluvial sands and gravels associated with the Kern River and its tributaries. The alluvial fan deposits are underlain by Pliocene to Pleistocene age non-marine clastic sediments of the Tulare Formation, which extend to depths in excess of 1,000 feet below the surface (Page 1983; Dibblee 2005a). In the Elk Hills where the Tulare Formation is exposed, both upper and lower members are present. The entire HECA site and a majority of the project linears lie in areas mapped as Quaternary alluvial fan deposits. Only the southern portions of the carbon dioxide pipelines extend into areas of the northern Elk Hills mapped as Tulare Formation. Both upper and lower members are crossed, as well as a one-meter thick marker bed known as the Lower limestone, which is a white to light grey, marly carbonate deposited in fresh water (Dibblee 2005a).

The proposed HECA plant site and project linears are not crossed by any known active faults and do not lie within a designated Alquist-Priolo Earthquake Fault Zone (CGS 2008). A number of major, active faults lie within 70 miles of the site. These faults are discussed in detail under the **Geological Hazards** section later in this section of staff's assessment.

The preliminary geotechnical report for the proposed site (HEI 2008a) indicates that 1.5 to 6 feet of uncontrolled silty sand fill was encountered in borings in the northwest, northeast, and southeast corners of the property. Undisturbed native surface soils are composed of fine-grained sandy lean and fat clays and sandy silts that extend to depths of 8 to 19 feet. The clay soils contain medium to high plasticity fines with moderate expansion indices. The fine-grained sediments were not identified as Quaternary alluvium or Tulare Formation in the project geotechnical report, but the materials were probably deposited in distal alluvial fan, lacustrine, and/or fluvial environments that are consistent with either unit. Dibblee (2005a) indicates that Quaternary alluvium is Holocene in age, but depth to underlying Pleistocene sediments is undetermined. Silty sand and poorly graded sand designated as Tulare Formation underlies fine-grained soils, and extends to the maximum depth of drilling at 101.5 feet (URS 2009a). The upper portions are medium dense, and become dense to very dense with depth.

The depth to ground water measured in local wells ranged from 19.3 feet below ground surface (bgs) to 35 feet bgs (URS 2009a). However, during the preliminary site geotechnical investigation, ground water was not encountered to the maximum depth of drilling at 101.5 feet bgs (URS 2009a). Water levels beneath the site likely vary seasonally and with pumping frequency of nearby irrigation wells.

Existing grade at the proposed power plant site slopes approximately 1% to the northeast (USGS 1954). Site drainage is probably by a combination of infiltration and overland sheet flow. A more complete discussion of on-site drainage is included in the **Soils and Surface Water** section of this staff assessment.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

This section considers two types of impacts. The first is the potential impacts the proposed facility could have on existing geologic, mineralogic, and paleontologic resources in the area. The second is the potential geologic hazards that could adversely impact the proper functioning of the proposed facility and create life/safety concerns.

METHOD AND THRESHOLD FOR DETERMINING SIGNIFICANCE

As discussed in the Introduction section of this document, this assessment analyzes the project's impacts pursuant to both the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA). The two statutes are similar in their requirements concerning analysis of a project's impacts. Therefore, unless otherwise noted, staff's use of, and reference to, CEQA criteria and guidelines also encompasses and satisfies NEPA requirements for this environmental document.

The CEQA guidelines, Appendix G, provide a checklist of questions that lead agencies typically address when assessing impacts related to geologic and mineralogic resources, and effects of geologic hazards.

- Section (V) (c) includes guidelines that determine if a project will either directly or indirectly destroy a unique paleontological resource or site, or a unique geological feature.
- Sections (VI) (a), (b), (c), (d), and (e) focus on whether or not the project would expose persons or structures to geologic hazards.
- Sections (XI) (a) and (b) concern the project's effects on mineral resources.

To assess potential impacts on unique geologic features and effects on mineral resources, staff has reviewed geologic and mineral resource maps for the surrounding area, as well as site-specific information provided by the applicant, to determine if geologic and mineralogic resources exist in the area.

To assess potential impacts on paleontological resources, staff reviewed existing paleontologic information and requested records searches from the Natural History Museum of Los Angeles County (LACM) for the site area. Site-specific information generated by the applicant for the proposed site and ancillary facilities was also reviewed (HEI 2008c, Appendix Q). All research was conducted in accordance with accepted assessment protocol (SVP 1995) to determine whether any known paleontologic resources exist in the general area. If present or likely to be present, conditions of certification that outline required procedures to mitigate impacts to potential resources are proposed as part of the requirements for project approval.

DIRECT/INDIRECT IMPACTS AND MITIGATION

An assessment of the potential impacts to geologic, mineralogic, and paleontologic resources, and from geologic hazards is provided below. The assessment of impacts is followed by a summary of potential impacts that may occur during construction and operation of the project and provides recommended conditions of certification that would ensure potential impacts are mitigated to a level that is less than significant. The recommended conditions of certification would allow the Energy Commission's compliance project manager (CPM) and the applicant to adopt a compliance monitoring scheme ensuring ongoing compliance with LORS applicable to geologic hazards and the protection of geologic, mineralogic, and paleontologic resources.

GEOLOGIC AND MINERALOGIC RESOURCES

The proposed HECA site is not located within an established Mineral Resource Zone (MRZ) and no economically viable mineral deposits are known to be present (CDMG 1990; CDMG 1998; CDMG 1999). The site would be in close proximity to several producing oil and gas fields of the regional Naval Petroleum Reserve, including the Elk Hills, North Coles Levee and South Coles Levee oil fields (Dibblee 2005a). The California Division of Oil, Gas, and Geothermal Resources (DOGGR) identifies a single well within the proposed project area that reportedly did not encounter significant oil or gas deposits. Although discovery of a petroleum resource beneath the HECA plant site is unlikely, directional drilling techniques could allow for exploitation of a resource from outside of the project boundaries. Therefore, the potential for impacting future petroleum production from beneath the site is considered to be low. Petroleum and gas fields underlie portions of the proposed project linears, but their presence is not likely to affect current or future recovery of petroleum reserves.

PALEONTOLOGIC RESOURCES

Staff reviewed correspondence from the LACM (McLeod 2009), and the confidential Paleontological Resources Technical Report (HEI 2008c) for information regarding known fossil localities and stratigraphic unit sensitivity within the proposed project area. The proposed HECA plant site is underlain to depths of 8 to 19 feet by fine-grained sediments that belong to Quaternary alluvial, fluvial and/or lacustrine deposits. Quaternary alluvium is known regionally to contain significant fossil resources, primarily terrestrial vertebrates, and is considered to be highly sensitive (HEI 2008c). Sensitivity increases with depth, according to McLeod (2009), although a depth at which higher sensitivity older allumium would be encountered was not specified. Remains of an extinct species of horse have been recovered along the Bakersfield Canal, and fossil wood is common. Freshwater invertebrate shells and ichnofossils (trace fossils) were identified in Quaternary alluvium at several localities within one mile of the proposed site and project linears during the field survey conducted for the Paleontological Resources Technical Report attached to the AFC (HEI 2008c, Appendix Q). The low energy environment of deposition for the fine-grained soils underlying the proposed site increases the potential for preservation of significant fossil remains.

The potential for a geologic unit on a site to yield scientifically significant, nonrenewable paleontological resources is referred to as its paleontological sensitivity (SVP 1995). Paleontological sensitivity is a qualitative assessment made by a professional paleontologist taking into account the paleontological potential of the stratigraphic units present, the local geology and geomorphology, and any other local factors that may suggest a probability of encountering fossils. According to the Society of Vertebrate Paleontology standard guidelines, sensitivity comprises (1) the potential for a geological unit to yield abundant or significant vertebrate fossils or for yielding a few significant fossils, large or small, vertebrate, invertebrate, or paleobotanical remains, and (2) the importance of recovered evidence for new and significant taxonomic, phylogenetic, paleoecological, or stratigraphic data (SVP 1995). The Bureau of Land Management has developed a potential fossil yield classification system that offers a more detailed system of evaluating the likelihood that a given geological unit may yield fossils (BLM and Chirstensen 2007). This system is described in detail, and also summarized in **Geology and Paleontology Table 2**.

Geology and Paleontology Table 2
SVP Paleontological Sensitivity Ratings (Sensitivity) and Equivalent Potential Fossil Yield Classifications (PFYC) Consistent with BLM Guidelines

Sensitivity (PFYC)	Definition
High and Very High (PFYC 4, 5)	Assigned to geological formations known to contain paleontological resources that include rare, well-preserved, and/or fossil materials important to on-going paleoclimatic, paleobiological and/or evolutionary studies. They have the potential to produce, or have produced vertebrate remains that are the particular research focus of many paleontologists, and can represent important educational resources as well.
Moderate and Unknown (PFYC 3a, 3b)	Stratigraphic units that have yielded fossils that are moderately well-preserved, are common elsewhere, and/or that are stratigraphically long-ranging would be assigned a moderate rating. This evaluation can also be applied to strata that have an unproven but strong potential to yield fossil remains based on its stratigraphy and/or geomorphologic setting.
Low (PFYC 2)	Sediment that is relatively recent, or that represents a high-energy subaerial depositional environment where fossils are unlikely to be preserved. A low abundance of invertebrate fossil remains, or reworked marine shell from other units, can occur but the paleontological sensitivity would remain low due to their lack of potential to serve significant scientific or educational purposes.
Very Low and Zero (PFYC 1)	Stratigraphic units with very low potential include pyroclastic flows and sediments heavily altered by pedogenesis. Most igneous rocks have zero paleontological potential. Other stratigraphic units deposited subaerially in a high energy environment (such as alluvium) may also be assigned a marginal or zero sensitivity rating. Manmade fill is also considered to possess zero (no) paleontological potential.

Pliocene to Pleistocene age Tulare Formation, which underlies the fine-grained sediments has a high sensitivity rating and high potential to contain significant fossil resources. Previously recorded localities from the unit include remains of a wide variety of vertebrate species, as well as freshwater invertebrates and fossil wood. A locality south of one of the carbon dioxide pipeline alternatives yielded fossil remains of rabbit and camel (McLeod 2009). Examination of exposures of the Tulare Formation during the field survey for the Paleontological Resources Technical Report revealed previously unknown occurrences of vertebrate bones, invertebrate shells and fossilized wood within one mile of the site (HEI 2008c, Appendix Q).

Recent, uncontrolled fill is present locally on the proposed site to depths of 1.5 to 6 feet. The material, where encountered, is considered to have no potential for producing meaningful fossils because any fossil remains discovered will be out of their natural geologic context. Similarly, a large portion of the proposed site has been disturbed during agricultural operations, so the upper 1 to 2 feet of the surface is also unlikely to contain significant paleontological resources.

Overall, staff considers the probability that paleontological resources would be encountered during site construction activities to be high. The potential for exposure of paleontological resources would increase with depth and volume of proposed construction excavations. This assessment is based on SVP criteria and the confidential paleontological report appended to the AFC (HEI 2008c). Proposed Conditions of Certification **PAL-1** to **PAL-7** are designed to mitigate paleontological resource impacts, as discussed above, to less than significant levels. These conditions essentially require a worker education program in conjunction with the monitoring of earthwork activities by a qualified professional paleontological resources specialist (PRS).

The proposed conditions of certification allow the Energy Commission's compliance project manager (CPM) and the applicant to adopt a compliance monitoring scheme ensuring compliance with LORS applicable to geologic hazards and the protection of paleontologic resources.

GEOLOGICAL HAZARDS

The AFC (HEI 2008c) provides documentation of potential geologic hazards at the proposed site, including site-specific subsurface information generated by a preliminary geotechnical investigation (HEI 2008c, Appendix P). Review of the AFC, coupled with staff's independent research, indicates that the potential for geologic hazards to impact the proposed plant site during its practical design life would be low if recommendations for mitigation of seismic shaking and expansive soils are adopted and followed. Geologic hazards related to seismic shaking and adverse soil conditions are addressed in a project geotechnical report per CBC (2010) requirements (HEI 2008c, Appendix P).

Staff's independent research included the review of available geologic maps, reports, and related data of the proposed HECA site. Staff's analysis of this information is provided below.

Faulting and Seismicity

Energy Commission staff reviewed numerous CGS, USGS, and other publications, (CGS 2002a and b; CGS 2007; CDMG 1994; CDMG 2003; Fiore et al. 2007; Nicholson 1990; SCEDC 2008; Smith 1992; USGS 2006; USGS 2008), informational websites, and analytical and database software (Blake 2000a and b) in order to gather data on the location, recency, and type of faulting in the project area. Type A and B faults within 70 miles (112 kilometers) of the site under consideration are listed in **Geology and Paleontology Table 3**. Type A faults have slip-rates of >5 mm per year and are capable of producing an earthquake of magnitude 7.0 or greater. Type B faults have slip-rates of 2 to 5 mm per year and are capable of producing an earthquake of magnitude 6.5 to 7.0. The fault type, potential magnitude, and distance from the proposed site are summarized in **Geology and Paleontology Table 3**. Type C and otherwise undifferentiated faults that are more than 20 miles from the proposed site are not discussed here because they are not likely to produce an earthquake of sufficient magnitude that could affect the project.

Geology and Paleontology Table 3
Active Faults in the Proposed Project Area

Fault Name	Distance From Site (miles)	Maximum Earthquake Magnitude (Mw)	Estimated Peak Site Acceleration (g)	Movement and Strike	Slip Rate mm/yr	Fault Type
San Juan	34.9	7.1	0.107	Right-Lateral Strike Slip (Northwest)	1.0	B
Big Pine	41.3	6.9	0.085	Left-Lateral Strike Slip (North)	0.8	B
Garlock (West)	43.9	7.3	0.100	Left-Lateral Strike Slip (North)	6.0	B
San Gabriel	51.5	7.2	0.084	Right-Lateral Strike Slip (Northwest)	1.0	B
San Luis Range (South Margin)	53.0	7.2	0.100	Reverse (North)	0.2	B
North Channel Slope	53.7	7.4	0.110	Reverse (West)	2.0	B
Great Valley 14	54.7	6.4	0.064	Reverse (North) Blind Thrust	1.5	B
Santa Ynez (East)	56.0	7.1	0.074	Left-Lateral Strike Slip (North)	2.0	B
M.Ridge – Arroyo Parida - Santa Ana	56.5	7.2	0.095	Reverse (West)	0.4	B
Santa Ynez (West)	57.40	7.1	0.073	Left-Lateral Strike Slip (North)	2.0	B
San Cayetano	58.4	7.0	0.083	Reverse (West)	6.0	B
San Andreas - Parkfield	59.2	6.5	0.052	Right-Lateral Strike Slip (Northwest)	34.0	A
Red Mountain	61.6	7.0	0.080	Reverse (West)	2.0	B
Los Alamos – West Baseline	61.8	6.9	0.075	Reverse (West)	0.7	B
Los Osos	62.1	7.0	0.079	Reverse (Southwest)	0.5	B
San Andreas – Whole	21.1	8.0	0.253	Right-Lateral Strike Slip (Northwest)	34.0	A
San Andreas – Carrizo, Ft. Tejon Rupture	21.1	7.8	0.228	Right-Lateral Strike Slip (Northwest)	34.0	A
White Wolf	23.5	7.3	0.196	Reverse, Left-Lateral, Oblique (West)	2.0	B
San Andreas – Cholame	27.2	7.3	0.144	Right-Lateral Strike Slip (Northwest)	34.0	A
Pleito Thrust	27.3	7.0	0.150	Reverse (West)	2.0	B

Twenty Type A and B faults and fault segments were identified within 62 miles (100 kilometers) of the proposed site (**Geology and Paleontology Figure 4)**. All three of the Type A faults are segments of the San Andreas Fault System. The closest of these is the Carrizo segment located 21 miles to the west and southwest. The San Andreas Fault is the dominant active tectonic feature of the Coast Ranges and represents the boundary of the North American and Pacific plates. Right-lateral strike-slip motion occurs along the structural zone at an average rate of 51.1 ± 2.5 millimeters per year. The Carrizo segment is capable of producing a moment magnitude earthquake of 7.8 (7.8M). Surface rupture occurred along a 225 mile stretch of the San Andreas fault, which included the Carrizo segment, Cholame segment to the northwest, and Mojave segment to the southeast, during the Magnitude 7.9 Fort Tejon Earthquake in 1857 (SCEDC 2008). The southern end of the Cholame segment is located approximately 27 miles northwest of the proposed site, and has been assigned a maximum moment magnitude of 7.3.

Faulting and uplift that resulted in the formation of the Elk Hills anticline began in the Miocene and continued through present time (Fiore et al. 2007; Nicholson 1990). Although historic surface rupture has not been observed along faults in the Elk Hills, Quaternary age, movement is well documented. Two major groups of Quaternary faults are mapped in the Elk Hills area (CDMG 1994; Dibblee 2005a; Fiore et al. 2007; Nicholson 1990). At least four northeast-striking faults are present in the eastern Elk Hills, the nearest of which is located approximately 500 feet southeast of the south end of the proposed carbon dioxide pipeline options. Eleven faults in the western Elk Hills are oriented east to northeast and northwest, and are located at least 6 miles west of the proposed HECA plant site (CDMG 1994; Dibblee 2005b).

Preliminary estimates of ground motion based on probabilistic seismic hazard analyses have been calculated for the project site using the USGS Earthquake Hazards application called the U.S. Seismic “DesignMaps” Web Application (**Geology and Paleontology Table 4**). This application produces seismic hazard curves, uniform hazard response spectra, and seismic design values. The values provided by this application are based upon data from the 2008 USGS National Seismic Hazard Mapping Project. These design parameters are for use with the 2012 International Building Code, the 2010 ASCE-7 Standard, the 2009 NEHRP Provisions, and their respective predecessors.

These parameters are project-specific and, based on HECA’s location, were calculated using latitude and longitude inputs of 35.339 degrees north and 119.393 degrees west, respectively. Other inputs for this application are the site “type” which is based on the underlying geologic materials and the “Structure Risk Category”. The assumed site class for HECA is “D”, which is applicable to stiff soil. These parameters can be updated as appropriate following the results presented in a project-specific geotechnical investigation report performed for the site. The assumed “Structure Risk Category” is “III”, which is based on its inherent risk to people and the need for the structure to function following a damaging event. Risk categories range from I (non essential) to IV (critical). Examples of risk category I include agriculture facilities, minor storage facilities, etc., while examples of category IV include fire stations, hospitals, nuclear power facilities, etc.

The ground acceleration values presented are typical for the area. Other developments in the adjacent area would also be designed to accommodate strong seismic shaking. The potential for and mitigation of the effects of strong seismic shaking during an earthquake should be addressed in a project-specific geotechnical report, per CBC 2010 requirements, and proposed **FACILITY DESIGN GEN-1**, **GEN-5** and **CIVIL-1**. Compliance with these conditions of certification would ensure the project is built to current seismic standards and potential impacts would be mitigated to less than significant levels in accordance with current standards of engineering practice.

Geology and Paleontology Table 4
Planning Level 2010 CBC Seismic Design Parameters Maximum Considered Earthquake, ASCE 7 Standard

Parameter	Value
Assumed Site Class	D
Structure Risk Category	III - Substantial
SS – Mapped Spectral Acceleration, Short (0.2 Second) Period	1.116 g
S1 – Mapped Spectral Acceleration, Long (1.0 Second) Period	0.448 g
Fa – Site Coefficient, Short (0.2 Second) Period	1.054
Fv – Site Coefficient, Long (1.0 Second) Period	1.552
SDS – Design Spectral Response Acceleration, Short (0.2 Second) Period	0.784 g
SD1 – Design Spectral Response Acceleration, Long (1.0 Second) Period	0.463 g
SMS – Spectral Response Acceleration, Short (0.2 Second) Period	1.176 g
SM1 – Spectral Response Acceleration, Long (1.0 Second) Period	0.695 g

ASCE = American Society of Civil Engineers
Values from USGS 2010b

Carbon dioxide produced during operation of the proposed HECA facility would be captured, piped southward to the actively producing Elk Hills oil and gas fields, and injected into porous rocks several thousand feet underground. These proposed operations would sequester the carbon dioxide underground, preventing its release into the atmosphere, and enhance oil recovery (Terralog 2008). The proposed volume of carbon dioxide injected would be less than the quantities of water, steam and gas currently injected to increase oil production in the Elk Hills. Fluid injection is known to have increased levels of small-scale seismicity at other locations in the United States, although none has been documented as a result of water, steam and gas injection in the Elk Hills oil and gas fields. Any additional seismic event resulting from proposed carbon dioxide injection is not expected to exceed a magnitude 4 earthquake (Terralog 2008). The maximum anticipated peak acceleration the proposed HECA site would experience is on the order of 0.01 g, which is more than an order of magnitude less intense than site accelerations associated with maximum credible earthquakes on faults listed in **Geology and Paleontology Table 3**. Since the proposed HECA plant would be designed to withstand much higher levels of ground shaking associated with earthquakes on active faults within 30 miles of the site, the potential for minor levels of increased seismicity associated with carbon dioxide injection poses no additional geologic hazard to the plant.

Local residences could be subject to an increase in frequency of seismic shaking related to fluid injection. The intensity of induced seismicity at local residences is likely to be very low and not sufficiently strong to cause damage. Therefore impacts to local residences due to induced seismicity are considered to be less than significant.

The potential for strong ground shaking would be addressed in proposed Facility Design Condition of Certification **GEN-1**. Proper design in accordance with this condition, as well as with requirements presented in a site-specific, design-level geotechnical report, should adequately mitigate seismic hazards to the current standards of practice.

Liquefaction

Liquefaction is a phenomenon whereby loose, saturated, granular soils lose their inherent shear strength because of excess pore water pressure build-up, such as that generated during repeated cyclic loading from an earthquake. A low relative density of the granular materials, shallow groundwater table, long duration, and high acceleration of seismic shaking are some of the factors favorable to cause liquefaction.

The presence of predominantly cohesive or fine-grained materials and/or absence of saturated conditions can preclude liquefaction. Liquefaction hazards are usually manifested in the form of buoyancy forces during liquefaction, increase in lateral earth pressures due to liquefaction, horizontal and vertical movements resulting from lateral spreading, and post-earthquake settlement of the liquefied materials.

Four of the parameters used to assess the potential for liquefaction are soil density, soil texture, depth to ground water, and the peak horizontal ground acceleration estimated for the site. Historic depths to ground water at the proposed project site range from approximately 19 feet (CDWR 2004) to 35 feet below the existing ground surface, although ground water was not encountered in hollow-stem auger borings advanced to a maximum depth of 101.5 feet. SPT testing conducted during the site geotechnical investigation indicates that soils below approximately 15 feet are generally too dense to be subject to liquefaction (HEI 2008c). However, ground water levels should be confirmed, and the liquefaction potential on the proposed HECA site should be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **FACILITY DESIGN GEN-1**, **GEN-5** and **CIVIL-1**.

Lateral Spreading

Lateral spreading of the ground surface can occur within liquefiable beds during seismic events. Lateral spreading generally requires an abrupt change in slope—that is, a nearby steep hillside or deeply eroded stream bank, etc.—but can also occur on gentle slopes. Other factors such as distance from the epicenter, magnitude of the seismic event, and thickness and depth of liquefiable layers also affect the amount of lateral spreading. The HECA site is underlain by predominantly unsaturated, cohesive, fine-grained materials that are not typically associated with liquefaction and there is no nearby steep hillside that would accommodate lateral spreading. Staff recommends that the liquefaction potential of underlying beds beneath the proposed HECA site be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **FACILITY DESIGN GEN-1, GEN-5** and **CIVIL-1**.

Dynamic Compaction

Dynamic compaction of soils results when relatively unconsolidated granular materials experience vibration associated with seismic events. The vibration causes a decrease in soil volume, as the soil grains tend to rearrange into a more dense state (an increase in soil density). The decrease in volume can result in settlement of overlying structural improvements. The site specific geotechnical investigation indicates the alluvial deposits in the proposed site subsurface are generally too dense to allow significant dynamic compaction (URS 2009a). Staff recommends that the potential for, and mitigation of, the effects of dynamic compaction of proposed site native and fill soils during an earthquake be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **FACILITY DESIGN GEN-1**, **GEN-5** and **CIVIL-1**. Common mitigation methods would include deep foundations (driven piles; drilled shafts) for severe conditions, geogrid reinforced fill pads for moderate severity and over-excavation and replacement for areas of minimal hazard.

Hydrocompaction

Hydrocompaction (also known as hydro-collapse) is generally limited to young soils that were deposited rapidly in a saturated state, most commonly by a flashflood. The soils dry quickly, leaving an unconsolidated, low density deposit with a high percentage of voids. Foundations built on these types of compressible materials can settle excessively, particularly when landscaping irrigation dissolves the weak cementation that is preventing the immediate collapse of the soil structure. Hydrocompaction is the process of the loss of soil volume upon the application of water.

Hydrocompaction has been documented in several areas in the southern San Joaquin Valley southwest and west of Bakersfield; however, the proposed HECA project site would not be located within any of these designated areas (Kern County 2000; USGS 1984). The potential for significant consolidation due to hydrocompaction is considered remote. The proposed site area has been irrigated and cultivated extensively, which would likely have induced settlement in soils that had a potential for hydrocompaction. The proposed site specific geotechnical investigation also indicates the subsurface alluvial deposits which underlie the site would generally be too dense to experience significant hydrocompaction (URS 2009a). Staff recommends that the potential for and mitigation of the effects of hydrocompaction of site soils be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **FACILITY DESIGN GEN-1**, **GEN-5** and **CIVIL-1**. Typical mitigation measures would include over-excavation/replacement, mat foundations or deep foundations, depending on severity and foundation loads.

Subsidence

Subsidence of surficial and near surface soil units can result from loading of loose or soft soils by foundations, or by the extraction of fluids from the subsurface. Load-induced consolidation has been addressed by the project geotechnical investigation (HEI 2008c, Appendix P), as required by Facility Design Conditions of Certification **GEN-5** and **CIVIL-1.**

Regional ground subsidence is typically caused by petroleum or ground water withdrawal that increases the effective unit weight of the soil profile, which in turn increases the effective stress on the deeper soils. This results in consolidation or settlement of the underlying soils. Subsidence due to ground water withdrawal has occurred throughout much of the San Joaquin Valley in the decades prior to the 1970's (USGS 1984; USGS 2000). Ireland and others show the site as lying outside areas with documented subsidence, in excess of one foot, due to ground water withdrawal (USGS 1984). Petroleum and gas fields are also located in the Elk Hills adjacent to the proposed project site area and throughout the southern portion of the Great Valley Geomorphic Province (CDC, 1998). Despite the proximity of oil fields relative to the proposed site, subsidence in the area was not indicated in the Geologic Hazards and Resources section of the AFC, or in the supporting preliminary geotechnical report (HEI

2008c, Appendix P) The potential impacts related to groundwater withdrawal for project supply are addressed in the **Water Supply** section of this analysis. Staff recommends that the potential for and mitigation of the effects of subsidence of site soils be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **FACILITY DESIGN GEN-1**, **GEN-5** and **CIVIL-1**. Typical mitigation measures would include over-excavation/replacement, mat foundations or deep foundations, depending on severity and foundation loads.

Expansive Soils

Soil expansion occurs when clay-rich soils with an affinity for water exist in-place at a moisture content below their plastic limit. The addition of moisture from irrigation, precipitation, capillary tension, water line breaks, etc. causes the clay soils to absorb water molecules into their structure, which in turn causes an increase in the overall volume of the soil. This increase in volume can correspond to excessive movement (heave) of overlying structural improvements.

Expansion potential of soils is usually measured by plasticity index and expansive index tests. The most hazardous soils have high clay contents, and the clays have a high shrink-swell potential and a high plasticity index. Near surface soils in the proposed project vicinity consist generally of sandy lean and fat clays, with measured plasticity indices of 29 and 41, and expansion indices of 73 and 83 (HEI 2008c, Appendix P). The soils classify as moderately expansive, which could pose a hazard to facility foundations if mitigation measures are not implemented (URS 2009a).

Staff recommends that the potential for, and mitigation of, the effects of expansive soils on the proposed site be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **FACILITY DESIGN GEN-1**, **GEN-5** and **CIVIL-1**. Mitigation would normally be accomplished by over-excavation and replacement of the expansive soils. For deep-seated conditions, deep foundations are commonly used. Lime-treatment (chemical modification) is often used to mitigate expansive clays in pavement areas.

Landslides

Landslides occur when masses of rock, earth, or debris move down a slope, including rock falls, deep failure of slopes, and shallow debris flows. Landslides are influenced by human activity (mining and construction of buildings, railroads, and highways) and natural factors (geology, precipitation, and topography). Frequently, they accompany other natural hazards. Although landslides sometimes occur during earthquake activity, earthquakes are rarely their primary cause.

The most common cause of a landslide is an increase in the down slope gravitational stress applied to slope materials (oversteepening). This may be produced either by natural processes or human activities. Undercutting of a valley wall by stream erosion is a common way in which slopes may be naturally oversteepened. Other ways include excessive rainfall or irrigation on a cliff or slope.

The site is relatively flat and located substantial distances from steep terrain. Therefore, the site is not subject to landslide hazards.

Flooding

The proposed site and linear facilities would be located in a shaded Zone X defined as "Areas of 0.2 percent annual chance flood, areas of one percent annual chance flood with average depth of less than one foot, or with drainage area of less than one (1) square mile; areas protected by levee from one percent annual chance flood" (FEMA 2008). Further analysis of site drainage and stormwater flows is discussed in the **Soil and Surface Water** section of this analysis.

Tsunamis and Seiches

Tsunamis are large-scale seismic-sea waves caused by offshore earthquakes, submarine landslides, landslides falling into water bodies and/or volcanic activity. Seiches are waves generated within enclosed water bodies such as bays, lakes or reservoirs caused by seismic shaking, rapid tectonic uplift, basin bottom displacement and/or land sliding. The proposed power plant site is located approximately 200 miles inland from the coast. There are no water bodies located at an elevation above the project site within the project vicinity. Therefore, the site is not subject to either tsunami of seiche hazards.

The design-level geotechnical investigation required for the proposed project by the CBC 2010 and proposed **FACILITY DESIGN GEN-1**, **GEN-5** and **CIVIL-1** should provide standard engineering design recommendations for mitigation of seismic shaking, ground subsidence, expansive clay soils, liquefaction and excessive settlement due to compressible soils or dynamic compaction, as appropriate.

Construction Impacts and Mitigation

The design-level geotechnical investigation, required for the proposed project by the CBC (2010) and proposed Conditions of Certification **GEN-1**, **GEN-5** and **CIVIL-1** of the **Facility Design** section of this document, provide standard engineering design recommendations for mitigation of earthquake ground shaking, excessive settlement and expansive soils.

As noted above, no viable geologic or mineralogic resources are known to exist in the vicinity of the proposed construction site or project linears, with the exception of the Elk Hills and associated oil and gas fields. Current and future oil and gas production from these deposits would not be expected to be adversely impacted by proposed construction of the HECA plant site and project linears.

Quaternary alluvium and Pliocene to Pleistocene Tulare Formation deposits beneath the proposed site have a high sensitivity rating for paleontologic impacts. Based on the soils profile, SVP assessment criteria, and the shallow depth of potentially fossiliferous geologic units, staff considers the probability of encountering paleontological resources during construction of the proposed HECA project to be high. Quaternary alluvium near the surface is less sensitive relative to deeper and older alluvium (McLeod 2009), however, all Quaternary sediments at the project site should be considered to have a high sensitivity rating until determined otherwise by a qualified professional paleontologist. Since the upper portion of the surface has been disturbed during agricultural operations, the upper 1 to 2 feet of ground would not be likely to yield fossil remains in their natural context. Any excavation into undisturbed native ground at the surface or below disturbed material at the proposed plant site and along project linears, would be considered to have a high potential to encounter significant paleontological resources.

Mass grading operations within proposed structure footprints, that could be required for removal of expansive clays, would have the potential to disturb paleontological resources. Fossil remains could also be encountered in deep trenches excavated for utilities, and for construction of drilled shaft foundations that may be used to support heavily loaded structures. Any fossil brought to the surface by drilling operations would be badly disturbed and out of context.

Proposed Conditions of Certification **PAL-1** to **PAL-7** are designed to mitigate any paleontological resource impacts, as discussed above, to a less than significant level. Essentially, these conditions would require a worker education program in conjunction with monitoring of earthwork activities by qualified professional paleontologists (PRS). Earthwork is halted any time potential fossils are recognized by either the paleontologist or the worker. The science of paleontology is advanced by the discovery, study and curation of new fossils. These fossils can be significant if they represent a new species, verify a known species in a new location, provide museum quality specimens, or if they include structures of similar specimens that had not previously been found preserved, among other criteria. Most fossil discoveries are the result of excavations, either purposeful in known or suspected fossil localities or as the result of excavations made during earthwork for civil improvements or mineral extraction. Proper monitoring of excavations at the proposed HECA facility, in accordance with an approved Paleontological Monitoring and Mitigation Plan (proposed **PAL-3**), could result in fossil discoveries that would enhance our understanding of the prehistoric climate, geology, and geographic setting of the region for the benefit of current and future generations. When properly implemented, the conditions of certification yield a net gain to the science of paleontology, since fossils that would not otherwise have been discovered can be collected, identified, studied, and properly curated.

A PRS is retained, for the project by the applicant, to produce a monitoring and mitigation plan, conduct the worker training, and provide the monitoring, per **PAL-3** through **PAL-6**. This plan is based on anticipated conditions, typically deduced from the available regional-level geologic mapping, museum records, and a brief site reconnaissance. Geologic conditions on the scale of a single project site can differ greatly from what was anticipated. During the monitoring, the PRS may petition the Energy Commission for a change in the monitoring protocol. Most commonly, this is a request for lesser monitoring after sufficient monitoring has been performed to ascertain that there is little chance of finding significant fossils (**PAL-5**). In other cases, the PRS may propose increased monitoring due to unexpected fossil discoveries or in response to repeated out-of-compliance incidents by the earthwork contractor. At the proposed HECA site, a PRS may evaluate Quaternary alluvium exposed in new excavations, and determine a minimum depth above which the potential for encountering paleontological resources is low. The PRS may then recommend decreased monitoring in excavations above this depth.

Based upon the literature and archives search, field surveys, and compliance documentation for the proposed project, the applicant proposes monitoring and mitigation measures for construction of the proposed power plant. Energy Commission staff agrees with the applicant that the project can be designed and constructed to minimize the effects of geologic hazards at the site, during project design life, and that impacts to vertebrate, invertebrate and trace fossils encountered during construction can be mitigated to levels of less than significant.

Operation Impacts and Mitigation

The operation of HECA would not present additional risk to geological resources (none identified) or paleontological resources. Once ground disturbing activity is complete, plant operation has no real potential to further affect paleontological resources. Therefore, routine plant operation would not increase potential cumulative effects on paleontological resources. The longer the plant operates, however, the more likely it is to be affected by geological hazards, primarily earthquake-related ground shaking. For example, USGS data indicates that there is a 20 percent probability that a bedrock ground acceleration of 0.206g would be exceeded at the site in any 50-year interval (USGS 2006). This equates to a recurrence interval of about 250 years. The CBC (2010) requires that the structures be designed for a 2,500 recurrence interval event (two percent probability in 50 years) which shows a much higher bedrock ground acceleration of 0.46g. The longer the project operates, the higher the probability of both an earthquake and high ground acceleration. This situation is the same for all developments anywhere and not unique to this project at this site. The design requirements of the CBC are intended to protect occupants from building collapse during the design-level earthquake, one with only two percent probability of being exceeded in any 50-year interval. The code does not require that the structures be salvageable after such an event. Construction and operation of the plant does not increase the potential of geological hazards at the site, but the potential for earthquake-generated ground shaking at the site unavoidably increases with every year of operation.

OEHI SETTING

The Elk Hills Oil Field (EHOF) is located along the southwest edge of the San Joaquin Valley, approximately 26 miles (42 Kilometers [km]) southwest of Bakersfield in western Kern County, California. The entire EHOF is approximately 48,000 acres.

The EHOF was originally developed as part of the federal Naval Petroleum Reserves. This area is situated immediately south of, and contiguous with, the Lokern Area of Critical Environmental Concern (ACEC) a part of which (3,111 acres) is controlled by the Bureau of Land Management (BLM). Portions of this surrounding area (2,050 acres), are managed as conservation areas by the Center for Natural Lands Management (CNLM) and OEHI (formerly Plains Exploration and Production Company and Nuevo Energy Company) Habitat Management Lands (200 acres). The remainder is owned by Chevron Corporation and others. The City of Buttonwillow is located directly to the north. McKittrick Valley and portions of Buena Vista Valley with Highway 33 running NW-SE are to the west. The cities of McKittrick and Derby Acres are located along Highway 33. Approximately ten miles to the west and across the Temblor Range is the Carrizo Plain National Monument (199,030 acres).

To the south of the EHOF is the Buena Vista Valley, the majority of which is within another Naval Petroleum Reserve oil field. The City of Taft is located approximately seven-miles to the south. Mostly undeveloped areas are located along Highway 119 to the southeast of EHOF. Lands to the immediate east include Coles Levee Ecological Preserve (CLEP; 6,059 acres), Kern Water Bank Authority (19,900 acres), Tule Elk Reserve State Park and the Kern River. The California Aqueduct and the West Side Canal converge and flow along the north and eastern boundary of EHOF, as does the Kern River. The Buena Vista Lake Bed is located immediately southeast of Highway 119. Bakersfield is approximately 26 miles to the northeast. The EHOF is circumscribed by Highway 5 to the north and east, Highways 119 and 33 to the south, Highway 33 to the west and Highway 58 to the north. Elk Hills Road runs north and south and bisects the Project area.

REGIONAL SETTING

The EHOF is located in the Great Valley geomorphic province. The Great Valley Province is characterized by a large northwest trending valley bounded by the Sierra Nevada province to the east and south, the Klamath Mountains province to the north, the Cascade Range province to the northeast, and the Coast Range province to the west. The Great Valley Province is filled with thick sediments eroded from the surrounding mountain ranges.

The Great Valley province is underlain by a thick (up to 80,000 feet thick) sequence of sedimentary units (the Great Valley Sequence) which are Jurassic age or younger. The valley is an asymmetrical synclinal trough with a more gently dipping eastern limb.

The project site is located on the western side of the San Joaquin Valley. The San Joaquin Valley is filled with thick Mesozoic and Tertiary marine and non-marine sediments covered by a relatively thin veneer of Quaternary alluvial sediments (Bailey 1966). Kettleman Hills, Elk Hills, and Buena Vista Hills provide the only significant topographic relief in the San Joaquin Valley portion of the Great Valley province (Stantec 2012).

Prior to the early Eocene epoch the bulk of the province was covered by seas. As the seas withdrew, increasing terrestrial sediments were deposited from the erosion of the Sierra Nevada to the east. During the Eocene there was uplift on the margins of the province causing the seas to gradually recede. During this time the Stockton Arch (the division between the northern and southern parts of the province) was also rising. Subsidence of the valley during late Eocene time caused the seas to again inundate the province. As the valley continued to fill with sediments, the seas occupied smaller areas. By the end of the Pliocene the seas had finally withdrawn for the last time from the southwestern portion of the province, the last area to be submerged. The last large lake to occupy the Great Valley Province was Lake Corcoran, about 600,000 years ago (URS, 2008). Lake Corcoran covered much of the western part of the San Joaquin Valley. The resulting Corcoran Clay (composed of fine clays, volcanic ash, and diatomite) covers more than 5,000 square miles and forms an extensive aquaclude creating a major confined aquifer (Stantec 2012).

The EHOF is located near the south-western edge of the San Joaquin Valley, approximately 25 miles southwest of the city of Bakersfield in Kern County, California.

The EHOF is approximately 17 miles long (generally east to west) and over 7 miles wide (generally north to south). The highest elevation in the Elk Hills is 1,551 feet above mean sea level, which is between 1,000 to 1,200 feet above the floor of the San Joaquin Valley. The Tertiary (Tulare Formation) and Quaternary-aged deposits underlying the Elk Hills and nearby areas are up to 24,000 feet thick (U.S. Department of Energy [DOE], 1997).

The Tulare Formation lies at the surface of Elk Hills and consists of gravel, sand, and silt derived from erosion of the Monterey Formation exposed in the Temblor Range to the west. (Stantec 2012). Lithologically, the Tulare Formation consists of argillaceous sand and silt deposits with lenses of coarse sand and gravel. Conglomerate units do occur, but are rare overall.

OEHI SITE DESCRIPTION

The original project description provided by ManageTech (2010) identified a projected total of 550 injection and production wells. Upon additional evaluation, OEHI has increased the number of projected wells to 720 (309 injection wells and 411 production wells). OEHI has designed the Project to utilize existing wells to the maximum extent feasible. It is estimated that 570 of the 720 wells necessary for the proposed Project would utilize pre-existing well locations. The remaining 150 wells would be new installations.

Utilizing existing wells and pads would substantially reduce the amount of Project disturbances and reduce the potential air quality, biologica,l and cultural impacts that could result from Project implementation. The disturbance footprint for each new well to be installed as part of the proposed Project was calculated based on the use of the Ensign 533 and 535 drilling rigs. The Ensign 533 and 535 drill rigs have an estimated 130 feet wide by 280 feet long (sump and drill rig/pad) disturbance footprint. This equates to an approximately 36,400 square-foot or approximately 0.84 acres of disturbance per new well.

The original project description estimated approximately 550 miles of ancillary piping for operation of the CO_2 EOR component (which equated to approximately 1 mile of pipeline per well). Further analyses of well and piping requirements performed by OEHI indicate that between approximately 552-652 miles of pipeline may be necessary. The higher estimate of 652 miles was developed in consideration of surface encumbrances (e.g., topographic constraints, goal of utilizing existing pipeline ROWs to the maximum extent feasible, and avoidance of environmentally and culturally sensitive areas of concern).

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

This section considers two types of impacts. The first is the potential impacts the proposed facility could have on existing geologic, mineralogic, and paleontologic resources in the area. The second is the potential geologic hazards that could adversely impact the proper functioning of the proposed facility and create life/safety concerns.

DIRECT/INDIRECT IMPACTS AND MITIGATION

An assessment of the potential impacts to geologic, mineralogic, and paleontologic resources, and from geologic hazards is provided below. The assessment of impacts is followed by a summary of potential impacts that may occur during construction and operation of the project and provides recommended conditions of certification that would ensure potential impacts are mitigated to a level that is less than significant. The recommended mitigation measures would allow the lead agency's compliance project manager and the applicant to adopt a compliance monitoring scheme ensuring ongoing compliance with LORS applicable to geologic hazards and the protection of geologic, mineralogic, and paleontologic resources.

GEOLOGIC AND MINERALOGIC RESOURCES

The mineral resources addressed in this section pertain to those resources that are classified under the Surface Mining and Reclamation Act of 1975 (SMARA). The SMARA requires the California State Mining and Geology Board (SMGB) to adopt state policy for the reclamation of mined lands and the conservation of mineral resources. The SMARA provides a comprehensive surface mining and reclamation policy with the regulation of surface mining operations to assure that adverse environmental impacts are minimized. The SMARA also encourages the production, conservation, and protection of the state's mineral resources. The SMARA was amended in 1980 to provide for the classification of non-urban areas subject to land-use threats incompatible with mining. The classification of land within California takes place according to a priority list that was established by the SMGB in 1982, or when the SMGB is petitioned to classify a specific area. Currently, the State Geologist's SMARA classification activities are carried out under a single program for urban and nonurban areas of the state. Mineral lands are mapped using the California Mineral Land Classification System. Priority is given to areas where future mineral resource extraction could be precluded by incompatible land use or to mineral resources likely to be mined during the 50-year period following their classification. Detailed mineral land classification and designation reports provided by the SMGB are on file at the county.

Pursuant to SMARA, the California Geological Survey within the State of California, Department of Conservation designates Mineral Resource Zones (MRZ) in portions of the state that are considered to have potentially significant mineral deposits. "Mineral resources" are those economical mineral concentrations in such form and amount that the economic extraction of a commodity from the concentrations is currently potentially feasible. A "reserve" is that part of the resource base that could be economically extracted or produced within the foreseeable future. For any given mineral resource, an area may be classified as follows:

- MRZ-1: Areas where the available geologic information indicates that no significant mineral deposits are present, or where it is judged that no significant likelihood exists for their presence.
- MRZ-2a: Areas where the available geologic information indicates that significant mineral deposits are present.
- MRZ-2b: Areas where the available geologic information indicates that there is likelihood for the presence of significant mineral deposits.

- MRZ-3a: Areas where the available geologic information indicates that mineral deposits exist, the significance of which cannot be evaluated from existing data.
- MRZ-3b: Areas where the available geologic information indicates that mineral deposits are likely to exist, the significance of which cannot be determined from available data.
- MRZ-4: Areas where available geologic information is inadequate for assignment into any other MRZ, or where there is not enough information available to determine the presence or absence of mineral deposits.

The MRZ classifications are applied based on available geologic information and upon geologic appraisal of the mineral resource potential of the land, including geologic mapping and other information on surface exposures, drilling records, and mine data; and on socioeconomic factors such as market conditions and urban development patterns. Within the Bakersfield production/ consumption region (including the EHOF), only MRZ-1 through MRZ-3 are used.

The major resources of sand and gravel within the county are in the stream deposits along the eastern side of the San Joaquin Valley and in the Sierra Nevada foothills, and in alluvial fan deposits along the north flank of the San Emidio and Tehachapi Mountains. Most of the recent alluvium in the San Joaquin Valley floor is composed of sand used as a source of road base material.

The Buttonwillow Compaction Products Mine is located northwest of the Project Site and is designated MRZ-2 for base and fill material. The proposed Project Site is state-designated as MRZ-3 on the 2009 production/consumption region for portland cement concrete grade aggregate (sand and gravel) resources; therefore, it is located within an area containing mineral deposits the significance of which cannot be evaluated from available data. The proposed Project Site is located within a currently active oil field and does not contain sand and gravel resources that are currently being extracted. In addition, there was no evidence of past or current sand and gravel extraction occurring within the proposed Project Site.

Gold has been the most important metallic mineral mined in Kern County, in terms of the total dollar value. It has been recovered by both placer and lode mining mainly in the Sierra Nevada and desert regions. Principal placer deposits are in the Rand District, El Paso Mountains and along the Kern River. About 1,500 gold claims have been registered in Kern County with approximately 280 of those claims activated as either lode or placer mines. The total amount of gold that was extracted from the Kern County sites is not available, as records were not kept during the more active lode mining activities prior to 1900.There is no evidence of gold or other precious metal mineral resources located within the proposed OEHI site.

Kern County produces more oil than any other county in California, and is one of the nation's leading petroleum-producing counties. Oil is found in 15 of the 58 counties in California. Mineral and petroleum resources are essential to the county's economy. As new recovery technologies are introduced, petroleum extraction should continue to be of economic importance to the county. As long as new urbanization is restricted in areas having important mineral and petroleum resources, the future production of these resources remains promising.

The oil industry dates backs to the nineteenth century. The first developed oil field in the county was at the McKittrick Field in 1898. Development was facilitated by existence of the Southern Pacific Railroad from Bakersfield to McKittrick Field. The Kern River Oil Field was established in 1899 and by 1903, 796 wells produced almost 17 million barrels of oil from the Kern River Field. In 1911, the EHOF was discovered, and in 2008 the EHOF was ranked fifth in recovery of California's Giant oil fields. In the mid-1930's, several valley oil fields were found in large anticlines in Miocene oil sands beneath the valley floor. These discoveries were made following the advent of the reflection seismograph. Discoveries included the Ten Section, Greeley, Rio Bravo North, Coles Levee, South Coles Levee, and Strand oil fields.

Kern County is located within District #4 of the State Department of Conservation, Division of Oil, Gas, and Geothermal Resources. With the exception of about one percent, which comes from Tulare, Kings and San Luis Obispo Counties, all resources produced in District #4 listed in state publications are from Kern County. The proposed Project Site is located within the EHOF, an active operating oil field.

As discussed above, the OEHI component is limited to utilizing CO_2 enhanced oil recovery within an existing oil and gas field. It does not include any component that would contribute to a substantial cumulative impact to mineral resources. Therefore, implementation of the proposed project would result in a less than significant cumulative mineral resources impact.

PALEONTOLOGIC RESOURCES

The OEHI site is known to contain paleontological resources. In 2009, PaleoResource Consultants conducted a field survey as part of an assessment of the potential adverse impacts on scientifically significant resources. During the field survey for prospective fossil localities, many previously unrecorded sites were found on the western half of the EHOF. Fossils at these localities included vertebrate fossil bone fragments, invertebrate shells, and fossilized wood. Numerous paleosols (fossil soils) containing ichnofossils (root and burrow casts and molds) were also discovered.

The paleontological sensitivity of a stratigraphic unit reflects: (1) its potential paleontological productivity, and (2) the scientific significance of the fossils it has produced." URS (2009) continues, "The potential paleontological productivity of a stratigraphic unit exposed in a project area is based on the abundance/densities of fossil specimens and/or previously recorded fossil sites in exposures of the unit in and near a project site. The underlying assumption of this assessment method is that exposures of a stratigraphic unit in a project site are most likely to yield fossil remains both in quantity and density similar to those previously recorded from that stratigraphic unit in and near the project site." URS (2009) further states, "All identifiable land mammal fossils are considered scientifically important because of their potential use in providing relative age determinations and paleo-environmental reconstructions for the sediments in which they occur. Moreover, vertebrate remains are comparatively rare in the fossil record. Although fossil plants are usually considered of lesser importance because they are less helpful in age determination, they are actually more sensitive indications of their environment (Miller et al. 1971) and as sedentary organisms, are more valuable than mobile animals for paleo-environmental reconstructions. For marine sediments, invertebrate and marine algal fossils, including microfossils, are scientifically important for the same reasons that land mammal and/or land plant fossils are valuable in terrestrial deposits. The value or importance of different fossil groups varies depending on the age and depositional environment of the stratigraphic unit that contains the fossils".

Tulare Formation

There are a number of previously recorded fossil sites in the Tulare Formation in the Elk Hills as well as neighboring areas. Several fossil localities described by Woodring et al (1932) are present in the Elk Hills, and include specimens of camel, horse, rabbit, wood rat, cotton rat, silicified wood, and freshwater invertebrates. According to URS (2009), "Based upon these fossil localities, Woodring et al (1932) stated, 'the Elk Hills offer a promising field for collecting vertebrate fossils, which would fill a gap in the succession of vertebrate faunas on the Pacific Coast.' Maher et al (1975) indicated that 'scattered fish remains,' mollusk fragments, reworked foraminifers, ostracodes, pelecypods, and small gastropods have been identified from wells in the Elk Hills".

As previously mentioned, PaleoResource Consultants discovered several previously unreported fossil localities within the Tulare Formation. Tulare formation fossils identified by PaleoResource Consultants included; vertebrate fossil bones, bone fragments, invertebrate shells, and fossilized wood. Numerous paleosols (fossil soils) containing ichnofossils (root and burrow casts and molds) were also identified (PaleoResource, 2008).

Quaternary Alluvium

Research by the applicant's consultant determined that no fossil localities have been reported from Quaternary alluvium in the vicinity of the EHOF (URS 2009). However, they stated that significant vertebrate fossils have been reported from Holocene and Pleistocene sediments in several areas within Kern County.The occurrence of large and small mammals are well documented from these and older subsurface deposits and with further observation of earth-moving activities and prospecting for fossils, more specimens could be unearthed. Since fossil vertebrates have been previously reported from Quaternary alluvium within Kern County, the onsite Quaternary alluvium is also judged to have a high sensitivity.

Summary

According to PaleoResource Consultants,(PaleoResource 2008), due to the numerous previously unidentified fossil localities in and around the vicinity of the Elk Hills, "there is a high probability of scientifically significant paleontological resources being unearthed during future ground disturbing activities".

Overall, staff considers the probability that paleontological resources would be encountered during site construction activities to be high. The potential for exposure of paleontological resources would increase with depth and volume of proposed construction excavations. This assessment is based on SVP criteria and the confidential paleontological report appended to the AFC (HEI 2008c). Recommended mitigation measures **OEHI PAL-1** to **OEHI PAL-7** are designed to mitigate paleontological resource impacts, as discussed above, to less than significant levels. These conditions essentially require a worker education program in conjunction with the monitoring of earthwork activities by a qualified professional paleontological resources specialist (PRS).

The recommended mitigation measures allow the lead agency's compliance project manager (CPM) and the applicant to adopt a compliance monitoring scheme ensuring compliance with LORS applicable to geologic hazards and the protection of geologic, mineralogic, and paleontologic resources.

All applicable recommended mitigation measures (**OEHI GEO-1**, **GEN-1**, **GEN-5**, **CIVIL-1**, and **OEHI PAL-1** to **OEHI PAL-7**) allow the lead agency's CPM and the applicant to adopt monitoring schemes to ensure compliance with all LORS applicable to geologic hazards and the protection of geologic, mineralogic, and paleontologic resources.

GEOLOGICAL HAZARDS

The AFC (HEI 2008c) provides documentation of potential geologic hazards at the proposed site, including site-specific subsurface information generated by a preliminary geotechnical investigation (HEI 2008c, Appendix P). Review of the AFC, coupled with staff's independent research, indicates that the potential for geologic hazards to impact the proposed plant site during its practical design life would be low if recommendations for mitigation of seismic shaking and expansive soils are adopted and followed. Geologic hazards related to seismic shaking and adverse soil conditions are addressed in a project geotechnical report per CBC 2010 requirements (HEI 2008c, Appendix P).

Staff's independent research included the review of available geologic maps, reports, and related data of the proposed OEHI site. Geological information was available from the California Geological Survey (CGS), California Division of Mines and Geology (CDMG,), the U.S. Geological Survey (USGS), the American Geophysical Union, the Geological Society of America, and other organizations. Staff's analysis of this information is provided below.

Faulting and Seismicity

Energy Commission staff reviewed numerous CGS, USGS, and other publications, (CGS 2002a and b; CGS 2007; CDMG 1994; CDMG 2003; Fiore et al. 2007; Nicholson 1990; SCEDC 2008; Smith 1992; USGS 2006; USGS 2008), informational websites, and analytical and database software (Blake 2000a and b) in order to gather data on the location, recency, and type of faulting in the project area. Numerous faults are located within the project vicinity. The fault with the highest probability of affecting the site is the San Andreas fault located approximately 25 miles southwest of the site.

Preliminary estimates of ground motion based on probabilistic seismic hazard analyses have been calculated for the project site using the USGS Earthquake Hazards application called the U.S. Seismic "DesignMaps" Web Application (**Geology and Paleontology OEHI Table 3**). This application produces seismic hazard curves, uniform hazard response spectra, and seismic design values. The values provided by this application are based upon data from the 2008 USGS National Seismic Hazard Mapping Project. These design parameters are for use with the 2012 International

Building Code, the 2010 ASCE-7 Standard, the 2009 NEHRP Provisions, and their respective predecessors.

These parameters are project-specific and, based on OEHI's's location, were calculated using latitude and longitude inputs of 35.276 degrees north and 119.382 degrees west, respectively. Other inputs for this application are the site "type" which is based on the underlying geologic materials and the "Structure Risk Category". The assumed site class for OEHI is "D", which is applicable to stiff soil. These parameters can be updated as appropriate following the results presented in a project-specific geotechnical investigation report performed for the site. The assumed "Structure Risk Category" is "III", which is based on its inherent risk to people and the need for the structure to function following a damaging event. Risk categories range from I (non essential) to IV (critical). Examples of risk category I include agriculture facilities, minor storage facilities, etc., while examples of category IV include fire stations, hospitals, nuclear power facilities, etc.

The ground acceleration values presented are typical for the area. Other developments in the adjacent area would also be designed to accommodate strong seismic shaking. The potential for and mitigation of the effects of strong seismic shaking during an earthquake should be addressed in a project-specific geotechnical report, per CBC 2010 requirements, and proposed **Facility Design** recommended mitigation measures **GEN-1**, **GEN-5** and **CIVIL-1**. Compliance with these recommended mitigation measures would ensure the OEHI component is built to current seismic standards and potential impacts would be mitigated to less than significant levels in accordance with current standards of engineering practice.

Geology and Paleontology OEHI Table 3
Planning Level 2010 CBC Seismic Design Parameters Maximum Considered Earthquake, ASCE 7 Standard

Parameter	Value
Assumed Site Class	D
Structure Risk Category	III - Substantial
SS – Mapped Spectral Acceleration, Short (0.2 Second) Period	1.202 g
S1 – Mapped Spectral Acceleration, Long (1.0 Second) Period	0.485 g
Fa – Site Coefficient, Short (0.2 Second) Period	1.019
Fv – Site Coefficient, Long (1.0 Second) Period	1.515
SDS – Design Spectral Response Acceleration, Short (0.2 Second) Period	0.817 g
SD1 – Design Spectral Response Acceleration, Long (1.0 Second) Period	0.490 g
SMS – Spectral Response Acceleration, Short (0.2 Second) Period	1.225g
SM1 – Spectral Response Acceleration, Long (1.0 Second) Period	0.735 g

ASCE = American Society of Civil Engineers
Values from USGS 2010b

Carbon dioxide produced during operation of the proposed OEHI plant would be captured, piped southward to the actively producing Elk Hills oil and gas fields, and injected into porous rocks several thousand feet underground. These proposed operations would sequester the carbon dioxide underground, preventing its release into the atmosphere, and enhance oil recovery (Terralog 2008). The proposed volume of carbon dioxide injection would be less than the quantities of water, steam and gas currently injected to increase oil production in the Elk Hills. Fluid injection is known to have increased levels of small-scale seismicity at other locations in the United States, although none has been documented as a result of water, steam and gas injection in the Elk Hills oil and gas fields. Any additional seismic event resulting from proposed carbon dioxide injection is not expected to exceed a magnitude 4 earthquake (Terralog 2008). The maximum anticipated peak acceleration the proposed OEHI site would experience is on the order of 0.01 g, which is more than an order of magnitude less intense than site accelerations associated with maximum considered earthquake listed on **Geology and Paleontology OEHI Table 3**. Since the proposed OEHI plant would be designed to withstand much higher levels of ground shaking associated with earthquakes on active faults within 30 miles of the site, the potential for minor levels of increased seismicity associated with carbon dioxide injection poses no additional geologic hazard.

The potential for strong ground shaking would be addressed in proposed Facility Design recommended mitigation measure **GEN-1**. Proper design in accordance with this condition, as well as with requirements presented in a site-specific, design-level geotechnical report, should adequately mitigate seismic hazards to the current standards of practice.

Liquefaction

Liquefaction is not a significant concern within the OEHI site as it is underlain by hard mudstone and discontinuous beds or lenses of boulders, cobbles, gravels and coarse sands. Liquefaction is also not considered problematic where the depth to groundwater is greater than 50 feet. Studies done at the nearby Elk Hills Power Plant indicated the depth to groundwater at that location is in excess of 1,000 feet (CEC 2000).

Based on the above, the groundwater depth in the vicinity of the OEHI site exceeds 100 feet and may be as deep as 1,000 feet. The geology, soil types, and the average groundwater level present in the OEHI site indicate that the potential for liquefaction is very low. However, ground water levels should be confirmed, and the liquefaction potential on the proposed OEHI site should be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **Facility Design** recommended mitigation measures **GEN-1**, **GEN-5** and **CIVIL-1**.

Lateral Spreading

The OEHI site is underlain by predominantly unsaturated, coarse-grained materials that are not typically associated with liquefaction. However, ground water levels should be confirmed and the liquefaction potential of underlying beds beneath the proposed OEHI site should be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **Facility Design** recommended mitigation measures **GEN-1, GEN-5** and **CIVIL-1**.

Dynamic Compaction

The site is underlain by coarse alluvium and consolidated sedimentary deposits. These materials are not susceptible to significant dynamic compaction. The potential for, and mitigation of, the effects of dynamic compaction of proposed site native and fill soils during an earthquake should be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **Facility Design** recommended mitigation measures **GEN-1**, **GEN-5** and **CIVIL-1**. Common mitigation methods would include deep foundations (driven piles; drilled shafts) for severe conditions, geogrid reinforced fill pads for moderate severity and over-excavation and replacement for areas of minimal hazard.

Hydrocompaction

Hydrocompaction has been documented in several areas in the southern San Joaquin Valley southwest and west of Bakersfield; however, the proposed OEHI project site would not be located within any of these designated areas (Kern County 2000; USGS 1984). The potential for significant consolidation due to hydrocompaction is considered remote. The potential for and mitigation of the effects of hydrocompaction of site soils should be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **Facility Design** recommended mitigation measures **GEN-1**, **GEN-5** and **CIVIL-1**.

Subsidence

The project site is located outside of areas with documented subsidence in excess of one foot due to ground water withdrawal (USGS 1984). The OEHI site is located within the Elk Hills Oil Field (EHOF). By the end of 2006, approximately 1.3 billion drums of oil had been extracted from the EHOF (Stantec 2012). Despite the proximity of active oil extraction surrounding the proposed site, subsidence in the area was not indicated in the Geologic Hazards and Resources section of the AFC, in the supporting preliminary geotechnical report (HEI 2008c, Appendix P) or in the Supplemental Environmental Information (Stantec 2012).

The project would not increase ground water withdrawal and, consequently, would not cause subsidence due to ground water pumping. The potential for, and mitigation of, the effects of subsidence of site soils should be addressed in a project-specific geotechnical report, per CBC 2010 requirements and proposed **Facility Design** recommended mitigation measures **GEN-1**, **GEN-5** and **CIVIL-1**. Typical mitigation measures would include over-excavation/replacement, mat foundations or deep foundations, depending on severity and foundation loads.

Expansive Soils

Expansion potential of soils is usually measured by plasticity index and expansive index tests. The most hazardous soils have high clay contents, and the clays have a high shrink-swell potential and a high plasticity index**.** Because the Project Site is predominantly composed of sandy loam with very little to no fine-grained soil, there is a low probability of impact due to shrink-swell soil behavior.

The potential for and mitigation of the effects of expansive soils on the proposed site should be addressed in a project-specific geotechnical report, per CBC 2010 requirements and **Facility Design** recommended mitigation measures **GEN-1**, **GEN-5** and **CIVIL-1**.

Landslides

The OEHI site has several areas of moderate to relatively steep slopes. By disturbing the land and removing vegetation, construction activities can destabilize soils and slopes and increase the potential for landslides. In addition, roads can concentrate water in the adjacent land, thereby decreasing the stability of soils in these areas. The OEHI site is not located within a State of California Seismic Hazard Zone for landslides, which would require an evaluation of the potential for seismically induced landslides. The dense, relatively hard soils in the portion of the Project Site where operating equipment and pipelines would be placed generally supports a very low potential for land sliding or other forms of natural slope instability.

The potential for and mitigation of the effects of landslides on the proposed site should be addressed in a project-specific geotechnical report, per CBC 2010 requirements and **Facility Design** recommended mitigation measures **GEN-1**, **GEN-5** and **CIVIL-1**.

Flooding

The OEHI site is characterized as mountainous terrain with slopes averaging 30 percent or greater within the EHOF. The topography slopes from southwest to northeast towards the California Aqueduct. The elevation of the project area ranges from 1,500 to 300 feet above mean sea level (at the Aqueduct).

The FEMA Insurance Rate Maps (FIRMs) for the proposed Project Site are included in Community Panel Numbers 060075 C2200E, C2225E, C2625E, and C2650E for Kern County Unincorporated Areas. The proposed Project does not fall in a FEMA designated flood zone.

The project area is located within an unnamed basin where several ephemeral washes flow across alluvial sediments and terminate at various points north of the EHOF. Per the Occidental of Elk Hills Construction General Permit Compliance Plan (Compliance Plan), this area has no common water conveyance connections that can be defined between various channels. Two constructed structures that cross over/under the California aqueduct are located north of Section 23 and at the northern extent of the basin near Highway 58 west of the Lokern Road junction. These washes terminate in fields east of the aqueduct and do not flow into jurisdictional waters. Furthermore, the Compliance Plan finds that the ephemeral washes are non-jurisdictional according to the analysis method provided by the U.S. EPA and the U.S. Army Corps of Engineers.

The potential for and mitigation of the effects of flooding on the proposed site should be addressed in a project-specific geotechnical report, per CBC 2010 requirements and **Facility Design** recommended mitigation measures **GEN-1**, **GEN-5** and **CIVIL-1**.

Tsunamis and Seiches

The OEHI site is located approximately 200 miles inland from the coast. There are no water bodies located at an elevation above the project site within the project vicinity. Therefore, the site is not subject to either tsunami of seiche hazards.

The design-level geotechnical investigation required for the proposed project by the CBC 2010 and **Facility Design** recommended mitigation measures **GEN-1**, **GEN-5** and

CIVIL-1 should provide standard engineering design recommendations for mitigation of seismic shaking, liquefaction, lateral spreading, hydrocompaction, expansive soils and excessive settlement due to compressible soils or dynamic compaction, as appropriate.

Construction Impacts and Mitigation

The design-level geotechnical investigation, required for the proposed project by the CBC 2010 and recommended mitigation measures **GEN-1**, **GEN-5** and **CIVIL-1** of the **Facility Design** section of this document provide standard engineering design recommendations for mitigation of earthquake ground shaking, excessive settlement and expansive soils.

As noted above, no viable geologic or mineralogic resources are known to exist in the vicinity of the proposed construction site or project linears, with the exception of the Elk Hills and associated oil and gas fields. Current and future oil and gas production from these deposits would not be expected to be adversely impacted by proposed construction of the OEHI facility and project linears.

Quaternary alluvium and Pliocene to Pleistocene Tulare Formation deposits beneath the proposed site have a high sensitivity rating for paleontologic impacts. Based on the soils profile, SVP assessment criteria, and the shallow depth of potentially fossiliferous geologic units, staff considers the probability of encountering paleontological resources during construction of the proposed OEHI component to be high. Quaternary alluvium near the surface is less sensitive relative to deeper and older alluvium (McLeod 2009). However, all Quaternary sediments at the OEHI site should be considered to have a high sensitivity rating until determined otherwise by a qualified professional paleontologist. Any excavation into undisturbed native ground at the surface or below disturbed material at the proposed OEHI site and along project linears, would be considered to have a high potential to encounter significant paleontological resources.

Grading operations within proposed structure footprints, that could be required for foundation construction, would have the potential to disturb paleontological resources. Fossil remains could also be encountered in deep trenches excavated for utilities.

Recommended mitigation measures **OEHI PAL-1** to **OEHI PAL-7** are designed to mitigate any paleontological resource impacts, as discussed above, to a less than significant level. Essentially, these conditions would require a worker education program in conjunction with monitoring of earthwork activities by qualified professional paleontologists (PRS). Earthwork is halted any time potential fossils are recognized by either the paleontologist or the worker. The science of paleontology is advanced by the discovery, study and curation of new fossils. These fossils can be significant if they represent a new species, verify a known species in a new location, provide museum quality specimens, and/or if they include structures of similar specimens that had not previously been found preserved, among other criteria. Most fossil discoveries are the result of excavations, either purposeful in known or suspected fossil localities or as the result of excavations made during earthwork for civil improvements or mineral extraction. Proper monitoring of excavations at the proposed OEHI facility, in accordance with an approved Paleontological Monitoring and Mitigation Plan (proposed **OEHI PAL-3**), could result in fossil discoveries that would enhance our understanding of the prehistoric climate, geology, and geographic setting of the region for the benefit of current and future generations. When properly implemented, the mitigation measures would yield a net gain to the science of paleontology since fossils that would not otherwise have been discovered can be collected, identified, studied, and properly curated.

A PRS is retained for the project by OEHI, LLC, to produce a monitoring and mitigation plan, conduct the worker training, and provide the monitoring, per **OEHI PAL-3** through **OEHI PAL-6**. This plan is based on anticipated conditions, typically deduced from the available regional-level geologic mapping, museum records, and a brief site reconnaissance. Geologic conditions on the scale of a single project site can differ greatly from what was anticipated. During the monitoring, the PRS may petition the lead agency for a change in the monitoring protocol. Most commonly, this is a request for lesser monitoring after sufficient monitoring has been performed to ascertain that there is little chance of finding significant fossils (**OEHI PAL-5**). In other cases, the PRS may propose increased monitoring due to unexpected fossil discoveries or in response to repeated out-of-compliance incidents by the earthwork contractor. At the proposed OEHI facility, a PRS may evaluate Quaternary alluvium exposed in new excavations, and determine a minimum depth above which the potential for encountering paleontological resources is low. The PRS may then recommend decreased monitoring in excavations above this depth.

Based upon the literature and archives search, field surveys, and compliance documentation for the proposed project, OEHI, LLC proposes monitoring and mitigation measures for construction of the proposed OEHI. Energy Commission staff agrees that the project can be designed and constructed to minimize the effects of geologic hazards at the site, during project design life, and that impacts to vertebrate, invertebrate and trace fossils encountered during construction can be mitigated to levels of insignificance.

Operation Impacts and Mitigation

Operation of the OEHI facility should not have any adverse impact on geologic, mineralogic, or paleontologic resources. Once the facility is constructed and operating, there would be no further disturbances that could affect these resources.
Potential geologic hazards, including strong ground shaking, ground subsidence, liquefaction, settlement, hydrocompaction, or dynamic compaction can be effectively mitigated through facility design such that these potential hazards should not affect future operation of the facilities. Compliance with recommended mitigation measures **GEN-1, GEN-5 AND CIVIL-1** in the **Facility Design** section would ensure the project is constructed to current seismic building standards and potential impacts would be mitigated in accordance with current standards of engineering practice.

CUMULATIVE IMPACTS AND MITIGATION

The geographic area considered for cumulative impacts on geology and paleontology is the south portion of the San Joaquin Valley, the southern end of the Great Valley geomorphic province in central California (Norris and Webb 1990). The potential cumulative impacts are limited to those involving paleontological resources since no geological or mineralogical resources have been identified within the boundaries of the proposed project. There are no geological hazards with potential cumulative effects. No adverse cumulative impacts would be anticipated with respect to current and future oil and gas recovery from the Naval Petroleum Reserve.

The potential impacts to paleontological resources due to construction activities at the HECA site would be mitigated by proposed Conditions of Certification **PAL-1** to **PAL-7**. Construction of the project would require localized excavation and trenching. Because the project area lies predominantly within geological units with high paleontological sensitivity, the required excavation could, potentially, damage paleontological resources. Any damage could be cumulative to damage from other projects within the same geological formations. Implementation and enforcement of a properly designed Paleontological Resource Monitoring and Mitigation Plan (PRMMP; proposed **PAL-3**) at the HECA site should result in a net gain to the science of paleontology by allowing fossils that would not otherwise have been found, to be recovered, identified, studied, and preserved. Cumulative impacts from HECA, in consideration with other nearby similar projects, should therefore be either neutral (no fossils encountered) or positive (fossils encountered, preserved, and identified).

The potential impacts to paleontological resources due to construction activities on the OEHI Component would be mitigated by recommended mitigation measures **OEHI PAL-1** to **OEHI PAL-7**. Construction of the project would require localized excavation and trenching. Because the project area lies predominantly within geological units with high paleontological sensitivity, the required excavation could, potentially, damage paleontological resources. Any damage could be cumulative to damage from other projects within the same geological formations. Implementation and enforcement of a properly designed Paleontological Resource Monitoring and Mitigation Plan (PRMMP) at the OEHI site should result in a net gain to the science of paleontology by allowing fossils that would not otherwise have been found, to be recovered, identified, studied, and preserved. Cumulative impacts from OEHI, in consideration with other nearby similar projects, should therefore be either neutral (no fossils encountered) or positive (fossils encountered, preserved, and identified).

Staff believes that the potential for significant adverse cumulative impacts to the proposed project from geologic hazards, during the project’s design life, would be low, and that the potential for isolated and cumulative impacts to geologic, mineralogic, and paleontologic resources would be very low.

The proposed conditions of certification allow the CPM and the applicant to adopt a compliance monitoring scheme ensuring compliance with applicable LORS for geologic hazards and geologic, mineralogic, and paleontologic resources as they pertain to HECA.

The recommended mitigation measures allow the regulatory agencies and OEHI, LLC to adopt a compliance monitoring scheme ensuring compliance with applicable LORS for geologic hazards and geologic, mineralogic, and paleontologic resources as they pertain to the OEHI Component.

FACILITY CLOSURE

Facility closure activities would not be expected to impact geologic, paleontologic, or mineralogic resources since no such resources are known to exist at the project location. In addition, the decommissioning and closure of the project should not negatively affect geologic, mineralogic, or paleontologic resources since the majority of the ground disturbed during plant decommissioning and closure would have been already disturbed, and mitigated as required, during construction and operation of the proposed project.

DEPARTMENT OF ENERGY'S (DOE) FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the applicant for the HECA Project. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

CONCLUSIONS

The proposed project would comply with applicable LORS, provided that the proposed conditions of certification are followed. The design and construction of the proposed project would have no adverse, isolated, or cumulative impacts with respect to geologic, mineralogic, and paleontologic resources. Staff proposes to ensure compliance with applicable LORS through the adoption of the proposed conditions of certification listed below.

OUTSTANDING INFORMATION REQUIRED FOR COMPLETION OF THE FSA/FEIS

Limestone would be mined and transported to the site to be used as a fluxant to reduce sulfur emissions. Currently it is unknown where the limestone is being mined, the entity that permitted the mine's operation, the capacity of the mine's resource and the estimated consumption of limestone during the project's design life.

Staff requests that this information be provided as its evaluation is necessary to complete the analysis for the completion of the FSA/FEIS.

RECOMMENDED MITIGATION MEASURES

The Energy Commission has no jurisdiction over compliance with LORS or mitigation of impacts resulting from construction and operation of the OEHI Component. Therefore, the following mitigation measures are recommendations that governing regulatory agencies (Kern County Building Department, State of California) could consider when permitting the OEHI Component.

General mitigation measures with respect to engineering geology are proposed under recommended mitigation measures **GEN-1, GEN-5**, and **CIVIL-1** in the **Facility Design** section. Proposed Geological Conditions of Certification follow.

OEHI GEO-1 The Soils Engineering Report required by Section 1803 of the 2010 CBC should specifically include laboratory test data, associated geotechnical engineering analyses, and a thorough discussion of hydrocompaction or dynamic compaction; and the presence of expansive clay soils. The report should also include recommendations for ground improvement and/or foundation systems necessary to mitigate these potential geologic hazards, if present.

The recommended mitigation measures to protect paleontological resources are listed below. It is staff's opinion that the likelihood of encountering paleontologic resources is high at the OEHI Component. Staff considers reduction in monitoring intensity could be realized at the recommendation of the project paleontologic resource specialist (PRS), following examination of sufficient, representative deep excavations that produce no significant fossil remains.

OEHI PAL-1 The project owner shall provide the lead agency's compliance project manager (CPM) with the resume and qualifications of its PRS for review and approval. If the approved PRS is replaced prior to completion of project mitigation and submittal of the Paleontological Resources Report, the project owner shall obtain the lead agency's CPM approval of the replacement PRS. The project owner shall keep resumes on file for qualified paleontological resource monitors (PRMs). If a PRM is replaced, the resume of the replacement PRM shall also be provided to the lead agency's CPM.

The PRS resume shall include the names and phone numbers of references. The resume shall also demonstrate to the satisfaction of the lead agency's CPM the appropriate education and experience to accomplish the required paleontological resource tasks.

As determined by the lead agency's CPM, the PRS shall meet the minimum qualifications for a vertebrate paleontologist as described in the SVP guidelines of 1995. The experience of the PRS shall include the following:

1. Institutional affiliations, appropriate credentials, and college degree;
2. Ability to recognize and collect fossils in the field;
3. Local geological and biostratigraphic expertise;
4. Proficiency in identifying vertebrate and invertebrate fossils; and
5. At least three years of paleontological resource mitigation and field experience in California and at least one year of experience leading paleontological resource mitigation and field activities.

The project owner shall ensure that the PRS obtains qualified paleontological resource monitors to monitor as he or she deems necessary on the project. Paleontologic resource monitors shall have the equivalent of the following qualifications:

- BS or BA degree in geology or paleontology and one year of experience monitoring in California; or
- AS or AA in geology, paleontology, or biology and four years' experience monitoring in California; or
- Enrollment in upper division classes pursuing a degree in the fields of geology or paleontology and two years of monitoring experience in California.

OEHI PAL-2 The project owner shall provide to the PRS and the lead agency's CPM, for approval, maps and drawings showing the footprint of the power plant, construction lay-down areas, and all related facilities. Maps shall identify all areas of the project where ground disturbance is anticipated. If the PRS requests enlargements or strip maps for linear facility routes, the project owner shall provide copies to the PRS and the lead agency's CPM. The site grading plan and plan and profile drawings for the utility lines would be acceptable for this purpose. The plan drawings should show the location, depth, and extent of all ground disturbances and be at a scale between 1 inch = 40 feet and 1 inch = 100 feet. If the footprint of the project or its linear facilities changes, the project owner shall provide maps and drawings reflecting those changes to the PRS and the lead agency's CPM.

If construction of the project proceeds in phases, maps and drawings may be submitted prior to the start of each phase. A letter identifying the proposed schedule of each project phase shall be provided to the PRS and lead agency's CPM. Before work commences on affected phases, the project owner shall notify the PRS and the lead agency's CPM of any construction phase scheduling changes.

At a minimum, the project owner shall ensure that the PRS or PRM consults weekly with the project superintendent or construction field manager to confirm area(s) to be worked the following week and until ground disturbance is completed.

OEHI PAL-3 The project owner shall ensure that the PRS prepares, and the project owner submits to the lead agency's CPM for review and approval, a Paleontological Resources Monitoring and Mitigation Plan (PRMMP) to identify general and specific measures to minimize potential impacts to significant paleontological resources. Approval of the PRMMP by the lead agency's CPM shall occur prior to any ground disturbance. The PRMMP shall function as the formal guide for monitoring, collecting, and sampling activities and may be modified with lead agency's CPM approval. This document shall be used as the basis of discussion when on-site decisions or changes are proposed. Copies of the PRMMP shall reside with the PRS, each monitor, the project owner's on-site manager, and the lead agency's CPM.

The PRMMP shall be developed in accordance with the guidelines of the SVP (1995) and shall include, but not be limited, to the following:

1. Assurance that the performance and sequence of project-related tasks, such as any literature searches, pre-construction surveys, worker environmental training, fieldwork, flagging or staking, construction monitoring, mapping and data recovery, fossil preparation and collection, identification and inventory, preparation of final reports, and transmittal of materials for curation will be performed according to PRMMP procedures;
2. Identification of the person(s) expected to assist with each of the tasks identified within the PRMMP and the conditions of certification;
3. A thorough discussion of the anticipated geologic units expected to be encountered, the location and depth of the units relative to the project when known, and the known sensitivity of those units based on the occurrence of fossils either in that unit or in correlative units;
4. An explanation of why, how, and how much sampling is expected to take place and in what units. Include descriptions of different sampling procedures that shall be used for fine-grained and coarse-grained units;
5. A discussion of the locations of where the monitoring of project construction activities is deemed necessary, and a proposed plan for monitoring and sampling;
6. A discussion of procedures to be followed in the event of a significant fossil discovery, halting construction, resuming construction, and how notifications will be performed;
7. A discussion of equipment and supplies necessary for collection of fossil materials and any specialized equipment needed to prepare, remove, load, transport, and analyze large-sized fossils or extensive fossil deposits;
8. Procedures for inventory, preparation, and delivery for curation into a retrievable storage collection in a public repository or museum, which meet the Society of Vertebrate Paleontology's standards and requirements for the curation of paleontological resources;
9. Identification of the institution that has agreed to receive data and fossil materials collected, requirements or specifications for materials delivered for curation and how they will be met, and the name and phone number of the contact person at the institution; and
10. A copy of the paleontological recommended mitigation measures.

OEHI PAL-4 Prior to ground disturbance and for the duration of construction activities involving ground disturbance, the project owner and the PRS shall prepare and conduct weekly CPM-approved training for the following workers: project managers, construction supervisors, foremen and general workers involved with or who operate ground-disturbing equipment or tools. Workers shall not excavate in sensitive units prior to receiving CPM-approved worker training. Worker training shall consist of an initial in-person PRS training program, or may utilize a CPM-approved video or other presentation format, during the project kick off for those mentioned above. Following initial training, a CPM-approved video or other approved training presentation/materials, or in-person training may be used for new employees. The training program may be combined with other training programs prepared for cultural and biological resources, hazardous materials, or other areas of interest or concern. No ground disturbance shall occur prior to the lead agency's CPM approval of the Worker Environmental Awareness Program (WEAP), unless specifically approved by the lead agency's CPM.

The WEAP shall address the possibility of encountering paleontological resources in the field, the sensitivity and importance of these resources, and legal obligations to preserve and protect those resources.

The training shall include:

1. A discussion of applicable laws and penalties under the law;
2. Good quality photographs or physical examples of vertebrate fossils for project sites containing units of high paleontologic sensitivity;
3. Information that the PRS or PRM has the authority to halt or redirect construction in the event of a discovery or unanticipated impact to a paleontological resource;
4. Instruction that employees are to halt or redirect work in the vicinity of a find and to contact their supervisor and the PRS or PRM;
5. An informational brochure that identifies reporting procedures in the event of a discovery;
6. A WEAP certification of completion form signed by each worker indicating that he/she has received the training; and
7. A sticker that shall be placed on hard hats indicating that environmental training has been completed.

OEHI PAL-5 The project owner shall ensure that the PRS and PRM(s) monitor consistent with the PRMMP all construction-related grading, excavation, trenching, and augering in areas where potential fossil-bearing materials have been identified, both at the site and along any constructed linear facilities associated with the project. In the event that the PRS determines full-time monitoring is not necessary in locations that were identified as potentially fossil bearing in the PRMMP, the project owner shall notify and seek the concurrence of the lead agency's CPM.

The project owner shall ensure that the PRS and PRM(s) have the authority to halt or redirect construction if paleontological resources are encountered. The project owner shall ensure that there is no interference with monitoring activities unless directed by the PRS. Monitoring activities shall be conducted as follows:

1. Any change of monitoring from the accepted schedule in the PRMMP shall be proposed in a letter or email from the PRS and the project owner to the lead agency's CPM prior to the change in monitoring and will be included in the monthly compliance report. The letter or email shall include the

justification for the change in monitoring and be submitted to the lead agency's CPM for review and approval.

2. The project owner shall ensure that the PRM(s) keep a daily monitoring log of paleontological resource activities. The PRS may informally discuss paleontological resource monitoring and mitigation activities with the lead agency's CPM at any time.
3. The project owner shall ensure that the PRS notifies the lead agency's CPM within 24 hours of the occurrence of any incidents of non-compliance with any paleontological resources conditions of certification. The PRS shall recommend corrective action to resolve the issues or achieve compliance with the conditions of certification.
4. For any significant paleontological resources encountered, either the project owner or the PRS shall notify the lead agency's CPM within 24 hours, or Monday morning in the case of a weekend event, where construction has been halted because of a paleontological find.

The project owner shall ensure that the PRS prepares a summary of monitoring and other paleontological activities placed in the monthly compliance reports. The summary will include the name(s) of PRS or PRM(s) active during the month; general descriptions of training and monitored construction activities; and general locations of excavations, grading, and other activities. A section of the report shall include the geologic units or subunits encountered, descriptions of samplings within each unit, and a list of identified fossils. A final section of the report will address any issues or concerns about the project relating to paleontologic monitoring, including any incidents of non-compliance or any changes to the monitoring plan that have been approved by the lead agency's CPM. If no monitoring took place during the month, the report shall include an explanation in the summary as to why monitoring was not conducted.

OEHI PAL-6 The project owner, through the designated PRS, shall ensure that all components of the PRMMP are adequately performed including collection of fossil materials, preparation of fossil materials for analysis, analysis of fossils, identification and inventory of fossils, the preparation of fossils for curation, and the delivery for curation of all significant paleontological resource materials encountered and collected during project construction. The project owner shall be responsible for paying any curation fees charged by the museum for fossils collected and curated as a result of paleontological mitigation.

OEHI PAL-7 The project owner shall ensure preparation of a Paleontological Resources Report (PRR) by the designated PRS. The PRR shall be prepared following completion of the ground-disturbing activities at each well pad and at any construction site. The PRR shall include an analysis of the collected fossil materials and related information and submit it to the lead agency's CPM for review and approval.

The report shall include, but is not limited to, a description and inventory of recovered fossil materials; a map showing the location of paleontological resources encountered; determinations of sensitivity and significance; and a statement by the PRS that project impacts to paleontological resources have been mitigated below the level of significance.

PROPOSED CONDITIONS OF CERTIFICATION

The Energy Commission does have jurisdiction over compliance with LORS and mitigation of impacts resulting from construction and operation of HECA. Therefore, staff proposes the following Conditions of Certification.

General conditions of certification with respect to engineering geology are proposed under Conditions of Certification **GEN-1, GEN-5**, and **CIVIL-1** in the **Facility Design** section. Proposed Geological Conditions of Certification follow.

GEO-1 The Soils Engineering Report required by Section 1803 of the 2010 CBC should specifically include laboratory test data, associated geotechnical engineering analyses, and a thorough discussion of hydrocompaction or dynamic compaction; and the presence of expansive clay soils. The report should also include recommendations for ground improvement and/or foundation systems necessary to mitigate these potential geologic hazards, if present.

Verification: The project owner shall include in the application for a grading permit a copy of the Soils Engineering Report which addresses the potential for liquefaction; settlement due to compressible soils, ground water withdrawal, hydrocompaction, or dynamic compaction; and the possible presence of expansive clay soils, and a summary of how the results of the analyses were incorporated into the project foundation and grading plan design for review and comment by the Chief Building Official (CBO). A copy of the Soils Engineering Report, application for grading permit and any comments by the CBO shall be provided to the CPM at least 30 days prior to grading.

Proposed paleontological conditions of certification are listed below. It is staff's opinion that the likelihood of encountering paleontologic resources is high at the plant site and along project linears. Staff will consider reducing monitoring intensity, at the recommendation of the project paleontologic resource specialist (PRS), following examination of sufficient, representative deep excavations that produce no significant fossil remains.

PAL-1 The project owner shall provide the CPM with the resume and qualifications of its PRS for review and approval. If the approved PRS is replaced prior to completion of project mitigation and submittal of the Paleontological Resources Report, the project owner shall obtain CPM approval of the replacement PRS. The project owner shall keep resumes on file for qualified paleontological resource monitors (PRMs). If a PRM is replaced, the resume of the replacement PRM shall also be provided to the CPM.

The PRS resume shall include the names and phone numbers of references. The resume shall also demonstrate to the satisfaction of the CPM the appropriate education and experience to accomplish the required paleontological resource tasks.

As determined by the CPM, the PRS shall meet the minimum qualifications for a vertebrate paleontologist as described in the SVP guidelines of 1995. The experience of the PRS shall include the following:

1. Institutional affiliations, appropriate credentials, and college degree;
2. Ability to recognize and collect fossils in the field;
3. Local geological and biostratigraphic expertise;
4. Proficiency in identifying vertebrate and invertebrate fossils; and
5. At least three years of paleontological resource mitigation and field experience in California and at least one year of experience leading paleontological resource mitigation and field activities.

The project owner shall ensure that the PRS obtains qualified paleontological resource monitors to monitor as he or she deems necessary on the project. Paleontologic resource monitors shall have the equivalent of the following qualifications:

- BS or BA degree in geology or paleontology and one year of experience monitoring in California; or
- AS or AA in geology, paleontology, or biology and four years' experience monitoring in California; or
- Enrollment in upper division classes pursuing a degree in the fields of geology or paleontology and two years of monitoring experience in California.

Verification: (1) At least 60 days prior to the start of ground disturbance, the project owner shall submit a resume and statement of availability of its designated PRS for on-site work.

(2) At least 20 days prior to ground disturbance, the PRS or project owner shall provide a letter with resumes naming anticipated monitors for the project, stating that the identified monitors meet the minimum qualifications for paleontological resource monitoring required by the condition. If additional monitors are obtained during the project, the PRS shall provide additional letters and resumes to the CPM. The letter shall be provided to the CPM no later than one week prior to the monitor's beginning on-site duties.

(3) Prior to the termination or release of a PRS, the project owner shall submit the resume of the proposed new PRS to the CPM for review and approval.

PAL-2 The project owner shall provide to the PRS and the CPM, for approval, maps and drawings showing the footprint of the power plant, construction lay-down areas, and all related facilities. Maps shall identify all areas of the project where ground disturbance is anticipated. If the PRS requests enlargements or strip maps for linear facility routes, the project owner shall provide copies to the PRS and CPM. The site grading plan and plan and profile drawings for the utility lines would be acceptable for this purpose. The plan drawings should show the location, depth, and extent of all ground disturbances and be at a scale between 1 inch = 40 feet and 1 inch = 100 feet. If the footprint of the project or its linear facilities changes, the project owner shall provide maps and drawings reflecting those changes to the PRS and CPM.

If construction of the project proceeds in phases, maps and drawings may be submitted prior to the start of each phase. A letter identifying the proposed schedule of each project phase shall be provided to the PRS and CPM. Before work commences on affected phases, the project owner shall notify the PRS and CPM of any construction phase scheduling changes.

At a minimum, the project owner shall ensure that the PRS or PRM consults weekly with the project superintendent or construction field manager to confirm area(s) to be worked the following week and until ground disturbance is completed.

Verification: (1) At least 30 days prior to the start of ground disturbance, the project owner shall provide the maps and drawings to the PRS and CPM.

(2) If there are changes to the footprint of the project, revised maps and drawings shall be provided to the PRS and CPM at least 15 days prior to the start of ground disturbance.

(3) If there are changes to the scheduling of the construction phases, the project owner shall submit a letter to the CPM within 5 days of identifying the changes.

PAL-3 The project owner shall ensure that the PRS prepares, and the project owner submits to the CPM for review and approval, a Paleontological Resources Monitoring and Mitigation Plan (PRMMP) to identify general and specific measures to minimize potential impacts to significant paleontological resources. Approval of the PRMMP by the CPM shall occur prior to any ground disturbance. The PRMMP shall function as the formal guide for monitoring, collecting, and sampling activities and may be modified with CPM approval. This document shall be used as the basis of discussion when on-site decisions or changes are proposed. Copies of the PRMMP shall reside with the PRS, each monitor, the project owner’s on-site manager, and the CPM.

The PRMMP shall be developed in accordance with the guidelines of the SVP (1995) and shall include, but not be limited, to the following:

1. Assurance that the performance and sequence of project-related tasks, such as any literature searches, pre-construction surveys, worker environmental training, fieldwork, flagging or staking, construction monitoring, mapping and data recovery, fossil preparation and collection, identification and inventory,

preparation of final reports, and transmittal of materials for curation will be performed according to PRMMP procedures;

2. Identification of the person(s) expected to assist with each of the tasks identified within the PRMMP and the conditions of certification;
3. A thorough discussion of the anticipated geologic units expected to be encountered, the location and depth of the units relative to the project when known, and the known sensitivity of those units based on the occurrence of fossils either in that unit or in correlative units;
4. An explanation of why, how, and how much sampling is expected to take place and in what units. Include descriptions of different sampling procedures that shall be used for fine-grained and coarse-grained units;
5. A discussion of the locations of where the monitoring of project construction activities is deemed necessary, and a proposed plan for monitoring and sampling;
6. A discussion of procedures to be followed in the event of a significant fossil discovery, halting construction, resuming construction, and how notifications will be performed;
7. A discussion of equipment and supplies necessary for collection of fossil materials and any specialized equipment needed to prepare, remove, load, transport, and analyze large-sized fossils or extensive fossil deposits;
8. Procedures for inventory, preparation, and delivery for curation into a retrievable storage collection in a public repository or museum, which meet the Society of Vertebrate Paleontology's standards and requirements for the curation of paleontological resources;
9. Identification of the institution that has agreed to receive data and fossil materials collected, requirements or specifications for materials delivered for curation and how they will be met, and the name and phone number of the contact person at the institution; and
10. A copy of the paleontological conditions of certification.

Verification: At least 30 days prior to ground disturbance, the project owner shall provide a copy of the PRMMP to the CPM. The PRMMP shall include an affidavit of authorship by the PRS and acceptance of the PRMMP by the project owner evidenced by a signature.

PAL-4 Prior to ground disturbance and for the duration of construction activities involving ground disturbance, the project owner and the PRS shall prepare and conduct weekly CPM-approved training for the following workers: project managers, construction supervisors, foremen and general workers involved with or who operate ground-disturbing equipment or tools. Workers shall not excavate in sensitive units prior to receiving CPM-approved worker training. Worker training shall consist of an initial in-person PRS training program, or may utilize a CPM-approved video or other presentation format, during the project kick off for those mentioned above. Following initial training, a CPM-approved video or other approved training presentation/materials, or in-person training may be used for new employees. The training program may be combined with other training programs prepared for cultural and biological resources, hazardous materials, or other areas of interest or concern. No ground disturbance shall occur prior to CPM approval of the Worker Environmental Awareness Program (WEAP), unless specifically approved by the CPM.

The WEAP shall address the possibility of encountering paleontological resources in the field, the sensitivity and importance of these resources, and legal obligations to preserve and protect those resources.

The training shall include:

1. A discussion of applicable laws and penalties under the law;
2. Good quality photographs or physical examples of vertebrate fossils for project sites containing units of high paleontologic sensitivity;
3. Information that the PRS or PRM has the authority to halt or redirect construction in the event of a discovery or unanticipated impact to a paleontological resource;
4. Instruction that employees are to halt or redirect work in the vicinity of a find and to contact their supervisor and the PRS or PRM;
5. An informational brochure that identifies reporting procedures in the event of a discovery;
6. A WEAP certification of completion form signed by each worker indicating that he/she has received the training; and
7. A sticker that shall be placed on hard hats indicating that environmental training has been completed.

Verification: (1) At least 30 days prior to ground disturbance, the project owner shall submit the proposed WEAP, including the brochure, with the set of reporting procedures for workers to follow, to the CPM for review and approval.

(2) At least 30 days prior to ground disturbance, the project owner shall submit the training program presentation/materials to the CPM for approval if the project owner is planning to use a presentation format other than an in-person trainer for training.

(3) At least 30 days prior to ground disturbance, the project owner shall submit the script and final video to the CPM for approval if the project owner is planning to use a video for interim training.

(4) If the owner requests the use of an alternate paleontological trainer, the resume and qualifications of the trainer shall be submitted to the CPM for review and approval prior to installation of an alternate trainer. Alternate trainers shall not conduct training prior to CPM authorization.

(5) In the monthly compliance report (MCR), the project owner shall provide copies of the WEAP certification of completion forms with the names of those trained and the

trainer or type of training (in-person or other approved presentation format) offered that month. The MCR shall also include a running total of all persons who have completed the training to date.

PAL-5 The project owner shall ensure that the PRS and PRM(s) monitor consistent with the PRMMP all construction-related grading, excavation, trenching, and augering in areas where potential fossil-bearing materials have been identified, both at the site and along any constructed linear facilities associated with the project. In the event that the PRS determines full-time monitoring is not necessary in locations that were identified as potentially fossil bearing in the PRMMP, the project owner shall notify and seek the concurrence of the CPM.

The project owner shall ensure that the PRS and PRM(s) have the authority to halt or redirect construction if paleontological resources are encountered. The project owner shall ensure that there is no interference with monitoring activities unless directed by the PRS. Monitoring activities shall be conducted as follows:

1. Any change of monitoring from the accepted schedule in the PRMMP shall be proposed in a letter or email from the PRS and the project owner to the CPM prior to the change in monitoring and will be included in the monthly compliance report. The letter or email shall include the justification for the change in monitoring and be submitted to the CPM for review and approval.
2. The project owner shall ensure that the PRM(s) keep a daily monitoring log of paleontological resource activities. The PRS may informally discuss paleontological resource monitoring and mitigation activities with the CPM at any time.
3. The project owner shall ensure that the PRS notifies the CPM within 24 hours of the occurrence of any incidents of non-compliance with any paleontological resources conditions of certification. The PRS shall recommend corrective action to resolve the issues or achieve compliance with the conditions of certification.
4. For any significant paleontological resources encountered, either the project owner or the PRS shall notify the CPM within 24 hours, or Monday morning in the case of a weekend event, where construction has been halted because of a paleontological find.

The project owner shall ensure that the PRS prepares a summary of monitoring and other paleontological activities placed in the monthly compliance reports. The summary will include the name(s) of PRS or PRM(s) active during the month; general descriptions of training and monitored construction activities; and general locations of excavations, grading, and other activities. A section of the report shall include the geologic units or subunits encountered, descriptions of samplings within each unit, and a list of identified fossils. A final section of the report will address any issues or concerns about the project relating to paleontologic monitoring, including any incidents of non-compliance or any changes to the monitoring plan that have been approved by the CPM. If no monitoring took place during the month, the report shall include an explanation in the summary as to why monitoring was not conducted.

Staff will consider reducing monitoring intensity, at the recommendation of the project PRS, following examination of sufficient, representative deep excavations that produce no significant fossil remains.

Verification: The project owner shall ensure that the PRS submits the summary of monitoring and paleontological activities in the MCR. When feasible, the CPM shall be notified 10 days in advance of any proposed changes in monitoring different from the plan identified in the PRMMP. If there is any unforeseen change in monitoring, the notice shall be given as soon as possible prior to implementation of the change.

PAL-6 The project owner, through the designated PRS, shall ensure that all components of the PRMMP are adequately performed including collection of fossil materials, preparation of fossil materials for analysis, analysis of fossils, identification and inventory of fossils, the preparation of fossils for curation, and the delivery for curation of all significant paleontological resource materials encountered and collected during project construction. The project owner shall be responsible for paying any curation fees charged by the museum for fossils collected and curated as a result of paleontological mitigation.

Verification: The project owner shall maintain in his/her compliance file copies of signed contracts or agreements with the designated PRS and other qualified research specialists. The project owner shall maintain these files for a period of three years after project completion and approval of the CPM-approved paleontological resource report (see Condition of Certification **PAL-7**). A copy of the letter of transmittal submitting the fossils to the curating institution shall be provided to the CPM.

PAL-7 The project owner shall ensure preparation of a Paleontological Resources Report (PRR) by the designated PRS. The PRR shall be prepared following completion of the ground-disturbing activities. The PRR shall include an analysis of the collected fossil materials and related information and submit it to the CPM for review and approval.

The report shall include, but is not limited to, a description and inventory of recovered fossil materials; a map showing the location of paleontological resources encountered; determinations of sensitivity and significance; and a statement by the PRS that project impacts to paleontological resources have been mitigated below the level of significance.

Verification: Within 90 days after completion of ground-disturbing activities, including landscaping, the project owner shall submit the PRR under confidential cover to the CPM for review and approval.

Certification of Completion
Worker Environmental Awareness Program
Hydrogen Energy California Project (08-AFC-8)

This is to certify these individuals have completed a mandatory California Energy Commission-approved Worker Environmental Awareness Program (WEAP). The WEAP includes pertinent information on cultural, paleontological, and biological resources for all personnel (that is, construction supervisors, crews, and plant operators) working on site or at related facilities. By signing below, the participant indicates that he/she understands and shall abide by the guidelines set forth in the program materials. Include this completed form in the Monthly Compliance Report.

POWER PLANT EFFICIENCY

Edward Brady

SUMMARY OF CONCLUSIONS

Please note that for the project's rated power capacity, staff uses 405 megawatt (MW) in this section of the Preliminary Staff Assessment/Draft Environmental Impact Statement (PSA/DEIS) despite the 431 MW capacity rating used elsewhere in the PSA. No information on the overall project heat rate and breakdown of auxiliary loads, based on the 431MW figure, is available to staff at this point in time. Staff will need to prepare the Final Staff Assessment/Final Environmental Impact Statement (FSA/FEIS) based on a corrected MW figure.

Based on the 405 MW figure, the combined cycle component of the project would generate a maximum net output of 158 MW using its primary fuel of hydrogen rich syngas produced from gasified coal and petroleum coke. The coal/coke/syngas produces a net fuel efficiency of 22.8 percent at lower heating value (LHV). In the back-up mode, the combined cycle plant would produce a net output of 300 MW using its secondary fuel of 100 percent natural gas with a net 50.3 percent efficiency at LHV at maximum full load and annual design ambient conditions[1].

While the project would internally consume substantial amounts of energy, it would still produce electricity in a reasonably efficient manner and still meet the project objectives of demonstrating the viability of carbon capture and sequestration, enhanced oil recovery, and the co-production of fertilizer products. It would not create significant adverse effects on energy supplies or resources. No energy efficiency standards apply to the project. Staff therefore concludes that the project would present no significant adverse impacts upon energy resources.

INTRODUCTION

The Energy Commission staff (staff) makes a recommendation as to whether energy use by Hydrogen Energy California (HECA) would result in significant adverse impacts on the environment, as defined in the California Environmental Quality Act (CEQA). If staff concludes that the HECA's consumption of energy would create a significant adverse impact, it must determine whether there are any feasible mitigation measures that could eliminate or minimize the impacts. In this analysis, staff addresses the issue of inefficient and unnecessary consumption of energy.

In order to support the staff's recommendations, this analysis:

- examines whether the facility would likely present any adverse impacts upon energy resources;
- examines whether these adverse impacts would be significant; and if so,

[1] At site temperature of 97°F with 20 percent humidity (HECA 2012a, AFC Table 2-2).

- examines whether feasible mitigation measures exist that would eliminate the adverse impacts, or reduce them to a level of less than significant.

LAWS, ORDINANCES, REGULATIONS AND STANDARDS

No Federal, State or local/county laws, ordinances, regulations or standards (LORS) apply to the efficiency of this project.

SETTING

The aggregation of the power block, fuel gasification, fertilizer production, and CO_2 transmission system is designated as an integrated gasification combined cycle (IGCC) project, designated HECA in this analysis.

Hydrogen Electric California LLC, the applicant, proposes to construct and operate HECA. As explained above, staff uses the original 405 MW capacity rating in this section of the PSA, instead of 431 MW used elsewhere in the PSA. This project would provide the flexibility to energize its own fuel conversion from a 75 percent sub-bituminous coal/25 percent petroleum coke (petcoke) feedstock mixture to low-carbon hydrogen-rich syngas; pressurize and transmit compressed carbon dioxide for petroleum extraction; deliver power to the manufacturing complex; and generate up to 158 MW (nominal net) for delivery to the electric power distribution system. The combined cycle power block would consist of a one-on-one power train with a single shaft Mitsubishi Heavy Industries (MHI) 501GAC combustion gas turbine generator (CTG), heat recovery steam generator (HRSG), and steam turbine generator (STG).

The project would incorporate a feedstock delivery/storage/handling system, gasifier unit, acid gas removal system, sulfur removal unit, ammonia synthesis unit, and carbon dioxide (CO_2) purification and compression facility. The fuel gasification system would capture carbon dioxide for delivery to the Elk Hills Oil Fields (EHOF) three miles away for use in the enhanced oil recovery (EOR) and carbon sequestration fields. The air separation unit (ASU) would be powered from the grid and would provide an on-site source of oxygen for use in the gasifier and nitrogen for ammonia generation. In turn, the ammonia would be used in the power block's low NO_X combustion emissions system and the ammonia manufacturing complex.

The integrated manufacturing complex would take nitrogen generated in the ASU using a method called pressure swing adsorption (PSA) to manufacture products such as nitric acid, ammonia nitrate and urea. In addition, the complex would purify the compressed carbon dioxide for urea pastillation (pelletization of the urea) along with sending compressed CO_2 to the EHOF (HECA 2012a, § 2.1.9). Urea is a convenient source of nitrogen for use as agricultural fertilizer. Two molecules of ammonia combine with one molecule of carbon dioxide to make urea and water [$2NH_3 + CO_2 \rightarrow (NH_2)_2CO + H_2O$]. The HECA design specifies that, at maximum power production, about 14.8% of the CO_2 released in the fuel gasification process would be used to make urea fertilizer, which would then be pelletized in a method called pastillation.

The linear utilities and transportation system would comprise the balance of off-site functions that support HECA. A combination of rail and truck transportation would be used to deliver the feedstock constituents to HECA and return the sulfur, solids products and ash generated from the fuel gasification system. Alternative 1 would include a 5-mile rail spur to the site from the San Joaquin Valley Railroad (SJVRR) Buttonwillow rail line. Alternative 2 would use truck transport from the coal terminus 27 miles away in Wasco to deliver coal. Petroleum coke would be transported by truck in both alternatives from refineries in Santa Maria and the Los Angeles area.

HECA would utilize natural gas as a back-up source of fuel to be used during gasifier shutdown and planned maintenances (HECA 2012a, § 2.9.2). The natural gas pipeline would be routed 13 miles and interconnected with an available PG&E pipeline (HECA 2012a, § 2.1.11.6). The project would use raw water provided by Buena Vista Water Storage District, which would deliver an average 4,600 gallons per minute (gpm) annually and a peak demand of 5,150 gpm (HECA 2012a, § 2.11.7, Figures 2-10 and 2-11). The project's water use efficiency is evaluated in the **Water Supply** section of this PSA.

Of the 10,800 short tons per day (stpd) of CO_2 released from the sour shift and acid gas removal processes, 9,200 stpd (85.2 percent) are transferred to the EOR for field sequestration. The balance of CO_2 (1,600 stpd or 14.8%) is purified and delivered to the manufacturing complex for chemically processing solid ammonia-based processes such as pastillation (HECA 2012a, Response to Data Request A25, Figure A-27.1). Approximately 40 MW of the total auxiliary (internal) power is assigned to CO_2 compression, i.e., 34 MW for CO_2 EOR compression and transmission, and 6 MW for manufacturing.

ASSESSMENT OF IMPACTS

METHOD AND THRESHOLD FOR DETERMINING SIGNIFICANCE OF IMPACTS TO ENERGY RESOURCES

CEQA Guidelines state that the environmental analysis "…shall describe feasible measures which could minimize significant adverse impacts, including where irrelevant, inefficient and unnecessary consumption of energy" (Cal. Code Regs., tit. 14, § 15126.4(a)(1)). Appendix F of the Guidelines further suggests consideration of such factors as the project's energy requirements and energy use efficiency; its effects on local and regional energy supplies and energy resources; its requirements for additional energy supply capacity; its compliance with existing energy standards; and any alternatives that could reduce wasteful, inefficient and unnecessary consumption of energy (Cal. Code Regs., tit. 14, § 15000 et seq., Appendix F).

The inefficient and unnecessary consumption of energy, in the form of non-renewable fuels such as natural gas, petcoke, coal, and oil, constitutes an adverse environmental impact. An adverse impact would be considered significant if it results in:

- adverse effects on local and regional energy supplies and energy resources;
- a requirement for additional energy supply capacity;

- noncompliance with existing energy standards; or
- the wasteful, inefficient and unnecessary consumption of fuel or energy.

PROJECT ENERGY REQUIREMENTS AND ENERGY USE EFFICIENCY

Any power plant large enough to fall under Energy Commission siting jurisdiction will consume large amounts of energy. Under average ambient conditions, HECA would process the 75 percent coal/25 percent petcoke feedstock into low-carbon/hydrogen-rich fuel at approximately 3,992 million Btu[2] per hour LHV and natural gas nominal rate of 2,034 million Btu per hour LHV (HECA 2012a, Table 2-10). The primary hydrogen fuel is limited only by the amount of feedstock products that will be delivered and stored at the project site. The secondary natural gas flow rate is a substantial rate of energy consumption, and holds the potential to impact energy supplies. But because it is a back-up fuel utilized to generate electrical power when the IGCC is down for planned maintenance, this demand on the natural gas supply would be intermittent, i.e. two one-week planned shutdowns under cold-start conditions would be 528 hours or about 6% annually.

Under typical ambient conditions, electricity would be generated using natural gas at a full load efficiency optimized for power production of approximately 50.3 percent LHV (HECA 2012a, Tables 2-4 through 2-11)[3].

ADVERSE EFFECTS ON ENERGY SUPPLIES AND RESOURCES AND ADDITIONAL ENERGY SUPPLY REQUIREMENTS

HECA would rely on the availability of petcoke and sub-bitumnous coal for the feedstock mixture of 75 percent coal and 25 percent petcoke. The base production rate assumes that the consumption of coal would be 4,580 stpd (short tons per day) or 1,600,000 short tons per year (stpy) (HECA 2012a, §2.1.11.2). Approximately 16,000 stpd or 6.0 million stpy of petcoke would provide the balance of the feedstock mixture. HECA expects to obtain western sub-bituminous coal from New Mexico. Fuel-grade petcoke would be available from existing refineries in Southern California and plant demand would consume about 7 percent of the existing petcoke production within California (HECA 20 12a, §§ 2.1.11.2, 2.1.11.3); this would not likely create a significant adverse impact on the other petcoke customers. (Petcoke customers primarily consist of customers in Far East and southern Asia.)

For the natural gas fuel, the applicant has described its source of supply of natural gas for the project (HECA 2012a, § 2.7.1.10, Table 2-10). Natural gas for the HECA project is used as a back-up fuel and would be supplied from an existing PG&E natural gas transmission pipeline. The PG&E natural gas system has access to gas from the Rocky Mountains, Canada and the southwest. This represents a resource of considerable capacity. It is therefore highly unlikely that the project would pose a significant adverse impact on natural gas supplies in California.

---

[2] British thermal units.

[3] Tables 2-4 through 2-11 provide high heating values (HHV). Tabulation of lower heating values (LHV) is used an industry standard. Derived LHV's based on the above referenced tables and 2011 Biomass Energy Data Book: Appendix A.

There is abundant supply of coal in the country; the coal resources stretch from Montana to New Mexico in the west and from West Virginia to Pennsylvania in the east. The project would receive coal from New Mexico. The resource in New Mexico from which the project would draw coal from has a capacity of 21,922,000 stpy. The project's annual consumption of coal would be 1,600,000 stpy, approximately 7.3 percent of the available resource from New Mexico alone, and approximately 1.3 percent of the overall capacity in the entire western region, 120,853,000 stpy.[4] There is no real likelihood that HECA would require the development of additional resources of coal or create a significant adverse impact on the other consumers of coal in the region.

The project's CO_2 will be used in the EHOF to produce more oil than is possible without the CO_2.

COMPLIANCE WITH ENERGY STANDARDS

No standards apply to the efficiency of HECA or other non-cogeneration projects.

ALTERNATIVES TO REDUCE WASTEFUL, INEFFICIENT AND UNNECESSARY ENERGY CONSUMPTION

HECA could be deemed to create significant adverse impacts on energy resources if alternatives existed that would reduce the project's use of fuel. Evaluation of alternatives to the project that could reduce wasteful, inefficient or unnecessary energy consumption first requires examination of the project's energy consumption. Project fuel efficiency, and therefore its rate of energy consumption, is determined by the configuration of the power producing system and by the selection of equipment used to generate power.

Project Configuration

The project objective is to provide intermediate power generation services during periods of normal electrical demand. At the same time, power is provided on a continuous basis to provide energy using low carbon hydrogen fuel, to manufacture ammonia products and transmit, via pipeline, compressed CO_2 to EHOF for enhanced oil recovery (EOR) and carbon sequestration (HECA 2012a, AFC § 1.1). An integrated gasification combined cycle configuration is consistent with this objective. HECA would be configured as a single CTG coupled by a common shaft with a HRSG and STG; a one-on-one combined cycle train (HECA 2012a, AFC §§ 1.1, 2.3.1). As a combined cycle plant on primary hydrogen fuel derived from gasified coal/coke, the system would require a 4-6 day ramping cycle[5] from cold start that would include stabilization of the fuel gasification. As a matter of comparison, a combined cycle natural gas plant would require six to ten hours ramping time from cold-start to full power.

Equipment Selection

Modern gas turbines embody the most fuel-efficient electric generating technology available today. HECA would employ a Mitsubishi MPCP1 one-on-one combined cycle train with an MHI-501GAC CTG with a gross capacity of 405 MW.

---

[4] U.S. Energy Information Administration, Annual Coal Report 2011, Table 1.

[5] Ramping is increasing and decreasing electrical output to meet fluctuating load requirements.

The MHI-501 CTG has a solid operational record and does not represent a design that uses high efficiency to justify a lower operating reliability. The combined cycle configuration with the MHI-501 Series G turbine was first developed in 1995 and the MHI-501 turbine frame has been commercially available since the early 1980's. These machines have proven to operate reliably. Also, the applicant proposes a one-year pilot operation before commercial use. Finally, a full scale 250 MW demonstration facility employing the Mitsubishi MHI-501G model was brought up to full power in Nakaso, Japan in 2007 and has been operational since. For these reasons, the reliance on a single CTG in a one-on-one configuration does not represent a measureable reduction in reliability.

The MHI-501GAC model is nominally rated at a combined cycle thermal efficiency of 59.2 percent LHV (GTW 2012). The HECA power block would produce a gross output of 405 MW. The auxiliary load of 247 MW (109 ASU power requirement + 138 of other loads) drops the net power output for availability on the grid to 158 MW. In the case of HECA, the "poly-generation" requirements of the fuel gasification, agricultural products manufacturing, and the onsite CO_2 compression and transmission draws the net output efficiency down to 13.5 percent LHV, with the ASU power requirement taken into account (HECA 2012a, Table 2-10; **Efficiency Table 1**).[6]

According to the applicant, HECA would operate at three optimal modes: 1) Optimal electric power generation using hydrogen fuel, 2) Optimal manufacturing complex operation using hydrogen fuel, and 3) Combined cycle operation using natural gas. **Efficiency Table 1** (entitled **Modes of Operation**) below provides a breakdown of these operating modes. The listed efficiencies are based on the feedstock input of a 75 percent blend of sub-bituminous coal and 25 percent petcoke.[7]

Note: Allocation of auxiliary loads based on the mass and energy flow rates provided in HECA 2012a, AFC Table 2-10, Figure A27-1 Simplified Block Flow Diagram and e-mail from KRushmore/URS to WWorl/CEC dated 4/25/13.

The measurement or level of thermodynamic efficiency is not mandated or prescribed by any mandatory standard. The only evaluative guideline is to compare HECA efficiencies with other systems of similar configuration. **Efficiency Table 2** (entitled **IGCC Cycle Comparisons**) provides a side-by-side comparison among HECA and other projects with carbon capture and sequestration and entrained flow gasifiers. When allocating auxiliary power requirements, HECA efficiency stands at 22.8 percent LHV[12] compared to the 36.4-38.5 percent range for the alternative IGCCs'. With comparable fuel heat rates, the efficiency difference can only be accounted for by the difference in the level of auxiliary power loads, where HECA comes in at an auxiliary/cross ration of 0.34, compared to 0.26-.27 to the system alternatives. In an effort to account for the

[8] HECA 2012a, Table 2-10 with modifications noted.

[9] Auxiliary load allocated to power block and industrial block based on mass flow rates specified in data request response Fig. A27-4 "Simplified Blcock Flow Diagram. For power block MW = (1289/3925) x 30 = 20. For manufacturing complex MW = (2636/3925) x 30 = 10 MW.

[10] Power requirement for CO_2 compression proportioned to mass flow from Fig. A27-4. For transfer to EOR, (9200/10800) x 40 = 34 MW. For use in pastillation, (1600/10800) x 40 = 6 MW.

[11] Air Separation Unit (ASU) power requirement not included in AFC Table 2-10. Value of 109 MW on-peak power requirement provided in e-mail response from Kathy Rushmore/URS dated 4/25/13. Allocated in same proportion as Gasefication Block.

[12] Higher Heating Value (HHV), called gross or total heating values, is the heat rate which includes the latent heat of evaporation. In the case of HECA, the feedstock constituents of coal and petcoke are furnished with 15.0 and 14.8 percent by weight moisture content respectively (HECA 2012a, AFC Tables 2-4 and 2-5). Lower Heating Value (LHV) excludes the latent heat of evaporation and by U. S. convention is the value that's used in a combustion-fuel engine. Because the gasification fuel is being furnished to the CTG with the moisture removed, the LHV is assumed where both heat values are not otherwise provided. HHV/LHV conversion ratio of 1.18 used.

difference, the net efficiency for HECA was calculated without the 109 MW ASU power load, yielding a 22.8 percent efficiency at LHV and a total auxiliary load ratio of 0.34. See **Efficiency Table 2**.

Efficiency Table 2
IGCC Cycle Comparison[13]
Net Plant Efficiency

Net Output (MW) – Post ASU	**158**			
Fertilizer Manufacturing	Yes	No	No	No
CO_2 Capture and Sequestration	Yes	Yes	Yes	Yes

Air Separation Unit (ASU)

The ASU converts air into oxygen and nitrogen. The principle use of the oxygen is the conversion of coal and petroleum feedstocks into hydrogen-rich syngas. The nitrogen will be used for agricultural products manufacturing and as a NO_x moderator in the combined cycle. The power requirements for the ASU would be imported from the electric transmission grid as a discrete entity. In an effort to account for the difference between the net efficiency for HECA and the other projects listed in **Efficiency Table 2** (ranging from 36.4 to 38.5 percent), the net efficiency for HECA was calculated without the 109 MW ASU power load, yielding a 22.8 percent efficiency at LHV and a total auxiliary load ratio of 0.34. See **Efficiency Table 2**. When accounting for the ASU load in calculating the project's efficiency, the overall efficiency drops considerably below 22.8 percent, to approximately 13.5 percent.

[13] Comparison among IGCC systems with different gasifiers and carbon capture and sequestion: "Caost and Performanc Baseline for Fossil Energy Plants. Vol. I: Bituminous Coal and Natural Gas to Electricity. Revision 2, November 2010, National Energy Technology Labortory (NETL), Department of Energy, DOE/NETL-2010/1397.

Qualitative Considerations

In addition to providing a source of electricity, HECA would be designed to address additional project goals, whose efficiency measurement is ancillary factor to the commercial-scale demonstration of an IGCC facility. A compendium of some of these goals and their implementation methods are listed in the following **Efficiency Table 3**.

Efficiency Table 3
HECA Project Goals and Methods

GOAL	METHOD
• Diversify Fuel Source.	• 75 percent coal from New Mexico • 25 percent petcoke from California refineries
• Reduce carbon emissions to or beyond natural gas fuel levels.	• Chemical isolation of CO_2 for EOR and pastillation manufacturing.
• Utilize natural gas, which is a relatively clean, inexpensive and readily available fuel.	• Provide a reliable back-up fuel for unplanned outages • Improve plant availability during planned maintenance • Provide a reliable pilot fuel for start-up of the fuel gasification system
• Provide a useful product for local agricultural use.	• Manufacturing and processing of nitrogen-based products for crop fertilization

Although, the efficiency of HECA would be at a considerable disadvantage to the other projects listed in **Efficiency Table 2**, staff concurs with the applicant that the combined functions of processing the coal and petroleum coke feedstocks into a low-carbon/hydrogen-rich fuel gas, transmitting CO_2 for use in an EOR process, and utilizing the onsite generation of nitrogen for the production and manufacture of agricultural products should be taken into consideration when evaluating the project's efficiency impacts. Thus, although the project would demonstrate a low efficiency, the above mentioned benefits might be a reasonable tradeoff between the loss in efficiency and the potential environmental and commercial benefits offered by HECA.

Efficiency of Alternatives to the Project

Alternative Generating Technologies

Alternative generating technologies for the HECA project are considered in the AFC (HECA 2012a, AFC § 6.5). Nuclear, geothermal, biomass, wind, and solar power are not suitable to meet project objectives. Solar is not dispatchable, so is incapable of producing the ancillary services needed. Wind energy is not always available at the project area. Geothermal is not available at the HECA project site, and biomass may present problems with availability.

The overall thermal efficiency of HECA would be lower than the other projects listed in **Efficiency Table 2** due to HECA's high auxiliary loads, but the combined functions of processing the coal and petroleum coke feedstocks into a low-carbon/hydrogen-rich fuel gas, transmitting CO_2 for use in an EOR process, and utilizing the onsite generation of nitrogen for the production and manufacture of agricultural products might be a reasonable tradeoff between the loss in efficiency and the potential environmental and commercial benefits offered by HECA.

Mitsubishi MHI-501 GAC

The Mitsubishi MHI-501GAC machine has been in development and operation since 1997.[14] A full scale 250 MW demonstration facility employing the G Series model of this machine was brought up to full power in Nakaso, Japan in 2007 and has been operational since. The applicant would employ a one-on-one combined cycle plant using an MHI-501 GAC CTG coupled with a HRSG and an STG (HECA 2012a, AFC § 2.3, Table 2-14). The MHI-501GAC gas turbine represents a competitive and industry-proven machine, nominally rated at 404 MW and 59.2 percent efficiency LHV at ISO[15] conditions (GTW 2012).

Alternatives to the MHI-501GAC Combined Cycle Train

Staff compares in **Efficiency Table 4** alternative machines' ISO ratings as a common baseline, since project-specific ratings are not available for the alternative machines. Alternative machines that can meet the project's objectives are the GE 107FA combined cycle train with the 7FA frame CTG and the Siemens SCC-800H1S train, which are heavy duty 60 Hz gas turbine engines combined with a heat recovery steam generator with duct reheat.

The GE 107FA combined cycle system using a 7F frame in a one-on-one configuration is rated for 323 MW and 57.7 percent efficiency LHV (GTW 2012)

The Siemens SCC-800H1S combined cycle system utilizing an SGT6-800H CTG yields a nominal rating of 410 MW at 60.0 percent efficiency LHV at ISO conditions (GTW 2012).

Efficiency Table 4
Combined Cycle Comparison (Natural Gas Fuel)

Machine	Generating Capacity (MW)	ISO Efficiency (LHV)
Mitsubishi MPCP1 1 X M-501GAC	**404**[16]	**59.2 percent**
GE 107FA 1 X 7FA.05	323	57.7 percent
Siemens SCC-800H1S 1 X SGT6-800H	410	60.0 percent

While the Siemens power train enjoys a slight advantage in fuel efficiency over the applicant-selected power train, any differences among the three in actual operating efficiency would be relatively insignificant. Other factors such as generating capacity

[14] Modern Power Systems, May 1997, Vol. 17 Issue 5, pp. 31-334

[15] International Standards Organization (ISO) standard conditions are 15°C (59°F), 60 percent relative humidity, and one atmosphere of pressure (equivalent to sea level).

[16] ISO rated Net Plant Output: 2012 Gas Turbine World (GTW) Handbook, pg. 89.

and commercial availability are some of the factors considered in selecting the turbine model.

CUMULATIVE IMPACTS

No nearby projects have been identified that could potentially combine with HECA to create cumulative impacts on natural gas resources. Note that fuel-grade petcoke would be available from existing refineries in Southern California and plant demand would consume about 7 percent of the existing petcoke production within California (HECA 20 12a, §§ 2.1.11.2, 2.1.11.3); this would not likely create a significant adverse impact on the other petcoke customers. Also, there is abundant supply of coal in the country; the coal resources stretch from Montana to New Mexico in the west and from West Virginia to Pennsylvania in the east. Finally the PG&E natural gas supply system draws from extensive supplies originating in the Rocky Mountains, in the southwest, and in Canada.

Staff believes the project's fuel system is adequate to supply the HECA project without adversely impacting its other customers.

NOTEWORTHY PUBLIC BENEFITS

The applicant proposes to provide flexible baseline and intermediate electric power supply that provides a platform for support of ammonia products manufacture, transmission of compressed carbon dioxide for enhanced oil recovery and sequestration of a greenhouse gas, and gasification of its own primary fuel source.

DOE'S FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the applicant for HECA. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

CONCLUSIONS

Please note that for the project's rated power capacity, staff uses 405 MW in this section of the PSA/DEIS despite the 431 MW capacity rating used elsewhere in the PSA/DEIS. No information on the overall project heat rate and breakdown of auxiliary loads, based on the 431 MW figure, is available to staff at this point. Staff will need to prepare the FSA based on a corrected MW figure.

Based on the 405 MW figure, the combined cycle component of the project would generate a maximum net output of 158 MW using its primary fuel of hydrogen rich syngas produced from gasified coal and petroleum coke. The coal/coke/syngas fuel cycle would produce a net fuel efficiency of 22.8 percent (13.5 percent with the ASU power requirement included) at lower heating value (LHV). In backup mode, the combined cycle plant (without the gasifier) would produce a net output of 300 MW using its secondary fuel of 100 percent natural gas with a net 50.3 percent efficiency at LHV at maximum full load and annual design ambient conditions[17].

While the project would internally consume substantial amounts of energy, it would still produce electricity in a reasonably efficient manner while meeting the project objectives of demonstrating the viability of carbon capture and sequestration and the production of fertilizer products. The combined functions of processing the coal and petroleum coke feedstocks into a low-carbon/hydrogen-rich fuel gas, transmitting CO_2 for use in an EOR process, and utilizing the onsite generation of nitrogen for the production and manufacture of agricultural products should be taken into consideration when evaluating the project's efficiency impacts.

The project would not create significant adverse effects on energy supplies or resources, would not require additional sources of energy supply, and would not consume energy in a wasteful or inefficient manner. No energy standards apply to the project. Staff therefore concludes that the project would present no significant adverse impacts upon energy resources. No cumulative impacts on energy resources are likely.

OUTSTANDING INFORMATION REQUIRED FOR COMPLETION OF THE FSA/FEIS

1. Reconciliation of the 405 MW gross power generation originally submitted in the AFC and the 431 MW power level currently under discussion elsewhere in this document;
2. Update of the mass and energy balance for the *entire* project boundary that uses *all* contemporaneous conditions, including the enhanced oil recovery (EOR) field, air separation (ASU), and the introduction of calcium carbonate to the feedstock blend, based on the 431 MW rating.
3. Identification and description of the major power block components, including the gasifier, based on the 431 MW rating.

PROPOSED CONDITIONS OF CERTIFICATION

No conditions of certification are proposed.

POWER PLANT RELIABILITY

Edward Brady

SUMMARY OF CONCLUSIONS

Hydrogen Energy California LLC, the applicant, predicts an equivalent power block availability factor of at least 91.3 percent, which staff believes would be possible upon the successful completion of the requisite one-year pilot operation. The applicant has not yet: 1) demonstrated adequate reliability of the project's industrial water supply and 2) assigned availability to the gasification system and ancillary systems upon which the power block is dependent. Pending the determination of the adequacy of the project's industrial water supply and completion of analysis to determine the reliability of the gasification system, staff cannot conclude that the Hydrogen Energy California Project (HECA) would be built and operated in a manner consistent with industry norms for reliable operation. No conditions of certification are currently proposed.

INTRODUCTION

In this analysis, California Energy Commission (Energy Commission) staff (staff) addresses the reliability issues of the project to determine if the power plant would likely be built in accordance with typical industry norms for reliability of power generation. Staff uses this level of reliability as a benchmark because it ensures that the resulting project would likely not degrade the overall reliability of the electric system it serves (see "Setting" below).

The scope of this power plant reliability analysis covers:

- equipment availability;
- plant maintainability;
- fuel and water availability; and
- power plant reliability in relation to natural hazards.

Staff examined the project design criteria to determine if the project would be built in accordance with typical industry norms for reliability of power generation. While the applicant predicted an equivalent availability factor of at least 91.3 percent for HECA (see below), staff uses typical industry norms as a benchmark, rather than the applicant's projection, to evaluate the project's reliability.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

No federal, state, or local/county laws, ordinances, regulations, and standards (LORS) apply to the reliability of this project.

SETTING

In the restructured competitive electric power industry, the responsibility for maintaining system reliability falls largely to the state's control area operators, such as the California

Independent System Operator (California ISO), that purchase, dispatch, and sell electric power throughout the state. Determining how the California ISO and other control area operators would ensure system reliability has been an ongoing effort. Protocols that allow sufficient reliability to be maintained under the competitive market system have been developed and put in place. “Must-run” power purchase agreements and “participating generator” agreements are two mechanisms that have been employed to ensure an adequate supply of reliable power.

The California ISO’s mechanisms to ensure adequate power plant reliability apparently were devised under the assumption that the individual power plants that compete to sell power into the system will each exhibit a level of reliability similar to that of power plants of past decades. However, there has been valid cause to believe that, under free market competition, financial pressures on power plant owners to minimize capital outlays and maintenance expenditures may act to reduce the reliability of many power plants, both existing and newly constructed. It is possible that, if significant numbers of power plants were to exhibit individual reliability sufficiently lower than this historical level, the assumptions used by California ISO to ensure system reliability would prove invalid, with potentially disappointing results. Accordingly, staff has recommended that power plant owners continue to build and operate their projects to the level of reliability to which all in the industry are accustomed.

The applicant proposes to operate a 405 to 431 megawatt (MW) (nominal gross), Integrated Gasification Combined Cycle (IGCC) electric power plant as part of a manufacturing complex that would include conversion of coal and petroleum coke (petcoke) feedstock into fuel (syngas), fertilizer, and delivery of carbon dioxide (CO_2) gas to the Occidental Elk Hill Incorporated (OEHI) processing facility for use in enhanced oil recovery (EOR) and sequestration (HECA 2012a, AFC § 2.1). The power plant portion of the project is expected to achieve an availability factor of at least 91.3 percent (HECA 2012, Response to Data Request A-90, November 2012). From the information provided from the applicant, staff calculated the net capacity factor (NCF) at 83.1 percent[1].assessment of impacts.

ASSESSMENT OF IMPACTS

METHOD FOR DETERMINING RELIABILITY

The Energy Commission must make findings as to the manner in which the project would to be designed, sited, and operated to ensure safe and reliable operation (Title 20, CCR §1752[c]). Staff takes the approach that a project is acceptable if it does not degrade the reliability of the utility system to which it is connected. This is likely the case if the project exhibits reliability at least equal to that of other power plants on that system.

[1] Appendix A “Definitions” and Appendix B “Equations”, 2007-2011 General Availability Report (GAR), North American Electric Reliability Corporation (NERC), AFC 2012a, Table 2-10 “Representative Heat and Material Balances”. Based on 16-hour per operation day at net maximum power production, 8-hours per day and maximum ammonia production, 351 hours planned outage and start-up, 91.3 percent availability factor (AF).

The availability factor for a power plant is the percentage of the time that it is available to generate power; both planned and unplanned outages subtracted from its availability. Measures of power plant reliability are based on the plant's actual ability to generate power when it is considered available and are based on starting failures and unplanned or forced outages. For practical purposes, reliability can be considered a combination of these two industry measures, making a reliable power plant one that is available when called upon to operate. Power plant systems must be able to operate for extended periods without shutting down for maintenance or repairs. Achieving this reliability is accomplished by ensuring adequate levels of equipment availability, plant maintainability with scheduled maintenance outages, fuel and water availability, and resistance to natural hazards. Staff examines these factors for the project and compares them to industry norms. If they compare favorably, staff can conclude that HECA would be as reliable as other power plants on the electric system and will therefore not degrade system reliability (see below for analysis).

EQUIPMENT AVAILABILITY

HECA would be composed of functional blocks that define discrete functions. Where a conventional combined cycle constitutes a single block, an IGCC is comprised of multiple functions organized into individual blocks:

- Solid Fuel Handling Block,
- Air Separation Unit Block,
- Gasification Block,
- Power Block, and
- Manufacturing Block.

The solid fuel handling block provides for delivery, storage, conveyance and preparation of the coal and petcoke feedstocks. The air separation unit (ASU) provides for the distillation of air into nitrogen and oxygen. The gasification system provides for the conversion of feedstock into syngas hydrogen fuel, which includes gasification, acid gas removal (AGR), solids waste handling, and carbon dioxide capture and sequestration (CCS). The power block is composed of the combustion turbine generator (CTG), the heat recovery steam generator (HRSG), the steam turbine generator, and the electric power generator. Lastly, the manufacturing block provides for the processing and manufacture of various ammonia based fertilizer products.

The availability of each succeeding block is dependent on the reliability of each preceding block. Feedstock handling and the ASU feed into the gasification, which needs feedstock materials and oxygen from the ASU. The power block relies on the gasification system for fuel and an on-site source of ammonia from the ASU through the manufacturing complex. In turn, the manufacturing complex depends on nitrogen from the ASU and electricity from the power block.

Dependencies can be ameliorated by redundancies, back-up fuels, and operating strategies that demand stringent quality assurance practices and quality control for materials and equipment. Examples of these strategies include:

- Utilization of parallel components and control systems;
- Substitution of natural gas for primary hydrogen fuel;
- Substitution of site generated nitrogen and ammonia with off-site sources; and
- Maintenance of on-site raw fuel reserves.

The power block is dependent on the gasification block and other upstream feeders: solid fuel handling and the ASU. Dependency on the feedstock handling is relieved by maintaining on-site storage reserves and the assumption that it is a mature industrial process with relatively few untested system components. Dependency on the ammonia from the manufacturing process is relieved by the ability to purchase and deliver a substitute for on-site chemical processing. The ASU and gasification system, then, become the critically reliable upstream blocks to the power systems.

The availability factor of the power block is estimated by industry operating data called Generating Availability Data System (GADS), which is compiled by the North American Electric Reliability Corporation (NERC). NERC publishes annual statistics, including the metrics called availability factor (AF) and equivalent availability factor (EAF). The AF reflects the annual planned outages and the EAF includes unplanned as well as planned periods off line. For the NERC combined cycle gas data base, AF equals 89.09 percent. With unplanned outages factored in, the EAF equals 86.76 percent.[2]

The applicant has presented an EAF of 91.3 percent for the power block, which is based on the anticipated planned outages of two 1-week periods plus 15 hours of start-ups and shutdowns[3] totaling 351 hours. The applicant subsequently provided a detailed cold start sequence of 4 days duration. For two cold startups, the additional planned outage for these two events would be 192 hours, bringing the total planned outage to 543 hours or 91.3 percent EAF.[4] See **Reliability Table 1** below.

Reliability Table 1
Comparison to NERC/GADS Database

Description	Planned Outage (hrs)	Unplanned Outage (hrs)	Total Outage (hrs)	EAF
HECA CONDITIONS:				
Applicant's EAF: (1 – 0.913) x 8760			762	91.3%
Two Maintenance Outages: 2 x 7 x 24	336			
Ramping: 15-hour Allowance	15			
Two Cold Starts: 2 x 4 x 24	192			
Subtotal	543	219	762	91.3%
NERC GADS COMPARISON (NGCC):				
(AF – EAF): (0.8909-0.8676) x 8760 hrs	956	204	1160	86.76%

Natural Gas Combined Cycle (NGCC), General Availability System (GADS)

[2] NERC GADS 2007-2011 "Annual Unit Performance Statistics, Combined Cycle", All MW sizes dated 9/13/12.

[3] HECA 2012a, Response to CEC Nos. A1-A123 Data Requests for A90 and A91, pg. A90-1

[4] E-mail from Robert Middlemore/HECA to Edward Brady/CEC dated 2/26/13: HECA Cold Startup.

The applicant anticipates 219 unplanned outage hours annual and the NERC database reflects that the average unplanned hours would be 204. Staff would agree that a 91.3 percent EAF would be attainable for the operation of the HECA power block. Although the availability factor submitted by the applicant covers the power block, it does not address the reliability of the upstream processes upon which the power block depends. The balance of plant reliability, particularly the gasification system and ASU, needs to be evaluated in order to complete the picture of integrated plant reliability.

GASIFICATION AVAILABILITY

The gasification block and the ASU are critical elements in evaluating reliability of the power block. Common to IGCC systems, their availability is calculated separately from the power block availability. The performance and availability are important because the gasification block and ASU are critical to the performance of the power block.

Polk Power Station in Tampa, Florida is an IGCC commissioned in the mid-1990s. It has a combined cycle gross power output of 315 MW. The gasifier is a Texaco slurry fed, oxygen blown entrained gasifier similar to the MHI gasifier proposed for the HECA project. The gasifier required a 30-day planned outage every other year. Polk experienced two ASU incidents requiring two unplanned shutdowns. After two years of shakedown operation, the gasifier availability after reaching mature operation averaged 82.0 percent. Power block availability was approximately 90.2 percent,[5] providing a compound availability factor of 74 percent.

Wabash River Coal Gasification Repowering Project completed its demonstration period in 1999. It has a 262 MW combined cycle power block with an E-Gas (Conoco Philips) gasifier. The first year availability factor was 22 percent but progressively improved its performance up to 76.0 percent by the end of 1999. The power block availability averaged around 96.1 percent,[6] factoring to a combined plant availability of 73.0 percent.

The gasification train, the ASU, and the combined cycle power blocks for Polk and Wabash are similar to the HECA project. For the purpose of comparing HECA's availability factor to similar projects, staff assumes that the gasifier availability is independent from the CCS and the manufacturing block (Polk and Wabash do not have CCS or a manufacturing block). Under this assumption, the block availabilities for Polk and Wabash would roughly apply to HECA. Using the average of the availability factors for Polk Power and Wabash River, or 79.0 percent, the combined gasifier and power blocks for HECA would have an availability factor of 72.1 percent. See **Reliability Table 2** (**Comparison of Systems and Plant Availability**) for a comparison among the selected gasification plants and HECA.

Reliability Table 2 presents a combination of published and derived AFs, and assumes that the reliability of up-stream systems upon which the power block is dependent is reflected in the gasification block availability. There would be a one-year pilot operation for HECA, which would allow for a shakedown of various components. This would offer

[5] Final Technical Report (August, 2002) Tampa Electric Poll Power Station Integrated Gasification Combined Cycle Project.

[6] Final Technical Report (August, 2000) Wabash River Goal Gasification Repowering Project.

the opportunity to improve HECA's equivalent availability factor of 72.1 to perhaps a figure comparable to the NERC's.

Reliability Table 2[7]
Comparison of Systems and Plant Availability

Description	Gasification Block Availability	Power Block Availability	Combined Availability
HECA Kern County, California	79.0 %	91.3%	72.1 %
Polk Power Tampa FL	82.0 %	90.2 %	74.0 %
Wabash River W. TerreHaute, Indiana	76.0 %	96.1 %	73.0 %

For a discussion of the role of natural gas as a back-up and redundant fuel supply, refer to the **Fuel Availability** section below.

The HECA Gasifier

The HECA gasifier would be sized to handle 5,800 short tons of feedstock per day (stpd), producing a clean syngas with an energy content of 3,925 mmBtu HHV (3,326 mmBtu LHV). HECA would use a 2-stage entrained downflow gasifier. Ash in the combustor section would melt to form a slag layer on the gasifier membrane walls, "sliding" toward the bottom of the gasifier. This slag gets water quenched and removed to a waste hopper. The remaining combustor gases rise toward the reductor section. Additional dry-milled feedstock is mixed with the hot combustor gases. The resulting syngas exits the reductor section and is cooled as it passes through a steam generator. At this point, a cyclone separator collects the remaining char in the syngas and recycles it to the combustor section, mixing with new fuel to increase overall carbon conversion efficiency.

The MHI gasifier proposed for this project has been through the same kind of testing and operation as the MH-501 gas turbine. In the early 1980's Mitsubishi partnered with the Japanese government to develop a 2 ton per day gasifier, concluding the developmental testing with a 200 ton unit. In 2004, MHI constructed a demonstration plant in Nakaso, Japan, coupling a 1,700 ton gasifier with a 250 MW power facility. The plant commenced operation in 2007.

Equipment availability would further be ensured by use of appropriate quality assurance/quality control (QA/QC) programs during design, procurement, construction and operation of the plant and by providing for adequate maintenance and repair of the equipment and systems (discussed below).

Quality Control Program

The applicant describes a program of process safety design (HECA 2012a, AFC § 2.8), which is similar to the classic quality control program and typical of the industrial process and power industries. Equipment would be purchased from qualified suppliers

[7] NETL On-line Gasifipedia: Gasification Research and Development, "Increasing Availability".

based on technical and commercial evaluations. The project owner would perform receipt inspections, test components, and administer independent testing contracts. Staff expects implementation of this program to yield typical reliability of design and construction. To ensure such implementation, staff has proposed appropriate conditions of certification under the portion of this document entitled **Facility Design**.

PLANT MAINTAINABILITY

Equipment Redundancy and Equivalency

A generating facility called on to operate in base-load service for long periods of time must be capable of being maintained while operating. A typical approach for achieving this is to provide redundant examples of those pieces of equipment most likely to require service or repair. In the initial phases of start up and operation, the applicant plans to spend one year in off-line testing and cycle balancing of the production complex.[8]

The power block would consist of one CTG (combustion turbine generator), one HRSG (heat recovery steam generator), and a gasifier. Except for a temporary shutdown during the Fukushima tsunami event, the Mitsubishi M501 GAC CTG has been in continuous field operation at MHI facilities in Nakaso, Japan since its start-up in 2007.

Enhanced system features designed to improve plant reliability at HECA include:

- Natural gas auxiliary boiler sized to provide 150,000 pounds per hour of steam when steam is not available from the gasification block or the HRSG. (HECA 2012a, § 2.5.8).
- Maintenance of a minimum one month's inventory of feedstock products on site to minimize the risk of plant shutdown due to short-term interruption or delivery delays of feedstock products. The natural gas back-up serves multiple functions:
    - 100 percent fuel back-up for the hydrogen gas produced on-site.
    - Serve as a reliable fuel to stabilize and control the 4-day cold start-up.[9]
    - Fuel substitute while gasification system is off-line for planned maintenance.
- Applicant's plan to operate as a pilot plant for one year prior to availability commitment to California ISO.
- Direct CO_2 vent allowance of 504 hours in the event of a transmission pipe break or Enhanced Oil Recovery (EOR) service interruption.

Taking into account these considerations, upon the successful completion of the one-year pilot operation, HECA would very likely demonstrate a combined gasifier and power blocks availability factor of greater than 72.1 percent and perhaps to a figure that would be comparable to the NERC's figures.

---

[8] HECA 2012a AFC, § 2.9-2, p. 2-74

[9] Discussion on start-up sequencing with Robert Middlemore/Fluor, confirmed by e-mail dated 2/26/13.

Maintenance Program

The applicant proposes to establish a preventive plant maintenance program typical of industry practice (HECA 2012a, AFC §§ 2.3.2.1, 2.9.2). Equipment manufacturers provide maintenance recommendations with their products; the applicant would base its maintenance program on these recommendations. The applicant has programmed two one-week planned shutdowns annually, twice the manufacturer's requirements and extended the system start-up period to one full year. Maintenance outages would be planned for periods of low electricity demand. In light of these plans, staff expects that the project would be adequately maintained to ensure acceptable reliability.

LINEAR SYSTEMS AVAILABILITY

For any power plant, the long-term availability of fuel and of water for cooling or process use is necessary to ensure reliability. The need for reliable sources of fuel and water is obvious; lacking long-term availability of either source, the service life of the plant may be curtailed, threatening the supply of power as well as the economic viability of the plant.

Fuel Availability

HECA will burn syngas refined on the plant site from coal and petcoke fuel stocks. There would be a minimum one month's inventory of feedstock products on site in case of interruption in availability of feedstock. As a means of providing redundant fuel supply, natural gas will be piped thirteen (13) miles to an existing Pacific Gas & Electric (PG&E) natural gas pipe line located north of the project site (HECA 2012a, AFC § 2.7.1.10).

PG&E's natural gas supply system represents a resource of considerable capacity and offers access to adequate supplies of gas from the Rocky Mountains, Canada, and the Southwest. PG&E will own, operate and maintain the gas pipeline. Maintenance of the natural gas pipeline will follow PG&E corporate policies and protocols.

The high reliability of the natural gas virtually elevates its role in HECA from a back-up to redundant fuel system. It has the capability of making the planned and unplanned outages that are not caused by power block failures to be completely transparent from the viewpoint of the power grid. The benefits of natural gas to selectively reduce outages that require repair or replacement of non-power block systems and components would be tied to the flexibility provided for in the power purchase agreement (PPA) under which HECA negotiates with an available utility provider.

Staff agrees with the applicant's prediction that there would be adequate fuel supply and pipeline capacity to meet the project's needs.

Water Supply Reliability

The project would use water for plant service needs, cooling system makeup, combustion turbine injection, combustion turbine evaporative cooling makeup, and secondary fire protection and other processes. This water would be supplied by Buena Vista Water Storage District (BVWSD) (HECA 2012a, AFC § 2.7.1.10) using brackish water from a well field and pipeline system, which would be owned by BVWSD. The process water pipeline route would run approximately 15 miles from Seventh Standard Road to the HECA site, along the existing BVWSD road on the northwest side of West Side Canal.

Under the present system design, the industrial water supply requirements for HECA would be 7416 acre-feet per year (afy) which would come from existing aquifers under the jurisdiction of BVWSD. Currently the water system modeling indicates that drawdown of some of the wells will have an effect on water quality. Staff cannot verify that the use of the proposed groundwater satisfies state and Energy Commission policies regarding the use and conservation of water resources (see the **Water Supply** section of this document). Since staff is relying on the applicant to consider or implement recommendations proposed in the **Water Supply** section of this document, staff will continue to consider this irresolution a significant impact until water system modeling could demonstrate otherwise.

Carbon Dioxide (CO_2) Pipeline and EOR Reliability

A CO_2 pipeline will be constructed to transfer the carbon dioxide produced by HECA to the Occidental Elk Hills Incorporated (OEHI) CO_2 processing facility for injection into deep underground hydrocarbon reservoirs for EOR (HECA 2012a, AFC § 2.7.1.10). The CO_2 pipelines will run three miles from the southwestern portion of the HECA project site, using horizontal directional drilling (HDD) to pass under the Outlet Canal, the Kern Valley Flood Control Chanel, and the California Aqueduct. From the south side of the aqueduct, the route extends southeast and south to the OEHI Processing Facility.

In the event that a pipeline break or an unplanned interruption of gas injection at the EOR field, an allowance has been made to atmospherically discharge CO_2 laden combustion gases from the CTG through the HRSG exhaust stack for an aggregate period of approximately 500 hours per year.[10] For this reason, temporary failure or downgrade of the carbon sequestration system is accommodated without interrupting electric power generation. See **Air Quality Table 5** for further description of the discharge air allowances.

POWER PLANT RELIABILITY IN RELATION TO NATURAL HAZARDS

Natural forces can threaten the reliable operation of a power plant. High winds, tsunamis (tidal waves), seiches (waves in inland bodies of water), and flooding would not likely represent a hazard for this project, but seismic shaking (earthquake) may present a credible threat to reliable operation.

Seismic Shaking

The HECA site and off-site linears (natural gas, water and CO_2 pipeline) are susceptible to ground shaking generated during earthquakes on nearby faults (HECA 2012a, AFC § 5.15.1.5). The site lies within the seismically active Southern California. Naturally occurring seismic events on the order of magnitude 6 and smaller, even if located in the

[10] Air quality analysis has been based on an annual allowance of 504 hours direct atmospheric discharge of carbon dioxide in the first year of pilot operation. Although the estimates for subsequent years are 120 hours for the life of the plant, the 504 hour allowance has been retained as the qualification basis.

immediate area of the field, should not cause significant damage to HECA or wells in the Elk Hills Oil Field (HECA 2012, AFC § 5.15.1). See “Faulting and Seismicity” portion of the **Geology and Paleontology** section of this document**.** Compliance with current seismic design LORS represents an upgrading of performance during seismic shaking compared to older facilities since these LORS have been continually upgraded. Because it would be built to the latest seismic design LORS, this project would likely perform at least as well as, and perhaps better than, existing plants in the electric power system. Staff has proposed conditions of certification to ensure this; see the section of this document entitled **Facility Design**. In light of the general historical performance of California power plants and the electrical system in seismic events, staff has no special concerns with the power plant’s functional reliability during earthquakes.

Flooding

The ground level elevation of the HECA site is at an elevation of approximately 188.5 feet above mean sea level (MSL). According to the Federal Emergency Management Agency (FEMA) Flood Insurance Rate Maps (FIRM), the site is not located in an area identified as having flood hazards or shallow groundwater (FEMA 2008; HECA 2012a, AFC § 5.14.1.3). According to Kern County General Plan Safety Element Fig. 14, the HECA site is not in an area identified as having flood hazards or shallow ground water (HECA 2012a, AFC § 5.15.1.5). The CO_2 pipeline extending to the south of the HECA site will cross a flood hazard zone associated with the Kern River Flood Control Canal. With proper plant design (ensured by adherence to the proposed **Facility Design** conditions of certification), staff believes there are no concerns with power plant functional reliability due to flooding. For further discussion, see **Soil and Water Resources** and **Geology and Paleontology**.

COMPARISON WITH EXISTING FACILITIES

Industry statistics for availability factors (as well as many other related reliability data) are kept by the North American Electric Reliability Corporation (NERC). NERC continually polls utility companies throughout the North American continent on project reliability data through its Generating Availability Data System (GADS) and periodically summarizes and publishes the statistics on the Internet [http://www.nerc.com]. NERC reports an equivalent availability factor of 86.7 percent as the generating unit average figure for the years 2007 through 2011 for natural gas-fired combined cycle systems (All MW sizes) (NERC 2012).

The model of gas turbine that would be employed in the HECA project, the M501GAC model, has been on the market for several years and can be expected to exhibit typically high availability. The G-series combustion gas turbine has been in full operational testing in Nakaso, Japan since 2007 and has reached the 5,000 hour milestone for continuous duty. In addition, MHI is building a 540 MW coal gasification facility with carbon capture in Queensland, Australia’s Zero Gen Project. Confident in the developmental testing, the owner/operator has bypassed the pilot phase of the project and proceeded directly to commercial-scale operation.

The applicant’s prediction of an annual availability factor of at least 91.3 percent for the CTG/HRSG power block alone (HECA 2012, Response to DR-90) appears reasonable, compared to the NERC figure for similar power blocks throughout North America (see above). But, the combined gasifer and power block availability factor of 72.1 percent seems too low to achieve 8,000 hours (91.3 percent) of operation. However, upon the successful completion of the one year pilot operation, 8,000 hours of power block operation may be possible. In light of the Mitsubishi's operating and testing plan prior to commercial offering, the one-on-one combined cycle facility proposed by the applicant can be expected to outperform the fleet of various (mostly older) gas turbines that make up the NERC statistics. The applicant has opted to run and test the HECA project for a full year before initiating commercial use. In addition, they have doubled the recommended planned maintenance outages from the amount recommended by Mitsubishi. Within this period of pilot operation, observation and testing would include:

- Performance monitoring of MHI's dry-bed entrainment gasifier at the selected feedstock blend.
- Refinement of cold-start procedures for ramping up to full power operation.
- Accumulation of commercial-level operating experience prior to commitment of availability to California ISO.
- Assessment of system characteristics when shifting daily between maximized ammonia plant operation and maximized electrical power generation.
- Verification of overall projected plant availability factors.

Taking into account the benefits, knowledge and experience garnered from the one-year pilot operation, the applicant's estimate of plant availability, therefore, appears reasonable. The stated procedures for assuring design, procurement, and construction of a reliable power plant appear to be in keeping with industry norms, and staff believes they are likely to yield an adequately reliable plant.

NOTEWORTHY PROJECT BENEFITS

The benefit of this project, as related to power plant reliability, should be that HECA not degrade the overall reliability of the electric system it serves. Staff cannot make a conclusion in this regard until it can determine the adequacy of the project's industrial water supply and the reliability of the gasification system to which the power block would depend on.

CONCLUSIONS

The staff's major focus is the reliability of the systems necessary to provide electric power to the grid. All of the systems, blocks and elements of HECA, whose function contribute to this function and purpose, constitute the areas of review. They are the power block and the gasification system, including the air separation unit.

The applicant has provided an availability factor of 91.3 percent, which only reflects the design and operational elements of the power block. The predicted availability factor for the combined gasifier and power blocks is 72.1 percent prior to the one-year pilot operation. HECA would have the opportunity to improve this availability factor to a greater than 72.1 percent figure, to perhaps a figure that would be comparable to the NERC's statistics. The countermanding conditions to this availability level are 1) the incorporation of natural gas as a readily available back up fuel; 2) the implementation of a one-year commissioning shakedown after construction is complete and before commercial operation commences; and 3) the study and development of Mitsubishi's IGCC (integrated generation /combined cycle) demonstration project that commenced in 2007 and includes analysis and review of CCS (carbon capture and sequestration).

Staff considers the issue of water supply pumping, which draws down some aquifers and affects water quality, has a potentially significant impact on the reliability of the facility's industrial water supply. Staff reserves an opinion on this impact until the applicant has the opportunity to undertake a more extensive modeling and review of the aquifers that are under consideration and potentially available for this project, and evaluate alternative water use efficiency technologies.

Pending the determination of the adequacy of the project's industrial water supply and completion of analysis to determine the reliability of the gasification systems, staff cannot conclude that the Hydrogen Energy California Project (HECA) would be built and operated in a manner consistent with industry norms for reliable operation. No conditions of certification are currently proposed.

OUTSTANDING INFORMATION REQUIRED FOR COMPLETION OF THE FSA/FEIS

The applicant has failed to assign an AF (availability factor) to the gasification system and ancillary systems upon which the power block is dependent. The applicant needs to assign this AF, demonstrate how it was derived, and explain how it affects the 91.3 percent AF assigned to the power block.

PROPOSED CONDITIONS OF CERTIFICATION

No conditions of certification are proposed.

HECA 2012a – Hydrogen California LLC, 08-AFC-8A. Amended Application for Certification, Volumes 1, 2, and 3 dated May 02, 2012. Submitted to CEC/Docket Unit on May 02, 2012.

NERC (North American Electric Reliability Council). 2012. 2007–2011 Generating Availability Report.

TRANSMISSION SYSTEM ENGINEERING

Sudath Edirisuriya and Mark Hesters

SUMMARY OF CONCLUSIONS

The proposed Hydrogen Energy California Project (HECA) outlet lines and termination are acceptable and would comply with all applicable laws, ordinances, regulations, and standards (LORS). No additional new transmission facilities that would require a California Environmental Quality Act (CEQA) review other than those proposed by the applicant are needed for the interconnection of the HECA project.

- A new offsite breaker and-a-half, 230kV, 63kA PG&E switchyard and 2.8 miles long generator tie line would be required to interconnect the HECA project to the California ISO grid. The new switchyard would be constructed by PG&E and is considered part of the HECA project.
- The Transition Cluster Phase I Interconnection Study Report (Phase I Study) indicated that the project contributes to South of Vincent flow Area Deliverability constraints. The recommended mitigation of the voltage instability would require upgrades in the SCE Mesa 500kV system. These upgrades would be done within the fence line of the existing Mesa substation.
- The installation of a new fiber optic line from the HECA switching station to the Midway Substation may necessitate CEQA analysis. The proposed 8.5 mile long fiber optic line will be constructed within the PG&E right-of-way by using the existing 230kV Transmission towers.

The Transition Cluster Phase II Interconnection Study Report (Phase II Study) for the HECA is scheduled to be issued by early July, 2013. Staff expects to analyze the Phase II Study to determine the downstream distribution impacts and any required mitigation.

STAFF ANALYSIS

The Transmission System Engineering (TSE) analysis examines whether or not the facilities associated with the proposed interconnection conform to all applicable LORS required for safe and reliable electric power transmission. Additionally, under CEQA, the Energy Commission must conduct an environmental review of the “whole of the action,” which may include facilities not licensed by the Energy Commission (California Code of Regulations, title 14, §15378). Therefore, the Energy Commission must identify the system impacts and necessary new or modified transmission facilities downstream of the proposed interconnection that are required for interconnection and represent a “connected action”.

Commission staffs rely on the interconnecting authority for the analysis of impacts on the transmission grid as well as the identification and approval of required new or modified facilities downstream from the proposed interconnection required as mitigation measures. The proposed HECA would connect to the Pacific Gas and Electric (PG&E)

230kV transmission network and requires the Phase II Study analysis by PG&E and approval of the California Independent System Operator (California ISO).

PACIFIC GAS & ELECTRIC'S ROLE

PG&E is responsible for ensuring electric system reliability in the PG&E system for addition of the proposed generating plant. PG&E will provide the analysis and reports in the upcoming Phase II Study for its Group 5 projects, along with approval of the facilities and changes required in the PG&E system for addition of the proposed transmission modifications.

CALIFORNIA ISO'S ROLE

The California ISO is responsible for ensuring electric system reliability for all participating transmission owners and is also responsible for developing the standards necessary to achieve system reliability. The California ISO is responsible for completing the studies of the PG&E system to ensure adequacy of the proposed transmission interconnection. The California ISO will determine the reliability impacts of the proposed transmission modifications on the PG&E transmission system in accordance with all applicable reliability criteria. According to the California ISO Tariff, the California ISO will determine the "Need" for transmission additions or upgrades downstream from the interconnection point to ensure reliability of the transmission grid. The California ISO will, therefore, review the Phase I Study performed by PG&E and/or any third party and will provide their analysis, conclusions and recommendations. Upon completion of the PG&E Phase II Study based on the expected September-2017 commercial operation date (COD), or current COD, the California ISO would execute a Large Generator Interconnection Agreement (LGIA) with the project owner. If necessary, the California ISO may provide written and verbal testimony on their findings at the Energy Commission hearings.

Laws, Ordinances, Regulations and Standards

- North American Electric Reliability Council (NERC) Planning Standards provide policies, standards, principles and guides to assure the adequacy and security of the electric transmission system. With regard to power flow and stability simulations, these planning standards are similar to WECC criteria for Transmission System Contingency Performance. The NERC planning standards provide for acceptable system performance under normal and contingency conditions. The NERC planning standards apply not only to interconnected system operation but also to individual service areas (NERC 1998).
- Western Electric Coordinating Council (WECC) Reliability Criteria provide the performance standards used in assessing the reliability of the interconnected system. These reliability criteria require the continuity of service to loads as the first priority and preservation of interconnected operation as a secondary priority. The WECC Reliability Criteria include the Reliability Criteria for Transmission System Planning, Power Supply Design Criteria, and Minimum Operating Reliability Criteria. Analysis of the WECC system is based to a large degree on WECC Section 4 "Criteria for Transmission System Contingency Performance" which requires that the results of power flow and stability simulations verify established performance levels.

Performance levels are defined by specifying the allowable variations in voltage, frequency and loading that may occur on systems other than the one in which a disturbance originated. Levels of performance range from no significant adverse effect outside a system area during a minor disturbance (loss of load or facility loading outside emergency limits) to a performance level that only seeks to prevent system cascading and the subsequent blackout of islanded areas. While controlled loss of generation, load, or system separation is permitted in extreme circumstances, their uncontrolled loss is not permitted (WECC 1998).

- California Public Utilities Commission (CPUC) General Order 95 (GO-95), "Rules for Overhead Electric Line Construction," formulates uniform requirements for construction of overhead lines. Compliance with this order ensures adequate service and safety to persons engaged in the construction, maintenance, operation, or use of overhead electric lines and to the public in general.
- California Public Utilities Commission (CPUC) General Order 128 (GO-128), "Rules for Underground Electric Line Construction," formulates uniform requirements for construction of underground lines. Compliance with this order ensures adequate service and safety to persons engaged in the construction, maintenance, operation, or use of underground electric lines and to the public in general.
- National Electric Safety Code 1999 provides electrical requirements for overhead and underground electric line construction and design.
- California ISO's Reliability Criteria also provide policies, standards, principles, and guides to assure the adequacy and security of the electric transmission system. With regard to power flow and stability simulations, these planning standards are similar to WECC Criteria for Transmission System Contingency Performance and the NERC Planning Standards. The California ISO Reliability Criteria incorporate the WECC Criteria and NERC Planning Standards. However, the California ISO Reliability Criteria also provide some additional requirements that are not found in the WECC Criteria or the NERC Planning Standards. The California ISO Reliability Criteria apply to all existing and proposed facilities interconnecting to the California ISO controlled grid. It also applies when there are any impacts to the California ISO grid due to facilities interconnecting to adjacent controlled grids not operated by the California ISO.

PROJECT DESCRIPTION

The applicant has proposed to interconnect the 300 MW (net) Hydrogen Energy California Project (HECA project) to a proposed PG&E 230kV switching station via 230kV single circuit. The 230kV switching station would be constructed solely for the interconnection of the HECA project. The HECA project would consist of one hydrogen-fueled gas/steam turbine single shaft generator (GTG-STG rated at 405 MW). The generator auxiliary load would be 105 MW resulting in a maximum net output of 300 MW at an 90 percent power factor. The GTG-STG generator would be connected to the low side of its generator step-up transformer through a gas insulated (SF6) breaker and a disconnect switch. The step-up transformer for the GTG-STG unit would be rated at 21/230 kV and 270/360/450 MVA and the high side of the step up transformer would be connected to the HECA project switching station via 2000 Amps disconnect switch and a breaker.

Generator Interconnection facilities:

The HECA project onsite switching station consist of PG&E revenue metering equipment and other switching gear to allow delivery of project output to the proposed PG&E 230kV switching station. The HECA project would interconnect to the PG&E 230kV switching station via a 230kV, single circuit (generator-tie-line) at the Olean Avenue and Elk Valley road intersection. The generator-tie line route leaves the project site east to Tupman road, continuing north to near Adohr road, then east to the new PG&E switching station. The generator tie line would be approximately 2.8 miles long, using 15 off site and 11 onsite single shaft galvanized 230kV tubular-steel structures. The proposed single three phase circuit will use 1272 kcmil ACSR conductor which is capable of carrying the full output of the project. The switching station would be built with 230kV bus work to facilitate eight circuit breakers, three bays with breaker and half configuration with six line positions. The line positions would be used to terminate the generator tie line of the HECA, a PG&E feeder to an ASU unit and four for the loop in of the Midway –Wheeler Ridge double circuit 230kV line (one position for each circuit as it enters and one as it leaves the switching station). Looping in the Midway - Wheeler Ridge double circuit line to the proposed switchyard would require the removal of two existing 230kV towers and the installation of two new dead end structures.

The applicant proposes to use the 230kV structures to support another 230kV single circuit which would enable them to import power into the onsite Air Separation Unit (ASU) from the PG&E grid. The proposed 100MW ASU unit is part of the project, but consumes power directly from the PG&E grid. (HECA 2012b, sections 2.1.12.1, 2.7.1.10 and Figures 2- 12 and 2-21 to 2-27)

Telecommunication Interconnection facilities:

In order to insure the reliability of the transmission grid after the interconnection of the HECA project, the installation of a new fiber optic line from the interconnection switching station to the Midway Substation would be required. The proposed 8.5 mile long fiber optic line will be constructed within the PG&E right-of-way using the existing 230kV transmission towers.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

For the interconnection of a proposed generating unit or transmission facility to the grid, the interconnecting utility and the control area operator are responsible for ensuring grid reliability. For the HECA, PG&E and the California ISO are responsible for ensuring grid reliability.

The California ISO’s generator interconnection study process is in transition from a serial process to an interconnection window cluster study process. The HECA was studied under the cluster process and the transmission reliability impacts of the proposed project are studied in the Phase I and Phase II Studies. The Phase I Study is similar to the former System Impact Study except it is now performed for a group of projects in the same geographical area of a utility that apply for interconnection in the same request window. The Phase II Study is performed after generators in each cluster meet specific milestones required to stay in the generator interconnection queue. The Phase II Study is then performed based on the number of generators left in each cluster.

The Phase I Study for projects in the transition cluster was conducted to determine the preferred and alternative generator interconnection methods and to identify any mitigation measures required to ensure system conformance with utility reliability criteria, NERC planning standards, WECC reliability criteria, and California ISO reliability criteria. Staff relies on the studies and any review conducted by the responsible agencies to determine the effect of the projects on the transmission grid and to identify any necessary downstream facilities or indirect project impacts required to bring the transmission network into compliance with applicable reliability standards (NERC2006, WECC 2006, California ISO 2002a, 2007a & 2009a).

The Phase I Study analyzes the grid with and without the generator or generators in a cluster under conditions specified in the planning standards and reliability criteria. The standards and criteria define the assumptions used in the study and establish the thresholds by which grid reliability is determined. The studies must analyze the impact of the projects for their proposed first year(s) of operation and thus are based on a forecast of loads, generation and transmission. Load forecasts are developed by the interconnected utility, which would be PG&E in this case. Generation and transmission forecasts are based on the interconnection queue. The studies are focused on thermal overloads, voltage deviations, system stability (excessive oscillations in generators and transmission system, voltage collapse, loss of loads or cascading outages), short circuit duties and substation evaluation

Under the new California ISO LGIP, generators are able to choose between either “full capacity” or “energy only” depending on whether or not the generator wants to have the right to generate energy 24-hours per day. A generator that chooses the full capacity option will be required to pay for transmission network upgrades that are needed to allow the generator to operate under virtually any system conditions and as such could sign contracts that allowed them to provide capacity to utilities. Energy only generators would not pay for network transmission upgrades, and essentially would have access to as available transmission capacity, and would likely not be able to sign capacity contracts.

If the studies show that the interconnection of the project or cluster of projects causes the grid to be out of compliance with reliability standards, the study will then identify mitigation alternatives or ways in which the grid could be brought into compliance with reliability standards. If the interconnecting utility determines that the only feasible mitigation includes transmission modifications or additions which require CEQA review as part of the “whole of the action,” the Energy Commission must analyze those modifications or additions according to CEQA requirements. Where the Phase I Study identifies transmission modifications required for the reliable interconnection of a cluster of generators, staff will analyze the proposed generating project’s impact on individual reliability criteria violations to determine whether or not the identified mitigation measures are a reasonably foreseeable consequence of the proposed project.

SCOPE OF INTERCONNECTION STUDY:

The queue cluster 5 (QC5) phase one interconnection study was performed by PG&E in coordination with California ISO to identify the transmission impacts caused by the cluster 5 projects on PG&E's 115/230/500-kV system. The study included 23 cluster 5 generation projects; four were PG&E Wholesale Distribution Tariff generation projects that are seeking full capacity deliverability status. Three general groups were formed based on the electrical impacts among the generation projects; Fresno, Kern and North Groups.

The Kern Group study report provides the impacts caused by the addition of QC5 phase one projects requesting interconnection in the Kern Group. Nine generation projects totaling a maximum output of 522.5 MW were included in the QC5 phase 1 Kern group study. In addition, the study included a number of transmission upgrades needed to support load growth and queued ahead generation projects in PG&E's Kern group area that were modeled in order to determine if additional facilities would be needed to support the QC5 Kern group. The base cases were developed to represent stressed scenarios of loading and generation conditions for the study group area, based on a 2016 load forecast. The power flow analyses were performed using PG&E's 2016 Summer Peak and Summer off Peak Full Loop Power Flow cases. The power flow cases modeled all California ISO approved PG&E transmission projects, regardless of their proposed in-service date. These base cases included all California ISO approved higher queued serial group, transition cluster QC5 generation projects with associated network upgrades and Special Protection Systems. The study included Deliverability Assessment, Reliability Network Assessment, Power Flow Analysis, Short Circuit Analysis, Reactive Power Deficiency Analysis and Transient and Post Transient Stability Analysis. The detailed study assumptions are described in the study.

TRANSITION CLUSTER STUDY RESULTS:

Detailed results of the Transitional Cluster Study are below. Where potential overloads are identified, mitigation is proposed that would eliminate the potential impact to reliability. Based on the information in the Phase I study, the HECA appears to be responsible for few of the impacts that are identified for the cluster, due to the HECA interconnection at the proposed switching station. Staff expects that the applicant will submit the complete phase II study with appendices to finalize the mitigation measures in time for it to be included in the the Final Staff Assessment (FSA).

Deliverability Assessment study results:

The study indicated that the project contributes to the South of Vincent flow deliverability constraints. The South of Vincent flow limit has been identified as driven by the voltage instability following an outage of the Lugo- Vincent 500kV number 1 and 2 circuits. It is an area deliverability constraint which impacts deliverability of generation north of Vincent. Therefore to improve the South of Vincent transfer capability network upgrades would be required.

> Mitigation: Upgrades to Southern California Edison's (SCE) Mesa area 500kV system and distribution upgrades to support the Mesa area 500kV system.

Reliability Assessment study results:

The reliability analysis was performed on power flow cases that include all energy-only and full capacity projects dispatched to maximum values for each power flow case. Energy-only projects dispatched to maximum values for each power flow case. Energy-Only projects often do not have transmission capacity upgrades and rely upon California ISO Congestion Management to manage thermal loading in the transmission system.

> The reliability analysis did not indicate that the HECA project contributes criteria violations that result in the need for downstream reliability network upgrades.

Local Delivery Network study results:

The project did not cause any thermal overloads or instability of the local delivery network.

> Therefore, HECA project is not responsible for any local delivery network upgrades.

Area Delivery Network study results:

The study indicated that the project contributes to the South of Vincent flow Area deliverability constrains. To improve the South of Vincent transfer capability the proposed area delivery network upgrades would be required.

> Mitigation: The recommended mitigation for this voltage instability are SCE Mesa area 500kV system upgrades and SCE Distribution upgrades to support the Mesa area 500kV system.

Steady State and Post-Transient Voltage Stability Assessment study results:

Thermal overloads occurring after modeling all delivery network upgrades are mitigated by congestion management in both pre- and post-project cases. There were no voltage or reactive power deficiencies identified in the reliability analysis for the Kern group.

Transient Stability Analysis results:

Stable and adequately damped transient stability performances were achieved following all of the outages simulated using both the pre-and post-cluster summer peak full loop base cases. The power flow studies of N-1 and N-2 contingencies showed that the project would not cause voltage drops of 5 percent or more from the pre-project levels or cause the PG&E system to fail to meet applicable voltage criteria. No transient frequency criteria violations were observed for all the contingencies simulated. The transient stability study projected that the transmission system's performance relative to the applicable reliability guidelines would not be adversely affected by the Phase I projects due to selected disturbances. A worst condition analysis for the outages did not result in any voltage or frequency violations by the project. Therefore no additional network upgrades are required due to the project.

Short Circuit Study Results:

Short circuit studies were performed to determine the degree to which the addition of Phase I projects would increase fault duties at PG&E's substations, adjacent utility substations, and the other 115 kV, 230 kV and 500 kV busses within the study area. For the buses at which faults were simulated, the maximum three-phase and single-line-to-ground fault currents, both with and without the project, and information on the breaker duties at each location, are summarized in Appendix H, short circuit study results, of the Phase I study report. The short circuit duty assessment found that the addition of Cluster 5 projects in the PG&E Kern group did not result any short circuit duty violations on the system.

COMPLIANCE WITH LORS

The Phase I study indicates that the project interconnection would comply with NERC/WECC planning standards and California ISO reliability criteria. The applicant would design, build and operate the proposed 230 kV HECA switchyard and overhead generator transmission lines. The proposed 230kV PG&E substation would be designed and built by the applicant, but would be turned over to PG&E for operation. Staff concludes that assuming the proposed conditions of certification are met; the project would meet the requirements and standards of all applicable LORS.

DOE'S FINDINGS REGARDING DIRECT AND INDIRECT IMPACTS OF THE NO-ACTION ALTERNATIVE

Under the No-Action Alternative, DOE would not provide financial assistance to the applicant for HECA. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No-Action Alternative. Accordingly, the No-Action Alternative would have no impacts associated with this resource area.

CONCLUSIONS

The proposed Hydrogen Energy California Project outlet lines and termination are acceptable and would comply with all applicable laws, ordinances, regulations, and standards (LORS). No additional new transmission facilities that would require a CEQA review other than those proposed by the applicant are needed for the interconnection of the HECA project.

- A new offsite breaker and-a-half, 230kV, 63kA switchyard and 2.8 mile long generator tie line would be required to interconnect the HECA project to the California ISO grid. The new switchyard would be constructed by PG&E and is considered part of the HECA project.
- The Transition Cluster Phase I Interconnection Study indicated that the project would contribute to South of Vincent flow Area Deliverability constraints. The recommended mitigation of the voltage instability would require SCE Mesa area 500kV system upgrades. These upgrades would be done within the existing Mesa substation and would not trigger CEQA.
- The installation of a new fiber optic line from the HECA switching station to the Midway Substation may necessitate CEQA analysis. The proposed 8.5 mile long

fiber optic line will be constructed within the PG&E right-of-way by using existing 230kV Transmission towers.

RECOMMENDATIONS

If the Commission approves the project, staff recommends the following conditions of certification to insure system reliability and conformance with LORS.

CONDITIONS OF CERTIFICATION FOR TSE

TSE-1 The project owner shall furnish to the CPM and to the CBO a schedule of transmission facility design submittals, a Master Drawing List, a Master Specifications List, and a Major Equipment and Structure List. The schedule shall contain a description and list of proposed submittal packages for design, calculations, and specifications for major structures and equipment. To facilitate audits by Energy Commission staff, the project owner shall provide designated packages to the CPM when requested.

<u>Verification:</u> At least 60 days (or a lesser number of days mutually agreed to by the project owner and the CBO) prior to the start of transmission facility construction, the project owner shall submit the schedule, a Master Drawing List, and a Master Specifications List to the CBO and to the CPM. The schedule shall contain a description and list of proposed submittal packages for design, calculations, and specifications for major structures and equipment (see a list of major equipment in **Table 1: Major Equipment List** below). Additions and deletions shall be made to the table only with CPM and CBO approval. The project owner shall provide schedule updates in the Monthly Compliance Report (MCR).

Table 1: Major Equipment List

Breakers
Step-up Transformer
Switchyard
Busses
Surge Arrestors
Disconnects
Take off facilities
Electrical Control Building
Switchyard Control Building
Transmission Pole/Tower
Grounding System

TSE-2 Prior to the start of transmission facility construction, the project owner shall assign an electrical engineer and at least one of each of the following to the project: A) a civil engineer; B) a geotechnical engineer or a civil engineer experienced and knowledgeable in the practice of soils engineering; C) a design engineer, who is either a structural engineer or a civil engineer fully competent and proficient in the design of power plant structures and equipment supports; or D) a mechanical engineer. (Business and Professions Code Sections 6704 et seq. require state registration to practice as a civil engineer or structural engineer in California.)

The tasks performed by the civil, mechanical, electrical or design engineers may be divided between two or more engineers, as long as each engineer is responsible for a particular segment of the project (e.g., proposed earthwork, civil structures, power plant structures, equipment support). No segment of the project shall have more than one responsible engineer. The transmission line may be the responsibility of a separate California registered electrical engineer. The civil, geotechnical or civil and design engineer assigned in conformance with Facility Design condition **GEN-5**, may be responsible for design and review of the TSE facilities.

The project owner shall submit to the CBO for review and approval, the names, qualifications and registration numbers of all engineers assigned to the project. If any one of the designated engineers is subsequently reassigned or replaced, the project owner shall submit the name, qualifications and registration number of the newly assigned engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer. This engineer shall be authorized to halt earthwork and to require changes; if site conditions are unsafe or do not conform with predicted conditions used as a basis for design of earthwork or foundations.

The electrical engineer shall:

1. Be responsible for the electrical design of the power plant switchyard, outlet and termination facilities; and
2. Sign and stamp electrical design drawings, plans, specifications, and calculations.

<u>Verification:</u> At least 30 days (or a lesser number of days mutually agreed to by the project owner and the CBO) prior to the start of rough grading, the project owner shall submit to the CBO for review and approval, the names, qualifications and registration numbers of all the responsible engineers assigned to the project. The project owner shall notify the CPM of the CBO's approvals of the engineers within five days of the approval.

If the designated responsible engineer is subsequently reassigned or replaced, the project owner has five days in which to submit the name, qualifications, and registration number of the newly assigned engineer to the CBO for review and approval. The project owner shall notify the CPM of the CBO's approval of the new engineer within five days of the approval. [3/12/03]

TSE-3 If any discrepancy in design and/or construction is discovered in any engineering work that has undergone CBO design review and approval, the project owner shall document the discrepancy and recommend corrective action. (1998 CBC, Chapter 1, Section 108.4, Approval Required; Chapter 17, Section 1701.3, Duties and Responsibilities of the Special Inspector; Appendix Chapter 33, Section 3317.7, Notification of Noncompliance]. The discrepancy documentation shall become a controlled document and shall be submitted to the CBO for review and approval and shall reference this condition of certification.

__Verification:__ The project owner shall submit a copy of the CBO's approval or disapproval of any corrective action taken to resolve a discrepancy to the CPM within 15 days of receipt. If disapproved, the project owner shall advise the CPM, within five days, the reason for disapproval, and the revised corrective action required obtaining the CBO's approval.

TSE-4 For the power plant switchyard, outlet line and termination, the project owner shall not begin any increment of construction until plans for that increment have been approved by the CBO. These plans, together with design changes and design change notices, shall remain on the site for one year after completion of construction. The project owner shall request that the CBO inspect the installation to ensure compliance with the requirements of applicable LORS. The following activities shall be reported in the MCR:

a) receipt or delay of major electrical equipment;

b) testing or energization of major electrical equipment; and

c) the number of electrical drawings approved, submitted for approval, and still to be submitted.

__Verification:__ At least 30 days (or a lesser number of days mutually agreed to by the project owner and the CBO) prior to the start of each increment of construction, the project owner shall submit to the CBO for review and approval the final design plans, specifications and calculations for equipment and systems of the power plant switchyard, outlet line and termination, including a copy of the signed and stamped statement from the responsible electrical engineer attesting to compliance with the applicable LORS, and send the CPM a copy of the transmittal letter in the next Monthly Compliance Report.

TSE-5 The project owner shall ensure that the design, construction and operation of the proposed transmission facilities will conform to all applicable LORS, including the requirements listed below. The project owner shall submit the required number of copies of the design drawings and calculations as determined by the CBO.

a) HECA will be interconnected to PG&E grid via a 230 kV, 1272 kcmil ACSR per phase, approximately 2.8 miles long single circuit. The HECA project on site switching station consist of a breaker, a disconnect switch and PG&E revenue metering equipments. The proposed new PG&E switchyard will consist of 8 Circuit breakers, three-bay, six positions breaker and-a-half configuration.

b) The power plant outlet line shall meet or exceed the electrical, mechanical, civil and structural requirements of CPUC General Order 95 or National Electric Safety Code (NESC), Title 8 of the California Code and Regulations (Title 8), Articles 35, 36 and 37 of the "High Voltage Electric Safety Orders", Cal-ISO standards, National Electric Code (NEC) and related industry standards.

c) Breakers and busses in the power plant switchyard and other switchyards, where applicable, shall be sized to comply with a short-circuit analysis.

d) Outlet line crossings and line parallels with transmission and distribution facilities shall be coordinated with the transmission line owner and comply with the owner's standards.

e) The project conductors shall be sized to accommodate the full output from the project.

f) Termination facilities shall comply with applicable PG&E interconnection standards.

g) The project owner shall provide to the CPM:

   i) Executed project owner and California ISO Large Generator Interconnection Agreement

Verification: At least 60 days prior to the start of construction of transmission facilities (or a lessor number of days mutually agreed to by the project owner and CBO, the project owner shall submit to the CBO for approval:

a) Design drawings, specifications and calculations conforming with CPUC General Order 95 or NESC, Title 8, Articles 35, 36 and 37 of the "High Voltage Electric Safety Orders", NEC, applicable interconnection standards and related industry standards, for the poles/towers, foundations, anchor bolts, conductors, grounding systems and major switchyard equipment.

b) For each element of the transmission facilities identified above, the submittal package to the CBO shall contain the design criteria, a discussion of the calculation method(s), a sample calculation based on "worst case conditions"[1] and a statement signed and sealed by the registered engineer in responsible charge, or other acceptable alternative verification, that the transmission element(s) will conform with CPUC General Order 95 or NESC, Title 8, California Code of Regulations, Articles 35, 36 and 37 of the, "High Voltage Electric Safety Orders", NEC, applicable interconnection standards, and related industry standards.

c) Electrical one-line diagrams signed and sealed by the registered professional electrical engineer in responsible charge, a route map, and an engineering description of equipment and the configurations covered by requirements **TSE-5** a) through f) above.

d) The executed Large Generator Interconnection Agreement.

TSE-6 The project owner shall inform the CPM and CBO of any impending changes, which may not conform to the requirements **TSE-5** a) through f, and have not, received CPM and CBO approval, and request approval to implement such changes. A detailed description of the proposed change and complete engineering, environmental, and economic rationale for the change shall accompany the request. Construction involving changed equipment or substation

[1] Worst case conditions for the foundations would include for instance, a dead-end or angle pole.

configurations shall not begin without prior written approval of the changes by the CBO and the CPM.

Verification: At least 60 days prior to the construction of transmission facilities, the project owner shall inform the CBO and the CPM of any impending changes which may not conform to requirements of **TSE-5** and request approval to implement such changes.

TSE-7 The project owner shall provide the following Notice to the California Independent System Operator (California ISO) prior to synchronizing the facility with the California Transmission system:

1. At least one week prior to synchronizing the facility with the grid for testing, provide the California ISO a letter stating the proposed date of synchronization; and
2. At least one business day prior to synchronizing the facility with the grid for testing, provide telephone notification to the ISO Outage Coordination Department.

Verification: The project owner shall provide copies of the California ISO letter to the CPM when it is sent to the California ISO one week prior to initial synchronization with the grid. The project owner shall contact the California ISO Outage Coordination Department, Monday through Friday, between the hours of 0700 and 1530 at (916) 351-2300 at least one business day prior to synchronizing the facility with the grid for testing. A report of conversation with the California ISO shall be provided electronically to the CPM one day before synchronizing the facility with the California transmission system for the first time.

TSE-8 The project owner shall be responsible for the inspection of the transmission facilities during and after project construction, and any subsequent CPM and CBO approved changes thereto, to ensure conformance with CPUC GO-95 or NESC, Title 8, CCR, Articles 35, 36 and 37 of the, "High Voltage Electric Safety Orders", applicable interconnection standards, NEC and related industry standards. In case of non-conformance, the project owner shall inform the CPM and CBO in writing, within 10 days of discovering such non-conformance and describe the corrective actions to be taken.

Verification: Within 60 days after first synchronization of the project, the project owner shall transmit to the CPM and CBO:

a) "As built" engineering description(s) and one-line drawings of the electrical portion of the facilities signed and sealed by the registered electrical engineer in responsible charge. A statement attesting to conformance with CPUC GO-95 or NESC, Title 8, California Code of Regulations, Articles 35, 36 and 37 of the, "High Voltage Electric Safety Orders", and applicable interconnection standards, NEC, related industry standards, and these conditions shall be provided concurrently.

b) An "as built" engineering description of the mechanical, structural, and civil portion of the transmission facilities signed and sealed by the registered engineer in responsible charge or acceptable alternative verification. "As built" drawings of the electrical, mechanical, structural, and civil portion of the transmission facilities shall be maintained at the power plant and made available, if requested, for CPM audit as set forth in the “Compliance Monitoring Plan”.

c) A summary of inspections of the completed transmission facilities, and identification of any nonconforming work and corrective actions taken, signed and sealed by the registered engineer in charge.

DEFINITION OF TERMS

AAC All Aluminum conductor.

ACSR Aluminum Conductor Steel-Reinforced.

SSAC Steel-Supported Aluminum Conductor.

Ampacity Current-carrying capacity, expressed in amperes, of a conductor at specified ambient conditions, at which damage to the conductor is nonexistent or deemed acceptable based on economic, safety, and reliability considerations.

Ampere The unit of current flowing in a conductor.

Bundled Two wires, 18 inches apart.

Bus Conductors that serve as a common connection for two or more circuits.

Conductor The part of the transmission line (the wire) that carries the current.

Congestion Management

Congestion management is a scheduling protocol, which provides that dispatched generation and transmission loading (imports) will not violate criteria.

Emergency Overload
: See Single Contingency. This is also called an L-1.

Kcmil or KCM
: Thousand circular mil. A unit of the conductor's cross sectional area, when divided by 1,273, the area in square inches is obtained.

Kilovolt (kV)
: A unit of potential difference, or voltage, between two conductors of a circuit, or between a conductor and the ground.

Loop
: An electrical cul de sac. A transmission configuration that interrupts an existing circuit, diverts it to another connection and returns it back to the interrupted circuit, thus forming a loop or cul de sac.

Megavar
: One megavolt ampere reactive.

Megavars
: Mega-volt-Ampere-Reactive. One million Volt-Ampere-Reactive. Reactive power is generally associated with the reactive nature of motor loads that must be fed by generation units in the system.

Megavolt Ampere (MVA)
: A unit of apparent power, equals the product of the line voltage in kilovolts, current in amperes, the square root of 3, and divided by 1000.

Megawatt (MW)
: A unit of power equivalent to 1,341 horsepower.

Normal Operation/ Normal Overload
: When all customers receive the power they are entitled to without interruption and at steady voltage, and no element of the transmission system is loaded beyond its continuous rating.

N-1 Condition
: See Single Contingency.

Outlet
: Transmission facilities (circuit, transformer, circuit breaker, etc.) linking generation facilities to the main grid.

Power Flow Analysis
: A power flow analysis is a forward-looking computer simulation of essentially all generation and transmission system facilities that identifies overloaded circuits, transformers and other equipment and system voltage levels.

Reactive Power
: Reactive power is generally associated with the reactive nature of motor loads that must be fed by generation units in the system. An adequate supply of reactive power is required to maintain voltage levels in the system.

Remedial Action Scheme (RAS)
: A remedial action scheme is an automatic control provision, which, for instance, will trip a selected generating unit upon a circuit overload.

SF6
: Sulfur hexafluoride is an insulating medium.

Single Contingency
: Also known as emergency or N-1 condition, occurs when one major transmission element (circuit, transformer, circuit breaker, etc.) or one generator is out of service.

Solid Dielectric Cable
: Copper or aluminum conductors that are insulated by solid polyethylene type insulation and covered by a metallic shield and outer polyethylene jacket.

Switchyard
: A power plant switchyard (switchyard) is an integral part of a power plant and is used as an outlet for one or more electric generators.

Thermal Rating
: See Ampacity.

TSE
: Transmission System Engineering.

Tap
: A transmission configuration creating an interconnection through a sort single circuit to a small or medium sized load or a generator. The new single circuit line is inserted into an existing circuit by utilizing breakers at existing terminals of the circuit, rather than installing breakers at the interconnection in a new switchyard.

Undercrossing
: A transmission configuration where a transmission line crosses below the conductors of another transmission line, generally at 90 degrees.

Underbuild
: A transmission or distribution configuration where a transmission or distribution circuit is attached to a transmission tower or pole below (under) the principle transmission line conductors.

ALTERNATIVES

Negar Vahidi and Scott Debauche[1]

SUMMARY OF CONCLUSIONS

This analysis evaluates a reasonable range of potential alternatives to the proposed Hydrogen Energy California project (HECA or project). As California Environmental Quality Act (CEQA) lead agency for HECA, the California Energy Commission is required to identify and evaluate a range of reasonable alternatives to the project that would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project. As part of this analysis, staff evaluated HECA by comparing the applicant's stated project objectives to expected HECA attributes. The guiding principles for selection of alternatives analyzed are consistent with the CEQA Guidelines, Cal. Code Regs., tit. 14, §15000 et seq., as described below.

The U.S. Department of Energy (DOE) must decide whether to provide financial assistance for the construction of the project; it must comply with the National Environmental Policy Act (42 United States Code [U.S.C.] §§ 4321 et seq.) in making this decision. For DOE, the reasonable alternatives at this point in the NEPA analysis are: (1) to fund the construction and operation of the project as proposed by the applicant and subject to any conditions imposed by the Energy Commission or other regulatory agencies; or (2) to refrain from funding the construction and operation of the project.[2] DOE assumes for purposes of NEPA that a decision to refrain from funding the project would result in the applicant abandoning its project. This alternative is referred to as the "No Action Alternative" under NEPA. It is equivalent to the "No Project Alternative" under CEQA. The first NEPA alternative constitutes DOE's "Proposed Action" and is equivalent to the HECA project (for CEQA, the project is not considered an alternative). In considering the Proposed Action (HECA), DOE considers other "project-level" alternatives that Energy Commission staff analyzes below such as the alternatives involving no fertilizer manufacture, different modes of transporting materials to the site, and different routes for rail spurs, pipelines, and transmission lines. For purposes of DOE's NEPA review, these "project-level alternatives" constitute action alternatives to DOE's Proposed Action – funding the project as proposed by the applicant.

---

[1] Preparation of this alternatives section includes technical analysis completed by staff issue area specialists. **Alternatives Appendix 1** of this staff assessment contains a list of staff contributors to the comparative and environmental analyses for alternatives evaluated in detail.

[2] DOE's NEPA procedures include specific requirements (10 CFR 1021.216) for analyzing alternatives in the context of competitive financial assistance. DOE reviews each responsive application and prepares an environmental critique for the official who will select the projects that will receive assistance. This brief comparative evaluation of environmental impacts allows the selecting official to make an informed decision when choosing projects for financial assistance. DOE then makes this information publicly available in an environmental synopsis that does not contain confidential and business sensitive information supplied by the applicants with their proposals. The environmental synopsis that discusses DOE's evaluation of the Proposed Action (HECA project) for financial assistance is included within the 2012 Amended AFC as Appendix B (HECA 2012e).

Based upon staff's analysis, the No Project Alternative would eliminate potentially significant environmental impacts associated with HECA, while the No Fertilizer Manufacturing Complex Alternative (Reduced Project Alternative) would lessen impacts in a number of environmental issue areas. **Alternatives Table 1** provides a brief comparison of the project environmental impacts and those of the alternatives evaluated in detail. The analysis of the DOE No Action Alternative is contained within each environmental issue area section of this Preliminary Staff Assessment and Draft Environmental Impact Statement (PSA/DEIS). A summary of NEPA requirements for alternatives analysis and the No Action Alternative is provided later in the subsection "NEPA Requirements." **Alternatives Table 1** provides summary details of alternatives analyzed within this PSA/DEIS.

Alternatives Table 3 provides a comparison of HECA to the applicant's stated project objectives. Energy Commission staff believes HECA is not likely to meet all of the applicant's stated objectives, as described further below. Thus, in the tables following **Alternatives Table 3,** staff evaluates HECA against those project objectives that it believes HECA could accomplish.

The identification of a CEQA environmentally superior alternative (Cal. Code Regs., tit. 14, §15126.6[e][2]) and NEPA environmentally preferred alternative (CEQ §1505.2[b]) will be identified in the Final Staff Assessment/Final Environmental Impact Statement (FSA/FEIS). At this time, Dry Cooling or Wet-Dry Hybrid Cooling Alternative, Natural Gas Combined Cycle with Carbon Capture and Storage Alternative, and Additional Alternative Sites remain under consideration. Staff will analyze these alternatives in the FSA/FEIS.

Five site alternatives (four presented by the applicant) were reviewed as potential alternative project sites and all were eliminated from detailed consideration.

Alternatives Table 1
Comparison of HECA and Alternatives

Alternatives Criteria	HECA Project[1] (CEQA)/ Proposed Action (NEPA)	No Project Alternative (CEQA)/ No Action Alternative (NEPA)[2]	No Fertilizer Manufacturing Complex (Reduced Project) Alternative (CEQA)[2] Action Alternative (NEPA)
Air Quality			
Construction related emissions	SM	Much less than HECA	Somewhat less than HECA
Project operations emissions	SM	Much less than HECA	Somewhat less than HECA
Biological Resources			
Loss of special-status species habitat	Indeterminate at this time	Much less than HECA	Similar to HECA
Impacts to wildlife regional movement	Indeterminate at this time	Much less than HECA	Similar to HECA
Habitat conversion	Indeterminate at this time	Much less than HECA	Similar to HECA
Impacts to San Joaquin kit fox Core Recovery Area	Indeterminate at this time	Much less than HECA	Similar to HECA
Potential take of state Fully Protected blunt-nosed leopard lizard	SU	Less than HECA	Similar to HECA
Increased risk of wildlife road mortality from increased traffic	Indeterminate at this time	Much less than HECA	Slightly less than HECA
Swainson's hawk foraging habitat loss	Indeterminate at this time	Much less than HECA	Similar to HECA
Potential loss of raptor nest trees and other migratory birds	Indeterminate at this time	Less than HECA	Similar to HECA
Potential impacts to wildlife exposed to contaminants from operation of evaporation ponds	SM	Less than HECA	Similar to HECA
Potential impacts to sensitive groundwater dependent vegetation	Indeterminate at this time	Less than HECA	Similar to HECA
Potential loss of jurisdictional state waters	Indeterminate at this time	Less than HECA	Similar to HECA
Potential loss of jurisdictional Waters of the U.S.	Indeterminate at this time	Less than HECA	Similar to HECA
Indirect effects to sensitive wildlife during construction and operation	SM	Less than HECA	Similar to HECA
Indirect effects to sensitive plant species during construction and operation	SM	Less than HECA	Similar to HECA
Potential direct impact to rare plant populations	Indeterminate at this time	Less than HECA	Similar to HECA

Alternatives Criteria	HECA Project[1] (CEQA)/ Proposed Action (NEPA)	No Project Alternative (CEQA)/ No Action Alternative (NEPA)[2]	No Fertilizer Manufacturing Complex (Reduced Project) Alternative (CEQA)[2] Action Alternative (NEPA)
Potential effects of nitrogen deposition to sensitive plants/wildlife	Indeterminate at this time	Less than HECA	Slightly less than HECA
Potential weed proliferation from increased GHG emissions during construction and operation	Indeterminate at this time	Less than HECA	Similar to HECA
Potential incremental contribution to cumulative effects to upland species of the southern San Joaquin Valley	Indeterminate at this time	Less than HECA	Similar to HECA
Impacts associated with CO_2-EOR project	Indeterminate at this time	Less than HECA	Similar to HECA
Carbon Sequestration and Greenhouse Gas Emissions			
Carbon sequestration	SM	Less than HECA	Same as HECA
Greenhouse gas emissions	SM	Less than HECA	Similar to HECA
Cultural Resources			
Potential Damage to Surface Archaeological Resources: HECA	PSU	Less than HECA	Similar to HECA
Potential Damage to Surface Archaeological Resources: EOR	Indeterminate at this time	Less than HECA	Same as HECA
Potential Damage to Buried Archaeological Resources: HECA/EOR	Indeterminate at this time	Less than HECA	Same as HECA
Potential Damage to Old Headquarters Weir	LS	Less than HECA	Same as HECA
Potential Damage to California Aqueduct	LS	Less than HECA	Same as HECA
Potential Impacts to Historic Built Environment Resources: EOR	Indeterminate at this time	Less than HECA	Same as HECA
Geology and Paleontology			
Potential impacts from strong seismic shaking	SM	Less than HECA	Similar to HECA
Potential impacts from soil failure caused by liquefaction, hydro-compaction, subsidence, expansive soils and/or dynamic compaction	SM	Less than HECA	Similar to HECA
Hazardous Materials	SM	Less than HECA	Slightly less than HECA
Land Use and Agriculture			
Conversion of prime farmland, unique farmland, or farmland of statewide importance.	PSM	Much less than HECA	Same as HECA

Alternatives Criteria	HECA Project[1] (CEQA)/ Proposed Action (NEPA)	No Project Alternative (CEQA)/ No Action Alternative (NEPA)[2]	No Fertilizer Manufacturing Complex (Reduced Project) Alternative (CEQA)[2] Action Alternative (NEPA)
Conflicts with existing agricultural zoning or Williamson Act contract.	PSM	Much less than HECA	Same as HECA
Conflict of zoning or cause rezoning of forestland.	—	Much less than HECA	Same as HECA
Result in loss of forest land.	—	Same as HECA	Same as HECA
Result in conversion of agricultural land to non-agricultural use.	PSM	Much less than HECA	Same as HECA
Physically divide or disrupt an established community.	PSM	Much less than HECA	Same as HECA
Conflict with any applicable land use plan, policy or regulation.	LS	Much less than HECA	Less than HECA
Conflict with applicable habitat conservation plan or natural community conservation plan.	—	Much less than HECA	Same as HECA
Noise and Vibration	SM	Less than HECA	Similar to HECA
Public Health and Safety	SM	Less than HECA	Slightly less than HECA
Socioeconomics			
Impacts to Socioeconomic Resources	LS	Less than HECA	Same as HECA
Soil and Surface Water			
Soil erosion by wind and water during project construction	PSM	Less than HECA	Less than HECA
Soil erosion by wind and water during project operations	PSM	Greater than HECA	Similar to HECA
Water quality impacts from contaminated storm water runoff	PSM	Somewhat greater than HECA	Somewhat less than HECA
Water quality impacts from increase of impervious areas	PSM	Less than HECA	Somewhat less than HECA
Water quality impacts from industrial operations	PSM	Less than HECA	Somewhat less than HECA
Water quality impacts from sanitary waste	PSM	Less than HECA	Similar to HECA
Potential impacts from on-site and off-site flooding	PSM	Somewhat greater than HECA	Similar to HECA
Potential to impede or redirect 100-year flood flows, as shown on Federal Emergency Management Agency maps	LS	Similar to HECA	Similar to HECA

Alternatives Criteria	HECA Project[1] (CEQA)/ Proposed Action (NEPA)	No Project Alternative (CEQA)/ No Action Alternative (NEPA)[2]	No Fertilizer Manufacturing Complex (Reduced Project) Alternative (CEQA)[2] Action Alternative (NEPA)
Impacts associated with CO_2-EOR project	PSM	Much less than HECA	Similar to HECA
Traffic & Transportation			
Potential impacts from increased traffic	SM	Much less than HECA	Less than HECA
Potential impacts from exhaust plumes	SM	Much less than HECA	Same as HECA
Transmission Line Safety and Nuisance			
Potential impacts from generated fields	LS	Less than HECA	Less than HECA
Fire, shock, and aviation impacts from physical presence	LS	Less than HECA	Less than HECA
Visual Resources			
Visual change/contrast of project facilities	SU	Much less than HECA	Same as HECA
Waste Management			
Potential for disposal or diversion of project materials to cause impacts on existing waste disposal or diversion facilities	PSU	Much less than HECA	Similar to HECA
Potential for impacts on human health and the environment related to past or present soil or water contamination	PSM	Less than HECA	Similar to HECA
Water Supply			
Water level lowering in local well owner wells	PSM	Much less than HECA	Indeterminate at this time
Increased Kern County sub-basin groundwater overdraft	PSM	Much less than HECA	Indeterminate at this time
Potential impacts to the California Aqueduct from subsidence	PSM	Less than HECA	Indeterminate at this time
Potential degradation of groundwater quality from project pumping	PSM	Much less than HECA	Indeterminate at this time
Potential non-compliance with State and Energy Commission water policies	PSM	Much less than HECA	Indeterminate at this time

Alternatives Criteria	HECA Project[1] (CEQA)/ Proposed Action (NEPA)	No Project Alternative (CEQA)/ No Action Alternative (NEPA)[2]	No Fertilizer Manufacturing Complex (Reduced Project) Alternative (CEQA)[2] Action Alternative (NEPA)
Worker Safety & Fire Protection	SM	Less than HECA	Slightly less than HECA

Notes: [1] The following correspond to impact determinations of HECA, as provided within each PSA/DEIS environmental analysis section:
— = no impact
LS = less than significant impact, no mitigation required
SM or PSM = significant or potentially significant impact that can be mitigated to less than significant
SU or PSU = significant and unavoidable or potentially significant and unavoidable impact that cannot be mitigated to less than significant

[2] This summary is comparative in nature, and corresponds to impact of the Alternative when compared to HECA as discussed within subsection "Alternatives Evaluated in Detail."

INTRODUCTION

DOE and Energy Commission staff reviewed the HECA alternatives analysis provided by the project applicant within the following documents:

- 2008 Application for Certification (AFC) (HEI 2008a);
- 2009 Revised AFC (HEI 2009c); and
- 2012 Amended AFC (HECA 2012e).

DOE and Energy Commission staff also analyzed alternatives recommended through agency and public comment, as well as those developed by staff (HECA 2012ll). Staff has evaluated the No Project Alternative and No Fertilizer Manufacturing Complex Alternative to meet the requirements of CEQA. The No Project Alternative has been evaluated to meet the requirements of NEPA for analyzing a No Action Alternative. While DOE will consider the No Fertilizer Manufacturing Complex Alternative, it doubts that this is a reasonable alternative under NEPA because the applicant would not proceed with its project if it does not include fertilizer manufacturing.

Dry Cooling or Wet-Dry Hybrid Cooling Alternative, Natural Gas Combined Cycle with Carbon Capture and Storage Alternative, and Additional Alternative Sites are alternatives still under consideration. Staff continues to evaluate these alternatives but cannot draw conclusions regarding their feasibility or ability to reduce significant environmental impacts, at this time. Final determinations and analysis of these alternatives (either eliminated from consideration or evaluated in detail) will be provided in the FSA/FEIS. Other alternatives eliminated from detailed analysis are also discussed in this section, as well as the reasons for eliminating them. The public is invited to comment on these alternatives and their feasibility.

On May 10, 2013, the applicant provided updated operating performance data developed in March 2013 for a hot day (97°F), a typical day (65°F) and a cold day (39°F). This updated data included an assumed 8,000 hours per year of operation, with the facility in a “maximum electricity production” mode for 16 hours per day and a “maximum fertilizer production” mode the remaining eight hours per day. On a typical day at 65°F, in the “electricity” mode, the facility would produce a net increase in electrical grid capacity of 52.5 megawatts (MW); and in the “fertilizer” mode on that same typical day the facility would consume a net 61.8 MW from the electrical grid. The grid-level change takes into account all electricity required to operate the facility as proposed by the applicant, including the air separation unit planned to be operated by a separate party and also including electricity consumed to recycle and re-inject the carbon dioxide produced with crude oil production. See the PSA/DEIS section on **Carbon Sequestration and Greenhouse Gas Emissions** for more details. The weighted average daily electricity production would be 14.4 MW. These new operating data were not available in time to inform the discussion below analyzing the No Fertilizer Manufacturing Complex (Reduced Project) Alternative (refer to subsection “Alternatives Evaluated in Detailed”), and evaluations and conclusions could be different when considering these new operating data in the FSA/FEIS.

NEPA REQUIREMENTS

DOE's Proposed Action is to provide financial assistance for the construction and operation of the HECA project, which would produce and sell electricity, carbon dioxide and fertilizer. DOE selected this project for an award of financial assistance through a competitive process under the Clean Coal Power Initiative (CCPI) program.

This PSA/DEIS will inform DOE's decision on whether to provide financial assistance for construction and operation of the project under its CCPI Program; DOE's financial assistance (or "cost share") would be limited to $408 million, about 10 percent of the project's total cost. DOE's financial assistance is also limited to certain aspects of the power and manufacturing plants, carbon capture, and sequestration. The PSA/DEIS evaluates the potential impacts of DOE's Proposed Action, the HECA project and its connected actions, and reasonable alternatives to DOE's Proposed Action.

PURPOSE AND NEED FOR DOE ACTION

Unlike the Energy Commission, DOE does not have regulatory jurisdiction over the HECA project. Its decisions are limited to whether and under what circumstances it would provide financial assistance to the project. The purpose and need for DOE action – providing limited financial assistance to the HECA project – is to advance DOE's CCPI program by funding projects that have the best chance of achieving the program's objective as established by Congress. The objective of the CCPI program is the commercialization of clean coal technologies that improve efficiency, environmental performance, and cost competitiveness well beyond those of technologies that are currently in commercial service.

NEPA ALTERNATIVES

NEPA requires that a federal agency evaluate the range of reasonable alternatives to the agency's proposed action. The range of reasonable alternatives encompasses those alternatives that would satisfy the underlying purpose and need for agency action. The purpose and need for DOE action – providing limited financial assistance to the HECA project – are to advance the CCPI program by selecting projects that have the best chance of achieving the program's objective as established by Congress. DOE's purpose and need is therefore different from the Energy Commission's, and DOE's alternatives differ somewhat from those of the Energy Commission, although many of them are the same.

DOE's NEPA regulations include a process for identifying and analyzing reasonable alternatives in the context of providing financial assistance through a competitive selection of projects proposed by entities outside the federal government. The range of reasonable alternatives in competitions for grants, loans and other financial support is defined in large part by the range of responsive proposals DOE receives. Unlike projects undertaken by DOE itself, the Department cannot mandate what outside entities propose, where they propose to do it, or how they propose to do it beyond establishing requirements in the funding opportunity announcement that further the program's objectives. DOE's decision is limited to selecting among the applications submitted by project sponsors that meet CCPI's goals.

Recognizing that the range of reasonable alternatives in the context of financial assistance and contracting is in large part determined by the number and nature of the proposals submitted, section 216 of DOE's NEPA regulations requires the Department to prepare an "environmental critique" that assesses the environmental impacts and issues relating to each of the proposals that the DOE selecting official considers for an award. *See* 10 C.F.R. § 1021.216. This official considers these impacts and issues, along with other aspects of the proposals (such as technical merit and financial ability) and the program's objectives, in making awards. DOE prepared a critique of the proposals that were deemed suitable for selection in this round of awards for the CCPI program.

DOE received 11 applications in response to the initial Funding Opportunity Announcement (FOA) issued August 11, 2008 for CCPI Round 3, all of which DOE determined met the mandatory eligibility requirements listed in the FOA (HECA 2012e, Appendix B). The applications covered a wide geographic range, including sites in 14 different states representing nearly every region of the country. In response to the reopened announcement (issued June 9, 2009), DOE received 38 applications, of which 25 were determined to have met the mandatory eligibility requirements listed in the announcement (HECA 2012e, Appendix B). The 25 applications offered projects involving sites in 19 different states representing nearly all geographic regions of the country (HECA 2012e, Appendix B).

The applications were evaluated against technical, financial, and environmental factors. By broadly soliciting proposals to meet the programmatic purpose and need for DOE action and by evaluating the potential environmental impacts associated with each proposal before selecting projects, DOE considered a reasonable range of alternatives for meeting the purpose and need of the CCPI solicitation (HECA 2012e, Appendix B). A detailed synopsis of the DOE CCPI Round 3 process and selection criteria is provided as Appendix B in the 2012 Amended AFC (HECA 2012e, Appendix B) and summarized in the subsection "DOE Alternatives Screening Process."

Once DOE selects a project for an award, the range of reasonable alternatives becomes the project as proposed by the applicant, any alternatives still under consideration by the applicant or agencies with regulatory jurisdiction over the project, and those that are reasonable within the confines of the project as proposed (e.g., the particular location of the generating plant on the site or the rights-of-way (ROWs) for linear facilities), and a No Action Alternative. Regarding the No Action Alternative, DOE assumes for purposes of the PSA/DEIS that, if it were to decide to withhold financial assistance from the project, the project would not proceed

As noted above under the subsection "Introduction," the "project-specific" alternatives that the applicant or the Energy Commission are still considering such as the coal delivery alternatives, dry cooling, wet-dry hybrid cooling, and other alternatives developed by the Energy Commission staff or suggested by the public are still under consideration. DOE would not make any decisions regarding these – the applicant or Energy Commission will make those decisions. Under the No Action Alternative, DOE would not provide funding to HECA. DOE assumes that the project applicant would not pursue its project, and there would be no impacts from the project. This alternative would not meet DOE's purpose and need for its CCPI program; however, DOE analyzes this option as its No Action Alternative in order to have a meaningful comparison between the impacts of DOE providing financial assistance and withholding that assistance.

CEQA REQUIREMENTS

As the CEQA lead agency for the HECA project, the California Energy Commission (Energy Commission) is required to consider and discuss alternatives to HECA. The guiding principles for the selection of alternatives for analysis are provided by the Energy Commission siting regulations and the CEQA Guidelines (Cal. Code Regs., tit. 14, § 15000 et seq.). Section 15126.6 of the CEQA Guidelines indicates that the alternatives analysis must:

- Describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project;
- Consider alternatives that would avoid or substantially lessen any significant environmental impacts of the project, including alternatives that would be more costly or would otherwise impede the project's objectives; and
- Evaluate the comparative merits of the alternatives.

The lead agency is responsible for selecting a range of project alternatives for examination and must publicly disclose its reasoning for selecting those alternatives (Cal. Code Regs., tit. 14, §15126.6[a]). CEQA does not require an agency to "consider every conceivable alternative to a project." Rather, CEQA requires consideration of a "reasonable range of potentially feasible alternatives." The reasonable range of alternatives must be selected and discussed in a manner that fosters meaningful public participation and informed decision making (Cal. Code Regs., tit. 14, §15126.6[f]). That is, the range of alternatives presented in this analysis is limited to ones that will inform a reasoned choice by the Energy Commissioners. Under the "rule of reason," an agency need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative (Cal. Code Regs., tit. 14, §15126.6[f][3]).

The CEQA lead agency is also required to:

(1) Evaluate a no project alternative,

(2) Identify alternatives that were initially considered but then rejected from further evaluation, and

(3) Identify the environmentally superior alternative among the other alternatives (Cal. Code Regs., tit. 14, §15126.6)

Alternatives may be eliminated from detailed consideration by the lead agency if they fail to meet most of the basic project objectives, are infeasible, or could not avoid any significant environmental effects (Cal. Code Regs., tit. 14, §15126.6[c]).

PROJECT OBJECTIVES

The process for selecting alternatives to evaluate under CEQA begins with the establishment of project objectives. Section 15124 of the CEQA Guidelines defines the requirement for a statement of objectives (Cal. Code Regs., tit. 14, §15124[b]):

> "A clearly written statement of objectives will help the lead agency develop a reasonable range of alternatives to evaluate in the EIR and will aid the decision makers in preparing findings or a statement of overriding considerations, if necessary. The statement of objectives should include the underlying purpose of the project."

The objectives for HECA as claimed by the applicant are to (HECA 2012e):

- Provide dependable, low-carbon electricity to help meet future power needs, and to help back-up intermittent renewable power sources, to support a reliable power grid.
- Enhance the production and availability of in-state nitrogen-based products for use in agricultural, transportation, and industrial applications by producing approximately 1 million tons per year of low-carbon products, including urea, UAN (a solution of urea and ammonium nitrate in water used as a fertilizer), and anhydrous ammonia.
- Conserve domestic energy supplies and enhance energy security by using abundant solid feedstocks, coal and petroleum coke, to generate electricity and manufacture low-carbon nitrogen based products.
- Mitigate impacts related to climate change by dramatically reducing average annual greenhouse gas (GHG) emissions relative to those emitted from a conventional coal-fired power plant and/or nitrogen-based product manufacturing facility by capturing, at a rate of at least 90 percent, and sequestering carbon dioxide (CO_2).
- Use captured CO_2 for enhanced oil recovery (EOR) to produce additional oil reserves.
- Demonstrate advanced solid fuel based technologies that can generate clean, reliable, and affordable electricity in the United States and prove out carbon capture and sequestration as a viable method for reducing the carbon footprint of power generation and manufacturing.
- Facilitate and support the development of hydrogen infrastructure in California by supplementing the quantities of hydrogen available for future energy and transportation technologies.
- Minimize environmental impacts associated with the construction and operation of the project through technology selection, project design, and implementation of feasible mitigation measures, where necessary.
- Site the project at a location over which SCS Energy California LLC (SCS Energy or project applicant) will have control, and which offers reasonable access to necessary infrastructure, including natural gas, process water supply, transmission and rail interconnection, and geologic formations appropriate for CO_2 EOR and sequestration.
- Ensure the economic viability of the project by integrating electricity production with the manufacture of multiple products to meet market demand.
- Meet all requirements necessary to secure and retain DOE funding for the project.

ENERGY COMMISSION STAFF'S ALTERNATIVES SCREENING PROCESS

Pursuant to CEQA, the purpose of staff's alternatives analysis is to identify potential significant impacts of HECA and then focus on alternatives that are capable of avoiding or substantially reducing those impacts while still meeting most of the basic objectives of the project.

To prepare the analysis of alternatives, staff used the methodology summarized below:

- Describe the objectives of the project and compare those against possible alternatives to the project;
- Identify any potential significant environmental impacts of the project;
- Evaluate the project as proposed by the applicant against their stated project objectives and evaluate alternatives against project objectives that staff believes HECA could meet;
- Identify and evaluate feasible alternatives that meet most of the project objectives that HECA could meet, to determine whether such alternatives would avoid or substantially lessen project impacts identified as significantly adverse, and determine whether such alternatives would result in impacts that are the same, less than, or greater than those of the project; and
- Evaluate the comparative merits of the alternatives.

ALTERNATIVES CONSIDERED IN THE APPLICATION FOR CERTIFICATION

The following provides a summary description and overview of all alternatives presented within the 2008 Application for Certification (AFC) (HEI 2008a), the 2009 Revised AFC (HEI 2009c), and the 2012 Amended AFC (HECA 2012e). An analysis of the alternatives eliminated from further consideration is provided later in the subsection "Alternatives Eliminated From Detailed Consideration." Those alternatives requiring comparative analysis to HECA are discussed later in the subsection "Alternatives Evaluated In Detail."

OFF-SITE ALTERNATIVES

Multiple siting evaluations in various parts of the state have been conducted since the HECA project was initially conceived. Because the project's fundamental goals include CO_2 capture and sequestration, the siting process has focused on the distance to, and viability of, carbon sequestration at or near the site, as well as other essential criteria (discussed in 2012 Amended AFC, Section 6.3).

During the siting evaluations, various factors have contributed to the elimination of sites, including but not limited to the criteria outlined in Section 6.0 of the 2012 Amended AFC (HECA 2012e). For example, locations evaluated outside of Kern County included the following (HECA 2012ll, Data Response A200):

- <u>Los Angeles County</u>. The project applicant considered siting the project on the property of the British Petroleum (BP) Carson Refinery in Los Angeles County, where the refinery could provide HECA with petroleum coke (petcoke), and HECA could provide the refinery with steam. However, in 2007, the applicant was unable to reach consensus with the multiple owners and operator of a nearby oil field for a viable off-take agreement for CO_2 injection.

- Ventura County. Siting within Ventura County was considered. Work on this was discontinued due to the lack of viable site locations, proven sequestration targets, and the distance from existing transmission infrastructure.

The HECA project has been proposed in three main filings with the Energy Commission, as follows:

- July 2008. An AFC (HEI 2008a) was submitted to the Energy Commission, proposing that the HECA project be located on a different site, south of the California Aqueduct.
- May 2009. A Revised AFC (HEI 2009c) was submitted to the Energy Commission, relocating the project to essentially the current project site, but with certain design differences when compared to the July 2008 filing.
- May 2012. An Amended AFC (HECA 2012e) was submitted to the Energy Commission, evaluating HECA on the current site as evaluated within this PSA/DEIS.

An AFC was submitted to the Energy Commission in July 2008, proposing that HECA be located south of the California Aqueduct. This site was located within the Elk Hills Oil Field (EHOF). After evaluating sites within and near the EHOF, the project applicant initially selected a moderately sloped site south of the California Aqueduct. Subsequent to filing the 2008 AFC, the site was moved following discussions with regulatory agencies regarding the presence of sensitive biological resources, and discussion of the site for inclusion in habitat protection plans. As a result, the project applicant conducted another extensive siting analysis to identify an alternative site near the EHOF.

Section 6.0 (Alternatives) of both the 2009 Revised AFC and the 2012 Amended AFC evaluated four additional site alternatives to the currently proposed HECA site, all within Kern County (HEI 2009c and HECA 2012e). The locations of the following four site alternatives are included in Amended AFC Section 6.0 (Alternatives), Figure 6-1, and include (HECA 2012e):

- Alternative Site 1: located approximately 1.1 miles west-northwest of the HECA site between Bellevue Road and Tupman Road, this 774 acre site is 98 percent farmland and 2 percent residential use (HECA 2012ll, Data Response A200).
- Alternative Site 2: located approximately 0.4 mile east of the HECA site south of Bellevue Road, this 769 acre site is 99.9 percent farmland and 0.1 percent canal use (HECA 2012ll, Data Response A200).
- Alternative Site 3: located approximately 4.0 miles north-northwest of the HECA site between Interstate 5 and State Route 58, this 515 acre site is 97 percent farmland and 3 percent undeveloped (HECA 2012ll, Data Response A200).
- Alternative Site 4: located approximately 13.2 miles southeast of the HECA site between Hill Road and Old River Road, this 4,199 acre site is 96 percent farmland

and 4 percent undeveloped (HECA 2012ll, Data Response A200).

The project applicant did not carry forward any of the four off-site alternatives for further evaluation because the characteristics of the sites did not meet the applicant's screening criteria (HECA 2012e). An analysis of these site alternatives is provided in the subsection "Alternatives Eliminated From Detailed Consideration."

ALTERNATIVE LINEAR UTILITIES ROUTES

Because the 2008 AFC proposed the HECA project at a different site, alternative linear infrastructure routes evaluated within the 2008 AFC are inapplicable to the current project site and, therefore, excluded from this discussion (HEI 2008a, Section 6.0). Additionally, as described in Section 6 (Alternatives) of the 2009 Revised AFC and 2012 Amended AFC, both natural gas and potable water line routing options were only minimally considered due to siting limitations and land ownership restrictions. As such, no alternate natural gas or potable water line routes were evaluated (HEI 2009c and HECA 2012e).

Within the 2009 Revised AFC, four route alternatives were screened for the transmission line between the project site and substation connection (HEI 2009c, Section 6.0). Of these four transmission line route alternatives, two were fully evaluated as viable alternatives within 2009 Revised AFC, Section 4.0.

Section 6.0 of the 2012 Amended AFC considered alternative linear electrical infrastructure routes for the HECA project, including interconnections to both Pacific Gas and Electric's (PG&E) Midway Substation north of the HECA site, as well as to a future PG&E switching station east of the site (HECA 2012e). Numerous routing options were evaluated in detail to the Midway Substation, including routes presented in the 2009 Revised AFC (HEI 2009c, Section 6.0).

As discussed in Section 2.0 of the 2012 Amended AFC, the project includes two options for transferring coal to the HECA site:

- <u>Rail Transportation</u>. An approximately 5-mile new industrial railroad spur would connect the HECA site to the existing San Joaquin Valley Railroad (SJVRR) Buttonwillow railroad line, north of the HECA site. This railroad spur would also be used to transport some HECA fertilizer complex products to customers.
- <u>Truck Transportation</u>. Truck transport would be via existing roads from an existing coal transloading facility northeast of the HECA site. The truck route distance is approximately 27 miles.

Because the HECA project includes both of these options, the analysis of these coal-transferring options is provided in detail within each technical section presented in Section 4.0 of this PSA/DEIS. DOE considers these alternatives to be among the project-level action alternatives to its Proposed Action.

ACID GAS REMOVAL SYSTEM ALTERNATIVES

As described in Section 6.0 of the 2012 Amended AFC, several acid gas removal (AGR) system alternatives were considered by the project applicant (HECA 2012e). Because only a few AGR methods have found widespread acceptance for gasification projects at the HECA project scale, and alternative methods are unlikely to reduce any project-related impacts, staff has not evaluated them further in this PSA/DEIS. For a description and analysis of potential AGR alternatives considered by the project applicant, please refer to Section 6.0 of the Amended AFC (HECA 2012e).

MANUFACTURING COMPLEX ALTERNATIVE

The major difference between the Revised AFC (2009) project and the Amended AFC (2012) project is the addition of the fertilizer manufacturing complex (HECA 2012ll, Response A207). Without the manufacturing complex, HECA would use the hydrogen to produce electricity only (HECA 2012ll, Response A207). The manufacturing complex simply allows HECA to use its hydrogen to produce fertilizers during periods of low electrical demand (HECA 2012ll, Response A207).

WATER SUPPLY ALTERNATIVES

As described in the 2012 Amended AFC Section 6.0, several potential alternative water supplies were studied for HECA, as well as potential technologies for reducing water demand. HECA would utilize groundwater as supplied by the Buena Vista Water Storage District (BVWSD).

The following briefly identify water supply options considered within the Amended AFC (2012) include (HECA 2012e, Section 6.0) that are no longer under consideration by Water Supply staff, and are therefore not discussed within the **Water Supply** section of this PSA/DIES:

- Ocean Water. The project site is approximately 75 miles from the Pacific Ocean. Although this supply is limitless, and desalination technology for its successful use proven, the capital cost for transporting, treating, and disposing of this option is high (>$500 million).
- Ocean Discharge. The project site is located approximately 75 miles from a significant source of wastewater disposed into the ocean. Although this supply is large, and technology for its successful use proven, the capital cost for transporting and treating the wastewater from this option is high (>$500 million).
- Brackish Water. Several alternative brackish water sources were considered in comparison to the HECA groundwater supplier (BVWSD), including:
  - **Industrial Wastewater**. Industrial wastewater in the form of produced water is available from the oilfields within 10 miles of the HECA site. Produced water refers to water that is “co-produced” from the many oil wells in the Kern County region. Produced water is an industrial wastewater that is separated from crude oil in the oil production process. Kern County oil well output is often 8 parts water to 1 part oil, leading to a large excess of produced water that the local oil producers must dispose of. The produced water is currently disposed by re-injection and discharge to evaporation ponds. There are approximately 15 million gallons per day (mgd) of produced water available when drawn from multiple locations within

a radius of 10 miles of the HECA site.

— **Semitropic Water Storage District**. The Semitropic Water Storage District (Semitropic) is in northwest Kern County. Agriculture in a portion of Semitropic District is impacted by shallow, brackish groundwater conditions resulting from agricultural irrigation. It has a groundwater storage capacity of 1.65 million acre-feet, with 650,000 acre-feet of capacity remaining. This impacted area is approximately 10 miles to the west/northwest of Wasco and affects an area of roughly 10 square miles.

- Inland Wastewaters. Several wastewater effluent providers were evaluated in comparison to the HECA groundwater supplier (BVWSD), including:

  — **Municipal Effluent**. The HECA site is located approximately 17 miles northeast of the city of Bakersfield Wastewater Treatment Plant #3. This plant treats a large portion of the municipal effluent generated from the city of Bakersfield. The project applicant contacted the city regarding their interest and availability in supplying water to the project. Currently, the city is selling its treated effluent to local farmers for irrigation purposes.

  — **Agricultural Wastewater**. Agricultural wastewater (i.e., tile drainage) is excess water from irrigation practices. Differing from Semitropic District water (as discussed above under Brackish Water), this source would be site specific as irrigation water from directly adjacent agricultural lands.

- Other Inland Waters. Several inland water supply providers were evaluated in comparison to the HECA groundwater supplier (BVWSD), including:

  — **State Water Project**. The State Water Project’s California Aqueduct is approximately 1,900 feet south of the HECA site. The project applicant does not have an allocation for the use of freshwater from the State Water Project.

  — **Fresh Groundwater**. Fresh groundwater is found in the vicinity of the HECA site and is feasibly available to the project.

  — **Municipal Water Supply**. Municipal water is available to the HECA project.

WASTEWATER DISPOSAL ALTERNATIVES

Section 6.0 of the 2012 Amended AFC considered several potential alternative wastewater disposal options in comparison to the HECA Zero Liquid Discharge (ZLD) wastewater system (HECA 2012e). Because ZLD is the preferred approach by the Energy Commission for reducing environmental impacts, alternatives to ZLD wastewater disposal are not evaluated further within this PSA/DEIS.

PUBLIC AND AGENCY PARTICIPATION

Preparation of the HECA alternatives analysis included Energy Commission staff’s participation in the following:

- Energy Commission Informational Hearing held in Tupman, CA (July 12, 2012) – TNs 65764, 67137, and 68216.
- Three Energy Commission staff workshops held in Bakersfield (November 7, 2012)

and Sacramento (June 20, 2012 and September 27, 2012) – TNs 68216, 65656, and 67137, respectively.

- One Energy Commission Committee meeting and one Committee Status Conference held in Sacramento (January 10, 2012 and January 16, 2013) – TN 68976.
- Energy Commission Staff Workshop – Water Supply, held in Sacramento (February 20, 2012) – TN 69387.
- San Joaquin Valley Air Pollution Control District Hearing – held on April 2, 2013 – TN 70249.

Oral and written agency, general public, and intervener comments regarding HECA project alternatives received during these meetings have been considered by staff in determining the scope and content of this analysis.

DOE published an Amended Notice of Intent (ANOI) in the *Federal Register* on June 19, 2012 (77 FR 36519). A public scoping meeting was conducted on July 12, 2012, at the Elk Hills Elementary School, in Tupman, California, and comments were accepted through August 3, 2012 (one week after July 27, 2012, the date the comment period closed). DOE considered these comments in identifying its reasonable alternatives for purposes of NEPA.

The following are public and agency written comments received during these public meetings and the ANOI scoping comment period that pertain to the CEQA and NEPA alternatives analysis:

- United States Environmental Protection Agency, TN 66381 – July 26, 2012: Requests that the alternatives analysis discuss the following alternatives:
    - Reduced Project Size Alternative
    - Alternative Technologies (for component processes)
    - Dry Cooling or Wet-Dry Hybrid Cooling Alternative
    - Dry Scrubbing Alternative
- Sierra Club, TN 66370 – July 27, 2012: Requests that the alternatives analysis discuss the following alternatives:
    - Renewable Energy Project Alternatives
    - No Fertilizer Production Alternative
    - Higher Percentage of Petcoke and/or Biomass Gasifier Alternative
    - Air Cooling System Alternative
    - Enclosed Ground Flare and Flare Recovery System Alternative
    - No Project Alternative
    - Consider the Local Economic Impact of the Different Alternatives and the Increased Health Care Costs
- Daniel Bell, TN 66248 – July 16, 2012: Requests that the alternatives analysis discuss other gasification processes besides the GE and Mitsubishi alternatives contained within the Amended AFC (2012), questioning what other technologies may use less coal in the process.
- Chris Romanini, TN 66382 – July 26, 2012: Requests that the alternatives analysis

include a no coal gasification alternative, suggesting a change to natural gas.

- Debbie Shepherd, TN 66498 – August 2, 2012: Requests that the alternatives analysis discuss a natural gas power plant instead of a coal-processing unit.
- California Public Utilities Commission, TN 68923 – December 13, 2012: Discusses the HECA rail line alignment, which passes through a primarily agricultural area, resulting in a high amount of slow moving agricultural vehicles at the rail crossings. This concern relates to potential rail line and coal storage alternatives.
- General public comments made during oral comment period at Energy Commission staff workshops and public meetings (as discussed above):
  - Solar photovoltaic (PV) Alternative, ensuring a discussion of tax generation of Solar PV Alternative versus HECA be included;
  - Rooftop Solar PV Alternative;
  - Natural Gas Alternative (versus coal); and
  - Water Supply Alternative as the proposed “brackish” water source is suitable for pistachio farming within Kern County.

In addition to these comments that were received during the public meetings and the ANOI scoping comment period, the following comment letters have been received:

- Kern County Planning and Community Development Department, TN 69831 – March 6, 2013: Requests that the alternatives analysis discuss/include the following (Kern County 2013a):
  - Review alternative sites for the HECA that do not contain Prime Agricultural Land.
  - Eliminate consideration of applicant’s Alternative Site 1, which is owned by the Romanini Family Trust (an intervener to the HECA).
  - Identify if the property owner(s) of Alternative Site 4 have been contacted by the project applicant, and consider this information in staff’s analysis of this alternative site.

An analysis of these alternatives, as well as those identified by staff, is provided below in the subsections “Alternatives Eliminated From Detailed Consideration” and “Alternatives Evaluated In Detail.”

POTENTIALLY SIGNIFICANT AND UNMITIGABLE ENVIRONMENTAL IMPACTS

The following identifies potentially significant and unmitigable impacts associated with HECA, as well as providing a brief analysis as to the cause of impact. HECA project significant and unmitigable impacts are the first addressed by staff when seeking to lessen or avoid project impacts via alternatives. However, while significant and unmitigable impacts were staff’s first focus when developing alternatives and evaluating them, all impacts were considered and evaluated for each alternative’s ability to lessen or avoid any HECA project-related impacts. It should be noted a number of issue areas and impact determinations remain unknown at the time of PSA/DEIS publication, and current impact determinations may change at the time of FSA/FEIS publication. Therefore, the following outline project-related significant and unmitigable impacts as determined by staff and identified within this PSA/DEIS (refer to **Alternatives Table 1**):

- Biological Resources:
  - — Traffic volumes and travel routes from fertilizer distribution pass through San Joaquin kit fox Core Recovery Areas.
  - — Facilities located on lands occupied by blunt-nosed leopard lizard habitat.
  - — CO_2 pipeline conflicts with a number of listed plant and wildlife species located within Elk Hills Oilfield.
- Visual Resources:
  - — Significant impact at KOP 1 (HECA). As of this PSA/DEIS, the applicant has indicated that it has reached out to the resident at KOP 1 regarding an off-site mitigation alternative (HECA, 2012q) that could reduce this impact to a less-than-significant level. As discussed within the **Visual Resources** PSA/DEIS section, staff has requested that the applicant provide more information/documentation on the off-site mitigation plan.

HECA's ABILITY TO MEET APPLICANT'S STATED PROJECT OBJECTIVES

The applicant's stated project objectives were described under "Project Objectives." However, the applicant has not shown how their project would meet these objectives, and Energy Commission staff believes that not all of these objectives would be met. As such, staff believes it is appropriate to first document which objectives HECA could meet, and then to evaluate alternatives against the project objectives. **Alternatives Table 2** lists all project objectives and sub-objectives that the applicant claims HECA could meet and staff's evaluation of them.

Alternatives Table 2
Comparison of HECA to Applicant's stated Project Objectives

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
Provide dependable, low-carbon electricity to help meet future power needs ….	No	HECA does not provide low-carbon electricity using the project description and scope used by Energy Commission staff. See the PSA/DEIS section titled "Carbon Sequestration and Greenhouse Gas Emissions" for a comparison of the approach used by the applicant and that used by staff. As evaluated by staff, during early operations the carbon intensity is greater than efficient natural gas fired power plants. During mature operations the carbon intensity of the electricity that would be provided by HECA is similar to other base load power plants recently approved by the Energy Commission.
…. and to help back-up intermittent renewable power sources, to support a reliable power grid.	No	HECA has not shown that it could provide capacity to help back-up intermittent renewable sources of electricity. To do so, it would have to be able to reliably ramp electricity production up and down. The California Independent System Operator would need to be able to dispatch HECA at a changing power output of about 5 MW per minute. The

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
		applicant has not stated that it could operate in this manner nor has it described how such operation would affect facility reliability or availability.
Enhance the production and availability of in-state nitrogen-based products for use in agricultural, transportation, and industrial applications by producing approximately one million tons per year of low-carbon products, including urea, UAN, and anhydrous ammonia.	Yes	
Conserve domestic energy supplies and enhance energy security by using abundant solid feed stocks, coal, and petroleum coke to generate electricity and manufacture low-carbon nitrogen based products.	Yes	
Mitigate impacts related to climate change by dramatically reducing average annual GHG emissions relative to those emitted from a conventional coal-fired power plant and/or nitrogen-based product manufacturing facility by capturing, at a rate of at least 90 percent, and sequestering CO_2.	Yes	
Use captured CO_2 for EOR to produce additional oil reserves.	Yes	However, HECA has not shown whether or not other methods could be used to produce targeted oil reserves.
Demonstrate advanced solid fuel based technologies that can generate clean, reliable, and affordable electricity in the United States and prove out carbon capture and sequestration as a viable method for reducing the carbon footprint of power generation and manufacturing.	Yes	However, HECA has not shown that the electricity produced would be competitive enough in price to meet its stated annual hours of operation.
… and prove out carbon capture and sequestration as a viable method for reducing the carbon footprint of power generation and manufacturing	No	HECA has not shown that it would reduce the carbon footprint of power generation facilities likely to be located in California.
Facilitate and support the development of hydrogen infrastructure in California by supplementing the quantities of hydrogen available for future energy and transportation technologies.	No	HECA has not shown that it would facilitate development of hydrogen infrastructure in California any more than would a steam reformer making hydrogen at a California refinery.
Minimize environmental impacts associated with the construction and operation of the project through technology selection, project design, and implementation of feasible mitigation measures, where necessary.	Yes	
Site the project at a location over which HECA LLC will have control, and which offers reasonable access to necessary infrastructure,	Yes	

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
including natural gas, process water supply, transmission and rail interconnection, and geologic formations appropriate for CO_2 EOR and sequestration.		
Ensure the economic viability of the project by integrating electricity production with the manufacture of multiple products to meet market demand.	Possibly	HECA has not shown that it is economically viable, especially given its expected annual hours of operation in the California electricity market.
Meet all requirements necessary to secure and retain DOE funding for the project.	Yes	

Notes: Even though staff has found HECA not meeting a number of project objectives and has provided a comment in the Consistency Analysis column, staff has evaluated alternatives against these project objectives.

ALTERNATIVES ELIMINATED FROM DETAILED CONSIDERATION

Section 15126.6(c) of the CEQA Guidelines defines the requirement to identify any alternatives that were considered by the lead agency but were rejected as infeasible. CEQA requires that the reasons underlying the lead agency's determination not to analyze these alternatives in detail be explained. Similarly, NEPA requires DOE to briefly discuss alternatives that were eliminated from detailed study and to explain why they were eliminated.

Of those alternatives identified earlier in the subsections "Alternatives Considered Within The Application For Certification" and "Public And Agency Participation," the following 10 (ten) alternatives were considered but eliminated from detailed consideration because they would not fulfill staff's alternatives screening criteria (i.e., to avoid or substantially lessen project impacts identified as significantly adverse). The following provides staff's reasons for eliminating these alternatives from detailed analysis. DOE agrees with Energy Commission staff that these 10 alternatives should be eliminated from further consideration.

ALTERNATIVE SITES

Since alternatives must consider the underlying objectives of the HECA project, staff confined the geographic area for site alternatives to be an independent analysis of:

- Potential sites located within the EHOF;
- Alternative sites considered by the project applicant within the AFC (2008), Revised AFC (2009), and Amended AFC (2012); and
- Alternative sites evaluated within California as part of the project applicant's DOE CCPI Program selection process and evaluation.

These site alternatives were evaluated by staff for their ability to fulfill project objectives and siting criteria, including but not limited to:

- Proximity to an available oil field for sequestration;
- Proximity to an available substation and switchyard;

- Location in an area appropriate for industrial development and potentially compatible with Kern County General Plan and Zoning Ordinance designations; and
- Proximity to infrastructural right-of-way demands, including coal and petroleum coke delivery, transmission lines, natural gas lines, and water delivery pipelines.

As described in the subsection “Energy Commission Staff Alternatives Screening Process,” staff evaluated these site alternatives to determine whether they would avoid or lessen project impacts identified as significantly adverse (refer to **Alternatives Table 2**).

ALTERNATIVE SITES WITHIN THE ELK HILLS OIL FIELD (EHOF)

<u>Original HECA Site</u>

The 2008 AFC evaluated the HECA project at a different site than that presented in the 2009 Revised AFC and 2012 Amended AFC. The location of this site is shown in Amended AFC Section 6.0, Figure 6-1 (HECA 2012e, Section 6.0). This 315-acre site is located approximately 1.1 miles south of the HECA site. This site was not evaluated in the 2012 Amended AFC because of the presence of sensitive biological resources, and for that reason, was eliminated from further consideration. The original HECA site was eliminated because of the significant impacts to sensitive biological resources.

<u>Additional Sites Within The EHOF</u>

Staff coordinated with Occidental of Elk Hills, Inc. staff (owners and operators of the EHOF) and independently reviewed the EHOF for a feasible alternative location to site the project. While land parcels suitable for siting HECA exist within the EHOF, environmental permitting would be extremely challenging as a large amount of the EHOF contains existing biological resource mitigation land (OXY 2013f). During the siting of HECA at the original project site, biological data indicated that the EHOF high-quality habitat mitigation lands contain fully-protected species. During this initial HECA coordination, the California Department of Fish and Wildlife (CDFW) stated that any lands within a one-mile buffer zone of HECA would no longer qualify as suitable habitat compensation lands because of the noise, lighting, and continuous activity associated with future plant operations (OXY 2013f). During evaluation of the original HECA site, CDFW recommended that HECA pursue purchasing developed agriculture lands adjacent to the EHOF for construction of the HECA project (OXY 2013f). Therefore, the project applicant selected the current HECA site for the project.

Based upon independent staff review of available land within the EHOF boundaries:

- Other 515-acre parcels within the EHOF either contain production equipment and/or service roads; and
- Other 515-acre parcels within the EHOF would impact adjacent conservation lands because HECA facilities would be sited within one-mile of adjacent conservation land buffer zones.

As such, staff has determined that siting HECA within the EHOF is infeasible.

As discussed in subsection “Public And Agency Participation,” the Kern County Planning and Community Development Department requested the review of an alternative site that is not designated as “Prime Agricultural Land.” It should be noted that in reviewing Kern County Zoning Map designations, virtually all parcels west of Interstate 5 and within a five-mile plus eastern radius of the EHOF are zoned by Kern County as Exclusive Agriculture (A) or Limited Agriculture (A-1) (Kern County 2013b). Therefore, any alternative sites in this area would impact Kern County agriculturally-zoned land.

To address Kern County’s request to avoid Prime Farmland, staff reviewed the EHOF for suitable sites that would avoid lands designated as Prime. According to the California Division of Land Resources Protection Farmland Mapping and Monitoring Program (FMMP), the EHOF is not designated as Prime Farmland (California Division of Land Resources Protection 2013). Because of the reasons discussed above, locating the project within the EHOF would be infeasible.

Alternative Sites 1 Through 4

As described in the subsection “Alternatives Considered Within The AFC,” four alternative sites for the project were evaluated in the 2012 Amended AFC. To establish feasibility and determine if Alternative Sites 1 through 4 would avoid or substantially lessen HECA impacts identified as significant (**Alternatives Table 1**), staff conducted an independent review of information related to topography; distance from the CO_2 custody transfer point; linear facility lengths; sensitive environmental receptors; and land availability for Alternative Sites 1 through 4. This review consisted of comparing these factors to the HECA site. A summary of this information is provided in **Alternatives Table 3**.

- **Topography**. The topography of Alternative Sites 1 through 4 is generally flat and similar to the HECA site. As such, these sites remain feasible from a topographical standpoint and would not significantly alter the amount of earthmoving activities associated when compared to the proposed site. As such, staff’s analysis concludes that topography is not a key factor in eliminating Alternative Sites 1 through 4.
- **Distance from the CO_2 Injection Facility**. The distance to the CO_2 injection point ranges from 3.2 miles (Alternative Site 2) to 13.6 miles (Alternative Site 4).
- **Linear Facility Length**. Although linear routes were not developed for Alternative Sites 1 through 4, straight-line measurements from the alternative site to the requested location (i.e., electrical and gas interconnection points, potable and process water supplies) are provided within **Alternatives Table 3** for comparison purposes. Distances from the sites to electrical transmission interconnection ranged from 0.9 mile (Alternative Site 2) to 15.1 miles (Alternative Site 4). Distances from the sites to natural gas interconnection ranged from 4.2 miles (Alternative Site 3) to 22.9 miles (Alternative Site 4). Distances from the site to potable water connection ranged from 0.02 mile (Alternative Site 2) to 15.6 miles (Alternative Site 4). Distances from the sites to the process water connection ranged from 9.2 miles (Alternative Site 3) to 29.7 miles (Alternative Site 4).
- **Sensitive Environmental Receptors**. None of the alternative sites are located in urban settings, and none are in proximity to a substantial number of residences. The

HECA site and Alternative Site 4 have the fewest residences in proximity to the site. Based on the California Natural Diversity Database search results, the most records of sensitive species are found in the area south of the California Aqueduct, which includes Alternative Site 4.

- **Land Availability**. Alternative Sites 1 through 4 are all used for agricultural purposes, and contain 96 percent farmland or greater. All of these sites contain Williamson Act Contract lands. In response to staff's data requests on Alternative Site 4, the project applicant responded that the property owner(s) are willing to sell their land (refer to land owner information provided in **Alternatives Table 3**).

As discussed in subsection "Public And Agency Participation," the Kern County Planning and Community Development Department informed staff that Alternative Site 1 is located on property that is owned by the Romanini Family Trust, an intervener on HECA. Therefore, staff assumes this site is not available for the project. Alternative Site 2 has been sold and is no longer available. Based on the inability of the project applicant to acquire either of these sites, Alternative Sites 1 and 2 have been eliminated by staff from further consideration.

Refer to **Alternatives Table 3** for a listing of the comparative data for Alternative Sites 3 and 4. Staff's analysis shows that Alternative Sites 3 and 4 would not avoid or substantially lessen project-related significant impacts to biological resources or land use and agriculture. While Alternative Sites 3 and 4 would result in slightly different CO_2 pipeline route lengths, the CO_2 pipelines from either site would need to traverse sensitive biological resource areas within the EHOF to reach the CO_2 injection location. Alternative Sites 3 and 4 would result in the removal of agricultural land. As discussed in subsection "Public And Agency Participation," the Kern County Planning and Community Development Department requested the review of an alternative site that is not designated as "Prime Agricultural Land." Alternative Site 3 is designated as Prime Farmland (California Division of Land Resources Protection 2013). Alternative Site 4 is designated as both Unique Farmland and Farmland of Statewide Importance (California Division of Land Resources Protection 2013).

Alternatives Table 3
Comparison Data for the HECA Site and Alternative Sites 1 through 4

Alternatives Criteria	Alternative Site 1	Alternative Site 2	Alternative Site 3	Alternative Site 4	HECA Site

	The surrounding farmland contains the following crop coverage: bok choy, cotton, alfalfa, wheat, onions, almonds, and persimmon.	The surrounding farmland contains the following crop coverage: bok choy, almonds, alfalfa, grape, tomato process, persimmon, cotton, and onion.	and rural commercial land. The surrounding farmland contains the following crop coverage: bok choy, almond, alfalfa, onion, carrot, wine grapes, sudan grass, and tomato process.	statewide importance, and semi-agriculture and rural commercial land. The surrounding farmland contains the following crop coverage: tomato process, wheat, alfalfa, onion, safflower, prune, pomegranate, wine grape, oats for food, corn for food, rapeseed, Napa cabbage, potato, and mustard.	700, and 1,900 feet south of the project site, respectively. Most of the land in the vicinity of the project site and linear routes is included in the Exclusive Agriculture (A) zone or the Limited Agriculture (A-1) zone. Farmland surrounding the project site is composed of Williamson Act Contracted Land, prime farmland, farmland of statewide importance, and semi-agriculture and rural commercial land. Land within 1 mile of the project site is primarily used for farming purposes (particularly the cultivation of cotton, alfalfa, and onions), undeveloped areas, and orchards for the cultivation of pistachios. The 453-acre project site and controlled area is currently used for farming purposes, including the cultivation of cotton, alfalfa, and onions.
Source: HECA 2012ll, Response A200					

Staff concludes that the increase in linear infrastructure associated with Alternative Sites 3 and 4 has the potential to result in an increase to significant biological resources and cultural impacts due to additional lengths traversing sensitive areas. Furthermore, while the linear routes serving Sites 3 and 4 can be partially assumed at this time, it is possible that these rights-of-way could create new and unknown land use incompatibility impacts. As such, the similar existing land uses of both sites (refer to **Alternatives Table 3)** and the required linear infrastructure right-of-way creates similar or worse significant impacts as those associated with HECA. Therefore, staff has eliminated Alternative Sites 3 and 4 from further consideration.

ALTERNATIVE LINEAR UTILITIES ROUTES

Linear Utility Infrastructure Routes

Section 6.0 of the 2008 AFC, 2009 Revised AFC, and 2012 Amended AFC evaluated electrical transmission interconnections to both Pacific Gas and Electric's (PG&E) Midway Substation north of the proposed HECA site, as well as to a future PG&E switching station east of the site (HEI 2008a, HEI 2009c, HECA 2012e).

PG&E Midway Substation Alternative. Numerous routing options were evaluated in Section 6.0 of the 2009 Revised AFC for interconnection to the PG&E Midway Substation (HEI 2009c). However, transmission interconnection to the PG&E Midway Substation has been eliminated from further consideration based on the following:

- PG&E has identified transmission interconnection congestion in and around the Midway Substation (HECA 2012e, Section 6.0); and
- PG&E's switching station represents the shortest and most direct interconnection point available to the site, with interconnection to the PG&E Midway Substation requiring a substantially longer transmission line length (i.e., more than five miles).

Due to the increased length, transmission interconnection into the PG&E Midway Substation would not avoid or lessen significant biological resources or land use and agriculture project impacts, as identified within **Alternatives Table 2**. Given congestion and increased impacts, an interconnection to the PG&E Midway Substation has been eliminated from further consideration.

PG&E Switching Station Route Alternatives. In selecting the HECA project interconnection route to the PG&E switching station, the following factors were provided to staff by the applicant and considered by staff within this analysis (**Alternatives Table 2)**:

- Feasibility of Land Acquisition. The proposed route involves a minimum number of landowners, with required right-of-way widths available for acquisition.
- Safety and Proximity to Potential Sensitive Receptors. There are no residences or other occupied buildings (i.e., residences, schools, day-care centers, etc.) along the entire HECA transmission interconnection route.

Because the HECA site is surrounded by agricultural uses, altering the transmission line interconnection route (lengthening) would increase temporary disturbance to agricultural uses. As such, staff's analysis shows that altering the proposed transmission line interconnection routes into the PG&E switching station would not avoid or substantially lessen significant biological resources or land use and agriculture project impacts, identified in **Alternatives Table 1**. Therefore, alternative interconnection routes to the PG&E switching station have been eliminated from further consideration.

Natural Gas Route Alternatives. The proposed PG&E natural gas pipeline would be co-located with the HECA railroad spur that would be utilized for coal and petroleum coke delivery. The natural gas supply pipeline would tap into PG&E's main supply pipeline. Based on review of alternative natural gas pipeline routes presented within Section 6.0 (Alternatives) of the AFC (2008), Revised AFC (2009), and Amended AFC (2012), the HECA pipeline route is intended to ensure:

- Collocation of two project linear facilities in the same right-of-way (i.e., the majority of the natural gas pipeline route with the railroad spur) to avoid siting of two separate routes; and
- Minimization of the length of the natural gas pipeline right-of-way interconnection to the PG&E main supply pipeline (i.e., for the remaining portion of the natural gas pipeline not collocated with the railroad spur).

The natural gas line would minimize total linear length and temporary land disturbance during installation. Because the site is surrounded by agricultural uses, altering the natural gas route would increase temporary disturbance to agricultural uses. As such, Energy Commission staff's analysis shows that altering the proposed underground natural gas pipeline route would not avoid or substantially lessen significant biological resources or land use and agriculture project impacts, identified in **Alternatives Table 1**. Furthermore, it should be noted that an alternative route could place this linear infrastructure closer to residents. Therefore, alternative natural gas pipeline routes are eliminated from further consideration.

CO_2 Pipeline Route Alternatives. As part of the project, an approximately three-mile CO_2 pipeline would transfer the CO_2 captured during gasification south to the Occidental of Elk Hills (OEHI) injection facility. The proposed CO_2 pipeline alignment has been sited to minimize impacts to resource areas, as discussed in the 2012 Amended AFC (HECA 2012e, Appendix A). Based on information provided in **Alternatives Table 2**, linear length distances to the OEHI CO_2 injection facility, alternative CO_2 pipeline routes would not avoid or lessen project-related significant biological resources or land use and agriculture impacts identified in **Alternatives Table 1**. The HECA CO_2 pipeline route minimizes length and occurs within lands controlled by the project applicant. Furthermore, it should be noted that an alternative route could place this linear infrastructure closer to residents. Therefore, staff has eliminated alternative CO_2 pipeline routes from further consideration.

WATER SUPPLY ALTERNATIVES

Please refer to the **Water Supply** section of this PSA/DEIS (Section 4.15), for a discussion of water supply alternatives identified earlier within the AFC. Also refer to the subsection "Alternatives Considered In The Application For Certification," for water supply alternatives still under consideration by staff.

REDUCED PROJECT ALTERNATIVES

As described in the subsection “Public And Agency Participation,” the US EPA and intervener comments requested the scope and content of this analysis include a Reduced Project Alternative. The HECA project would generate electricity and fertilizer (sequestering CO_2 in the gasification process). Reduced Project Alternatives could include reducing production of electricity or fertilizer and/or a reduced project footprint.

- Reduced Production of Electricity or Fertilizer and other Nitrogen-Based Products. To evaluate this alternative, staff requested data from the project applicant that would reduce the overall project by 25 percent (HECA 2012ll, Response A202). HECA has been configured around Mitsubishi Heavy Industries (MHI) gasification and combustion turbine technology. The project applicant has stated these two key equipment systems are only offered in the sizes used for HECA, and are not scalable by 25 percent or any other value. The selection of these key technologies also determines the amount of hydrogen that can be produced for combustion turbine fuel and fertilizer production, as well as the CO_2 available for Enhanced Oil Recovery (EOR) and permanent sequestration. The applicant has not provided any data showing that the gasifier could operate at a feedstock charge rate of less than that associated with full gasifier capacity. Issues that might arise when operating off-design point can include performance degradation, deviations in syngas quality and slag characteristics, maintenance issues, etc.

  Because electricity and fertilizer production technologies are not individually able to reduce output by 25 percent, a Reduced Project Alternative is best evaluated through the No Fertilizer Manufacturing Alternative. Without the fertilizer manufacturing complex, HECA could use hydrogen to produce electricity only. The fertilizer manufacturing complex simply allows HECA to use hydrogen to produce fertilizers during periods of low electrical demand (HECA 2012ll, Response A207). Reducing the manufacture of fertilizer has the potential to avoid or lessen a number of the significant project-related impacts identified in **Alternatives Table 1.** The No Fertilizer Manufacturing Complex (Reduced Project) Alternative is further evaluated below in the subsection “Alternatives Evaluated In Detail.”

- Reduced Project Footprint. According to the project applicant, the HECA engineering design work process includes optimizing the plot plan by minimizing the site footprint to the extent feasible, and accounting for space required for plant facilities and maintenance (HECA 2012ll, Response A202). Additionally, the HECA site boundary was selected to consider safety, constructability, and to lessen environmental impacts. A 25 percent reduction in the 453-acre footprint would only slightly decrease impacts to existing agricultural uses, as 99.8 percent of the site is used for agricultural production (refer to **Alternatives Table 3**). Therefore, reducing the project footprint would only slightly decrease the amount of agricultural land loss associated with the project. The remaining project site would continue to be impacted by the development of an industrial use sited within a Kern County agricultural zone. Impacts related to removal of agricultural land would be nominally lessened but not avoided. Furthermore, while this alternative would decrease the overall site boundary, it would not reduce ground disturbing activities as identical project features would still be built. As such, the Reduced Project Site Alternative is eliminated from further consideration because it would only nominally lessen project-related impacts to removal of agricultural land, which have been mitigated to a less than significant level (refer to **Land Use and Agriculture** section).

DRY SCRUBBING ALTERNATIVE

During the ANOI scoping comment period the US EPA recommended the evaluation of a dry scrubbing alternative to reduce the HECA water use. However, dry scrubbing is not applicable to an Integrated Gasification Combined Cycle (IGCC) plant such as HECA (HECA 2012ll, Response A204). Dry scrubbing is a post-combustion, low-pressure (near atmospheric) technology for removal of sulfur dioxide from a fired boiler flue gas stream. Air quality staff reviewed the information provided by the applicant regarding dry scrubbing and concur that this technology is not applicable to HECA. This alternative is not applicable, as the HECA project would not use a fire boiled flue gas stream. Therefore, a Dry Scrubbing Alternative to reduce water consumption would not be applicable to HECA and has been eliminated from further consideration.

RENEWABLE ENERGY PROJECT ALTERNATIVES

Public and intervener comments requested the scope and content of this analysis include a Renewable Energy Project Alternative. These comments did not identify any specific environmental impacts this alternative seeks to potentially lessen or avoid, but merely requested staff to compare this alternative against the HECA project. **Alternatives Table 4** provides an analysis of a renewable project alternative in comparison to the HECA objectives (as identified in the subsection "Project Objectives").

Alternatives Table 4
Comparison of Renewable Energy Project Alternative to HECA Project Objectives

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
Provide dependable, low-carbon electricity to help meet future power needs …. (Note: HECA may not meet this project objective.)	Potentially (biomass boiler)	Some renewable facilities, such as biomass fired boilers or geothermal resources, can provide dependable renewable power to the grid. Other renewable energy resources such as wind and solar facilities are intermittent and cannot provide dependable power by themselves. While geothermal facilities do not seem to be an alternative given the site location, biomass fueled facilities exist in Kern County and could be deployed at a sufficient scale to meet the new capacity that HECA would add to the electricity grid. However, the availability of sufficient nearby biomass is currently unknown.
… and to help back-up intermittent renewable power sources, to support a reliable power grid. (Note: HECA would not meet this project objective.)	Yes	Back-up supplies of electricity are not needed if the renewable energy project is base load, such as a biomass boiler.
Enhance the production and availability of in-state nitrogen-based products for use in agricultural, transportation, and industrial applications by producing approximately one million tons per year of low-carbon products, including urea, UAN, and	No	A Renewable Energy Project Alternative would not produce hydrogen that could be utilized in the production of nitrogen-based products. Therefore, a Renewable Energy Project Alternative would not attain this project objective.

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
anhydrous ammonia.		
Conserve domestic energy supplies and enhance energy security by using abundant solid feedstocks, coal, and petroleum coke to generate electricity and manufacture low-carbon nitrogen based products.	Potentially	A Renewable Energy Project Alternative would conserve domestic energy supplies. However, some Renewable Energy Project Alternatives would not utilize domestic solid feedstocks, coal, or petroleum coke to generate electricity and would not generate hydrogen that could be utilized in the production of nitrogen-based products. Therefore, a Renewable Energy Project Alternative may or may not attain this project objective.
Mitigate impacts related to climate change by dramatically reducing average annual GHG emissions relative to those emitted from a conventional power plant and/or nitrogen-based product manufacturing facility by capturing, at a rate of at least 90 percent, and sequestering CO_2.	No	A Renewable Energy Project Alternative would reduce GHG emissions toward mitigating impacts related to climate change relative to those emitted from a conventional power plant. However, while wind and solar Renewable Energy Project Alternative would not generate any GHG emissions (except solar thermal generators that utilize natural gas boilers), this type of project would not capture CO_2 for sequestration purposes nor generate hydrogen that could be utilized in the production of nitrogen-based products. Therefore, a Renewable Energy Project Alternative would not attain this project objective.
Use captured CO_2 for EOR to produce additional oil reserves.	No	A Renewable Energy Project Alternative would not capture CO_2 for enhanced oil recovery purposes. Therefore, a Renewable Energy Project Alternative would not attain his project objective.
Demonstrate advanced solid fuel based technologies that can generate clean, reliable, and affordable electricity in the United States … (Note: HECA may not meet this project objective.)	Potentially	A biomass fired boiler would utilize solid fuel based technologies to generate clean, reliable and affordable electricity.
… and prove out carbon capture and sequestration as a viable method for reducing the carbon footprint of power generation and manufacturing. (Note: HECA would not meet this project objective.)	No	Renewable Energy Project Alternatives would not capture CO_2 for sequestration purposes. Therefore, most Renewable Energy Project Alternatives would not attain this project objective.
Facilitate and support the development of hydrogen infrastructure in California by supplementing the quantities of hydrogen available for future energy and transportation technologies. (Note: HECA would not meet this project objective.)	No	A Renewable Energy Project Alternative would not produce hydrogen that could be utilized for energy generation purposes. Therefore, a Renewable Energy Project Alternative would not attain this project objective.
Minimize environmental impacts associated with the construction and operation of the project through technology selection, project design, and implementation of feasible mitigation measures, where necessary.	Yes	Absent knowing the specific type of renewable energy technology used, location of such a renewable energy site, or conducting a cursory environmental analysis, staff assumes a renewable energy facility of comparable net MW output to HECA can be completed in an environmentally responsible manner. Therefore, it is assumed most renewable energy projects of equal net MW output could attain this project objective.
Site the project at a location over which HECA LLC will have control, and which offers reasonable access to necessary infrastructure, including natural gas, process	No	While the HECA site does offer reasonable access to necessary infrastructure, a Renewable Energy Project Alternative would not capture CO_2 for sequestration purposes. Therefore, a Renewable Energy Project Alternative would not attain this project objective.

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
water supply, transmission and rail interconnection, and geologic formations appropriate for CO_2 EOR and sequestration.		
Ensure the economic viability of the project by integrating electricity production with the manufacture of multiple products to meet market demand. (Note: HECA may not meet this project objective.)	No	A Renewable Energy Project Alternative would not produce hydrogen that could be utilized for electricity generation and the production of fertilizer or other hydrogen based products. Therefore, a Renewable Energy Project Alternative would not attain this HECA project objective. However, a Renewable Energy Project Alternative might not need the revenue stream from by-product sales to be financially viable.
Meet all requirements necessary to secure and retain DOE funding for the project.	No	Because there would be no coal involved in biomass, solar or wind power generation, a Renewable Energy Project Alternative would not meet DOE CCPI Program funding requirements or the DOE purpose and need for HECA. Therefore, a Renewable Energy Project Alternative would not attain this project objective. However, a Renewable Energy Project Alternative might not need the DOE funding to be financially viable.

Based on the analysis in **Alternatives Table 3**, other than a biomass fired boiler, Renewable Energy Project Alternatives are inconsistent with most of the HECA project objectives (inconsistent with more than HECA). As such, except for biomass fired boilers, Renewable Energy Project Alternatives have been eliminated from further consideration (consistent with CEQA §15126.6[a]). A Biomass Boiler Alternative is discussed further under the subsection “Alternatives Still Under Consideration.”

NATURAL GAS PROJECT ALTERNATIVE

Public comments requested that the scope and content of this analysis include a Natural Gas Project Alternative. These comments did not identify any specific environmental impacts this alternative would potentially lessen or avoid, but merely requested staff to compare this alternative against the HECA project. Staff has conducted an analysis of a Natural Gas Project Alternative in the form of a conventional natural gas-fired electric generation facility at the HECA site that would generate electricity only. Staff’s analysis of this alternative assumes the natural gas-fired electric generation facility would not include CO_2 capture or storage, EOR at the EHOF, or production of any fertilizer or other nitrogen-based products. It should be noted that an alternative considering a new or existing natural gas combined cycle facility capable of CO_2 capture and storage, as well as EOR at an existing oil field, remains under consideration by staff and is discussed below in the subsection “Alternative Still Under Consideration.”

Alternatives Table 5 provides an analysis of this alternative in comparison to the HECA project objectives.

Alternatives Table 5
Comparison of Natural Gas Project Alternative to HECA Project Objectives

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
Provide dependable, low-carbon electricity to help meet future power needs … (Note: HECA may not meet this	Yes	A Natural Gas Project Alternative would provide lower-carbon intensity electricity.

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
project objective.)		
… and to help back-up intermittent renewable power sources, to support a reliable power grid. (Note: HECA would not provide this project objective.)	Yes	A Natural Gas Project Alternative would provide dependable electricity and back-up intermittent power sources serving the grid.
Enhance the production and availability of in-state nitrogen-based products for use in agricultural, transportation, and industrial applications by producing approximately one million tons per year of low-carbon products, including urea, UAN, and anhydrous ammonia.	No	A Natural Gas Project Alternative absent a reformer added would not produce hydrogen that could be utilized in the production of nitrogen-based products. Therefore, a Natural Gas Project Alternative would not attain this project objective.
Conserve domestic energy supplies and enhance energy security by using abundant solid feedstocks, coal, and petroleum coke to generate electricity and manufacture low-carbon nitrogen based products.	No	A Natural Gas Project Alternative would not conserve domestic energy supplies (in the form of natural gas) nor utilize domestic solid feedstocks, coal, or petroleum coke to generate electricity. Furthermore, a natural gas electrical facility would not generate hydrogen and nitrogen that could be utilized in the production of nitrogen-based products. Therefore, a Natural Gas Project Alternative would not attain this project objective.
Mitigate impacts related to climate change by dramatically reducing average annual GHG emissions relative to those emitted from a conventional power plant and/or nitrogen-based product manufacturing facility by capturing, at a rate of at least 90 percent, and sequestering CO_2.	No	Within California, a Natural Gas Power Plant is considered a conventional power plant. As such, a Natural Gas Project Alternative could reduce GHG emissions toward mitigating impacts related to climate change relative to those emitted from any older (and dirtier) conventional power plant generation sources. Furthermore, a Natural Gas Project Alternative without CCS would emit less GHG/MWh than the HECA project. While natural gas plants can meet California's GHG Emission Performance Standard threshold without sequestration, a conventional natural gas electrical facility would not capture CO_2 for sequestration purposes nor generate hydrogen that could be utilized in the production of nitrogen-based products. Therefore, a conventional Natural Gas Project Alternative would not attain the whole of this project objective. Please refer to the subsection entitled "Alternatives Still Under Consideration" for the status of evaluating a natural gas with CCS alternative.
Use captured CO_2 for EOR to produce additional oil reserves.	No	A Natural Gas Project Alternative would not capture CO_2 for sequestration purposes, and therefore would not attain this project objective.
Demonstrate advanced solid fuel based technologies that can generate clean, reliable, and affordable electricity in the United States … (Note: HECA may not meet this project objective.)	No	A Natural Gas Project Alternative would not utilize advanced solid fuel based technologies. Therefore, a conventional Natural Gas Project Alternative would not attain this project objective. Please refer to the subsection entitled "Alternatives Still Under Consideration" for the status of evaluating a natural gas with CO_2 capture and storage alternative.
… and prove out carbon capture and sequestration as a viable method for reducing the carbon footprint of power generation and manufacturing. (Note: HECA would not meet this	No	A Natural Gas Project Alternative would not utilize capture CO_2 for sequestration purposes. Therefore, a conventional Natural Gas Project Alternative would not attain this project objective. Please refer to the subsection entitled "Alternatives Still Under Consideration" for the status of evaluating a natural gas with CO_2 capture and storage alternative.

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
project objective.)		
Facilitate and support the development of hydrogen infrastructure in California by supplementing the quantities of hydrogen available for future energy and transportation technologies.	No	A Natural Gas Project Alternative would not produce hydrogen that could be utilized for energy purposes. Therefore, a Natural Gas Project Alternative would not attain this project objective.
Minimize environmental impacts associated with the construction and operation of the project through technology selection, project design, and implementation of feasible mitigation measures, where necessary.	Yes	A Natural Gas Project Alternative could reduce GHG emissions toward mitigating impacts related to climate change relative to those emitted from any older (and dirtier) conventional power plant generation sources. While natural gas plants can meet California's GHG threshold without sequestration, a conventional natural gas electrical facility would likely result in similar or lower overall construction and operational impacts when compared to the HECA project at the same site. Therefore, a Natural Gas Project Alternative would attain this project objective.
Site the project at a location over which HECA LLC will have control, and which offers reasonable access to necessary infrastructure, including natural gas, process water supply, transmission and rail interconnection, and geologic formations appropriate for CO_2 EOR and sequestration.	Yes	The HECA site does offer reasonable access to necessary infrastructure. As such, this alternative would attain this project objective.
Ensure the economic viability of the project by integrating electricity production with the manufacture of multiple products to meet market demand. (Note: HECA may not meet this project objective.)	No	A Natural Gas Project Alternative would not produce hydrogen and nitrogen that could be utilized for electricity generation and production of fertilizer and other hydrogen based products. Therefore, a Natural Gas Project Alternative would not attain this project objective. However, a Natural Gas Project Alternative might not need the revenue stream from by-product sales to be financially viable.
Meet all requirements necessary to secure and retain DOE funding for the project.	No	Because there would be no coal involved in natural gas power generation, this alternative would not meet the DOE CCPI Program funding requirements or the DOE purpose and need for the HECA project. Therefore, a Natural Gas Project Alternative would not attain this project objective. However, a Natural Gas Project Alternative might not need the DOE funding to be financially viable.

A Natural Gas Project Alternative without carbon capture and storage would not meet a number of HECA project objectives (inconsistent with more than HECA). As such, a Natural Gas Project Alternative has been eliminated from further consideration (consistent with CEQA §15126.6[a]). However, a Natural Gas Project Alternative with Carbon Capture and Storage is discussed further under the subsection "Alternatives Still Under Consideration."

ENCLOSED GROUND FLARE AND FLARE RECOVERY SYSTEM ALTERNATIVE

Intervener Sierra Club requested the scope and content of this analysis include an Enclosed Ground Flare and Flare Recovery System Alternative instead of the elevated flares proposed by HECA. Sierra Club has indicated that the proposed flare system is inefficient and would result in increased air quality emissions compared to those of a possible Enclosed Ground Flare and Flare Recovery System Alternative. Staff has conducted an analysis assuming a ground level enclosed flare suggested by Sierra Club would be a thermal oxidizer. As provided in **Alternatives Appendix 1**, the following analysis was conducted in cooperation with Air Quality staff.

Overall, ground level enclosed flares would have lower volatile organic compounds (VOC), carbon monoxide (CO), and particulate matter (PM) emissions due to better combustion of most pollutants. However, sulfur oxide (SOx) emissions would be the same and nitrogen oxide (NOx) emissions would likely be higher. Overall, the emissions of the HECA flare system (while high for the short-term when the flares are running) are not significant over the long term. Furthermore, the short-term and long-term air quality impacts of the HECA flare system are low due to the high release height for these elevated flares and thermal buoyancy of the flares.

The cost and size of a ground level enclosed flare design for the HECA could affect the feasibility of using this alternative. Elevated flares, as designed for HECA, are typically used for larger volumes of gasses. As such, Air Quality staff concurs with the project applicant that the HECA project use an elevated flare because the project gasification flare is required to handle large volumes of off gasses. The cost to include a ground-level flare to address HECA's limited flaring events would be very high on a dollar/ton basis.

In addition to these constraints, elevated flares also have a simpler design, and therefore are more reliable than ground flares (HECA 2012x, Data Response 55). Additionally, elevated flares are inherently safer than ground flares because they are physically removed from the ground and are therefore not a danger to persons, buildings, or other structures on the ground. Also, ground flares rely on a refractory shell to separate persons or buildings on the ground from the heat released by the combustion of the flared gasses. Elevation of flares provides better dispersion of the flared gasses, protecting people on the ground, both within and outside the HECA site. No significant air quality impacts have been identified for use of elevated flares by HECA. Based on the discussion provided above, an Enclosed Ground Flare and Flare Recovery System Alternative would not avoid or substantially lessen any significant project-related air quality impacts (refer to **Alternatives Table 1**). Therefore, the Enclosed Ground Flare and Flare Recovery System Alternative has been eliminated from further consideration due to not avoiding or substantially lessening any significant project-related air quality impacts and for safety reasons.

REDUCED COAL/INCREASED PETCOKE UPON CONCLUSION OF FIVE-YEAR SECTION 48A PROGRAM REQUIREMENT PERIOD ALTERNATIVE

This alternative evaluates increasing petcoke and decreasing coal in the fuel blend after completion of the two-year demonstration phase requirement of utilizing 75 percent coal and five-year Section 48A program requirement. This alternative has the ability to reduce or lessen long-term impacts associated with the transport of coal to the HECA site from the source mine in New Mexico. These impacts include, but are not limited to, air quality emissions from transport uses, impacts to biological species during transport, and traffic impacts resulting from vehicle trips.

Overview

The applicant is the recipient of a $408 million CCPI Round 3 grant from DOE. The minimum requirement for coal use for projects selected by DOE in Round 3 of the CCPI grant program is 55 percent coal, with the main focus being on carbon capture technologies (HECA 2013n). The project applicant's specific Cooperative Agreement with the DOE requires that HECA use coal for at least 75 percent of the energy input for operations during the first two years of operations (HECA 2013n).

In addition to DOE funding, the project applicant is the recipient of approximately $103 million in Section 48A federal tax credits (HECA 2013n). The Section 48A program requires that qualifying projects use 75 percent coal for the first five years of operations (HECA 2013n). This alternative evaluates increasing petcoke use and decreasing coal in the fuel blend after completion of the Section 48A five year requirement of utilizing 75 percent coal.

The project applicant has also stated that the 75 percent coal and 25 percent petcoke fuel blend stems from technological requirements associated with the MHI gasifier after a thorough review of all commercially viable gasifier technologies (HECA 2013n). To date, the maximum performance guarantee the manufacturer is willing to provide the project applicant is a 75 percent coal 25 percent petcoke blend (HECA 2013n). This performance guarantee is required to obtain long-term financing (HECA 2013n). In addition, the project applicant has stated that coal procurement conforms to investor preferences as coal providers seek long term (typically 20+ years) supply contracts enabling them to recoup the high capital outlays associated with mine development (HECA 2013n).

Gasifier Technology

MHI technology forms the HECA project selection for IGCC. Alternative gasification and hydrogen electrical generating equipment that could be utilized by HECA has been evaluated in Section 6.0 of the 2008 AFC, 2009 Revised AFC, and 2012 Amended AFC. Other gasification technology options were considered, including those of GE, Shell, and ConocoPhillips. The use of the Mitsubishi IGCC technology was selected for HECA to generate low-carbon power using hydrogen-rich fuel produced from a solid feedstock (HECA 2012e, Section 6.0). Other technologies such as pulverized coal technology and oxyfuel technology were briefly analyzed but would not meet carbon capture goals, were environmentally inferior (lower efficiency, higher water usage, and higher emissions), or were an unproven technology at the HECA project scale (HECA 2012e, Section 6.0).

The MHI gasifier has the theoretical capability to achieve feedstock flexibility similar to that of the previously proposed General Electric (GE) slurry fed refractory lined gasifier, which was the technology included within the original HECA project filing in 2008 (HECA 2013n). While the General Electric gasifier had the ability to operate with 100 percent petcoke and support flexibility to operate with up to 60 percent coal (HEI 2008a), the MHI gasifier technology is designed to improve efficiency with a dry feed system, and improve reliability with a membrane wall and slagging ash removal. Staff agrees that the MHI gasifier design is the likely direction of solid fuel gasification and CCS projects, despite current HECA limits on coal/pet coke blends.

Actions Associated With the Reduced Coal/Increased Petcoke Upon Conclusion Of The Five-Year Section 48a Program Requirement Period Alternative

This alternative assumes that to reduce coal use after completion of either two-years or five-years of operations, the HECA project owner would:

- Operate the proposed gasifier at a different coal/petcoke blend; or
- Replace the gasifier with one similar or identical to that proposed within the 2008 Revised AFC, which could operate with 100 percent petcoke and support flexibility to operate with up to 60 percent coal (HEI 2008a).

Ability to Meet HECA Project Objectives

Alternatives Table 6 provides information on how this alternative would meet HECA project objectives. Kern County Planning and Community Development Department, public, and intervener comments requested the scope and content of this analysis include an alternative that would reduce coal use and transport. As such, staff further evaluated a Reduced Coal/Increased Petcoke Alternative.

Alternatives Table 6
Comparison of Reduced Coal/Increased Petcoke Alternative to HECA Project Objectives

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
Provide dependable, low-carbon electricity to help meet future power needs … (Note: HECA may not meet this project objective.)	No	Reducing the percentage use of coal in HECA's fuel blend after the five-year Section 48A Program requirement period would not affect HECA's inability to produce dependable low-carbon electricity.
… and to help back-up intermittent renewable power sources, to support a reliable power grid. (Note: HECA would not meet this project objective.)	No	Reducing the percentage use of coal in HECA's fuel blend after the five-year Section 48A Program requirement period would not affect HECA's inability to back-up intermittent renewable power sources.
Enhance the production and availability of in state nitrogen-based products for use in agricultural, transportation, and industrial applications by producing approximately 1 million tons per year of low-carbon products, including urea, UAN, and anhydrous ammonia.	Yes	Reducing the percentage use of coal in the HECA project fuel blend after the five-year Section 48A Program requirement period would not impact the HECA project's ability to produce nitrogen-based products.
Conserve domestic energy supplies and enhance energy security by using abundant solid feedstocks, coal, and petroleum coke to generate electricity and manufacture low-carbon nitrogen based products.	Yes	Reducing the percentage use of coal in HECA's fuel blend after the five-year Section 48A Program requirement period would not significantly impact HECA's ability to conserve domestic energy supplies and enhance energy security by using petroleum coke (and to some extent coal) to generate electricity.
Mitigate impacts related to climate change by dramatically reducing	Yes	Reducing the percentage use of coal in HECA's fuel blend after the five-year Section 48A Program

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
average annual GHG emissions relative to those emitted from a conventional power plant and/or nitrogen-based product manufacturing facility by capturing, at a rate of at least 90 percent, and sequestering CO_2.		requirement period would not impact HECA's ability to mitigate GHG emissions when compared to a conventional power plant and would not impact the ability for CO_2 capture and sequestration by HECA.
Use captured CO_2 for EOR to produce additional oil reserves.	Yes	Reducing the percentage use of coal in HECA's fuel blend after the five-year Section 48A Program requirement period would not affect HECA's ability for CO_2 capture, sequestration and EOR.
Demonstrate advanced solid fuel based technologies that can generate clean, reliable, and affordable electricity in the United States … (Note: HECA may not meet this project objective.)	Yes	Reducing the percentage use of coal in HECA's fuel blend after the five-year Section 48A Program requirement period would not affect HECA's ability to demonstrate advanced solid fuel based technologies for low-carbon electrical generation or impact CO_2 capture and sequestration.
… and prove out carbon capture and sequestration as a viable method for reducing the carbon footprint of power generation and manufacturing. (Note: HECA would not meet this project objective.)	No	HECA has not shown that it would reduce the carbon footprint of power generation facilities likely to be located in California. Reducing the percentage of coal in HECA would not change this conclusion.
Facilitate and support the development of hydrogen infrastructure in California by supplementing the quantities of hydrogen available for future energy and transportation technologies. (Note: HECA would not meet this project objective.)	No	Reducing the percentage use of coal in HECA's fuel blend after the five-year Section 48A Program requirement period would not affect the project's ability to generate hydrogen and facilitate/support the development of hydrogen infrastructure in California.
Minimize environmental impacts associated with the construction and operation of the project through technology selection, project design, and implementation of feasible mitigation measures, where necessary.	Yes	Reducing the percentage use of coal in the HECA project fuel blend after the five-year Section 48A Program requirement period would lessen environmental impacts associated with the transport of coal to the project site.
Site the project at a location over which HECA LLC will have control, and which offers reasonable access to necessary infrastructure, including natural gas, process water supply, transmission and rail interconnection, and geologic formations appropriate for CO_2 EOR and sequestration.	Yes	Reducing the percentage use of coal in the HECA project fuel blend after the five-year Section 48A Program requirement period would not impact the HECA project's ability to site this alternative within the HECA project site and utilize proposed linear infrastructure.
Ensure the economic viability of the project by integrating electricity production with the manufacture of multiple products to meet market demand. (Note: HECA may not meet this project objective.)	Possibly	Reducing the percentage use of coal in HECA's fuel blend after the five-year Section 48A Program requirement period would not affect the project's ability to produce hydrogen for use in producing nitrogen-based products.
Meet all requirements necessary to secure and retain DOE funding for	Yes	This alternative would reduce the percentage use of coal in the HECA project fuel blend after fulfillment of the two-

HECA PROJECT OBJECTIVE	Meets Objective?	Consistency Analysis
the project.		year DOE demonstration period. As such, it would not conflict with DOE's CCPI Program requirements.

Feasibility

Energy Commission engineering staff have evaluated the feasibility of this alternative. In response to a staff data request, the project applicant reiterated a long-term commitment to the 75/25 mix under the condition that they "retain the capability to run more than 25 percent petroleum coke (petcoke), either for economic reasons or in response to fuel supply disruptions" (HECA 2012q). The project applicant restated this position in their response to questions raised at the January 16, 2013 Status Conference, citing the lack of commercial operating experience at varied feedstock blends, specifically stating (HECA 2013n):

- "The MHI gasifier has the theoretical capability to achieve feedstock flexibility similar to that of the previously proposed General Electric refractory lined gasifier; however, more operating experience is necessary to determine whether this theoretical capability can be fully realized."
- "Demonstration (of petcoke) at scale must be incorporated into the experience base of MHI before the full range of feedstock flexibility can be determined and guarantees can be made."
- "In sum, from an investor's prospective, the use of petcoke as a feedstock is less desirable than coal due to a perceived increased risk of supply disruption."

Based upon engineering staff review and analysis, unless and until the Mitsubishi power block and gasifier can be shown to have feedstock flexibility and commercial viability, modifying the existing system is not a reasonable alternative. Among the major manufacturers that offer a pairing of fuel gasification with a combined cycle (IGCC), only GE has a commercial track record with varying the feedstock blends of coal and petcoke. GE utilizes an entrained flow gasifier originally developed by Chevron-Texaco (Breault 2010). Given the limitation of current commercial scale knowledge, the case for adjusting feedstock blends in response to market availability is not an inevitable outcome. The cost benefit of securing long-term fuel contracts for the life of the facility at the 75/25 coal to petcoke fuel mix would have to be weighed against impacts of:

- Cost of design and development of a system consisting of a manufacturing hybrid, i.e. GE and Mitsubishi;
- Lost electrical power production in Year 6 in order to make the necessary plant modifications;
- Lost product production with the temporary shutdown of the ammonia manufacturing facility; and
- Interruption and potential loss of the enhanced oil recovery (EOR) system, which is dependent upon the generation and transmission of carbon dioxide (CO_2).

Engineering staff evaluation of this alternative also included review and analysis of the following items:

- Feasibility of MHI System to Accommodate Variable Fuel Blend: MHI has no commercial track record on the use of liquid petroleum refining by-products with its gasifier beyond the commitment to provide reliable operation at the 75 percent coal and 25 percent petcoke fuel blend.
- Maximum Petcoke Blend Ratio During Demonstration Period: The MHI gasifier is an entrained flow gasifier co-developed jointly with Combustion Engineering. It is a dry feed system for low rank coals having high moisture content, demonstrated at a plant started up in 2007 in Nakoso, Japan. Beyond the commitment by MHI to guarantee performance at 75/25, MHI has no track record with coal and liquid petroleum refinery by-products blends (Breault 2010). Without further demonstration, the safe and acceptable range of fuel blends beyond 75/25 is unknown.
- Design Requirements to Replace Gasifier: It is unlikely that the replacement of a single component would be sufficient to maintain the chemical and energy equilibrium of the existing HECA system. Achieving equilibrium would require modifications of all the intermediate processes including conversion of feedstock blend to a hydrogen gas fuel, removal of sulfur and other solid constituents from the raw fuel mix, operation of a proprietary method for acid gas removal (Rectisol), and the carbon dioxide transmitted to the enhanced oil recovery system. The design effort to evaluate and modify the changes would be concomitantly significant.
- Impact of Gasifier Modification to Fertilizer Manufacturing Output: The most obvious effect on the fertilizer manufacturing facility would be the disruption of product production during the shutdown time required to modify the gasification system.
- Cost to Replace Gasifier: Staff is currently unable to determine this.
- Adequacy of Petcoke Feedstock Within California Operating at 100 Percent Petcoke: The HECA applicant estimated that, at the fuel blend using 25 percent petcoke, HECA would consume 1,140 short tons per day (stpd), 400,000 short tons per year (sty) or about 7 percent of the total in-state production (HECA, 2012e, p. 2-16). If the petcoke consumption quadrupled to 100 percent, the consumption of the available petcoke inventory would increase by four times (4x) to 28 percent. This is a significant increase.

Energy Commission Staff Conclusion

Independent staff review of general information regarding IGCC technology corroborates information reviewed and assessed for the specific conditions of the HECA project:

1. The loss of power and fertilizer production would cause an interruption in providing service reliably.
2. Without commercial operating experience, the option to vary the feedstock blends is not a legitimate alternative.
3. More effort would be involved in implementing the above modifications than the simple replacement of the MHI gasifier furnished in the design outlined in the Amended AFC (2012) and subsequent written correspondence with the project applicant on this subject (HECA 2013n).

This alternative has the ability to lessen or avoid long-term impacts associated with coal transport and operation of HECA and would achieve a similar number of the project objectives when compared to HECA. However, staff's analysis shows that the Reduced Coal/Increased Petcoke Upon Conclusion Of The Five-Year Section 48a Program Requirement Period Alternative would be technologically infeasible.

ALTERNATIVES STILL UNDER CONSIDERATION

This section briefly discusses known alternatives still under consideration by Energy Commission staff. Some of these will also be considered by DOE as part of the NEPA process. Analysis of these alternatives will be provided in the FSA/FEIS. It should be noted that the alternatives still under consideration will be evaluated in the FSA/FEIS as either feasible (and evaluated in detail) or infeasible (and eliminated from further evaluation).

For a description of water supply alternatives to be evaluated within the FSA/FEIS, please refer to the **Water Supply** section within this PSA/DEIS (Section 4.15).

The public and other interested entities are invited to comment on these alternatives and their feasibility.

DRY COOLING OR WET-DRY HYBRID COOLING ALTERNATIVE

Agency, public, and intervener comments requested the scope and content of this analysis include a Dry Cooling or Wet-Dry Hybrid Cooling Alternative. The project applicant has indicated that output, cost, and efficiency penalties associated with using only air cooling are much more significant for the HECA project than for a typical natural gas combined cycle (NGCC) project because for an NGCC, the efficiency impact is confined to the steam turbine; whereas in the HECA process units (gasification, gas treatment, and manufacturing complex), the impacts occur to many pieces of equipment, most of which are significantly more sensitive to heat rejection temperature than a steam turbine (HECA 2012ll, Response A203). The applicant indicates that HECA would have cooling towers for the air separation unit, the power block and the gasifier processes.

The project applicant has stated that the efficiency loss (increase in auxiliary load) and capital cost impacts associated with implementing air cooling in the process portion of the plant makes this alternative infeasible with no real benefit (HECA 2012ll, Response A203). Based on its research, the applicant has stated the selection of an air-cooled process would result in the following (HECA 2012ll, Response A203):

- Capital cost differential of approximately $20-30 million;
- Reduced power output of between 20 to 40 megawatts (MW); and
- Overall total cost impact of about $50 million.

At the time of the PSA/DEIS publication, Water Supply staff is unable to determine if Dry Cooling or Wet-Dry Hybrid Cooling Alternative is feasible and has the potential to reduce significant water use impacts. Therefore, a Dry Cooling or Wet-Dry Hybrid Cooling Alternative will be evaluated in the FSA/FEIS to determine if it can reduce

HECA's water consumption. For a further discussion of the Dry Cooling or Wet-Dry Hybrid Cooling Alternative, please refer to the **Water Supply** section within this PSA/DEIS (Section 4.15). DOE believes that is a project-level alternative that merits further analysis and consideration.

NATURAL GAS COMBINED CYCLE WITH CARBON CAPTURE AND STORAGE (CCS)

As described in the subsection "Alternatives Eliminated From Detailed Consideration," staff has eliminated the Natural Gas Project Alternative which consists of a conventional natural gas-fired electric generation facility that would generate electricity but would not include CO_2 capture or storage, EOR at the Elk Hills Oil Field, or production of any fertilizer or other nitrogen-based products.

To conduct a thorough and robust alternatives analysis, staff is considering an alternative that would consist of a natural gas combined cycle electrical generation facility capable of carbon capture and storage (CCS) for EOR at the Elk Hills Oil Field. This alternative includes the possible development of a new natural gas combined cycle facility (either at the HECA site or another site). Engineering staff considers that CCS coupled with natural gas power plants should be evaluated, especially when looking to the future as easily dispatchable natural gas capacity is expected to be used to back up intermittent renewable energy sources, not base-loaded coal facilities. Additionally, many depleted oil fields that are the targets of CCS deposits and EOR are within California.

Staff acknowledges that many HECA project objectives are linked to coal/petcoke gasification for electrical production, CCS, and production of fertilizer and other nitrogen-based products. Staff also acknowledges the issue of losing project funding resulting from implementation of a natural gas combined cycle with CCS Alternative versus the HECA project is an important consideration, as it would eliminate coal-fueled electricity production (a requirement for DOE funding and section 48a tax credits) from the project while still demonstrating CCS and EOR at the EHOF. Additionally, to separate carbon dioxide from the other constituents inherent in natural gas combustion versus combustion of hydrogen derived from gasification of coal/petcoke, this alternative may require different above-ground components than those associated with the HECA project. For example, a steam reformer may be needed to produce hydrogen-rich fuel in place of the coal/pet coke gasification system, if the objective is to capture carbon before combustion and/or to incorporate fertilizer production into the project. The cost of the natural gas system should be compared to the cost of the coal/pet coke system (including gasifier, air separation unit, coal/pet coke delivery and storage onsite) and the difference in cost should be compared to the DOE funding and section 48a tax credits that would be lost. Furthermore, the differential cost between coal/pet coke and natural gas would need to be included for a more complete cost comparison. Finally, at the quantity of carbon dioxide proposed by HECA to be sequestered, a natural gas system with CCS is likely to be able to generate more new incremental MW capacity than HECA's net incremental MW capacity that would be added to the grid. This result is expected because natural gas has approximately half the carbon per BTU than does coal.

As this alternative would not require the transport and use of coal and petcoke feed stocks, as well as transport of nitrogen based products, the environmental benefits of this alternative would be to lessen or avoid adverse impacts (Air Quality, Transportation/Traffic, Biological Resources) associated with these HECA project features. Please refer to all relevant environmental issue area analyses (refer to Section 4 of this PSA/DEIS).

This alternative is not a reasonable one for DOE's purpose and need. DOE's authority to provide financial assistance is limited to projects that use coal. This is an example of a situation in which there is a divergence of alternatives under CEQA and NEPA.

BIOMASS BOILER ALTERNATIVE

Staff is considering an alternative that would consist of a biomass-fired boiler that would provide the same net new electrical capacity and energy as HECA. This alternative may not provide carbon capture and storage, but would provide a new, local renewable energy facility with essentially a zero-carbon footprint, depending on how far the biomass would have to be transported to the facility site. There is at least one existing biomass-fired boiler in Kern County, which recently converted from coal. The availability of biomass to fuel a new boiler in southern San Joaquin Valley has yet to be evaluated. It should also be noted that this alternative was requested by Sierra Club, as identified in the subsection "Public and Agency Participation."

This alternative is not a reasonable one for DOE's purpose and need. DOE's authority to provide financial assistance is limited to projects that use coal. This is an example of a situation in which there is a divergence of alternatives under CEQA and NEPA.

ADDITIONAL ALTERNATIVE SITES

Alternative sites evaluated in the subsection "Alternatives Eliminated From Detailed Consideration" focused on locations proximate to the EHOF. Public comments provided at the San Joaquin Valley Air Pollution Control District (SJVAPCD) Preliminary Determination of Compliance public workshop on April 2, 2013 for the HECA project included a request that Energy Commission staff evaluate alternative sites for the HECA project located up to 200 miles from the proposed site, with the project including an expansive CO_2 pipeline to the EHOF for EOR. Due to the timing of this comment and the size and scale of this request, staff was unable to consider this alternative prior to publication of this PSA/DEIS. Staff's preliminary review has shown power plant facilities within the United States successfully demonstrating CCS with CO_2 pipelines over 200 miles long providing EOR. For example, the Great Plains Synfuels Plant near Beulah, North Dakota transports CO_2 via a 205-mile pipeline to an oil field near Weyburn, Saskatchewan, Canada for EOR. This alternative will be considered within the FSA/FEIS.

This alternative is not a reasonable one for DOE's purpose and need. DOE's authority to provide financial assistance using monies appropriated by the Recovery Act prohibits changes in the project's scope (including significant location changes) after September 20, 2010. Also, the applicant has invested significant financial resources in obtaining the option to purchase the site, and would be unable or unwilling to move the project at this late date. This is another example of a situation in which there is a divergence of alternatives under CEQA and NEPA.

COAL TRANSFER ROUTE ALTERNATIVES

The HECA project includes both rail and truck options for coal delivery from the rail transfer point. These options are analyzed in the **Traffic and Transportation** and **Land Use** sections of this PSA/DEIS. With respect to alternative rail and truck routes, each proposed route option was selected to utilize existing rail and roadways, minimize travel distance, and minimize any potential ground disturbance activities. As discussed in the **Biological Resources** section of this PSA/DEIS, the proposed project would result in potentially significant impacts to San Joaquin kit fox as a result of fox being run over by trucks. At present, an adequate mitigation proposal has not been received. At this time, creation of new coal transport rights-of-way or longer travel distances for coal via rail or truck are not known to lessen or avoid any impacts associated with the coal transport options being evaluated. Alternatives staff will continue to coordinate with Biological Resources staff to determine if alternative truck routes may be developed for the FSA/FEIS. At this time, therefore, alternative coal transport routes were not developed by staff and may be evaluated or eliminated from consideration in the FSA/FEIS. DOE believes that is a project-level alternative that merits further analysis and consideration.

ALTERNATIVES EVALUATED IN DETAIL

An analysis comparing the environmental effects of HECA to each of the project alternatives warranting detailed evaluation is provided below. The project action alternatives evaluated in detail meet the alternatives screening requirements discussed earlier in the subsection “CEQA Requirements.” **Alternatives Table 7** provides a summary of each alternative’s ability to fulfill project objectives.

Following an overview of each alternative, an environmental analysis by resource area is provided for each alternative. The analysis is focused on the ability of the alternative to avoid or lessen any significant project impacts (as identified within **Alternatives Table 1**). **Alternatives Appendix 1** contains a list of staff contributors to the environmental analysis of alternatives evaluated in detail.

Alternatives Table 7
Summary Comparison of Alternatives Evaluated in Detail to Project Objectives

Project Objective	No Project Alternative (CEQA) No Action Alternative (NEPA)	No Fertilizer Manufacturing Complex (Reduced Project) Alternative
Provide dependable, low-carbon electricity to help meet future power needs … (Note: HECA would not meet this project objective.)	No. Under the No Project Alternative, no electricity would be produced by the HECA project.	Potentially. If HECA is constructed and attains mature operations, it would demonstrate that coal facilities could be carbon-equivalent to natural gas facilities
… and to help back-up intermittent renewable power sources, to support a reliable power grid. (Note: HECA would not meet this project objective.)	No. HECA could not back up intermittent renewable power sources.	Under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, without the fertilizer manufacturing complex the facility would have less ability to ramp up and down by approximately 114 megawatts.
Enhance the production and availability of in state nitrogen-based products for use in agricultural, transportation, and industrial applications by producing approximately 1 million tons per year of low-carbon products, including urea, UAN, and anhydrous ammonia.	No. Under the No Project Alternative, no nitrogen-based products would be produced by the HECA project. Pet coke would continue to be exported to other countries for their use (with associated GHG emissions).	No. Under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, no nitrogen-based fertilizer products would be produced by HECA.
Conserve domestic energy supplies and enhance energy security by using abundant solid feedstocks, coal, and petroleum coke to generate electricity and manufacture low-carbon nitrogen based products.	No. The No Project Alternative would not produce electricity or nitrogen based products. However, the facility would have less ability to ramp up and down by approximately 114 megawatts.	No. While this alternative would enhance energy security by using petcoke and coal to generate electricity, no nitrogen-based fertilizer products would be produced under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative.
Mitigate impacts related to climate change by dramatically reducing average annual GHG emissions relative to those emitted from a conventional power plant and/or nitrogen-based product manufacturing facility by capturing, at a rate of at least 90 percent, and sequestering CO_2.	No. While the No Project Alternative would not generate any GHG emissions, no nitrogen-based products would be produced and no CO_2 sequestration by HECA would occur.	**Yes.** Under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, no nitrogen-based fertilizer products would be produced by HECA, which would reduce air quality emissions from transporting fertilizer products produced by the project. Furthermore, this alternative would not impact the ability for CO_2 capture and sequestration by the HECA project.
Use captured CO_2 for EOR to produce additional oil reserves.	No. Under the No Project Alternative, no CO_2 sequestration for EOR would occur by HECA.	**Potentially**. The No Fertilizer Manufacturing Complex (Reduced Project) Alternative would not affect the ability for CO_2 capture, sequestration and EOR by the HECA project. However, HECA has not shown that their project would produce oil reserves that could not otherwise be produced by other means.
Demonstrate advanced solid fuel based technologies that can generate clean, reliable, and affordable electricity in the United States …	No. Under the No Project Alternative, no electricity or carbon capture would be created by HECA.	**Potentially**. The No Fertilizer Manufacturing Complex (Reduced Project) Alternative would not impact the ability of the HECA project, if it reaches

Project Objective	No Project Alternative (CEQA) No Action Alternative (NEPA)	No Fertilizer Manufacturing Complex (Reduced Project) Alternative
(Note: HECA may not meet this project objective.)		mature operations, to generate low-carbon electricity utilizing solid fuel based technologies or impact CO_2 capture and sequestration, assuming project financing was not adversely affected. If HECA is constructed and attains mature operations, it would demonstrate that coal facilities could be carbon-equivalent to natural gas facilities. However, the applicant has not shown that the electricity produced by HECA would be priced at a low enough price to meet their stated annual hours of operation and at a high enough price to make their facility operate reliably.
… and prove out carbon capture and sequestration as a viable method for reducing the carbon footprint of power generation and manufacturing. (Note: HECA would not meet this project objective.)	No. Under the No Project Alternative, no carbon capture and sequestration would be included as a means of reducing the carbon footprint of power generation and manufacturing.	No. HECA has not shown that its facility would reduce the carbon footprint of power generation facilities likely to be located in California.
Facilitate and support the development of hydrogen infrastructure in California by supplementing the quantities of hydrogen available for future energy and transportation technologies. (Note: HECA would not meet this project objective.)	No. Under the No Project Alternative, no hydrogen infrastructure would be developed by HECA.	No. HECA has not shown that their facility would facilitate development of hydrogen infrastructure in California.
Minimize environmental impacts associated with the construction and operation of the project through technology selection, project design, and implementation of feasible mitigation measures, where necessary.	**Yes.** Under the No Project Alternative, none of the environmental impacts associated with HECA would occur.	**Yes.** Under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, no nitrogen-based fertilizer products would be produced by the project, which would reduce significant solid waste impacts associated with HECA.
Site the project at a location over which HECA LLC will have control, and which offers reasonable access to necessary infrastructure, including natural gas, process water supply, transmission and rail interconnection, and geologic formations appropriate for CO_2 EOR and sequestration.	No. Under the No Project Alternative, the HECA project would not be built.	**Yes.** Under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, the proposed fertilizer complex would not be built, and the project's ability to site this alternative within the HECA project site and utilize proposed linear infrastructure would not be significantly affected.
Ensure the economic viability of the project by integrating electricity production with the manufacture of multiple products to meet market demand. (Note: HECA may not meet this project objective.)	No. Under the No Project Alternative, the HECA project would not be built.	No. Under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, no nitrogen-based fertilizer products would be produced by the HECA project. The project is likely to be less financially viable if no fertilizer is manufactured.
Meet all requirements necessary to secure and retain DOE funding for the project.	No. Under the No Project Alternative, the HECA project would not be built.	**Yes.** Under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, the proposed fertilizer complex would not be built.

Project Objective	No Project Alternative (CEQA) No Action Alternative (NEPA)	No Fertilizer Manufacturing Complex (Reduced Project) Alternative
		However, the elimination of this facility would not conflict with DOE CCPI Program requirements.

NEPA NO ACTION ALTERNATIVE

Environmental Analysis

The analysis of the impacts of NEPA's No Action Alternative is contained within each environmental issue area section of this PSA/DEIS. Under the No Fund (NEPA No Action) Alternative, DOE would not provide financial assistance to the applicant for the HECA project. The applicant could still elect to construct and operate its project in the absence of financial assistance from DOE, but DOE believes this is unlikely. For the purposes of analysis in the PSA/DEIS, DOE assumes the project would not be constructed under the No Action Alternative.

CEQA NO PROJECT ALTERNATIVE

Overview

While the No Project Alternative would be inconsistent with all but one HECA project objective (refer to **Alternatives Table 7**), this analysis evaluates the No Project Alternative to the HECA project to fulfill Energy Commission requirements under CEQA §15126 and DOE's obligation to analyze a No Action Alternative under NEPA (40 C.F.R. § 1502.14(d)). As described in Section 6.2 of the Amended AFC (2012), under the No Project Alternative, HECA would not receive authorization from the Energy Commission to construct and operate a low-carbon IGCC polygeneration facility. As a result, under the No Project Alternative, the HECA project would not be developed (HECA 2012ll, Response A201).

Environmental Analysis

Air Quality

There would be no direct, localized emission changes to the SJVAPCD under the No Project Alternative. Therefore, there would be no direct impacts related to air quality and no mitigation agreements would be required under the No Project Alternative.

Biological Resources

HECA and its associated linear facilities are located in a rural, agricultural setting. Under the No Project Alternative, staff assumes most of the project area would remain in active agriculture. No natural allscale scrub habitat would be converted to agriculture for the project's associated transmission lines and linears. Agriculture is a land use that is relatively non-compatible with most terrestrial wildlife and special-status plant species that occur in the project area. Under the No Project Alternative, direct and indirect sources of biological impacts would remain at current levels including habitat disturbance, traffic, air emissions, ambient noise and lighting sources. Biological effects associated with implementation of the proposed project would not occur and the biological baseline would remain relatively unchanged. Staff also assumes under the No Project Alternative, that the Occidental CO_2 EOR project would not be implemented, and there would be few changes to the current impacts to special-status plant and wildlife species as a result of oil and gas activities on the EHOF. Therefore, the current endangered species permitting and mitigation strategy for ongoing oil and gas activities on EHOF would also remain in effect under the No Project Alternative and the biological baseline on EHOF would remain relatively unchanged. In summary, the potential for impacts to biological resources under the No Project Alternative would be less than those under the HECA project.

Carbon Sequestration and Greenhouse Gas Emissions

There would be no direct greenhouse gas emissions and there would be no carbon sequestration under the No Project Alternative. Therefore, no impacts would occur related to greenhouse gas emissions, climate change, and there would be no geologic or other impacts related to carbon sequestration under the No Project Alternative.

While the No Project Alternative would not result in direct emissions of greenhouse gases, other sources of these would continue to operate. Other less efficient or more CO_2-emitting power and fertilizer plants might be constructed in its place or existing plants might be operated more, thereby increasing their CO_2 emissions,

Domestically produced oil, with or without EOR, reduces CO_2 emissions caused by the transportation of foreign oil into the United States. The average distance of "water carrier" transport of imported oil is estimated at 4,300 miles/barrel (bbl). The CO_2 equivalent emissions associated with this transport are estimated at approximately 12 pounds of CO_2 per barrel of foreign oil transported to refineries in the United States. Based on the estimated increased production of domestic oil resulting from the use of the project's CO_2 for EOR at the OEHI (4,500 to 22,500 bbl/day), HECA could result in a CO_2 reduction of 10,000 to 49,000 tons/yr. This potential reduction in CO_2 would not be realized under the No Project Alternative.[3]

Similarly, under the No Action Alternative, there would be no production of urea or other nitrogenous compounds. HECA is estimated to generate 550,000 tons/yr of pelletized urea. Presently, all of the urea consumed in California's Central Valley is produced outside of California. Accordingly, the No-Project Alternative would require California to continue to import 100 percent of its urea, resulting in CO_2 from its transportation. Unlike the urea produced by HECA, it is likely that this imported urea is produced by facilities that do not capture and sequester their CO_2 emissions.

Finally, the No Project Alternative would not present the opportunity to demonstrate carbon capture and sequestration at a commercial scale.

Cultural Resources

Under the No Project Alternative, the current mix of land use practices in the project area of analysis/area of potential effects (PAA/APE) would continue (refer to the **Cultural Resources** section of this PSA/DEIS, Section 4.4, subsection "Project Area of

[3] Variations in crude oil and relationships of supply and demand are not reflected in these numbers. Numbers calculated using DOE-NETL's UpStreamDashBoard_v2.0.3 (DOE 2013) available at http://www.netl.doe.gov/energy-analyses/refshelf/PubDetails.aspx?Action=View&PubId=439

Analysis and Area of Potential Effects"). For the HECA site, controlled area, associated linears, and CO_2 pipeline north of the California Aqueduct, lands within the PAA/APE would remain in agricultural production and water conveyance. For the proposed CO_2 pipeline south of the California Aqueduct and EOR project elements, lands within the PAA/APE would be subject to maintenance of water conveyance structures, grazing, and oil production. The proposed EOR project elements would remain in oil production. Each of these types of activities would entail ground disturbance: disking and deep-ripping fields, off-pavement vehicular traffic, the passage of cattle, road maintenance and development, and well drilling and maintenance.

Although ground disturbance would continue under the No Project Alternative and result in impacts to surface archaeological resources identified in **Cultural Resources Table 8**, these impacts would occur at current intensity and generally at shallower depths than under the HECA project. The No Project alternative would result in impacts less severe than those of the HECA project. However, staff cannot currently assess the significance of impacts on buried archaeological resources in the PAA/APE or surface archaeological resources in the proposed EOR area; therefore, the significance of ground-disturbing impacts on buried archaeological resources in the PAA/APE and surface archaeological resources in the EOR area under the No Project Alternative is unknown.

Under the No Project Alternative, the only reasonably foreseeable impacts on significant historic built environment resources (Old Headquarters Weir and California Aqueduct) would be alteration of the structures for maintenance purposes. The significance level of impacts on these two cultural resources would be similar (less than significant).

Staff cannot currently assess the significance of impacts on historic built environment resources in the proposed EOR area. Therefore, the significance of impacts on historic built environment resources in the proposed EOR area under the No Project Alternative is unknown.

Geology and Paleontology

HECA is located in an active geologic area of the southern Great Valley geomorphic province in western Kern County, California. Because of its geologic setting, the site could be subject to moderate to high levels of earthquake-related ground shaking. Significant thicknesses of expansive clay soils are also present at the surface.

There are no known viable geologic or mineralogical resources at the site, with the exception of the oil and gas fields of the Naval Petroleum Reserve. Paleontological resources have been documented regionally within Quaternary alluvium and Tertiary Tulare Formation, similar to deposits that underlie the HECA site.

The No Project Alternative would not create a facility on the site and would therefore, not cause site grading or foundation construction that could disturb site soils that may potentially contain important fossils. Additionally, the absence of site development would preclude the erection of structures that could be susceptible to potential geologic hazards.

Therefore, the No Project Alternative would create no activities or objects that would increase impacts to geological or paleontological resources or be subject to geological hazards. Therefore, no impacts would occur related to geology and paleontology.

Hazardous Materials

Under the No Project Alternative, the need for hazardous materials management would be reduced to zero during either construction or operations. No hazardous materials would be transported to or from the facility, used at the site, or stored on the site. Therefore, no impacts would occur to the off-site public.

Land Use and Agriculture

No activities would impact land use or agricultural activities under the No Project Alternative. Therefore, no impacts would occur related to land use and agriculture.

Noise and Vibration

No activities that would increase noise or groundborne vibration levels above existing conditions would occur under the No Project Alternative. Therefore, no impacts would occur related to noise and vibration.

Public Health and Safety

Under the No Project Alternative, impacts on public health would be reduced to zero risk due to no exposure to toxic air contaminant during either construction or operations.

Socioeconomics

No activities that would impact socioeconomic resources would occur under the No Project Alternative. Staff notes that the No Project Alternative would eliminate any potential economic benefits that might otherwise result from HECA project construction and operation.

Soil and Surface Water

Under the No Project Alternative, continuing agricultural activities could cause potential soil erosion. The HECA project conservatively assumes that all 453 acres of the site would be disturbed during construction, which would be similar to the disturbance for the No Project Alternative, assuming agricultural activities would include a significant portion of the 453-acre site. However, construction of the HECA project would also include substantially more earthwork (such as excavation of unsuitable soil and construction of large berms), use of large construction equipment, and a larger number of active vehicles and personnel at the site. Although construction activities under the HECA project and agricultural activities under the No Project Alternative would both implement appropriate Best Management Practices (BMPs) to reduce the amount of soil erosion, staff believes that the No Project Alternative would have less impacts to soil erosion compared to the HECA project during construction due to the much larger amount of earthwork.

Conversely, the No Project Alternative would have greater impacts to soil erosion compared to the HECA project during operations, because ground disturbing activities would end after the HECA project is constructed and the site is stabilized. Ongoing farming activities would result in continued ground disturbance and potential soil erosion with the No Project Alternative. Furthermore, the HECA project would implement soil stabilizing measures (such as hydroseeding, paving, and gravel) to reduce erosion during operations.

The No Project Alternative does not include any of the facilities associated with the HECA project and there would be no impacts to water quality from the increase of impervious areas, operation of an industrial facility, or sanitary waste. As a result, these impacts under the No Project Alternative would be much less than the HECA project. In addition, because No Project Alternative does not include a CO_2 EOR component, all impacts associated with the CO_2 EOR facility would be much less than the HECA project. The No Project Alternative would generally maintain existing drainage patterns during times when rainfall produces runoff, allowing gradual sheet flow across agricultural land and into an onsite irrigation ditch, or to the site boundary and offsite. Although the increased impervious area of the HECA project could potentially increase the impacts of both onsite and offsite flooding, onsite retention basins would mitigate these impacts by directing flows away from proposed facilities and preventing the increased volume of runoff from flowing offsite. For this reason, staff believes that the potential impacts from onsite and offsite flooding of the No Project Alternative would be somewhat greater than the HECA project. During extremely large rain events (100-year storm or larger), some of the smaller unlined retention basins may overflow storm water runoff onto the site. The proposed berm located at the north border of the site could dam and redirect flow to cause localized flooding and erosion. For this situation, the No Project Alternative would be similar to the HECA project.

Assuming the No Project Alternative could potentially use pesticides or herbicides during agricultural activities, contaminated runoff could potentially impact water quality of offsite water resources (though BMPs could reduce these impacts). The HECA project would retain all wastewater and storm water runoff onsite, therefore the No Project Alternative would have somewhat greater potential impacts to water quality from contaminated runoff. The HECA project site is located outside the designated Federal Emergency Management Agency (FEMA) 100-year flood zone, the potential for the project to impede or re-direct expected 100-year flood flows would be less than significant. Therefore, these impacts under the No Project Alternative would be similar to the HECA project.

Traffic and Transportation

Activities that would increase traffic on the local roadway system above existing conditions and that would introduce a potential aircraft hazard (i.e., exhaust plumes) would not occur under the No Project Alternative. Therefore, no impacts would occur related to traffic and transportation.

Transmission Line Safety and Nuisance

With the No Project alternative, the field and non-field impacts from operating the project-related transmission lines would not occur. The field impacts would relate to the perceptible and non-perceptible field impacts described in staff's analysis as noise impacts, shock hazards, interference with radio-frequency communication, and fire hazards and human exposure to electric and magnetic fields. The noted hazard to area aviation would relate to the physical presence of the line itself. Although the proposed line design and operational plan would reduce these field and non-field impacts to levels of environmental insignificance, introduction of the line would generate such impacts in an area that would have been without them. The No Project Alternative would have no impacts in this area.

Visual Resources

The No Project Alternative would leave the site in a condition identical to its current state. The 453-acre project site is currently being used for farming purposes, including the cultivation of alfalfa, cotton, and onions. The No Project Alternative would eliminate the significant visual impact at KOP 1 (view of the HECA project site, looking west from Station Road), as this impact, resulting from the visual contrast and intrusion of the HECA project facilities, would not occur. Therefore, there would be no impacts to visual resources under present conditions compared to those of HECA.

Waste Management

Three Phase I Environmental Site Assessments (ESAs) and one Phase II ESA were completed for the HECA site. The last Phase I ESA was dated April 2012 and was prepared by URS for the 473-acre project site. The ESA was completed in accordance with the American Society for Testing and Materials Standard Practice E 1527-05 for ESAs. The December 2010 Phase II ESA, prepared by AECOM, was completed to evaluate the recognized environmental conditions (RECs) that were identified in the April 2009 and August 2010 HECA Phase I ESAs. A REC is considered to be the presence or likely presence of any hazardous substances or petroleum products on a property under the conditions that indicated an existing release, past release, or a material threat of a release of any hazardous substance or petroleum products into structures on the property or in the ground, groundwater, or surface water of the property. Most of the RECs for this project are depicted in **Waste Management Figure 1** (refer to the **Waste Management** section of this PSA/DEIS). The RECs for the proposed project site include: five former underground storage tanks (USTs), unidentified concrete structures, a farm equipment wash pad, a former PO fertilizing manufacturing facility (PO), outdoor and indoor tailings piles of raw materials used by PO, PO East Sump, and a number of locations with stained surface soil (HECA 2012e, Appendix L).

Based on available information, the No Project Alternative consists of retaining the HECA site in its current condition. No action would be taken and no energy project would be constructed and operated on the site. No other use is reasonably foreseeable;

therefore, it is assumed that existing conditions would persist at the site absent the proposed project. The No Project alternative would not cause any waste management impacts on existing disposal facilities because no waste would be generated and there would be no disturbance of contamination on site that could impact human health and the environment.

Water Supply

Under the No Project Alternative, baseline conditions would conceivably persist at both the HECA site, the Buena Vista Water Storage District (BVWSD) proposed well field, and at the West Kern Water District (WKWD) well field. No other activities were identified for these locations if HECA were not to receive authorization for operation. An additional 7,500 acre-feet per year (AF/y) would not be extracted from the BVWSD well fields, 12 AF/y would not be extracted from the WKWD well fields, and no water would be extracted from the HECA site.

Impacts resulting from continuation of baseline conditions (No Project Alternative) would be much less than those identified in the **Water Supply** section of this PSA/DEIS (refer to Section 4.15) for the proposed project. The following impacts would potentially be lessened under the No Project alternative:

- Water level lowering in local well owner wells;
- Increased Kern County sub-basin groundwater overdraft;
- Potential impacts to the California Aqueduct from subsidence; and
- Potential degradation of groundwater quality from project pumping.

Worker Safety and Fire Protection

Under the No Project Alternative, impacts on worker safety would be reduced to zero due to no workers being exposed to an industrial environment during either construction or operations. Fire protection would not be needed if no construction or operation occurred and thus there would be no direct or cumulative impact on the Kern County Fire Department.

NO FERTILIZER MANUFACTURING COMPLEX (REDUCED PROJECT) ALTERNATIVE

Overview

While the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would not meet a number of project objectives, this alternative was evaluated for its potential to avoid or substantially lessen significant environmental impacts. Additionally, both public and intervener comments requested the scope and content of this alternatives analysis include a No Fertilizer Complex (Reduced Project) Project Alternative. Therefore, this alternative is evaluated in detail.[4]

The applicant has stated, absent the fertilizer manufacturing complex, HECA would use the hydrogen it produces to generate electricity only (HECA 2012ll, Response A207). The project applicant has stated the prior HECA design, without the fertilizer manufacturing complex (2009 Revised AFC), was abandoned by the previous project owners, in part because it was not economically viable (HECA 2012ll, Response A207).

HECA has the ability to limit the amount of fertilizer produced (HECA 2012ll, Response A207). To evaluate the ability of this alternative to avoid or lessen significant impacts, the No Fertilizer Manufacturing Complex (Reduced Project) Alternative assumes complete elimination of the fertilizer manufacturing facility from the project. This alternative assumes the remaining HECA project facilities would be constructed as proposed within the same project site footprint, but absent the fertilizer complex and necessary infrastructure to serve fertilizer and other nitrogen-based product manufacture and distribution.

Energy Commission engineering staff made the following assumptions and observations regarding the No Fertilizer Manufacturing Complex (Reduced Project) Alternative:

- According to the applicant, the HECA gasifier only comes in one size. Therefore, the No Fertilizer Manufacturing Complex (Reduced Project) Alternative could operate the gasifier at 100 percent capacity with the same coal/petcoke tonnage input and the same ash output. This would hold the fuel delivery and ash removal trains/trucks at the same number. This would also mean that the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would have more H2 to combust in the power block (as H2 can no longer be diverted to the fertilizer plant). This would require the power block to be bigger or run harder, both would increase water use in the cooling tower and also mean more ammonia deliveries for the SCR than ammonia tonnage the HECA project would get from the fertilizer plant. The No Fertilizer Manufacturing Complex (Reduced Project) Alternative would also not have H2 storage on site, so this alternative must burn the excess H2 as it is made.

- Gasifiers (and most solid fuel power plants) are not as flexible as gas plants. They are much easier to operate and maintain if they are operated at a steady state. Once these plant types are brought to a steady fuel input rate state, their H2 output to the CTCC is also fairly fixed.

- Alternatively, under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, the applicant could buy the same gasifier and only operate it at 75 percent of its rated capacity. This would lower the fuel delivery and ash removal trains/trucks. However, staff does not know if the gasifier can turndown that much

[4] DOE believes this may not be a reasonable alternative for purposes of NEPA because the applicant is unlikely to proceed with the project without fertilizer manufacture as it is essential to its financing of the project. This is another example of a situation in which there is a divergence of alternatives under CEQA and NEPA.

and still operate, or what are its operating characteristics (efficiency, syngas and slag composition, etc.) at 75 percent capacity.

- Energy Commission staff acknowledges that the fertilizer plant is a very useful flywheel to allow some flexibility between electricity and fertilizer production, as the H2 production out of the gasifier is fairly fixed.

- Under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, the downstream effects should follow. If the gasifier has to operate at 100 percent capacity: coal, ash, sulfur, and electricity should all be tied to that. Should staff determine that the gasifier can operate at 75 percent, downstream numbers could reflect that change, with staff acknowledging any consequences to the gasifier operating off of its design point.

Environmental Analysis

Air Quality

Total HECA project criteria air emissions would change if the fertilizer plant is not built. Nitrogen oxide (NOx) emissions from the fertilizer plant are approximately 11 percent of the total NOx and particulate emissions including inhalable particulate matter less than 10 microns in diameter (PM10). Fine particulate less than 2.5 microns in diameter (PM2.5) are approximately 2 percent of the total PM10 and PM2.5 emissions from stationary source operation of the HECA plant. These emission reduction percentiles are based on the annual permitted HECA stationary source emissions totals (refer to **Air Quality Table 17** within Section 4.1 of this PSA/DEIS) and do not include emissions associated with the OEHI EOR component, nor the expected emissions reductions associated with reduced cooling tower heat rejection. The addition of the fertilizer plant to the HECA project also provides operational flexibility for the gasifier's hydrogen and CO_2 products use, so removing the fertilizer plant could cause an increase in gasifier startup and shutdown frequency that could increase the operating emissions. However, the emissions increase from the loss of operational flexibility is expected to be less than the emissions reduction from removing the fertilizer plant. In addition, emissions from construction and from product transportation during operation would decrease if the fertilizer plant is not built. However, with Energy Commission staff's proposed conditions of certification, air quality impacts from HECA, including impacts from construction and transportation, would be fully mitigated. Therefore, the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would not lessen or avoid any significant (and unmitigable) air quality impact.

Biological Resources

Under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, the HECA project's habitat impact calculation would not change with the removal of this component from the site plan since staff considers use of the 453-acre project site a complete loss of habitat values. However, with the removal of the fertilizer plant and necessary infrastructure to serve the fertilizer complex manufacturing and distribution, fewer vehicle trips would be necessary during operations which would benefit terrestrial wildlife by reducing the effects of increased traffic volumes on wildlife population dynamics, such as vehicle-related road mortality, disturbance and stress from increased human encroachment, changes in prey availability and predator abundance, and reduced genetic exchange as a result of fewer road crossing attempts by wildlife. Although the number of vehicle trips that would decrease from not constructing the fertilizer complex is unknown, staff believes the number of truck trips directly attributed to the manufacturing and distribution of nitrogen-based products is a small percentage of the total operational traffic. While the number of vehicle trips would not be reduced significantly, fewer vehicle trips on roadways would reduce the potential of direct traffic mortality to terrestrial wildlife, primarily San Joaquin kit fox, blunt-nosed leopard lizard, and other upland species of the southern San Joaquin Valley. Overall, impacts related to biological resources would be slightly less under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative when compared to HECA, primarily due to the reduced number of vehicle trips on roadways.

Carbon Sequestration and Greenhouse Gas Emissions

The carbon sequestration operations of the HECA project would not be directly affected by the removal of the fertilizer plant from the project. The CO_2 emissions from the gasifier would still be separated in the same proportions and sent to OEHI for use in EOR and carbon sequestration. Staff has provided conditions of certification and associated verifications to ensure that the impacts from carbon sequestration are less than significant. Therefore, with staff's proposed mitigation measures, the carbon sequestration impacts would be less than significant for the No Fertilizer Manufacturing Complex (Reduced Project) Alternative.

The greenhouse gas emissions from the HECA project would be reduced by a small degree if the fertilizer plant is not built. The carbon dioxide equivalent (CO_2E) emissions from the fertilizer plant are approximately two percent of the total HECA stationary source CO_2E emissions (refer to **Carbon Sequestration and Greenhouse Gas Emissions Table 4** in Section 4.3 of this PSA/DEIS). In addition, greenhouse gas emissions from construction and from product transportation during operation would decrease if the fertilizer plant is not built. However, the removal of the fertilizer plant would not directly impact the carbon sequestration requirements for the facility or impact the CO_2E emissions from the OEHI CO_2 EOR component. The removal of the fertilizer plant would not change the impact determination of the HECA project's greenhouse gas emissions, which were evaluated in the context of the electricity system as a whole and would be less than significant for the No Fertilizer Manufacturing Complex (Reduced Project) Alternative. Yet to be studied is whether operation of the No Fertilizer Manufacturing Complex Alternative facility's electricity would meet California's Environmental Performance Standard developed in response to SB 1368. This may depend on the facility's ability to operate reliably without swinging gasifier output between electricity production and fertilizer manufacturing.

Cultural Resources

Although the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would involve less ground disturbance compared to HECA, staff believes that the impact conclusions would be essentially identical. Removal of the fertilizer manufacturing complex would reduce the horizontal extent of ground disturbance on the HECA site, but all other project elements would remain the same for the purposes of the cultural resources analysis. Specifically, this alternative would affect the same suite of surface archaeological resources as HECA project components, and the severity of impact would be the same. Because the applicant has not yet provided staff with adequate information to assess the proposed project's impacts on buried archaeological resources and cultural resources in the EOR components of the proposed project (see the **Cultural Resources** section of this PSA/DEIS), staff cannot analyze the impacts of this alternative on such resources. Removal of the fertilizer manufacturing complex would not change the project's impacts on the Old Headquarters Weir or the California Aqueduct: as with the HECA project, these impacts would be less than significant under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative.

Geology and Paleontology

The No Fertilizer Manufacturing Complex (Reduced Project) Alternative would slightly reduce the number and size of the facility's structures. Because staff is not able to make assumptions based upon the scale of this possible reduction, staff assumes the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would be constructed within the same project site footprint, absent the fertilizer complex and necessary infrastructure to serve fertilizer and other nitrogen-based product manufacturing and distributing.

Both HECA and the No Fertilizer Manufacturing Complex (Reduced Project) Alternative are located in an active geologic area of the southern Great Valley geomorphic province in western Kern County, California. Because of its geologic setting, the site could be subject to moderate to high levels of earthquake-related ground shaking. Significant thicknesses of expansive clay soils are also present at the surface.

There are no known viable geologic or mineralogical resources at the site, with the exception of the oil and gas fields of the Naval Petroleum Reserve. Paleontological resources have been documented regionally within Quaternary alluvium and Tertiary Tulare Formation, similar to deposits that underlie the project site. Quaternary alluvium and Pliocene to Pleistocene Tulare Formation deposits beneath the proposed site have a high sensitivity rating for paleontologic impacts. Based on the soils profile, assessment criteria, and the shallow depth of potentially fossiliferous geologic units, staff considers the probability of encountering paleontological resources during construction of HECA to be high. Quaternary alluvium near the surface is less sensitive relative to deeper and older alluvium (refer to **Geology and Paleontology** section of this PSA/DEIS, Section 5.2), however, all Quaternary sediments at the project site should be considered to have a high sensitivity rating until determined otherwise by a qualified professional paleontologist. Since the upper portion of the surface has been disturbed during agricultural operations, the upper 1 to 2 feet of ground would not be likely to yield fossil remains in their natural context. Any excavation into undisturbed native ground at the surface or below disturbed material at the proposed HECA site and along project linears, would be considered to have a high potential to encounter significant paleontological resources.

Mass grading operations within structure footprints of the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, that could be required for removal of expansive clays, would have the potential to disturb paleontological resources. Fossil remains could also be encountered in deep trenches excavated for utilities.

As this alternative proposes a slight reduction in the HECA project, all conditions of certification applicable to the project that would mitigate impacts to paleontological resources would be applicable to the No Fertilizer Manufacturing Complex (Reduced Project) Alternative.

The No Fertilizer Manufacturing Complex (Reduced Project) Alternative would not increase impacts to geological or paleontological resources or be subject to geological hazards above the HECA project level. Therefore, no impacts would occur from the No Fertilizer Manufacturing Complex (Reduced Project) Alternative with the incorporation of Conditions of Certification identical to that presented within the **Geology And Paleontology** section of this PSA/DEIS.

Hazardous Materials Management

The No Fertilizer Manufacturing Complex (Reduced Project) Alternative would most likely eliminate the need for many “up-stream” intermediate hazardous and flammable materials that would be produced, used, and stored on the site that are associated with the fertilizer manufacturing complex. To more accurately assess the impacts of a No Fertilizer Manufacturing Complex (Reduced Project) Alternative, staff has made the following assumptions:

- No fertilizer plant, no urea unit, urea pastillation unit, and no urea pastille handling and transfer unit.
- No anhydrous ammonia production or storage of up to 3.8 million gallons of anhydrous ammonia would occur on-site. Instead, aqueous ammonia would be imported onto the site in tanker trucks for use in Selective Catalytic Reduction (SCR).
- The Air Separation Unit (ASU) would no longer be used to produce nitrogen for fertilizer production but would continue to be used to provide oxygen for the gasifier.
- There would be no need for the production and storage of nitric acid, an intermediate substance produced and then used in the UAN production process (UAN is a solution of urea and ammonium nitrate in water used as a fertilizer), and thus on-site storage of extremely large volumes (5,200,000 pounds) of highly concentrated acid (~60 percent by weight) for up to three days on-site would be eliminated.

Given the above assumptions, the need for hazardous materials management on the site and impacts to the off-site public during both construction and operations would be reduced under this alternative, but only by a small amount. The removal of large amounts of stored anhydrous ammonia, nitric acid, and UAN liquid would reduce the need to properly manage these hazardous materials and would reduce slightly the potential impacts to the off-site public. The remaining project components under this alternative would include:

- Coal/pet coke gasification plant;
- ASU;
- Syngas scrubber, sour shift, low-temperature gas cooling, sour water treatment facility;
- Mercury removal unit;
- Acid gas removal (Rectisol process) unit;
- A sulfur recovery unit that includes the storage of up to 1.4 million pounds (700 tons) of liquid sulfur at elevated temperatures;
- 13-mile natural gas pipeline;
- 3-mile pressurized CO_2 pipeline;
- EOR Facility; and
- Storage of large volumes of other hazardous materials including sodium hydroxide (60,000 gallons of 5-50 percent concentration), sodium hypochlorite (7,000 gallons of unknown concentration), diesel fuel (2000 gallons), gasoline during construction (4000 gallons), 220,000 pounds of methyldiethanolamine (40 percent), and 300,000 gallons of methanol.

These remaining components would continue to constitute a highly complex industrial environment necessitating increased vigilance and risk management. Furthermore, the need to import aqueous ammonia for selective catalytic reduction (SCR) would result in new potential risks to the off-site public during transportation, transfer operations from tanker truck to an on-site storage tank, and storage.

Staff has repeatedly found at numerous other power plants that the greatest risk of an accidental release occurs during the transfer of liquid hazardous materials to/from a tanker truck. Since no anhydrous ammonia would be transported to or from the facility under the original project and no transfer between an on-site storage tank and a tanker truck would occur, the need to import aqueous ammonia under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would add an increased risk to the off-site public. Therefore, the decrease in hazards due to the elimination of anhydrous ammonia and other large-volume hazardous materials would be off-set by the addition of a new risk of aqueous ammonia transport and transfer, thus resulting in a net minimal reduction in overall risk posed to the off-site public. Staff concludes that there would be a slight reduction in impacts on hazardous materials management with the No Fertilizer Manufacturing Complex (Reduced Project) Alternative. Staff therefore would continue to recommend that all proposed conditions of certification in the **Hazardous Materials Management** section of the PSA/DEIS be retained to mitigate the impacts.

Staff bases its proposed mitigation for the No Fertilizer Manufacturing Complex (Reduced Project) Alternative on two factors:

- The complexity of the proposed HECA facility even when modified; and
- The use and storage of vast amounts of flammable and combustible materials even when modified.

The presence of numerous chemical processes - specifically the larger gasification process and sulfur recovery process that consists of large amounts of hazardous materials in closed tanks and piping at elevated temperature and pressure - could potentially pose significant risks if not managed properly. Staff determined that all of the proposed processes, even under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative, must be managed and monitored in greater detail than usual, regardless if the quantities of hazardous materials present are below the federal or state thresholds that would trigger this increased level of safety management. Staff continues to propose that the project owner be required to develop a Process Safety Management Plan (PSM Plan) which includes a Hazard and Operability analysis to address several different processes, a Risk Management Plan (RMP) which would include several new Offsite Consequence Analyses, and a Spill Prevention Control and Countermeasures (SPCC) Plan for each of the approximately ten processes that would remain as part of the project under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative.

Staff believes that these plans will identify potential system failures before failure can occur and indicate/implement mitigation to reduce the risk of on-site and off-site consequences to less than significant. Establishing and implementing a strict code of process safety management and implementing engineering and administrative controls to prevent accidents, followed by quick and effective spill containment, control, and cleanup should an accidental release occur, would reduce both the chance and severity of an impact to an insignificant level.

In conclusion, staff finds that the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would result in only a slight reduction of the impacts on hazardous materials management but that no difference in proposed mitigation is warranted.

Land Use and Agriculture

The initial Amended HECA AFC (2012) submitted by the project applicant included a chemical manufacturing complex proposed to produce products for agricultural, transportation and industrial uses. Kern County provided response letters in June and July of 2012 stating that such a manufacturing complex would constitute an industrial land use and would require a zone change and a General Plan Amendment to a compatible land use designation (Kern County 2012d, Kern County 2012e). To address this issue, the project applicant revised the HECA project to restrict production of "nitrogen-based products" (including urea, urea ammonium nitrate and anhydrous ammonia) to manufactured products for the purpose of "fertilizer manufacture and storage for agricultural use only" (HECA 2012jj). It should be noted that LORS conformance is a CEQA issue, as discussed within the **Land Use** section of this PSA/DEIS.

The March 6, 2013 Kern County Planning Department letter stated the revised HECA project description to restrict the chemical manufacturing and storage of fertilizers for agricultural use only, would comply with the County General Plan and Zoning Ordinance (Kern County 2013a). Kern County staff recommends that if approved by the Energy Commission, the project “include Mitigation Measure(s) to restrict the items produced on site and in the Manufacturing Complex to ’fertilizer manufacture and storage for agricultural use only’ per Section 19.12.030.A of the Kern County Zoning Ordinance.” Staff is recommending Condition of Certification **LAND-6**, which would require the project applicant to restrict the products from the chemical manufacturing complex to fertilizer for agricultural use only.

The No Fertilizer Alternative would remove this issue from the land use and agriculture analysis and eliminate proposed Condition of Certification **LAND-6.** Therefore land use impacts would be less under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative than that of HECA.

Noise and Vibration

There would be less noise and vibration impacts under this alternative due to the elimination of one of the sources of noise, the manufacturing complex, and product truck transport to market.

Public Health and Safety

The No Fertilizer Manufacturing Complex (Reduced Project) Alternative would most likely eliminate the need for other processes associated with the manufacture of fertilizer. The same assumptions as made by staff above under Hazardous Materials Management are utilized to more accurately assess the impacts of the No Fertilizer Manufacturing Complex (Reduced Project) Alternative. Given these assumptions, the number of sources of emissions that could potentially impact public health would be slightly reduced.

Staff analysis shows the public health and safety impacts of HECA would be below the level of significance during the construction phase when diesel particulate matter (DPM) emissions from construction equipment and vehicles would be emitted. A somewhat shorter construction period would result in slightly lower emissions of DPM from ground moving equipment and other construction equipment. This difference would be negligible.

For the operations phase of HECA, the project applicant and staff modeled 294 emitting units and 54 toxic air contaminants that would be emitted from stacks, flares, or as fugitive emissions from valves, flanges, and other sources. Eliminating the above-mentioned sources under a No Fertilizer Manufacturing Complex (Reduced Project) Alternative would bring these values down to approximately 250 emitting units and 48 toxic air contaminants. Staff's analysis in the **Public Health** section of this PSA/DEIS (refer to Section 4.8) found that toxic air contaminants from the following sources contributed the most to the risk posed to public health: Heat Recovery Steam Generator (HRSG), coal dryer, CO_2 vent, gasification fugitives, shift area fugitives, Acid Gas Recovery (AGR) fugitives, Sulfur Recovery Unit (SRU) fugitives, and (Sour Water Strippers (SWS) fugitives. Not one of the units staff assumed would not exist under the No Fertilizer Manufacturing Complex Alternative was found to contribute significantly to the risk posed to public health. Therefore, staff concludes that the reduction in emissions under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would not result in any significant reduction in risk.

Under this alternative, the remaining project components would include:

- Coal/pet coke gasification plant;
- ASU;
- Syngas scrubber, sour shift, low-temperature gas cooling, sour water treatment facility;
- Mercury removal unit;
- Acid gas removal (Rectisol process) unit;
- Sulfur recovery unit that includes the storage of up to 1.4 million pounds (700 tons) of liquid sulfur at elevated temperatures;
- 13-mile natural gas pipeline;
- 3-mile pressurized CO_2 pipeline;
- EOR facility; and
- Storage of large volumes of other hazardous materials including sodium hydroxide (60,000 gallons of 5-50 percent concentration), sodium hypochlorite (7,000 gallons of unknown concentration), diesel fuel (2000 gallons), gasoline during construction (4000 gallons), 220,000 pounds of methyldiethanolamine (40 percent), and 300,000 gallons of methanol plus vehicular emissions.

Staff has determined these components would pose an insignificant risk to public health as estimated by staff. However, staff continues to propose mitigation for the No Fertilizer Manufacturing Complex (Reduced Project) Alternative. To ensure that long-term routine operating emissions would not, as estimated, pose a significant risk to the off-site public, staff proposes that routine sampling of certain toxic air contaminants that pose the greatest potential risk and hazard to the public be required and that a health risk assessment be conducted, as per the requirements and schedule of Conditions of Certification **PUBLIC HEALTH-1, PUBLIC HEALTH-2, and PUBLIC HEALTH-3**, as found in the **Public Health** section of this PSA/DEIS (refer to Section 4.8).

In conclusion, staff finds that the estimated risks posed to public health from the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would be similar to HECA.

Socioeconomics

Because HECA would not result in significant impacts to socioeconomic resources, no significant socioeconomic impacts would likely occur under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative. The reduction in the project scope would decrease the construction and operations workforce necessary for HECA project implementation, therefore, lessening the total potential impact on socioeconomic resources. The reduction in the HECA project scope would also likely reduce the value of the economic benefits (namely jobs and construction spending) that would accrue to communities in the project area.

Soil and Surface Water

Staff estimates that removing the fertilizer manufacturing facility from the HECA project would reduce the total impervious area by roughly 35 percent. Due to this reduction, the impacts of this alternative for potential erosion during construction would be less than HECA. Although this alternative would decrease the amount of impervious area and eliminate the potential for contamination of nitrogen-based manufacturing, impacts to water quality would only be somewhat less than HECA because the use of retention basins would reduce these impacts to offsite water resources. Because all other aspects of the project would remain the same, the other impacts of this alternative relating to soil and surface water would be similar to the HECA project.

Traffic and Transportation

Elimination of the fertilizer manufacturing facility from HECA would reduce the number of truck trips generated during operations. The number of truck trips that would be generated by the fertilizer manufacturing facility account for approximately one-third of the total truck trips generated during construction and operation activities. Potential impacts associated with increased traffic and potential aircraft hazards (i.e., exhaust plumes) would remain with implementation of this alternative. Overall, impacts related to traffic and transportation would be less under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative.

Transmission Line Safety and Nuisance

Without the fertilizer manufacturing facility, the additional transmission line for importing power (from the PG&E power grid) for the identified on-site Air Separation Unit would be the same as the proposed project, because the air separation unit would still be needed to provide oxygen for the main gasifier.

Visual Resources

The No Fertilizer Manufacturing Complex (Reduced Project) Alternative would remove the structures associated with the manufacturing of low-carbon, nitrogen-based products. As such, some of the manufacturing complex’s more prominent structures (i.e. the urea and UAN storage units) would be removed from the view at KOP 1. However, the feedstock barn, the largest and most prominent structure from the view at KOP 1, would remain unaffected by this alternative. Therefore, the visual impact associated with the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would be identical to HECA’s significant visual impact.

Waste Management

HECA would produce thousands of tons per year of waste during the operation of the facility due to the operation of the gasification process. The majority of the waste from HECA would be gasification solids. The fertilizer plant does not produce gasification solids. Waste management impacts from the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would be similar to HECA with respect to volume of waste disposal. Potential impacts to human health and the environment would be slightly less since the area of soil disturbance in potentially contaminated areas would be less.

Water Supply

Staff cannot determine what change there may be in the impacts to water supply when considering the No Fertilizer Manufacturing Complex (Reduced Project) Alternative. Figure 2-10 of the Amended AFC shows that production of 'Low-Carbon Nitrogen Products' would require the use of 5% of the total project water use. This would constitute approximately 375 acre feet per year of the maximum total water use of 7,500 AFY. If the reduction in water use for the No Fertilizer Manufacturing Complex (Reduced Project) Alternative is proportionate to the HECA project water use then the level of impacts would be somewhat less than HECA. If the reduction in water use is not proportionate and the No Fertilizer Manufacturing Complex (Reduced Project) Alternative results in increased power production due to more availability of hydrogen gas for combustion, then water use for cooling could increase and impacts could be somewhat to significantly increased. Staff needs more information on how the gasifier and combined cycle could or would be operated to evaluate the relative impact from the No Fertilizer Manufacturing Complex (Reduced Project) Alternative.

Worker Safety and Fire Protection

Although worker safety is evaluated on the basis of LORS conformity and not CEQA, staff has provided an analysis of changes in potential worker safety impacts for this alternative. The No Fertilizer Manufacturing Complex **(**Reduced Project) Alternative would most likely eliminate the need for many "up-stream" intermediate hazardous and flammable materials to be produced, used, and stored on the site. Assumptions made by staff above in Hazardous Materials Management are used to more accurately assess the impacts of the No Fertilizer Manufacturing Complex Alternative. Given these assumptions, the on-site impacts to workers during construction and operations would be reduced under this alternative but not by a significant amount.

The removal of large amounts of stored anhydrous ammonia, nitric acid, and UAN liquid would reduce hazards to workers somewhat but the remaining project components would include:

- Coal/pet coke gasification plant;
- ASU;
- Syngas scrubber, sour shift, low-temperature gas cooling, sour water treatment facility;
- Mercury removal unit;
- Acid gas removal (Rectisol process) unit;
- Sulfur recovery unit that includes the storage of up to 1.4 million pounds (700 tons) of liquid sulfur at elevated temperatures;
- 13-mile natural gas pipeline;
- 3-mile pressurized CO_2 pipeline;
- EOR facility; and
- Storage of large volumes of other hazardous materials including sodium hydroxide (60,000 gallons of 5-50 percent concentration), sodium hypochlorite (7,000 gallons of unknown concentration), diesel fuel (2000 gallons), gasoline during construction

(4000 gallons), 220,000 pounds of methyldiethanolamine (40 percent), and 300,000 gallons of methanol plus vehicular emissions.

Staff has determined that all of these components would continue to constitute a dangerous work environment necessitating increased vigilance to protect worker safety. Furthermore, the need to import aqueous ammonia for SCR would result in a new risk to workers during transfer operations from a tanker truck to an on-site storage tank. Therefore, the net results in hazards posed to workers would be minimal and staff concludes that there would be no significant reduction in impacts on worker safety with the No Fertilizer Manufacturing Complex (Reduced Project) Alternative.

Regarding impacts on fire protection, there would continue to be a serious need for fire detection, suppression, and off-site response under this alternative. Although HECA would be somewhat reduced under this alternative, the remaining project components would continue to require on-site fire protection measures and off-site response by the Kern County Fire Department (KCFD). Therefore, staff also concludes that there would remain a significant direct and cumulative impact on the Kern County Fire Department. As stated in staff's **Worker Safety and Fire Protection** section of this PSA/DEIS (refer to Section 4.16), the KCFD identified the need for nine specific mitigation measures:

1. Provide a fire-fighting foam pumper/tender to fight methanol fires.
2. Provide a fire protection specialist to be hired by the KCFD during the plan review process.
3. Purchase a plot of land for the relocation of KCFD station 53 and a helipad.
4. Provide 50 percent of the costs of a KCFD fire prevention inspector during the construction phase.
5. Provide the costs of training the crews at five fire stations who would respond to emergencies at the facility.
6. Purchase to the KCFD a fire rescue truck with a rotator crane to assist in vehicular accidents within Kern County.
7. Provide air monitoring equipment to the KCFD that will monitor multiple toxic gases.
8. Provide funds for six fire engineer positions needed to operate the foam pumper/tender.
9. Contribute annual funds to help maintain the reverse 9-1-1 system.

Staff independently arrived at the same opinion for some of the requested mitigation and has proposed Condition of Certification **WORKER SAFETY-8** to address the direct incremental and cumulative impacts on the KCFD and to ensure that emergency response for fires, spills, rescue, and EMS are adequate. The mitigation staff proposes for the full project is also proposed for the No Fertilizer Manufacturing Complex (Reduced Project) Alternative because the need for mitigation would remain.

Staff bases its proposed mitigation for the No Fertilizer Manufacturing Complex (Reduced Project) Alternative on several factors. First, the complexity of the HECA project facility, the use and storage of vast amounts of flammable and combustible materials, the relatively remote location, and the size of the industrial environment, even for a reduced project, all dictate the need for the following efforts to be undertaken by the KCFD:

1. Complex plan reviews.
2. Frequent hazmat and fire inspections.
3. Emergency Response including medical, fire, rescue, and hazardous materials incidents.

Second, as stated in the **Worker Safety and Fire Protection** section of this PSA/DEIS, standard fire department responses for a fire and for a hazmat spill include response from two fire stations and at least three fire fighters from each station regardless of the number and amounts of hazardous materials stored on the site. No matter what size the fire or how many workers are initially in need of rescue, the KCFD would dispatch engines from at least two fire stations so that at a minimum, six firefighters are sent to the scene. Also, the issue of “draw-down” remains a concern even under the No Fertilizer Manufacturing Complex (Reduced Project) Alternative if two or more fire stations are dispatched to the HECA site. The community cannot be left without fire response and thus crews from other KCFD stations would be dispatched to cover the areas vacated by those going to aid at the HECA facility. Because of the very serious threat of escalation from a small incidence to a much larger incidence at the HECA facility even if it is reduced in size and number of industrial processes, dispatch from more stations will be the rule rather than the exception and draw-down would occur more rapidly.

Third, it is very important to note that the HECA facility would be located in an area that has a rather harsh environment in the summer months and the ability of a fire fighter to perform duties while wearing a turn-out coat, heavy boots, and a respirator (self-contained breathing apparatus) is limited under the best of circumstances. Severe limits on a fire fighter’s ability to perform duties necessitate the mobilization of more fire fighters to respond to an emergency and hence potential for greater draw-down impact.

In conclusion, staff finds that on the whole, the No Fertilizer Manufacturing Complex (Reduced Project) Alternative would not substantially reduce the impacts on fire protection or on the impacts to the KCFD.

CEQA ENVIRONMENTALLY SUPERIOR ALTERNATIVE

A CEQA environmentally superior alternative (Cal. Code Regs., tit. 14, §15126.6[e][2]) will be identified in the FSA/FEIS.

NEPA ENVIRONMENTALLY PREFERRED ALTERNATIVE

A NEPA environmentally preferred alternative (CEQ §1505.2[b]) will be identified in the FSA/FEIS.

U.S. DEPARTMENT OF ENERGY

Environmental Consequences

1.1 U. S. DEPARTMENT OF ENERGY - ENVIRONMENTAL CONSEQUENCES

1.1.1 Air Quality

The Project would generate emissions of criteria pollutants including nitrogen oxide (NO_X), carbon monoxide (CO), volatile organic compounds (VOCs), sulfur dioxide (SO_2), and particulates less than or equal to 10 microns in diameter and 2.5 microns in diameter (PM_{10} and $PM_{2.5}$) during construction and operations.

In the construction phase, emissions would be reduced through the implementation of fugitive dust mitigation and diesel equipment exhaust mitigation. Construction emissions will be further mitigated through participation in the San Joaquin Valley Air Pollution Control District's Emission Reduction Incentive Program, pursuant to which the Hydrogen Energy California (HECA) Project will pay fees to the District to be invested in emission reduction projects in the vicinity of the HECA Project.

During operations, emissions will be mitigated through the installation of best available emission control technology. Remaining emissions of NO_X, VOC, SO_2, and PM_{10} would be fully offset by providing emission reductions from emission reduction credits. Transportation emissions associated with trucks and/or trains will be mitigated through participation in the District's Emission Reduction Incentive Program described above. The air dispersion modeling analyses conducted for NO_X, CO, SO_2, PM10 and PM2.5 results show that the HECA Project, with the planned emission control systems and other forms of mitigation, would neither cause an exceedance of the California and National Ambient Air Quality Standards nor contribute significantly to an existing exceedance.

By complying with all applicable laws, ordinances, regulations, and standards (LORS), as well as implementing Project design features and Conditions of Certification, the Project would not result in significant impacts to air quality.

1.1.2 Biological Resources

No threatened or endangered plant or wildlife species were identified on the HECA Project Site. However, threatened or endangered plant or wildlife species could be impacted by construction of the HECA Project linears or the Occidental of Elk Hills, Inc. Project. To ensure that no threatened or endangered plant or animal species are affected by the Project, avoidance and Conditions of Certification—such as pre-construction surveys and exclusionary fencing—would be implemented to reduce impacts on threatened and endangered species.

The Project construction and operation would avoid nearly all of the potential jurisdictional waters in the delineation study area. Portions of the CO_2 pipeline will be constructed using horizontal directional drilling (HDD) to avoid environmentally sensitive areas associated with the California Aqueduct and Kern River Flood Control Channel. Wetland features adjacent to the proposed natural gas linear right-of-way would be avoided.

Only a total of 0.20 acre of potential jurisdictional nonwetland waters of the United States would be temporarily impacted during construction associated with the natural gas pipeline. No wetlands would be impacted, and no permanent impacts to any jurisdictional features are expected, pending final jurisdictional determination.

1.1.3 Climate

A key objective of HECA is to mitigate impacts related to climate change by reducing greenhouse gas emissions relative to those emitted from conventional coal-fuel–fired power generation and nitrogen-based fertilizer manufacturing by capturing and sequestering CO_2 emissions. HECA would emit less than 400 lb CO_2 per megawatt hour by capturing approximately 90 percent of the carbon in the synthesis gas, and beneficially using it for Enhanced Oil Recovery at a nearby oil field. (Energy Commission staff's CEQA analyses indicate that HECA would emit 1,000 to 1,120 lb CO_2 per MWh during early operations and 788 to 843 lb CO_2 per MWh if and when it reaches mature operations, expected after about two years of early operations.) The development of the clean coal technology and demonstration of carbon capture and sequestration at this scale will pave the way for future low-carbon projects. Therefore, HECA provides a benefit toward minimizing climate change. If HECA is constructed and attains mature operations, it would demonstrate that coal facilities could be carbon-equivalent to natural gas facilities.

1.1.4 Cultural Resources

Cultural resources have been identified in the Project area. The Applicant proposes to avoid these resources to ensure that no significant impacts would occur. However, the applicant has not yet demonstrated the ability to avoid damaging known cultural resources. In addition, the historical significance of most identified cultural resources in the Project area has not been determined. As such, staff is unable to draw definite conclusions regarding the significance of the proposed project's impacts on cultural resources. Similarly, staff is currently unable to determine whether the proposed project would comply with all applicable LORS. These information gaps prevent staff from determining whether the proposed project would result in significant impacts on cultural resources.

1.1.5 Geologic Hazards and Resources

There are no known active or potentially active faults in the immediate Project area. The primary geologic hazards include ground motion from a seismic event centered on nearby active faults, and the potential for expansive soils due to high clay content in surface soils.

Project facilities would be designed in accordance with applicable building code seismic design criteria. To reduce the potential for adverse differential settlement, removal of the susceptible soils and replacement with engineered fill has been recommended where appropriate.

By complying with all applicable LORS as well as implementing Project design features and Conditions of Certification, the Project would not be adversely impacted by geologic hazards and would not result in significant impacts on geologic resources.

1.1.6 Hazardous Materials Handling

Of the chemicals proposed for use at the HECA Project Site, only anhydrous ammonia would be stored in quantities above the federal threshold found in 40CFR 68.130 (10,000 lbs).,And, only anhydrous ammonia would be stored on the site in a quantity greater than the California Accidental Release Prevention Program threshold (10,000 lbs). Based on the results of the Offsite Consequence Analysis, no offsite impact is expected to occur.

By complying with all applicable LORS as well as implementing Project design features and Conditions of Certification, the Project would not result in significant impacts from hazardous materials handling.

1.1.7 Land Use

The majority of the HECA Project Site is currently used for agricultural purposes, and is designated Prime Farmland. The Project Site is also under Williamson Act contract. Williamson Act restrictions on the HECA Project Site would need to be cancelled pursuant to California Government Code Section 51280(b)..While the project would meet zoning requirements with a conditional use permit, it is unclear whether or not the project is fundamentally compatible with existing land uses and if the conditional use permit findings of approval can be met. Staff cannot reach a conclusion on the potential significant issues on land use until the outstanding information identified in the technical areas requesting such information is provided.

1.1.8 Noise

Noise impacts on sensitive receptors were evaluated for construction, commissioning, operations, groundborne vibrations, and vehicle traffic. In addition, worker exposure noise impacts were evaluated. Construction noise is usually considered a temporary phenomenon, but the construction period for HECA would extend beyond what is reasonably considered “a temporary phenomenon” (approximately 3.5 years). Construction-related traffic noise may cause significant impacts at noise-sensitive receptors within the proximity of the project’s truck route, and therefore, mitigation measures may be required near those receptors to reduce the noise impacts to less than significant. This would be accomplished by Condition of Certification **NOISE-9**, which would require an evaluation of the impacts, and if found necessary, implementation of appropriate mitigation measures. The Project has also incorporated extensive noise-reduction features to minimize noise levels during operation.

1.1.9 Paleontological Resources

Project construction could impact paleontological resources within the Quaternary alluvium and the Plio-Pleistocene Tulare Formation. Therefore, Conditions of Certification would be implemented to reduce potential adverse impacts on paleontological resources resulting from Project construction. The paleontological resources impact mitigation program would ensure that direct, indirect, and cumulative adverse environmental impacts on paleontological resources would not be significant. Conditions of Certification would allow for the salvage of fossil remains and associated specimen data and corresponding geologic and geographic site data that otherwise might be lost to earth-moving and to unauthorized fossil collecting.

By complying with all applicable LORS as well as implementing Project design features and Conditions of Certification, the Project would not result in significant impacts on paleontological resources.

1.1.10 Public Health

During construction, toxic air contaminant (TAC) emissions would be reduced through the implementation of diesel equipment exhaust mitigation. During operations, the emissions control systems of the Project would minimize potential TAC emissions. The maximum incremental cancer risk from Project emissions during construction and operations is estimated to be below the significance criterion of 10 in one million. The maximum chronic and acute total hazard indices are both estimated to be less than the significance criterion of 1.0. Project emissions are expected to pose no significant cancer or noncancer health effects; therefore, emissions from the Project do not pose a significant adverse public health risk. However, Energy Commission staff notes that the integration of coal/petcoke gasification with the production of fertilizer, sulfur, electricity and carbon dioxide results in a complex project and that careful monitoring is needed to ensure that public health and worker safety are not adversely affected by the project.

1.1.11 Socioeconomics and Environmental Justice

The construction and operation of the Hydrogen Energy California (HECA) Project, described in the Amended Application for Certification (AFC), would not result in significant direct, indirect, or cumulative adverse socioeconomic impacts on project area housing, schools, law enforcement services, and parks. The project would not induce substantial population growth, displacement of population, or demand for housing and public services. The Project would have a positive impact on fiscal resources and provide job opportunities in the local community and region. Environmental justice communities were identified near the Project based on a review of U.S. Census data, including low-income and minority communities. Therefore, the Project was evaluated to determine whether these communities might experience disproportionately high and adverse effects as a result of the Project.

Based on the environmental analyses presented in the Preliminary Staff Assessment/ Draft Environmental Impact Statement, several technical areas have identified potential significant unmitigated impacts from the construction and operation of the proposed HECA project, but have not concluded if their significant impacts would remain unmitigated. Therefore, based on the information available to staff, these impacts could have adverse or disproportionate impacts on an environmental justice population.

HECA may result in an increased use of the Wasco coal transloading facility which could result in impacts related to air quality, public health, and traffic and transportation, among others. The potential need for expansion and improvements of the coal transloading facility near Wasco was not analyzed in the PSA/DEIS. Staff will be analyzing these potential impacts in the FSA/FEIS. **Socioeconomic Table 2** shows that on April 1, 2010 there was an 86 percent minority population in Wasco. Staff will assess whether there is an environmental justice population in the immediate vicinity of the transloading facility that could be adversely or disproportionately impacted. Staff will provide updated information in the FSA/FEIS.

1.1.12 Soils

The surficial soils of the HECA Project Site would likely be excavated and recompacted or replaced with granular soils from adjacent onsite areas. Soil removed through grading activities is expected to be reused on the HECA Project Site. During construction and installation of the linear facilities, the soil within the alignment for the linear facilities may become more susceptible to erosion and could result in sediment-laden runoff. The extent of this construction-related impact on water quality and agricultural lands, however, would be temporary and minimized through implementation of appropriate best management practices (BMPs), including erosion control measures.

By complying with all applicable LORS as well as implementing Project design features and Conditions of Certification, the Project would not result in significant impacts on native soil, receiving water bodies, or agricultural lands at or near Project facilities.

1.1.13 Traffic and Transportation

Construction of the Project would result in a temporary increase in traffic associated with the movement of construction vehicles, equipment, and personnel on the transportation network serving the Project area. Where warranted, the Project would use proper signs and traffic control measures in accordance with California Department of Transportation (Caltrans) and Kern County requirements during the construction period. The Project would also coordinate construction activities, including the transport of oversized and overweight loads on state and county roadways, with appropriate Caltrans, California Highway Patrol, and Kern County departments, and with other jurisdictions to maintain traffic flow and safety. In addition, recommended Conditions of Certification by Energy Commission staff would require improvements at six roadway intersections along with redesigning and/or repaving roadway segments identified as needed prior to construction activities to adequately serve the increased heavy truck traffic.

During Project operations, the Project's surrounding area would experience a substantial increase in the frequency of heavy truck operations on local roadways associated primarily with feedstock deliveries. Although Conditions of Certification beyond typical actions is being recommended, the project site is located in an area not adequately served by existing roadways. Specifically, the current roadway system is not designed to support the high number of truck trips that would occur during construction and particularly during operation with implementation of the no rail spur option (Alternative 2). . As a result, recommended Conditions of Certification would require ongoing roadway restoration during operations.

1.1.14 Visual Resources

In general, the HECA Project area is composed primarily of agricultural lands with farming activities and scattered residences. However, it is also characterized by oilfield extraction, grain storage, fertilizer production activities/industrial facilities, and electrical transmission lines. Although the HECA Project would be clearly visible from the west, north, and east, with sporadic visibility from areas located to the south and southeast (within the identified 5-mile radius), the overall landscape is already highly modified by human activity and is considered of low scenic quality.

1.1.15 Waste Management

Wastes generated by the Project during construction and operation include nonhazardous and hazardous wastes. Nonhazardous wastes include scrap metal, paper, sanitary waste, some types of spent catalysts, and storm water. Hazardous wastes that would be generated include paint, solvents, cleaners, sludges, oil, batteries, and hazardous spent catalysts. During operation the project would also generate approximately 306,000 tons (271,584 cubic yards) of gasification solids per year.

An undefined percentage of gasification solids generated from HECA are expected to be used for beneficial reuse, and not disposed in a landfill. The applicant has not provided sufficient data to show a significant quantity would be reused. Based on the remaining capacity and estimated closure dates of the Class I, II, and III landfills in California the project has the potential to consume as much as ten percent of Kern County's Class III landfill capacity, which would be a significant impact. The gasification waste could be excluded from hazardous waste regulations (i.e., 40 CFR Section 261.4 (b) (7) (ii) (F) and Title 22 CCR Section 66261.4(b) (5) (A). However, prior to acceptance of the gasification solids into a Kern County owned and operated landfill the solids must be analyzed and classified as non-hazardous or hazardous waste according to California hazardous waste testing standards. If the solids are determined to be hazardous, the amount of hazardous waste would be burdensome to the State of California and disposal would be costly to the applicant.

Wastewater generated during construction of the Project would include sanitary wastes, equipment wash water, hydrostatic test water, and storm water runoff. Nonhazardous hydrostatic test water would be tested and then disposed. During operation, sanitary wastewater would be disposed in an onsite sanitary leach field. There would be no direct surface water discharge of industrial wastewater or storm water from process areas. Process wastewater would be treated on the HECA Project Site in a zero liquid discharge unit, and recycled within the gasification and Project systems.

1.1.16 Water Resources

HECA would use local groundwater and treat it on site to meet Project standards. Groundwater would be supplied from Buena Vista Water Storage District (BVWSD), as part of BVWSD's Brackish Groundwater Remediation Project, which is designed to remediate brackish groundwater that is considered to be unsuitable for agricultural or drinking uses. Potable water would be supplied by the West Kern Water District. Potable water would be used for drinking and sanitary purposes only. Energy Commission staff's analysis shows that it is likely the proposed supply would have beneficial uses for agriculture and may be usable as a drinking water supply. Energy Commission staff has also concluded given current data that there may be potential impacts to groundwater quality due to BVWSD pumping from the proposed well field. BVWSD and the applicant have indicated they have additional data that was not available to staff at the time of this PSA/DEIS that may show there would be no impacts.

During construction, BMPs would be implemented to minimize the potential for erosion and minimize impacts on offsite areas, including the nearby canals. For portions of the CO_2 pipeline that cross the Outlet Canal, the Kern River Flood Control Channel, and the California Aqueduct, the HDD installation method and appropriate BMPs would be implemented.

The Project Site is not located in a designated floodplain. Pipelines that cross floodplain areas would be buried or installed using HDD technology at canal crossings.

The Project would contribute to overdraft of the Kern county subbasin and create water quality impacts within the aquifer. The project, therefore, could result in significant impacts to water resources.

1.1.17 Worker Safety and Health

Worker exposure to physical and chemical hazards would be minimized through adherence to appropriate engineering design criteria, implementation of appropriate safety and administrative procedures, use of personal protective equipment, and compliance with applicable health and safety regulations. By complying with all applicable LORS as well as implementing Project design features and Conditions of Certification, the Project would not result in significant impacts on worker safety and health.

U.S. DEPARTMENT OF ENERGY

Project Potential Cumulative Impacts

U.S. DEPARTMENT OF ENERGY - Project Potential Cumulative Impacts

Compliance with the National Environmental Policy Act requires an analysis of cumulative impacts for each action (40 Code of Federal Regulations [CFR] § 1508.25[c][3]). The Council on Environmental Quality defines a cumulative impact as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions" (40 CFR § 1508.7). Cumulative impacts can result from actions that have individually minor impacts, but that collectively impose significant impacts over a period of time. The U.S. Department of Energy considers a reasonably foreseeable action to be a future action that has a realistic expectation of occurring. These include (but are not limited to) actions under analysis by a regulatory agency, proposals being considered by state or local planners, plans that have begun implementation, or future actions that have been funded.

1.0 Past, Present, and Reasonably Foreseeable Future Actions

Past actions in the area include the construction, use, operation, and maintenance of the surrounding agricultural properties; of residential, commercial, and industrial structures; and of roads in the project vicinity. Ongoing and current projects are limited to the use and maintenance of the developed facilities in the project vicinity (e.g., ongoing maintenance of roads, agricultural activities). These past and current actions are assumed to have created the existing affected environment; therefore, the impacts of such actions are detailed in the subsections of the Preliminary Staff Assessment (PSA)/Draft Environmental Impact Statement (DEIS).

Based on California Energy Commission (ENERGY COMMISSION) requirements, reasonably foreseeable future development was considered in the context of specific projects proposed for development within 6 miles of the Hydrogen Energy California HECA Project Site. The predicted environmental impacts of reasonably foreseeable actions were considered together with those of the HECA Project to produce a description of the combined or cumulative environmental impacts. For the purpose of this analysis, a list of proposed projects, presented in Table 1-1, was obtained by URS Corporation from the Kern County Planning Department (URS, 2012).

In addition to the information provided by Kern County, a public record request was submitted to the San Joaquin Valley Air Pollution Control District (SJVAPCD), to evaluate cumulative impacts to air quality. Based on ENERGY COMMISSION requirements, the record request asked for a list of large stationary source projects that met the following criteria: 1) projects with greater than 5 tons of permitted emissions of any single criteria pollutant; 2) projects located within 6 miles of the Project Site; and 3) projects that have been recently permitted but did not start operation prior to 2009, or that are in the process of being permitted. The SJVAPCD identified the following facilities in the Project area that met criteria 2 and 3, but none met criteria 1:

- E-Z Trip Food Store Gas Station
- Stockdale 76 Gas Station

- Shiralian ENT INC, DBA E-Z TRIP-B/W Gas Station
- California Highway Patrol Fueling Station
- Buttonwillow Chevron Gas Station
- Mobil Mart Gas Station
- Rio Bravo Tomato Company LLC

Therefore, because the seven projects listed above are relatively minor sources, they were not required to be included in the Air Quality modeling cumulative analysis.

2.0 Cumulative Impacts Analysis

The potential cumulative impacts to resource areas are discussed below. If an action would have no or negligible direct or indirect impacts to a resource, that action is assumed to not contribute to any cumulative impact on that resource, and the resource topic relative to that action is not discussed further in this section.

Notably, the Project would have negligible impacts on Worker Safety and Health through implementation of standard industry practices. Therefore, the Project would not contribute to any cumulative impact regarding Worker Safety and Health, and no further evaluation of this topic is warranted.

Table 2-1 provides a discussion and summary of the cumulative impacts regarding each of the remaining resource disciplines. Additional details are provided in the cumulative impact analysis subsection for each resource topic of the PSA/DEIS. Section 3.0 provides the conclusions of the cumulative impact analysis based on Table 2-1.

3.0 Conclusions

Based on the analyses presented in Table 2-1, with implementation of Project design features and Conditions of Certification, the Project is not expected to have significant cumulative impacts. No further analysis regarding cumulative impacts is warranted.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
Air Quality	Project emissions, in combination with conservative background concentrations, would not cause a violation of any the CAAQS or NAAQS, and with mitigation measures, would not significantly contribute to the existing violations of the federal and state PM_{10} and $PM_{2.5}$ standards. In addition, all of the Project's operational emissions of PM_{10}, NO_X, VOCs, and SO_X would be offset to ensure a net air quality benefit. $PM_{2.5}$ emissions would be mitigated by the PM_{10} ERCs, because $PM_{2.5}$ is a subset of PM_{10}. Because NO_2 impacts from HECA exceeded the 1-hour SIL, a regional analysis was conducted, and the impacts from the major sources in the region, plus background, plus the HECA project would not cause a violation of the NAAQS.	Based on the SJVAPCD list, all of the sources of emissions emit less than the 5 tons/year emission threshold for any criteria pollutant; and no sources with emissions greater than 5 tons/year have been permitted in the past few years, or would be permitted in the foreseeable future, within 6 miles of the Project Site. Emissions from activities associated with the operation and construction of EOR at OEHI would occur at the same time as the HECA Project. OEHI prepared an environmental assessment that demonstrated that impacts from the OEHI project would not be significant with mitigation. During the construction phase, Conditions of Certification would be implemented to minimize fugitive dust and equipment exhaust. OEHI operations would provide ERCs to mitigate emissions from permitted sources. The OEHI operations and construction would move	The potential impacts from HECA and nearby sources were analyzed, and it was determined that HECA would not would not cause a violation of a CAAQS or NAAQS, or significantly contribute to existing violations of the federal and state PM_{10} and $PM_{2.5}$ standards.	Significant adverse cumulative impacts on air quality are not expected.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
		throughout the site as needed to access the wells needing EOR. The potential air impacts from OEHI would also move as the sources move, and may be as close as 4 miles and as far as 15 miles from the HECA property line. Because the OEHI impacts are not significant, and because the emissions are far from the HECA Project and variable in location, it is expected that the emissions from OEHI would not cause a cumulatively significant impact to air quality with the HECA Project. Therefore, because no large nearby sources were identified, and because OEHI is not expected to be cumulatively significant with HECA, cumulative modeling for CEQA was not necessary.		
Biological Resources	No threatened or endangered plant or wildlife species were identified on the HECA Project Site. However, construction, operation, and	Development of the proposed projects would potentially have similar adverse impacts to the same species affected by the HECA Project. All of the potential projects in the vicinity	Cumulative impacts of the Project in association with impacts of the proposed projects would contribute to a cumulatively adverse	Significant cumulative impacts to biological resources are not expected to

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	decommissioning of the HECA Project, including associated linears (pipelines, rail spurs, transmission lines, etc.) are likely to adversely affect the following species: blunt-nosed leopard lizard, giant kangaroo rat, Tipton kangaroo rat, San Joaquin kit fox, Buena Vista Lake shrew, Nelson's antelope squirrel, and Swainson's hawk. Impacts are associated with temporary and permanent loss of habitats and mortality of individuals. Avoidance and minimization measures would be implemented that would reduce potential take of these species and provide long-term beneficial impacts. These measures include actions that would avoid or minimize the potential for mortality, disturbance, habitat degradation, and other	of the Project area would be required to comply with applicable federal, state, and local regulatory requirements that also protect state and federally listed wildlife species. Impacts from these projects are expected to be mitigated through the regulatory pathways that would reduce their cumulative impacts. Construction of other projects could adversely affect waters of the United States or waters of the State; however, impacts from these projects are expected to be mitigated through the regulatory pathways that would reduce their cumulative impacts.	impact to the identified species. Implementation of avoidance and conservation measures, as well as habitat compensation as appropriate and as required by the regulatory agencies, would substantially reduce the potential for adverse impacts on the affected species. Compliance with federal, state, and local regulatory requirements that protect federally and state listed wildlife species would reduce cumulative impacts. Projects that place fill in jurisdictional wetlands and nonwetland waters of the United States require either an individual or a nationwide permit from the USACE. Projects that affect waters of the State would be required	occur.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	potential adverse impacts on the species. Additional conservation measures would restore and provide permanent protection and enhancement of habitats for affected species. Collectively, when implemented, these measures would avoid jeopardy of the affected species, and improve opportunities for recovery of the species. The Project design has included avoidance measures so that construction and operation would avoid nearly all of the potential jurisdictional waters in the Project Area. The Project is expected to permanently affect less than 0.2 acre of waters of the United States and less than 0.14 acre of waters of the State. The Project would obtain a nationwide permit from the USACE, and a Lake and Streambed		to comply with State permitting requirements. Because all projects would need to comply with the appropriate regulatory requirements, cumulative impacts on wetlands would not be significant.	

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	Alteration Agreement from CDFW to cover these impacts. With implementation of Conditions of Certification, impacts of the Project on biological resources would not be significant.			
Climate	A key objective of the Project is to mitigate impacts related to climate change by dramatically reducing GHG emissions relative to those emitted from conventional coal-fuel–fired power generation and nitrogen-based fertilizer manufacturing. This reduction would be achieved by capturing and sequestering CO_2 emissions. HECA would emit less than 400 pounds of CO_2 per MWh, and would capture and sequester approximately 90 percent of the carbon from the syngas. (Energy Commission staff analyses indicate that HECA would emit 1,000 to 1,120 lb CO_2 per MWh during early operations and 788 to 843 lb CO_2 per	Some GHG emissions would be emitted from the OEHI Project during EOR, and from the reasonably foreseeable future sources near the HECA Project.	GHG emissions and climate change by nature are a cumulative issue. HECA would emit GHGs, but significantly less than similar conventional projects. HECA would emit less than 400 pounds of CO_2 per MWh, which is significantly less than the state or national average for power production facilities. (Energy Commission staff analyses indicate that HECA would emit 1,000 to 1,120 lb CO_2 per MWh during early operations and 788 to 843 lb CO_2 per MWh if and when it reaches mature operations, expected after about two years of early	Significant cumulative impacts to climate change are not expected to occur. The development of the clean coal technology and demonstration of CCS at this scale would pave the way for future low carbon projects; therefore, the HECA project provides a cumulative benefit toward minimizing

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	MWh if and when it reaches mature operations, expected after about two years of early operations).		operations)	climate change. If HECA is constructed and attains mature operations, it would demonstrate that coal facilities could be carbon-equivalent to natural gas facilities.
Cultural Resources	Archaeological resources have been identified in and adjacent to the project area of analysis/area of potential effects (PAA/APE), and Project-related ground disturbance could have adverse impacts on these resources. Although staff has proposed Conditions of Certification to reduce the significance of identified impacts, staff needs additional information from the applicant to prepare a conclusive analysis of project impacts on cultural resources. All buildings (built environment resources)	Construction of other projects could impact cultural resources within the Project area. Staff requires additional information from the applicant concerning cultural resources before it can draw conclusions related to cumulative impacts on cultural resources.	Staff cannot evaluate the cumulative impacts from the Project on the regional cultural resources until the applicant provides additional, staff-requested information on cultural resources	Inconclusive, to be analyzed in the FSA/FEIS.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	constructed before 1964 within the study area were recorded and evaluated. Two historic buildings/structures that qualify as significant cultural resources are located in the PAA/APE. The proposed project would not affect these two resources, however.			
Electrical Transmission	The Project would provide approximately 300 MW of new, low-carbon baseload electric-generating capacity during operations. This would result in beneficial impacts associated with electrical transmission.	Development projects would increase the demand on the electrical systems in the Project Area and in the region.	The Project would supply electricity in the Project Area to assist in meeting the increased demand from other projects.	Significant cumulative impacts to electrical transmission are not expected to occur.
Geological and Mineral Resources	Drawdowns associated with Project-specific pumping from BVWSD's well field are expected. Localized subsidence could result from the proposed project's pumping. A monitoring program accompanied by an action plan is recommended. The CO_2 captured by the Project would enable	Development projects are not in an area mapped as having measured land subsidence or hydro-compaction. Based on the location of the proposed projects identified in Table 1-1, and/or on the fact that these projects are not expected to withdraw large volumes of groundwater from the same aquifer, development projects in the Project area would not result in significant subsidence	The Project could contribute to a cumulatively significant impact associated with subsidence from groundwater withdrawal. Mitigation is proposed. CO_2 capture, injection, and oil recovery however is not expected to contribute to subsidence.	Cumulative impacts to geological and mineral resources can be mitigated.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	geologic storage at a rate of approximately 3 million tons of CO_2 per year, and would increase domestic oil production (DOE, 2011).	impacts. None of the reasonably foreseeable projects identified in this analysis would result in CO_2 capture or oil recovery. Therefore, none of these projects would contribute to CO_2 capture or increase in domestic oil production.		
Hazardous Materials Management	The Project would store anhydrous ammonia in double-integrity, steel-refrigerated storage tanks for maximum safety. Based on the quantity of anhydrous ammonia to be stored, the Project would be required to comply with federal and state Risk Management Plan and Process Safety Management regulations and Conditions of Certification. OCA modeling results for anhydrous ammonia demonstrated that under a worst-case scenario, the release of anhydrous ammonia would not extend beyond the Project Site boundary. HECA is not producing,	The projects listed in Table 1-1 are not expected to store large quantities of methanol, CO_2, hydrogen sulfide, or other hazardous chemicals used by HECA in substantial quantities, other than anhydrous ammonia. Anhydrous ammonia is frequently used by the agriculture industry as a fertilizer component, and is applied throughout agricultural fields. Because ammonia is applied throughout agricultural fields, mobile ammonia tanks can be potentially found in various locations of an agricultural field. The facilities that use hazardous chemicals are highly regulated through federal, state, and local	The project in combination with the other cumulative projects would not result in adverse cumulative hazard risks.	Significant cumulative impacts from hazardous materials are not expected to occur.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	storing, or using dry ammonium nitrate, and has specifically chosen a liquid form to avoid explosion concerns. Therefore, the potential impacts from the use and storage of anhydrous ammonia by the Project would not be significant. No other hazardous materials stored or used at the Project Site are anticipated to produce impacts with respect to hazards. Consequently, it is anticipated that the potential impacts from the operation of the Project would not be significant.	requirements, and would be required to comply with similar regulatory requirements that depend on the quantities stored. Therefore, impacts from these projects are expected to be mitigated through the regulatory pathways that would reduce their impacts.		
Land Use	The HECA Project is consistent with adopted General and Specific Plans and the Kern County Zoning Ordinance, and would not conflict with existing land uses in the vicinity. The Project would result in the conversion of the Project Site from agricultural to a power-generating plant and to fertilizer manufacturing and	Development of the proposed projects would result in physical changes that would introduce new land uses. Some of these projects could convert prime farmland to other uses and require Williamson Act cancellation, but these would be a small percentage of the overall acreage of Kern County Prime Farmland. Although developments would result in	The Project and other proposed future projects are expected to be consistent with adopted General and Specific Plans and zoning designations and would not conflict with existing land uses in the Project vicinity. Therefore, the Project in combination with other development	Significant cumulative impacts to land use are not expected to occur.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	storage use (agricultural use only). This area represents approximately 0.07 percent of the 608,789 acres of Kern County Prime Farmland inventoried in 2010. Existing farmland would also be converted for the construction of the railroad spur, electrical transmission line, PG&E gas metering station, and switching station. Construction would temporarily disturb areas, including land required for construction laydown and installation of underground offsite linears. Based on the small percentage of farmland affected by the Project and recommended Conditions of Certification, it would not result in significant impacts to agricultural lands and activities.	noticeable physical changes to the vicinity, such changes would not result in a significant cumulative land use impacts because the uses would be required to be consistent with surrounding development and adopted General and Specific Plans and zoning designations.	projects in the study area would not significantly result in adverse impacts to land use.	
Noise and Vibration	Noise emissions resulting from the construction and operation of the HECA Project would not be significant, and would comply with the Kern	Based on the proximity to the HECA Project Site, the dairy farm was identified as a future project that could potentially influence ambient levels at noise sensitive receptors in the	Based on the results of cumulative noise modeling for the Project and dairy farm operations, the Project and dairy farm are not	Significant cumulative impacts from noise and vibration are not expected to

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	County noise standard.	Project area. Although no details are currently available for this development, noise from dairy operations is estimated to be in the range of 75 to 85 dB (unweighted decibels); this is approximately equivalent to 57 to 67 dBA. Based on expected levels of onsite dairy noise, and in consideration of the distances to the nearest sensitive receptors, the dairy facility is expected to contribute negligible, if any, additional noise levels to the environment around the HECA Project Site. For potential Project operations noise impacts to the future dairy facility, the 121 acres of cow yards and milking facilities were assumed, as a worst case, to be located immediately to the west of the HECA Project Site, across Dairy Road. Project modeling for this location indicated an expected daytime contribution of 51 dBA (which is approximately equivalent to 68 dB unweighted). The majority of Project noise sources would be more than	expected to result in cumulative noise impacts on sensitive receptors in the study area. Furthermore, Project operations are not expected to have significant impacts on the future dairy facility.	occur.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
		0.5 mile away; and, based on predicted Project contributions, the estimated dairy facility self-generated noise is expected to eclipse the Project equipment noise levels by a difference of about 6 dB or more dB. Therefore, noise impacts from the Project are not expected to be significant at the closest potential dairy facility.		
Paleontological Resources	Any Project-related ground disturbance could have adverse impacts on paleontological resources; however, with implementation of the proposed mitigation program, and compliance with Conditions of Certification, impacts would not be significant.	Construction of other projects could impact paleontological resources in the Project area. All of the potential projects in the vicinity of the Project area would be required to comply with state and local regulatory requirements. Impacts from these projects are expected to be mitigated through the regulatory pathways that would reduce their cumulative impacts.	Cumulative impacts from the Project on the regional paleontological resources would not be significant with implementation of Conditions of Certification.	Significant cumulative impacts to paleontological resources are not expected to occur.
Public Health	The emissions of TACs were modeled to determine the potential health risks to nearby residents and workers. The model predictions showed that the	There are no large sources of TAC/HAPs or criteria pollutants near the Project Site, and none are known to be proposed or under development.	Because there are no large nearby sources, and the project would not exceed any of the health thresholds, the Project in combination	Significant cumulative impacts to public health are not expected to occur.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	HECA project impacts would not exceed any of the health thresholds; therefore, the project would not cause a significant adverse health risk.		with the other cumulative projects would not result in adverse cumulative health risks. . However, Energy Commission staff notes that a facility such has HECA has not previously been built or operated in the United States and that careful monitoring is needed to ensure public health and worker safety are not adversely affected by the project.	

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
Socioeconomics and Environmental Justice	The Project would not result in significant direct, indirect, or cumulative adverse socioeconomic impacts on project area housing, schools, law enforcement services, and parks. The project would not induce substantial population growth, displacement of population, or demand for housing and public services. The Project would result in beneficial impacts to populations in the short term from increased employment opportunities during construction. Several technical areas have identified potential significant unmitigated impacts from the construction and operation of the HECA Project, but have not concluded if their significant impacts would remain unmitigated. Therefore, based on the information available to staff, these impacts could have adverse or disproportionate impacts on an environmental justice population.	Beneficial impacts to populations in the short term from increased employment opportunities would result during the construction phases of the cumulative projects. Based on **Socioeconomics Table 14** which identifies a list of cumulative projects that could impact socioeconomics resources, staff identified 17 industrial, infrastructure, and natural resource projects with labor needs that could potentially overlap with those of the HECA power plant component, possibly affecting construction workforce availability, thus creating a demand for workers that may not be met by the labor force in Kern County. With the information available on the 17 cumulative projects, staff cannot conclude on whether these projects would or would not have an adverse or disproportionate impact on an environmental justice population.	Staff concluded that none of the projects considered together with the Project would create cumulative impacts with regard to labor supply. Staff, thereby, concludes that the proposed Project would not result in any significant and adverse cumulative impacts on population, housing, schools, parks and recreation, or law enforcement. As several technical areas have identified potential significant unmitigated impacts from the construction and operation of the HECA Project, but have not concluded if their significant impacts would remain unmitigated, staff (based on the available information)_consider these impacts could have an adverse or disproportionate impacts on an environmental justice population .	Significant cumulative impacts to socioeconomics are not expected to occur. At this time, several technical areas have identified potential significant unmitigated impacts from the construction and operation of the HECA Project. Staff has not concluded if these impacts would remain unmitigated. Therefore, there could be disproportionate impacts on an environmental justice populationSignificant cumulative impacts to socioeconomics, minorities, or low-income populations are not expected to occur.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	on an environmental justice population.		.	
Soils	During construction, the potential for erosion would be managed with the implementation of BMPs to minimize impacts, and compliance with Conditions of Certification. After construction, the potential for erosion would be minimal due to surface coverage and stormwater management.	Construction of the cumulative projects would have the potential to result in soil erosion. However, similar to the Project, other developments would have to comply with local regulations and implement BMPs to reduce erosion impacts. In the long term, overall soil loss in the area would be reduced due to the change in land use from agricultural uses to developed areas, such as commercial and industrial uses.	Soil loss resulting from the construction and operation of the Project and other development projects would be minimal. Therefore, cumulative impacts on soils would not be significant.	Significant cumulative impacts to soils are not expected to occur.
Traffic and Transportation	During Project construction and operations, the Project study area would experience increases in traffic associated primarily with worker commute trips, material and equipment deliveries, products truck trips, and operation and maintenance trips. With implementation of Conditions of Certification, Project impacts related to traffic would not be	Based on information provided by Kern County Road's Department staff, the Project's construction traffic would not coincide with any potential future project in the immediate vicinity of the HECA Project Site, so the Project's contribution to cumulative traffic impacts during construction would not be considered significant. For Project operations, the traffic modeling conducted to	The results of the traffic analysis showed that the Project construction and operational traffic, combined with future ambient traffic growth, would not result in significant cumulative impacts to traffic and transportation.	Significant cumulative impacts to traffic and transportation are not expected to occur.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	significant.	evaluate Project impacts assumed a conservative 2 percent annual ambient traffic growth to account for development that may come online in the study area. The projects listed in Table 1-1 are expected to be captured in this 2 percent growth estimate.		
Visual Resources	The Project would potentially result in significant impacts at Key Observation Point No. 1; however, impacts would be reduced to less than significant with the implementation of Conditions of Certification. Although the Project is expected to change the existing character of the site, significant impacts to the scenic attractiveness of the Visual Sphere of Influence as a whole are not anticipated due to existing industrial and agricultural activities.	Development projects within the VSOI can be characterized primarily as zone changes, lot line/property line adjustments, roadway improvements, home remodeling, agricultural supply services, or activities related to agriculture or to oil and mining operations. Based on the location of the proposed future projects identified in Table 1-1, no new residential or recreational uses are proposed that may generate additional sensitive visual receptors. A new dairy operation is planned across the road from the HECA Project Site, situated on the north side of Adohr Road and the west side of Dairy Road. The Project area is generally characterized by agricultural	The dairy facilities would be visually subordinate to the Project, and the adjacency of the two projects would not result in significant impacts for viewers in the area. The addition of the Project would alter the existing landscape and visual setting at the Project Site. However, the addition of any of the other listed projects, when considered in combination with the Project, would not cumulatively create significant impacts to the visual setting within the VSOI.	Significant cumulative impacts to visual resources are not expected to occur.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
		activities, oil extraction, and other industrial facilities. Therefore, the dairy facilities would not significantly contribute to the alteration of the landscape in the Project area.		
Waste Management	Based on the remaining capacity and estimated closure dates of the Class III landfills in California, the nonhazardous wastes that cannot be recycled are expected to significantly impact the capacity of the Kern County Class III landfills. The project has the potential to consume as much as ten percent of Kern County's Class III landfill capacity. An undefined percentage of gasification solids generated from the Project are expected to be used for beneficial reuse, and not disposed in a landfill. The gasification waste could be excluded from hazardous waste regulations (i.e., 40 CFR Section 261.4 (b) (7) (ii) (F)	Future foreseeable projects are estimated to increase the amount of waste generated in the Project Area. The projects would be required to comply with Kern County's recycling requirements. The waste management impacts of the proposed project, in combination with past, present and reasonably foreseeable projects in the area would be cumulatively considerable The project has the potential to consume as much as ten percent of Kern County's Class III landfill capacity. The large quantity of waste would significantly impact Kern County landfills and possibly compromise the county's compliance with Public Resources Code section 40000 et seq and implementing	Future foreseeable projects, including the Project, would generate waste. There are, however, adequate recycling facilities and landfill capacities to dispose of the waste from the Project over the next 25 years. Waste generated by the Project would add to the total waste generated in Kern County and in California, Unless comprehensive waste diversion or recycling programs are implemented the large quantity of waste would significantly impact Kern County landfills and possibly compromise the county's compliance with Public Resources Code	Significant cumulative impacts from waste management are expected to occur.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	and Title 22 CCR Section 66261.4(b) (5) (A). However, prior to acceptance of the gasification solids into a Kern County owned and operated landfill the solids must be analyzed and classified as non-hazardous or hazardous waste. If the solids are determined to be hazardous, the amount of hazardous waste would be burdensome to the State of California and disposal would be costly to the applicant.	regulations.	section 40000 et seq and implementing regulations.	
Water Resources	The Project would use groundwater from BVWSD's Brackish Groundwater Remediation Project for process water demands. Annual pumping for the Project is expected to average 7,430 afy, with a maximum of 7,500 afy per the HECA/BVWSD agreement. Construction activities could affect surface water quality of nearby canals through	The cumulative development projects include agriculture, residential, and commercial projects that would have varying water demands. Water would be provided by private groundwater wells and/or the local water districts that provide water from groundwater and surface water. The projects' demands are expected to also contribute to overdraft of the Kern county subbasin. Therefore, a cumulative impact	Overall, Project-specific pumping would contribute to overdraft of the Kern county subbasin. Therefore, a cumulative impact to local water resources is expected.	Significant cumulative impacts to water resources could occur and would require mitigation.

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	inadvertent spills or discharges. Construction activities could also increase the potential for erosion and uncontrolled runoff of stormwater contaminated with sediments or other pollutants that could impact surface water quality and sedimentation. These potential impacts would be prevented or reduced to a level of less than significant with the implementation of BMPs, a final DESCP, construction SWPPP, and compliance with all applicable erosion and stormwater management LORS and Conditions of Certification. During operations, the Project would introduce impervious surfaces that would increase the amount of stormwater runoff and would use and store materials that could contaminate stormwater. The Project would be constructed in such a way	to local water resources is expected . The cumulative development projects have the potential to generate water quality impacts during construction and operation activities. However, it is expected that existing programs, policies, and regulatory requirements would prevent and/or minimize the potential water quality impacts to a level below a substantial impact.		

Table 2-1
Cumulative Impact Analysis

Resource	Contribution from the HECA Project	Contribution from Other Reasonably Foreseeable Projects	Total Cumulative Impacts	Conclusion
	that stormwater runoff would be contained in retention basins and reused at the Project Site. Wastewater would be discharged to the ZLD unit. The Project would implement BMPs to properly store and handle all materials and prevent spills. Therefore, there would be no discharges to surface waters and no impacts to surface water quality.

U.S. DEPARTMENT OF ENERGY

Irreversible or Irretrievable Commitments of Resources

U.S. DEPARTMENT OF ENERGY - Irreversible or Irretrievable Commitments of Resources

A commitment of resources is irreversible when the primary (direct) or secondary (indirect) impacts from the use limit the future options for that resource. Irreversible commitments of resources refer to the use or consumption of a resource that cannot be reversed except over a very long time period (e.g., minerals). An irretrievable commitment of resources refers to the use or consumption of resources that is neither renewable nor recoverable for use by future generations and that cannot be restored. This commitment can refer to the use of non-renewable resources such as cultural resources, and the expenditure of labor or funds that, when used, would not be available for future use.

The No Action Alternative would not directly require the commitment of human or fiscal resources. However, this alternative fails to achieve all of the Project objectives related to production of energy, advancement of technology, and enhancement of energy security. The No-Action Alternative would not contribute to DOE goals of accelerating advanced emission controls and demonstrating new coal technologies that capture and beneficially use CO_2. In the long run, this alternative would not provide environmental benefits with regard to greenhouse gases, and would not help California meet its obligations under AB 32, SB 1368, and AB 1925.

The Action Alternatives would each involve irreversible or irretrievable commitment of resources, including the materials, energy, labor, and funds required during construction and operation. Implementation of Conditions of Certification, identified for this Project would minimize these commitments.

Non-renewable and irretrievable fossil fuels and construction materials (e.g., petroleum) would be required for both construction and operation. Use of raw building materials would be an irretrievable commitment of resources from which these materials were produced. Consumption or use of widely available materials such as gasoline and cement would not be anticipated to result in shortages.

Resources that would be irreversibly used during the construction of the Project include land and raw materials. Areas needed for construction of the Project and the associated linear facilities would be modified (e.g., cleared, graded, filled) to meet Project design requirements. The land resources needed would be physically altered, and the alteration of these land resources would constitute a permanent commitment of land for the life of the Project to a developed use and would decrease the amount of open/ agricultural land available for other uses. Access to lands in the Project Site would also be limited to authorized personnel, thus limiting the use of those lands for other uses.

Construction and operation would also result in an irreversible loss of biological resources, including loss of habitat and individual plants and animals which could be destroyed or displaced during construction and operation activities. The direct mortality of wildlife would be an irreversible impact and the loss of habitat would be an irretrievable impact.

Cultural and paleontological resources are non-renewable, and any disturbance of these resources from the action alternatives would constitute and irreversible and irretrievable commitment.

Construction and operation of the Project would result in an irretrievable commitment of resources such as non-renewable fuels to generate power and operate equipment and vehicles. Resources consumed during operation would include diesel oil, fuel oil, and gasoline.

An irretrievable expenditure of labor would occur during both construction and operation for all action alternatives. Funding would also be committed as part of any of the action alternatives, would not be available for other uses, and would therefore be irretrievable. Labor would also irreversibly and irretrievably be committed during preparation and creation of the construction materials.

Although the implementation of the action alternatives would result in the commitment of resources as described above, the alternatives would allow for the addition of a nominal 300 megawatts of baseload low-carbon power to the grid, provide environmental benefits with regard to greenhouse gases (among others), and help California meet its obligations under AB 32, SB 1368, and AB 1925.

1.1 THE RELATIONSHIP BETWEEN SHORT-TERM USES OF THE ENVIRONMENT AND LONG-TERM PRODUCTIVITY

This section addresses the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity.

The No Action Alternative would not result in short-term uses of the environment. However, this alternative fails to achieve all of the Project objectives related to production of energy, advancement of technology, and enhancement of energy security. In the long run, this alternative would not provide environmental benefits with regard to greenhouse gases, nor help California meet its obligations under AB 32, SB 1368, and AB 1925.

Regardless of the Action Alternative, short-term uses of the environment would occur as a result of construction activities. These uses include impacts on air, noise, soils, water, and transportation resources. These short-term impacts would be minimized through the use of Best Management Practices and through the implementation of Conditions of Certification described for this Project. In addition, these short-term uses would allow for long-term productivity of several resources, as discussed below.

Some greenhouse gases would be emitted during construction and operation of the Project. However, implementation of the Project would result in long-term greenhouse gas benefits by dramatically reducing average annual greenhouse gas emissions relative to those emitted from a conventional coal-fueled power plant and nitrogen-based-product manufacturing facility by capturing and sequestering CO_2 emissions.

Short-term use of the construction labor force would result in substantial long-term productivity in the economic environment, given the short- and long-term benefits to local and regional employment and tax revenue.

Short-term commitment of non-renewable and irretrievable fossil fuels and energy would be required for both construction and operation, as discussed above. However, implementation of the Project would conserve domestic energy supplies and enhance energy security by using coal and a byproduct from the oil-refining process (petcoke) to generate electricity and by enhancing production of domestic petroleum reserves that may otherwise be unrecoverable.

In the long term, implementation would support the Project's objective to produce hydrogen for low-carbon baseload power generation and nitrogen-based products, and demonstrate carbon capture and sequestration on a commercial scale. If HECA is constructed and attains mature operations, it would demonstrate that coal facilities could be carbon-equivalent to natural gas facilities The Project would support the DOE's Clean Coal Power Initiative, to further the commercialization of clean coal technologies that advance efficiency, environmental performance, and cost competitiveness well beyond the level of technologies that are currently in commercial service. The Project would contribute an approximately 300-megawatt output of low-carbon baseload electricity to the grid during operations, and thus feed major load sources while providing environmental benefits regarding greenhouse gases (among others) and helping California to meet its obligations under California AB 32 and AB 1925, California SB 1368, and California Executive Orders S-7-04 and S-3-05. Energy Commission staff understands that HECA is designed to generate up to 431 megawatts (MW) of gross power but the overall project is expected to provide only up to 52.5[1] MW of new base load electricity to the grid. If other older coal-fueled power plants were replaced with newer plants similar to the Project's, the total domestic and international emissions of pollutants could be reduced, and there will be an increase in the efficient use of non-renewable resources.

If implemented, once the Project reaches mature operations it would contribute to long-term positive impacts through the reduction of CO_2 emissions per megawatt generation. In addition, the integrated production of nitrogen-based products would enhance the production and availability of nitrogen-based products by producing approximately 1 million tons per year of low-carbon nitrogen-based products (including Urea, Urea Ammonium Nitrate, and anhydrous ammonia) for regional markets, which will result in long-term productivity increases.

[1] This net power value includes all project-wide power generation and power consumption sources, including the power consumption of the third-party owned air separation unit and the power consumption required by the OEHI CO_2 EOR component.

INTENTIONALLY LEFT BLANK

INTRODUCTION

The U.S. Department of Energy (DOE or the Department) prepared this Environmental Synopsis pursuant to the Department's responsibilities under section 1021.216 of DOE's National Environmental Policy Act (NEPA) Implementing Procedures set forth in 10 CFR Part 1021. This synopsis summarizes the consideration given to environmental factors and records that the relevant environmental consequences of reasonable alternatives were evaluated in the process of selecting projects seeking financial assistance under Round 3 of the Clean Coal Power Initiative (CCPI). DOE selected five applicants seeking financial assistance under CCPI Round 3 during its merit review process. In addition to financial and technical elements, DOE considered relevant environmental factors and consequences of the projects proposed to DOE in response to the funding opportunity announcements. As required by section 1021.216, this synopsis does not contain business, confidential, trade secret or other information that statutes or regulations would prohibit DOE from disclosing. It also does not contain data or other information that may in any way reveal the identity of the offerors.[1]

BACKGROUND

Coal is an abundant and indigenous energy resource and supplies almost 50 percent of the United States' electric power. Demand for electricity is projected to increase by more than 30 percent by 2030. Based on analyses conducted by the EIA, it is projected that this power increase can only be achieved if coal use is also increased. Furthermore, nearly half of the nation's electric power generating infrastructure is more than 30 years old, with a significant portion in service for twice as long. These aging facilities are - or soon will be - in need of substantial refurbishment or replacement. Additional capacity must also be put in service to keep pace with the nation's ever-growing demand for electricity. Therefore, DOE expects that nearly half of the nation's electricity needs will continue to be served by coal for at least the next several decades. Given heightened awareness of environmental stewardship, while at the same time meeting the demand for a reliable and cost-effective electric power supply, it is clearly in the public interest for the nation's energy infrastructure to be upgraded with the latest and most advanced commercially viable technologies to achieve greater efficiencies, environmental performance, and cost-competitiveness. However, to realize acceptance and replication of these advanced technologies into the electric power generation sector, the technologies must first be demonstrated (i.e., designed and constructed to industrial standards and operated at significant scale under industrial conditions).

Public Law 107-63, enacted in November 2001, first provided funding for the Clean Coal Power Initiative, or CCPI. The CCPI is a multi-year federal program tasked with accelerating the commercial readiness of advanced multi-pollutant emissions control, combustion, gasification, and efficiency improvement technologies to retrofit or repower existing coal-based power plants and for deployment in new coal-based generating facilities. The CCPI encompasses a broad spectrum of commercial-scale demonstrations that target environmental challenges, including reducing greenhouse gas (GHG) emissions, by boosting the efficiency at which coal is converted to electricity or other energy forms. The CCPI is closely linked with DOE's research and development activities directed toward creating ultra-clean, fossil fuel-based energy complexes in the 21st century. When integrated with other DOE initiatives, the CCPI will help the nation successfully commercialize advanced power systems that will produce electricity at greater efficiencies, produce almost no emissions, and create clean fuels. Improving power plant efficiency is a potentially significant way to reduce carbon dioxide (CO_2) emissions in the near- and midterm. In the longer term, the most recent future funding opportunity announcements targeted CCPI technologies employing CO_2 capture and storage, or beneficial reuse. Accelerating

[1] The five projects selected for awards are identified in this synopsis and information on these projects is available on the DOE National Energy Technology Laboratory web site at http://www.netl.doe.gov/technologies/coalpower/cctc/ccpi/index.html.

commercialization of clean coal technologies also positions the United States to supply these technologies to a rapidly expanding world market.

Congress provided for competitively awarded federal cost-shared funding for CCPI demonstration projects. In contrast to other federally funded activities, CCPI projects are not federal projects seeking private investment; instead, they are private projects seeking federal financial assistance. Under the CCPI funding opportunities, industry proposes projects that meet its needs and those of its customers while furthering the national goals and objectives of DOE's CCPI. Demonstration projects selected by the CCPI program become private-public partnerships that satisfy a wide set of industry and government needs. Through the CCPI program, industry may satisfy its short-term need to retrofit or repower a facility, develop new power generating capacity, or obtain critical economic or technical evaluation of emerging commercial-scale technologies, all for the benefit of its customers. By providing financial incentives to the energy sector that reduce risks associated with project financing and technical challenges for emerging clean coal technologies, the government: (a) supports the verification of commercial readiness leading toward the long-term objective of transitioning the nation's existing fleet of electric power plants to more efficient, environmentally sound, and cost-competitive facilities; and (b) facilitates the adoption of technologies that can meet more stringent environmental regulation through more efficient power generation, advanced environmental controls, and production of environmentally attractive energy carriers and byproduct utilization.

DOE selects projects for CCPI funding in a series of rounds, each of which starts with a Funding Opportunity Announcement (FOA) that asks project proponents to submit applications for federal cost-sharing for their demonstration projects. DOE issued the first CCPI FOA (Round 1) in March 2002 and a second FOA (Round 2) in February 2004. These funding opportunities focused on projects involving advanced coal-based power generation, including gasification, efficiency improvements, optimization through neural networking, environmental and economic improvements, and mercury control. For Round 3, DOE issued a Financial Assistance FOA on August 11, 2008 (DE-PS26-08NT43181) to solicit applications and subsequently issued Amendment 005 (as DE-FOA-0000042) on June 9, 2009, to reopen the FOA and provide a second closing date (August 24, 2009) for additional applications. Projects receiving awards under the amended FOA could be funded, in whole or in part, with funds appropriated by the American Recovery and Reinvestment Act of 2009, Public Law 111-5.

Applications for demonstrations under CCPI Round 3 were evaluated against specific programmatic criteria:

• Technology merit, technical plan, and site suitability;

• Project organization and project management plan;

• Commercialization potential;

• Funding plan;

• Financial business plan.

Evaluations against these criteria represented the total evaluation scoring. However, the selection official also considered the results of the environmental evaluation and the applicant's budget information and financial management system, as well as program policy factors, in making final selections.

As a Federal agency, DOE must comply with NEPA (42 U.S.C. §§ 4321 et seq.) by considering potential environmental issues associated with its actions prior to deciding whether to undertake these actions. The environmental review of applications received in response to the CCPI Round 3 FOA was conducted pursuant to Council on Environmental Quality Regulations (40 Code of Federal Regulations (CFR) Parts 1500 - 1508) and DOE's NEPA Implementing Procedures (10 CFR Part 1021), which provide directions specific to procurement actions that DOE may undertake or fund before completing the NEPA process.

PURPOSE AND NEED

The purpose and need for DOE's selections of projects under the CCPI Program are to satisfy the responsibility Congress imposed on the Department to demonstrate advanced coal-based technologies that can generate clean, reliable, and affordable electricity in the United States.

The specific objectives of the Round 3 FOAs were:

- The CO_2 capture process must operate at a CO_2 capture efficiency of at least 90 percent;
- Progress is made toward carbon capture and sequestration (CCS) at less than a 10 percent increase in the cost of electricity for gasification systems and less than 35 percent increase for combustion and oxy-combustion systems;
- Progress is made toward CCS of 50 percent of plant CO_2 output at a scale sufficient to evaluate the full impact of the carbon capture technology on plant operations, economics, and performance; and
- At least 300,000 tons per year of CO_2 emissions from the demonstration plant must be captured and sequestered or put to beneficial use.

ALTERNATIVES

DOE received eleven (11) applications in response to the initial FOA (issued August 11, 2008) for CCPI-3, all of which were determined to have met the mandatory eligibility requirements listed in the FOA. The applications covered a wide geographic range, including sites in fourteen different states representing nearly every region of the country. In response to the reopened FOA (issued June 9, 2009), DOE received thirty eight (38) applications, of which twenty five (25)were determined to have met the mandatory eligibility requirements listed in the FOA. The requirements for the reopened FOA were the same as for the initial. The twenty five applications offered projects involving sites in nineteen different states representing nearly all geographic regions of the country. Several applicants in the initial FOA also resubmitted modified applications in response to the reopened FOA. The applications were evaluated against technical, financial and environmental factors. The criteria for evaluating applications received under CCPI-3 were published in the FOA. The technical and financial evaluations resulted in separate numerical scores; the environmental evaluation, while not scored, was considered in making selections. Each applicant was required to complete and submit a standard environmental questionnaire for each site proposed in its application.

The evaluations focused on the technical description of the proposed project, financial plans and budgets, potential environmental impacts, and other information that the applicants submitted. Following reviews by technical, environmental and financial panels and a comprehensive assessment by a merit review board, a DOE official selected those projects that best met the CCPI program's purpose and need. By broadly soliciting proposals to meet the programmatic purpose and need for DOE action and by evaluating the potential environmental impacts associated with each proposal before selecting projects, DOE considered a reasonable range of alternatives for meeting the purpose and need of the CCPI Round 3 solicitation.

For the initial FOA, applications were divided into three broad categories:

- Retrofit of CCS to an existing integrated gasification combined cycle (IGCC) facility or to an IGCC facility under construction;
- Retrofit of CCS to an existing pulverized coal (PC)-fired facility; and
- Construction and operation of new IGCC or Fluidized Bed Combustion (FBC) facilities with integrated CCS.

DOE received no less than two applications in each of the above groupings, which provided DOE with a range of reasonable alternatives for meetings the Department's need to demonstrate, at a commercial scale, new technologies that capture CO_2 emissions from coal-based power plants and either sequester the CO_2 or put it to beneficial reuse. The applications included demonstration of CCS integrated into new facilities using advanced technologies for power generation, as well as retrofits of CCS to existing facilities or ones already under construction, including both advanced and conventional technologies for power generation.

For the reopened FOA, DOE divided the applications into four groups, because of the larger number of submissions received:

- Retrofit of CCS to an existing plant (already permitted and operating);
- Retrofit of CCS to a planned or authorized power plant (but not yet constructed or operating);
- Construction and operation of a new power plant with CCS on an existing industrial site; and
- Construction and operation of a new power plant with CCS on an undeveloped site.

DOE received no less than four applications in each of the above groupings.

ENVIRONMENTAL REVIEW

DOE assembled environmental review teams to assess all applications that met the mandatory requirements. The review teams considered twenty (20) resource areas that could potentially be impacted by the projects proposed under CCPI-3. These resource areas consisted of:

Aesthetics	Floodplains	Soils
Air Quality	Geology	Surface Water
Biological Resources	Ground Water	Transportation and Traffic
Climate	Human Health and Safety	Utilities
Community Services	Land Use	Wastes and Materials
Cultural Resources	Noise	Wetlands
Environmental Justice	Socioeconomics	

The review teams were composed of environmental professionals with experience evaluating the impacts of power plants and energy-related projects, and with expertise in the resource areas considered by DOE. The review teams considered the information provided as part of each application, which included narrative text, worksheets, and the environmental questionnaire(s) for the site(s) proposed by the applicant. In addition, reviewers independently verified the information provided to the extent practicable using available sources commonly consulted in the preparation of NEPA documents, and conducted preliminary analyses to identify the potential range of impacts associated with each application. Reviewers identified both direct and indirect, as well as short-term impacts, which might occur during construction and start-up, and long-term impacts, which might occur over the expected operational life of the proposed project and beyond. The reviewers also considered any mitigation measures proposed by the applicant and any reasonably available mitigation measures that may not have been proposed.

Reviewers assessed the potential for environmental issues and impacts using the following characterizations:

- **Beneficial** – Expected to have a net beneficial effect on the resource in comparison to baseline conditions.

- **None (negligible)** – Immeasurable or negligible in consequence (not expected to change baseline conditions).
- **Low** – Measurable or noticeable but of minimal consequence (barely discernable change in baseline conditions).
- **Moderate** – Adverse and considerable in consequence but moderate and not expected to reach a level of significance (discernable, but not drastic, alteration of baseline conditions).
- **High** – Adverse and potentially significant in severity (anticipated substantial changes or effects on baseline conditions that might not be mitigable).

Applications in Response to the Initial FOA

Based on the technologies and sites proposed, none of the applications for the initial FOA were deemed to have a high potential for adverse impacts in nineteen of the twenty resource areas. However, four applications could have a potential for high adverse impacts to biological resources. The following impacts by resource area were considered in the selection of candidates for award:

Aesthetics – No impacts would be expected for one project at an existing power plant. Low to moderate impacts would be expected for other existing facilities or facilities to be constructed. Impacts ranged from temporary impacts during construction to new construction within the line-of-sight of public property, including nearby roads and highways.

Air Quality – Low to moderate impacts would be expected from emissions of criteria pollutants from new sources and fugitive emissions of dust. Compliance with Prevention of Significant Deterioration increments would be required for three projects; and new source reviews would be required for four projects. Increased emissions of volatile organic compounds (VOCs) and ammonia would be expected for more than half of the projects. Some increase in cooling tower drift could be expected for two projects.

Biological Resources – Four applications could potentially impact threatened or endangered species or their critical habitat, waterfowl and other migratory bird flyways or their crucial habitat, or wildlife refuges either because of new plant construction or installation of pipelines for CO_2 transport. No impacts were expected for two projects at existing plants. Low to moderate potential impacts would be expected for five applications.

Climate – No impacts would be expected for four projects at existing power plants. Low to moderate impacts would be expected for other existing facilities or facilities to be constructed. Impacts ranged from potential operational impacts from severe weather to localized increases in fogging or icing. Successful demonstration of CCS could contribute to reduced carbon footprints of fossil-fuel power plants.

Community Services – No impacts would be expected at the sites of two existing plants. Low to moderate impacts would be expected for the remaining applications. Generally, projects anticipating a larger temporary workforce during construction would be expected to place a higher demand on community services – particularly in smaller, more rural communities where currently existing community services are more limited.

Cultural Resources – No impacts would be expected at three existing facilities. Low to moderate impacts would be expected for the remaining applications. Potential impacts include tribal concerns over pipeline routes. Impacts would vary with the extent of known tribal claims and their proximity to the proposed project or pipeline route.

Environmental Justice – No impacts would be expected for five applications with no environmental justice populations present. There is a moderate potential for environmental justice issues at all but one of the remaining sites either because of environmental justice populations near the proposed site or along a proposed pipeline route. Potential impacts at the remaining site are expected to be low because of more limited environmental justice populations in the project area.

Floodplains – No impacts would be expected for two proposed projects. Low to moderate potential impacts during construction or pipeline routing would be expected for the remaining proposed projects.

Geology – The potential for low to moderate impacts exists for all applications either from CO_2 injection into saline aquifers or use for enhanced oil recovery. Some impacts could be expected from increased demand for coal if such demand contributes to opening new coal mines or expanding existing mines.

Ground Water – No impacts would be expected for one application involving an existing facility. Low to moderate impacts could be expected for the other applications. Impacts could include displacement of saline waters in reservoirs targeted for CO_2 injection or loss of CO_2 containment should injection pressures be too high.

Human Health and Safety – Potential impacts would be low to moderate and consist mainly of hazards associated with construction. The level of risk is generally related to the size and complexity of the planned construction. There could also be risk to human health and safety from loss of containment of CO_2 during transport and injection. This risk is present for all applications and generally varies from low to moderate with distance and population density along the CO_2 transport route where shorter routes through sparsely populated areas would have a lower risk than longer routes through regions of higher population.

Land Use – No impacts were identified for applications at existing facilities where the proposed project would not increase the footprint of the existing plant. Low to moderate impacts would be expected for applications proposing new construction. The level of potential impacts would generally be higher for new facilities on land currently used for other than industrial purposes. The assessment of impacts included both the plant site, sequestration site, and required pipeline routes for CO_2 transport.

Noise – No impacts would be expected for one project at an existing power plant. Low to moderate impacts could result from increases to ambient noise during construction and operation. Impacts would generally vary with distance and population density.

Socioeconomics – Expected impacts would be low for all applications. All applications would provide some additional employment during construction and operations. Most employment opportunities would be in the local area.

Soils – No impacts would be expected for one project at an existing power plant. Low impacts related to increased erosion during construction would be expected for other existing facilities requiring new pipelines or new facilities to be constructed.

Surface Water – Low to moderate impacts, including increased demand for cooling water and discharges to surface waters, would be expected for most of the applications. Some applications offered plans to maximize on-site reuse of water. Sediment control during construction was also considered.

Transportation and Traffic – Low to moderate impacts to traffic flow would be expected for all applications. Impacts would generally be higher during construction. Impacts expected during operations vary depending on increased rail or truck traffic. Projects in more rural areas would generally have lower impacts than new or existing facilities in more urban areas, where some increases in travel time could be expected during periods of peak construction.

Utilities – Low to moderate impacts would be expected for all applications. These would include an energy penalty for CCS retrofitted to existing power plants and increased demand for natural gas, potable water and wastewater treatment and disposal. Expected impacts would be higher for new plants proposed at sites not previously serviced by public utilities.

Wastes and Materials – Low to moderate impacts would be expected for all applications. Applications for projects that would include associated construction and operation of a new power plant would generally involve more material and waste impacts than would retrofits to existing plants.

Wetlands – No wetlands are located on the preferred site for one application. The potential for low to moderate impacts could be expected to small jurisdictional wetlands located on the proposed site or near proposed pipeline routes.

Applications in Response to the Reopened FOA

Based on the technologies and sites proposed, none of the applications for the reopened FOA were deemed to have a high potential for adverse impacts in sixteen of the twenty resource areas. All applications that would involve construction and operation of a new power plant were considered to have potentially high air quality impacts based on the need for new source permitting. Four applications were determined to have high potential for adverse impacts on biological resources; three applications were determined to have high potential for adverse impacts on surface waters; and one was determined to have high potential for adverse impacts on floodplains. The following impacts by resource area were considered in the selection of candidates for award:

Aesthetics – Impacts would be negligible for six projects that would involve retrofit or new construction at existing power plants or industrial sites. Low to moderate impacts would be expected for other retrofits to existing facilities or new facilities to be constructed. Moderate adverse impacts would result in the case of four applications involving construction of new power plants that would introduce line-of-sight impacts from superstructure and exhaust stacks where similar structures do not exist.

Air Quality – Impacts would result from emissions of criteria pollutants from new sources and fugitive emissions of dust. Twelve projects would have potentially high adverse impacts relating to emissions from proposed new plants. Lowest potential impacts would result from retrofits to existing or already-planned power plants.

Biological Resources – Four applications could potentially impact threatened or endangered species or their critical habitat, waterfowl and other migratory bird flyways, crucial habitat, or wildlife refuges either because of new plant construction or installation of pipelines for CO_2 transport. Moderate potential impacts would be expected for seven applications based on the locations of pipelines and other features. Low potential impacts would be expected for fourteen applications.

Climate – All applications were considered to present net beneficial effects on climate, because successful demonstration of CCS could contribute to reduced carbon footprints for fossil-fuel power plants. Potential adverse climate effects on plant operations were considered more from the perspective of engineering and design challenges to plant construction and maintenance.

Community Services – Negligible to low impacts would be expected for twenty applications. Five applications were determined to have potential for moderate impacts based on the size of the proposed projects to be located in smaller, more rural communities where existing community services are more limited.

Cultural Resources – Low potential for impacts would be expected for seventeen applications, including most retrofit projects. Moderate impacts would be expected for eight applications that could involve construction of structures or pipelines in proximity to tribal areas or historic sites.

Environmental Justice – Negligible to low potential for impacts would be expected for twenty three applications involving locations where environmental justice populations are not present. There is a moderate potential for environmental justice issues relating to the two remaining applications because of low-income or minority populations near the proposed site or along a proposed pipeline route.

Floodplains – One application would involve construction of structures within a 100-year floodplain with high potential for adverse impacts. Four applications were determined to have moderate potential impacts during construction of structures or pipelines. Negligible to low potential for impacts would be expected for twenty applications that do not directly involve actions in floodplains.

Geology – Negligible to low potential for impacts would be expected for twenty two applications based on CO_2 injection into saline aquifers or use for enhanced oil recovery. Three applications would have potential for moderate impacts based on limited information and uncertainties relating to target formations for proposed CO_2 injection.

Ground Water – Negligible to low potential for impacts would be expected for eighteen applications. Moderate impacts could be expected for the seven other applications relating to limited information about groundwater capacity to supply plant operations or the potential effects on groundwater sources from required dewatering operations.

Human Health and Safety – Moderate potential for impacts would be expected for seventeen applications; low potential would be expected for eight. The level of risk is generally related to the size and complexity of the planned construction. There could also be risk to human health and safety from loss of containment of CO_2 during transport and injection. This risk is present for all applications and generally varies from low to moderate with distance and population density along the CO_2 transport route.

Land Use – Negligible to low potential for impacts would be expected for twenty applications, mainly including projects involving retrofit at existing facilities or new construction on industrial sites. Moderate potential for impacts would be expected for five applications particularly requiring new construction on land currently used for other than industrial purposes.

Noise – Negligible to low potential for impacts from increases to ambient noise during construction and operation for all applications. Moderate potential for impacts could occur in the cases of five applications if coal would be transported by truck instead of by rail.

Socioeconomics – All applications were determined to provide beneficial impacts to the respective host areas based on economic multipliers associated with project spending as well as additional employment during construction and operations.

Soils – Low potential for impacts would be expected for twenty applications, mainly including projects involving retrofit at existing facilities or new construction on industrial sites. Moderate potential for impacts would relate to increased erosion during construction of structures or pipelines for five applications.

Surface Water – Three applications could have high potential for impacts attributable to substantial planned withdrawals from surface waters for plant operations, construction of pipelines along impaired surface waters, or planned discharges to surface waters. Moderate potential for impacts would be expected for eight applications; low potential would be expected for fourteen, including most retrofit projects.

Transportation and Traffic – Negligible to low potential for impacts could result from increases in traffic during construction and operation for all applications. Moderate potential for impacts could occur in the cases of five applications if coal would be transported by truck instead of by rail.

Utilities – Low potential for impacts would be expected for twelve applications that would not require extensive new pipelines and transmission lines. Thirteen applications would have potential for moderate impacts based on the need for longer pipeline and/or transmission line construction.

Wastes and Materials – Low potential for impacts would be expected for nine applications, including most projects proposing retrofits. Sixteen applications would have potential for moderate impacts based on the development of new facilities or new processes at existing facilities that would increase demands for management of materials and wastes.

Wetlands – The potential for negligible to low impacts could be expected for nineteen applications. Six applications would have potential for moderate impacts based on the lengths and routing of utility features and the potential for encountering wetlands along corridors.

CONCLUSION

The applications received in response to the CCPI-3 FOAs provided reasonable alternatives for accomplishing the Department's purpose and need to satisfy the responsibility Congress imposed on DOE to demonstrate advanced coal-based technologies that can generate clean, reliable and affordable electricity in the United States. The alternatives available to DOE would also meet the Department's goal of accelerating the deployment of carbon capture and storage. An environmental review was part of the evaluation process of these applications. DOE prepared a critique containing information from this environmental review. That critique, summarized here, contained summary as well as project-specific environmental information. The critique was made available to, and considered by, the selection official before selections for financial assistance were made.

DOE determined that selecting two applications in response to the initial FOA, and three applications in response to the reopened FOA, would meet its purpose and need. The following provides a list of the projects selected, their locations, brief descriptions of the projects, and the anticipated level of NEPA review:

CCPI-3 initial FOA:

- Hydrogen Energy California Project (Kern County, CA). Hydrogen Energy International LLC, a joint venture owned by BP Alternative Energy and Rio Tinto, would design, construct, and operate an IGCC power plant that would take blends of coal and petroleum coke, combined with non-potable water, and convert them into hydrogen and CO_2. The CO_2 would be separated from the hydrogen using the methanol-based Rectisol process. The hydrogen gas would be used to fuel a power station, and the CO_2 would be transported by pipeline to nearby oil reservoirs where it would be injected for storage and used for enhanced oil recovery. The project, which would be located in Kern County, California, would capture more than 2,000,000 tons per year of CO_2. The anticipated level of NEPA review for this project is an EIS.
- Basin Electric Power Cooperative - Post Combustion CO_2 Capture Project - Basin Electric Power Cooperative proposed to add CO_2 capture and sequestration (CCS) to Basin Electric's existing Antelope Valley Station, located near Beulah, N.D. Negotiations are still ongoing to define the project scope and schedule.

CCPI-3 reopened FOA:

- Mountaineer Carbon Dioxide Capture and Storage Demonstration (New Haven, WV). American Electric Power (AEP) would design, construct, and operate a chilled ammonia process that is expected to effectively capture at least 90 percent of the CO_2 (1.5 million metric tons per year) in a 235 megawatt (MW) flue gas stream at the existing 1,300 MW Appalachian Power Company (APCo) Mountaineer Power Plant near New Haven, WV. The captured CO_2 would be treated, compressed, and then transported by pipeline to proposed injection sites located near the capture facility. During the operation phase, AEP proposed to permanently store the entire amount of captured CO_2 in two separate saline formations located approximately 1.5 miles below the surface. The project team includes AEP, APCo, Schlumberger Carbon Services, Battelle Memorial Institute, CONSOL Energy, Alstom, and an advisory team of geologic experts. The anticipated level of NEPA review for this project is an EIS.
- The Texas Clean Energy Project. Summit Texas Clean Energy, LLC (Bainbridge Island, WA) would integrate Siemens gasification and power generating technology with carbon capture technologies to effectively capture 90% of the carbon dioxide (2.7 million metric tons per year) at a 400 MW plant to

be built near Midland-Odessa, TX. The captured CO_2 would be treated, compressed and then transported by CO_2 pipeline to oilfields in the Permian Basin of West Texas, for use in enhanced oil recovery (EOR) operations. The Bureau of Economic Geology (BEG) at the University of Texas would design and assure compliance with a state-of-the-art CO_2 sequestration monitoring, verification, and accounting program. The anticipated level of NEPA review for this project is an EIS.

- The Parish Post-Combustion CO_2 Capture and Sequestration Project (Thompsons, Texas). NRG Energy, Inc. (NRG) would design, construct, and operate a system that would capture and store approximately 400,000 tons of carbon CO_2 per year. The system would employ Fluor's Econamine FG Plus technology to capture at least 90 percent of the CO_2 from a 60 MW flue gas stream of the 617-MW Unit 7 at the W.A. Parish Generating Station located in Thompsons, Texas. Fluor's Econamine FG Plus CO_2 capture system features advanced process design and techniques, which lower the energy consumption of existing amine-based CO_2 capture processes by more than 20 percent. The captured CO_2 would be compressed and transported by pipeline to a mature oil field for injection into geologic formations for permanent storage through an enhanced oil recovery operation. The site would be monitored to track the migration of the CO_2 underground and to establish the permanence of sequestration. DOE is in the process of evaluating the appropriate level of NEPA documentation for this project.

COMPLIANCE CONDITIONS
INCLUDING THE COMPLIANCE MONITORING PLAN

Joseph Douglas

INTRODUCTION

The project's Compliance Conditions of Certification, including a Compliance Monitoring Plan (Compliance Plan), are established as required by Public Resources Code section 25532. The Compliance Plan provides a means for assuring that the facility is constructed, operated, and closed in compliance with public health and safety, environmental, all other applicable laws, ordinances, regulations, and standards (LORS), and the conditions adopted by the Energy Commission and specified in the written Decision on the Hydrogen Energy California, LLC (HECA), Application for Certification or otherwise required by law.

The Compliance Plan is composed of elements that:

- set forth the duties and responsibilities of the Compliance Project Manager (CPM), the project owner or operator (project owner), delegate agencies, and others;
- set forth the requirements for handling confidential records and maintaining the compliance record;
- state procedures for settling disputes and making post-certification changes;
- state the requirements for periodic compliance reports and other administrative procedures that are necessary to verify the compliance status for all Energy Commission approved conditions of certification;
- establish contingency planning, facility non-operation protocols, and closure requirements; and
- establish a tracking method for the technical area conditions of certification that contain measures required to mitigate potentially adverse project impacts associated with construction, operation, and closure below a level of significance; each technical condition of certification also includes one or more verification provisions that describe the means of assuring that the condition has been satisfied.

PROJECT CERTIFICATION

Project certification occurs on the day the Energy Commission dockets its Decision after adopting it at a publically noticed Business Meeting or hearing. At that time, all Energy Commission conditions of certification become binding on the project owner and the proposed facility.

KEY PROJECT EVENT DEFINITIONS

The following terms and definitions help determine when various conditions of certification are implemented.

Site Assessment and Pre-Construction Activities

Many of the Energy Commission's conditions of certification require compliance submittals and CPM approvals prior to the start of construction. The below-listed site assessment and pre-construction activities may be initiated or completed prior to the start of construction, subject to the CPM's approval of the specific site assessment or pre-construction activities.

Site assessment and pre-construction activities include the following, but only to the extent the activities are minimally disruptive to soil and vegetation and will not affect listed or special-status species or other sensitive resources:

1. the installation of environmental monitoring equipment;
2. a minimally invasive soil or geological investigation;
3. a topographical survey;
4. any other study or investigation to determine the environmental acceptability or feasibility of the use of the site for any particular facility; and
5. any minimally invasive work to provide safe access to the site for any of the purposes specified in 1-4, above.

Site Mobilization and Construction

When a condition of certification requires the project owner to take an action or obtain CPM approval prior to the start of construction, or within a period of time relative to the start of construction, that action must be taken, or approval obtained, prior to any site mobilization or construction activities, as defined below.

Site mobilization and construction activities are those necessary to provide site access for construction mobilization and facility installation, including both temporary and permanent equipment and structures, as determined by the CPM.

Site mobilization and construction activities include, but are not limited to:

1. ground disturbance activities like grading, boring, trenching, leveling, mechanical clearing, grubbing and scraping;
2. site preparation activities, such as access roads, temporary fencing, trailer and utility installation, construction equipment installation and storage, equipment and supply laydown areas, borrow and fill sites, temporary parking facilities, and chemical spraying and controlled burns; and
3. permanent installation activities for all facility and linear structures, including access roads, fencing, utilities, parking facilities, equipment storage, mitigation and landscaping activities, and other installations, as applicable.

Commissioning

Commissioning activities test the functionality of the installed components and systems to ensure the facility operates safely and reliably. Commissioning provides a multistage, integrated, and disciplined approach to testing, calibrating, and proving all of the project's systems, software, and networks. For compliance monitoring purposes, examples of commissioning activities include interface connection and utility pre-testing, “cold” and “hot” electrical testing, system pressurization and optimization tests, grid synchronization, and combustion turbine “first fire”.

Start of Commercial Operation

For compliance monitoring purposes, “commercial operation” or “operation” begins once commissioning activities are complete, the certificate of occupancy has been issued, and the power plant has reached reliable steady-state electrical production. At the start of commercial operation, plant control is usually transferred from the construction manager to the plant operations manager. Operation activities can include a steady state of electrical production, or, for “peaker plants,” a seasonal or on-demand operational regime to meet peak load demands.

Non-Operation and Closure

Non-operation is time-limited and can encompass part or all of a facility. Non-operation can be a planned event, usually for minor equipment maintenance or repair, or unplanned, usually the result of unanticipated events or emergencies.

Closure is a facility shutdown with no intent to restart operation. It may also be the cumulative result of unsuccessful efforts to re-start over an increasingly lengthy period of non-operation, condemned by inadequate means and/or lack of a viable plan. Facility closures can occur due to a variety of factors, including, but not limited to, irreparable damage and/or functional or economic obsolescence.

ROLES AND RESPONSIBILITIES

Provided below is a generalized description of the compliance roles and responsibilities for Energy Commission staff (staff) and the project owner for the construction and operation of the HECA project.

COMPLIANCE PROJECT MANAGER RESPONSIBILITIES

The CPM’s compliance monitoring and project oversight responsibilities include:

1. ensuring that the design, construction, operation, and closure of the project facilities are in compliance with the terms and conditions of the Decision;
2. resolving complaints;
3. processing post-certification project amendments for changes to the project description, conditions of certification, ownership or operational control, and requests for extension of the deadline for the start of construction (see **COM-10** for instructions on filing a Petition to Amend or to extend construction start date);
4. documenting and tracking compliance filings; and
5. ensuring that compliance files are maintained and accessible.

The CPM is the central contact person for the Energy Commission during project pre-construction, construction, emergency response, operation, and closure. The CPM will consult with the appropriate responsible parties when handling compliance issues, disputes, complaints, and amendments.

All project compliance submittals are submitted to the CPM for processing. Where a submittal requires CPM approval, the approval will involve appropriate Energy Commission technical staff and management. All submittals must include searchable electronic versions (.pdf, MS Word, or equivalent files).

Pre-Construction and Pre-Operation Compliance Meeting

The CPM usually schedules pre-construction and pre-operation compliance meetings prior to the projected start-dates of construction, plant operation, or both. These meetings are used to assist the Energy Commission and the project owner's technical staff in the status review of all required pre-construction or pre-operation conditions of certification, and take proper action if outstanding conditions remain. In addition, these meetings ensure, to the extent possible, that the Energy Commission's conditions of certification do not delay the construction and operation of the plant due to last-minute unforeseen issues or a compliance oversight. Pre-construction meetings held during the certification process must be publicly noticed unless they are confined to administrative issues and processes.

Energy Commission Record

The Energy Commission maintains the following documents and information as public records, in either the Compliance files or Dockets files, for the life of the project (or other period as specified):

1. all documents demonstrating compliance with any legal requirements relating to the construction and operation of the facility;
2. all Monthly and Annual Compliance Reports filed by the project owner;
3. all project-related complaints of alleged noncompliance filed with the Energy Commission; and
4. all petitions for project or condition of certification changes and the resulting staff or Energy Commission action.

CBO DELEGATION AND AGENCY COOPERATION

While monitoring project construction and operation, staff acts as, and has the authority of, the Chief Building Official (CBO), as required by CITE. Staff may delegate CBO responsibility to either an independent third-party contractor or a local building official. However, Staff retains CBO authority when selecting a delegate CBO, including the interpretation and enforcement of state and local codes, and the use of discretion, as necessary, in implementing the various codes and standards.

Energy Commission staff may also seek the cooperation of state, regional, and local agencies that have an interest in public and worker health and safety and environmental quality when conducting project monitoring.

PROJECT OWNER RESPONSIBILITIES

The project owner is responsible for ensuring that all conditions of certification in the HECA Decision are satisfied. The project owner will submit all compliance submittals to the CPM for processing unless the conditions specify another recipient. The compliance conditions regarding post-certification changes specify measures that the project owner must take when modifying the project's design, operation, or performance requirements, or to transfer ownership or operational control. Failure to comply with any of the conditions of certification may result in a correction order, an administrative fine, license revocation, or any combination thereof, as appropriate. A summary of the compliance conditions of certification are included as **Compliance Table 1** at the conclusion of this section.

COMPLIANCE ENFORCEMENT

The Energy Commission's legal authority to enforce the terms and conditions of its Decision are specified in Public Resources Code sections 25534 and 25900. The Energy Commission may amend or revoke a project certification and may impose a civil penalty for any significant failure to comply with the terms or conditions of the Decision. The Energy Commission's actions and fine assessments would take into account the specific circumstances of the incident(s).

PERIODIC COMPLIANCE REPORTING

Many of the conditions of certification require submittals in the Monthly and/or Annual Compliance Reports. All compliance submittals assist the CPM in tracking project activities and monitoring compliance with the terms and conditions of the HECA Decision. During construction, the project owner or an authorized agent will submit compliance reports on a monthly basis. During operation, compliance reports are submitted annually. These reports and the requirements for an accompanying compliance matrix are described below.

NONCOMPLIANCE COMPLAINT PROCEDURES

Any person or agency may file a complaint alleging noncompliance with the conditions of certification. Such a complaint will be subject to review by the Energy Commission pursuant to Title 20, California Code of Regulations, section 1237, but, in many instances, the issue(s) can be resolved by using an informal dispute resolution process. Both the informal and formal complaint procedures, as described in current state law and regulations, are summarized below. Energy Commission staff will follow these provisions unless superseded by future law or regulations. The California Office of Administrative Law provides on-line access to the California Code of Regulations at http://www.oal.ca.gov/.

Informal Dispute Resolution Process

The following informal procedure is designed to resolve code and compliance interpretation disputes stemming from the project's conditions of certifications and other LORS. The project owner, the Energy Commission, or any other party, including members of the public, may initiate the informal dispute resolution process. Disputes may pertain to actions or decisions made by any party, including the Energy Commission's delegate agents.

This process may precede the formal complaint and investigation procedure specified in Title 20, California Code of Regulations, section 1237, but is not intended to be a prerequisite or substitute for it. This informal procedure may not be used to change the terms and conditions of certification in the Decision, although the agreed-upon resolution may result in a project owner proposing an amendment. The informal dispute resolution process encourages all parties to openly discuss the conflict and reach a mutually agreeable solution. If a dispute cannot be resolved, then the matter must be brought before the full Energy Commission for consideration via the complaint and investigation procedure specified in Title 20, California Code of Regulations, section 1237.

Request for Informal Investigation

Any individual, group, or agency may request the CPM conduct an informal investigation of alleged noncompliance with the Energy Commission's conditions of certification. Upon receipt of an informal investigation request, the CPM will promptly provide both verbal and written notification to the project owner of the allegation(s), along with all known and relevant information of the alleged noncompliance. The CPM will evaluate the request and, if the CPM determines that further investigation is necessary, will ask the project owner to promptly conduct a formal inquiry into the matter and provide within seven days a written report of the investigation results, along with corrective measures proposed or undertaken. Depending on the urgency of the matter, the CPM may conduct a site visit and/or request that the project owner provide an initial verbal report within 48 hours.

Request for Informal Meeting

In the event that either the requesting party or Energy Commission staff are not satisfied with the project owner's investigative report or corrective measures, either party may submit a written request to the CPM for a meeting with the project owner. The request shall be made within 14 days of the project owner's filing of the required investigative report. Upon receipt of such a request, the CPM will attempt to:

1. immediately schedule a meeting with the requesting party and the project owner, to be held at a mutually convenient time and place;
2. secure the attendance of appropriate Energy Commission staff and staff of any other agencies with expertise in the subject area of concern, as necessary; and
3. conduct the meeting in an informal and objective manner so as to encourage the voluntary settlement of the dispute in a fair and equitable manner.

After the meeting, the CPM will promptly prepare and distribute copies to all parties, and to the project file, of a summary memorandum that fairly and accurately identifies the positions of all parties and any understandings reached. If no agreement was reached, the CPM will direct the complainant to the formal complaint process provided under Title 20, California Code of Regulations, section 1237.

Formal Dispute Resolution Procedure

Any person may file a complaint with the Energy Commission's Dockets Unit alleging noncompliance with a Commission Decision adopted pursuant to Public Resources Code section 25500. Requirements for complaint filings and a description of how complaints are processed are provided in Title 20, California Code of Regulations, section 1237.

POST-CERTIFICATION CHANGES TO THE ENERGY COMMISSION DECISION

The project owner must petition the Energy Commission pursuant to Title 20, California Code of Regulations, section 1769, to modify the design, operation, or performance requirements of the project and/or the linear facilities, or to transfer ownership or operational control of the facility. **It is the responsibility of the project owner to contact the CPM to determine if a proposed project change should be considered a project modification pursuant to section 1769.** Implementation of a project modification without first securing Energy Commission approval may result in an enforcement action including civil penalties in accordance with Public Resources Code, section 25534.

Below is a summary of the criteria for determining the type of approval process required, and reflects the provisions of Title 20, California Code of Regulations, section 1769, at the time this Compliance Plan was drafted. If the Energy Commission modifies this regulation, the language in effect at the time of the requested change shall apply. Upon request, the CPM can provide sample formats of these submittals.

Amendment

The project owner shall submit a Petition to Amend the Energy Commission Decision, pursuant to Title 20, California Code of Regulations, section 1769(a), when proposing modifications to the design, operation, or performance requirements of the project and/or the linear facilities. If a proposed modification results in an added, changed, or deleted condition of certification, or makes changes causing noncompliance with any applicable LORS, the petition will be processed as a formal amendment to the Decision, triggering public notification of the proposal, public review of the Energy Commission staff's analysis, and consideration of approval by the full Energy Commission.

Change of Ownership and/or Operational Control

Change of ownership or operational control also requires that the project owner file a petition pursuant to section 1769(b). This process requires public notice and approval by the full Commission. The petition shall be in the form of a legal brief and fulfill the requirements of section 1769(b).

Staff-Approved Project Modification

Modifications that do not result in additions, deletions, or changes to the conditions of certification, that are compliant with the applicable LORS, and that will not have significant environmental impacts, may be authorized by the CPM as a staff-approved project modification pursuant to section 1769(a)(2). Once the CPM files a Notice of Determination of the proposed project modifications, any person may file an objection to the CPM's determination within 14 days of service on the grounds that the modification does not meet the criteria of section 1769(a)(2). If there is a valid objection to the CPM's determination, the petition must be processed as a formal amendment to the Decision and must be considered for approval by the full Commission at a publically noticed Business Meeting or hearing.

Verification Change

Each condition of certification (except for the compliance conditions) has one or more means of verifying the project owner's compliance with the provisions of the condition. These verifications specify the actions and deadlines by which a project owner demonstrates compliance with the Energy Commission-adopted conditions. A verification may be modified by the CPM without requesting a Decision amendment if the change does not conflict with any condition of certification, does not violate any LORS, and provides an effective alternative means of verification.

CONTINGENCY PLANNING AND INCIDENT REPORTING

To protect public health and safety and environmental quality, the conditions of certification include contingency planning and incident reporting requirements to ensure compliance with necessary health and safety practices. A well-drafted contingency plan avoids or limits potential hazards and impacts resulting from serious incidents involving personal injury, hazardous spills, flood, fire, explosions or other catastrophic events and ensures a comprehensive timely response. All such incidents must be reported immediately to the CPM and documented. These requirements are designed to build from "lessons learned" limit the hazards and impacts, anticipate and prevent recurrence, and provide for the safe and secure shutdown and re-start of the facility.

FACILITY CLOSURE

The Energy Commission cannot reasonably foresee all potential circumstances in existence when a facility permanently closes. Therefore, the closure conditions provided herein must be flexible to address circumstances that may exist at some future time. Most importantly, facility closure must be consistent with all applicable Energy Commission conditions of certification and the LORS in effect at that time.

Although a non-operational facility may intend to resume operations, if it remains non-operational for longer than one year, unless the project owner can present a viable plan to resume operation, the Energy Commission can conclude that closure is imminent and direct the project owner to commence closure procedures. Should the project owner effectively abandon a facility, the Energy Commission can access the required financial assurance funds to begin closure, but the owner remains liable for all associated costs.

COMPLIANCE CONDITIONS OF CERTIFICATION

COM-1: UNRESTRICTED ACCESS

The project owner must take all steps necessary to ensure that the CPM, responsible Energy Commission staff, and delegated agencies or consultants have unrestricted access to the facility site, related facilities, project-related staff, and the records maintained on-site to facilitate audits, surveys, inspections, and general or closure-related site visits. Although the CPM will normally schedule site visits on dates and times agreeable to the project owner, the CPM reserves the right to make unannounced visits at any time, whether such visits are by the CPM in person or through representatives from Energy Commission staff, delegated agencies, or consultants.

COM-2: COMPLIANCE RECORD

The project owner must maintain electronic copies of all project files and submittals on-site, or at an alternative site approved by the CPM, for the operational life and closure of the project. The files shall also contain at least one hard copy of:

1. the facility's Applications for Certification;
2. all amendment petitions and Energy Commission orders;
3. all site-related environmental impact and survey documentation;
4. all appraisals, assessments, and studies for the project;
5. all finalized original and amended structural plans and "as-built" drawings for the entire project;
6. all citations, warnings, violations, or corrective actions applicable to the project, and
7. the most current versions of any plans, manuals and training documentation required by the conditions of certification or applicable LORS.

Energy Commission staff and delegate agencies must, upon request to the project owner, be given unrestricted access to the files maintained pursuant to this condition.

COM-3: COMPLIANCE VERIFICATION SUBMITTALS

Verification lead times associated with the start of construction may require the project owner to file submittals during the AFC process, particularly if construction is planned to commence shortly after certification. The verification procedures, unlike the conditions, may be modified as necessary by the CPM.

A cover letter from the project owner or an authorized agent is required for all compliance submittals and correspondence pertaining to compliance matters. **The cover letter subject line shall identify the project by AFC number, the appropriate condition(s) of certification number(s), and a brief description of the subject of the submittal**. When submitting supplementary or corrected information, the project owner shall reference the date of the previous submittal and the condition(s) of certification applicable. The project owner shall also identify those submittals **not** required by a condition of certification with a statement such as: "This submittal is for informational purposes only and is not required by a specific condition of certification."

All reports and plans required by the project's conditions of certification must be submitted in a searchable electronic format (.pdf, MS Word, or Excel, etc.) and include standard formatting elements such as a table of contents, identifying by title and page number, each section, table, graphic, exhibit, or addendum. All report and/or plan graphics and maps must be adequately scaled and must include a key with descriptive labels, directional headings, a bar scale, and the most recent revision date.

The project owner is responsible for the content and delivery of all verification submittals to the CPM, whether the actions required by the verification were satisfied by the project owner or an agent of the project owner. All submittals must be accompanied by an electronic copy on an electronic storage medium, or by e-mail, as agreed upon by the CPM. If hardcopy submittals are required, please address as follows:

Camille Remy Obad
HECA Compliance Project Manager
(08-AFC-8C)
California Energy Commission
1516 Ninth Street (MS-2000)
Sacramento, CA 95814

COM-4: PRE-CONSTRUCTION MATRIX AND TASKS PRIOR TO START OF CONSTRUCTION

Prior to start of construction, the project owner must submit to the CPM a compliance matrix including only those conditions that must be fulfilled before the start of construction. The matrix will be included with the project owner's first compliance submittal or prior to the first pre-construction meeting, whichever comes first, and will be submitted in a format similar to the description below.

Site mobilization and construction activities will not start until all of the following occur: submittal of the pre-construction matrix and compliance verifications pertaining to all pre-construction conditions of certification, and the CPM has issued an authorization to construct letter to the project owner. The deadlines for submitting various compliance verifications to the CPM allow sufficient staff time to review and comment on, and if necessary, allow the project owner to revise the submittal in a timely manner. These procedures help ensure that project construction proceeds according to schedule. Failure to submit required compliance documents by the specified deadlines may result in delayed authorizations to commence various stages of the project.

If the project owner anticipates site mobilization immediately following project certification, it may be necessary for the project owner to file compliance submittals prior to project certification. In these instances, compliance verifications can be submitted in advance of the required deadlines and the anticipated authorizations to start construction. The project owner must understand that submitting compliance verifications prior to these authorizations is at the owner's own risk. Any approval by Energy Commission staff prior to project certification is subject to change based upon the Commission Decision, and early staff compliance approvals do not imply that the Energy Commission will certify the project for actual construction and operation.

COM-5: COMPLIANCE MATRIX

The project owner must submit a compliance matrix to the CPM with each Monthly and Annual Compliance Report. The compliance matrix provides the CPM with the status of all conditions of certification in a spreadsheet format. The compliance matrix must identify:

1. the technical area (e.g., biological resources, facility design, etc.);
2. the condition number;

3. a brief description of the verification action or submittal required by the condition;
4. the date the submittal is required (e.g., sixty (60) days prior to construction, after final inspection, etc.);
5. the expected or actual submittal date;
6. the date a submittal or action was approved by the Chief Building Official (CBO), CPM, or delegate agency, if applicable;
7. the compliance status of each condition (e.g., “not started,” “in progress,” or “completed” (include the date); and
8. if the condition was amended, the updated language and the date the amendment was proposed or approved.

The CPM can provide a template for the compliance matrix upon request.

COM-6: MONTHLY COMPLIANCE REPORT/KEY EVENT LIST

The first Monthly Compliance Report is due one month following the docketing of the project’s Decision unless otherwise agreed to by the CPM. The first Monthly Compliance Report will include the AFC number and an initial list of dates for each of the events identified on the **Key Events List. The Key Events List form is found at the end of the Compliance Conditions section.**

During project pre-construction and construction the project owner or authorized agent will submit an electronic searchable version of the Monthly Compliance Report within ten (10) days after the end of each reporting month, unless otherwise specified by the CPM. Monthly Compliance Reports shall be clearly identified for the month being reported. The searchable electronic copy may be filed on an electronic storage medium or by e-mail, subject to CPM approval. The compliance verification submittal condition provides guidance on report production standards, and the Monthly Compliance Report will contain, at a minimum:

1. a summary of the current project construction status, a revised/updated schedule if there are significant delays, and an explanation of any significant changes to the schedule;
2. documents required by specific conditions to be submitted along with the Monthly Compliance Report; each of these items must be identified in the transmittal letter, as well as the conditions they satisfy, and submitted as attachments to the Monthly Compliance Report;
3. an initial, and thereafter updated, compliance matrix showing the status of all conditions of certification;
4. a list of conditions that have been satisfied during the reporting period, and a description or reference to the actions that satisfied the condition;
5. a list of any submittal deadlines that were missed, accompanied by an explanation and an estimate of when the information will be provided;
6. a cumulative listing of any approved changes to the conditions of certification;

7. a listing of any filings submitted to, or permits issued by, other governmental agencies during the month;
8. a projection of project compliance activities scheduled during the next two months; the project owner shall notify the CPM as soon as any changes are made to the project construction schedule that would affect compliance with conditions of certification;
9. a listing of the month's additions to the on-site compliance file; and
10. a listing of complaints, notices of violation, official warnings, and citations received during the month; a description of the actions taken to date to resolve the issues; and the status of any unresolved actions.

COM-7: ANNUAL COMPLIANCE REPORT

After construction is complete, the project owner must submit searchable electronic Annual Compliance Reports instead of Monthly Compliance Reports. The reports are for each year of commercial operation and are due each year on a date agreed to by the CPM. Annual Compliance Reports must be submitted over the life of the project, unless otherwise specified by the CPM. The searchable electronic copy may be filed on an electronic storage medium or by e-mail, subject to CPM approval. Each Annual Compliance Report must include the AFC number, identify the reporting period, and contain the following:

1. an updated compliance matrix showing the status of all conditions of certification (fully satisfied conditions do not need to be included in the matrix after they have been reported as completed);
2. a summary of the current project operating status and an explanation of any significant changes to facility operations during the year;
3. documents required by specific conditions to be submitted along with the Annual Compliance Report; each of these items must be identified in the transmittal letter with the condition it satisfies and submitted as an attachment to the Annual Compliance Report;
4. a cumulative listing of all post-certification changes approved by the Energy Commission or the CPM;
5. an explanation for any submittal deadlines that were missed, accompanied by an estimate of when the information will be provided;
6. a listing of filings submitted to, or permits issued by, other governmental agencies during the year;
7. a projection of project compliance activities scheduled during the next year;
8. a listing of the year's additions to the on-site compliance file;
9. an evaluation of the Site Contingency Plan, including amendments and plan updates; and
10. a listing of complaints, notices of violation, official warnings, and citations received during the year, a description of how the issues were resolved, and the status of any unresolved matters.

COM-8: CONFIDENTIAL INFORMATION

Any information that the project owner designates as confidential must be submitted to the Energy Commission's Executive Director with an application for confidentiality pursuant to Title 20, California Code of Regulations, section 2505 (a). Any information deemed confidential pursuant to the regulations will remain undisclosed as provided for in Title 20, California Code of Regulations, section 2501.

COM-9: ANNUAL ENERGY FACILITY COMPLIANCE FEE

Pursuant to the provisions of Section 25806(b) of the Public Resources Code, the project owner is required to pay an annually adjusted compliance fee. Current compliance fee information is available on the Energy Commission's website http://www.energy.ca.gov/siting/filing_fees.html. The project owner may also contact the CPM for the current fee information. The initial payment is due on the date the Energy Commission dockets its final Decision. All subsequent payments are due by July 1st of each year in which the facility retains its certification.

COM-10: AMENDMENTS, OWNERSHIP CHANGES, STAFF-APPROVED PROJECT MODIFICATIONS, AND VERIFICATION CHANGES

The project owner must petition the Energy Commission pursuant to Title 20, California Code of Regulations, section 1769, to modify the design, operation, or performance requirements of the project or linear facilities, or to transfer ownership or operational control of the facility. The CPM will determine whether staff approval will be sufficient or whether Commission approval will be necessary based upon whether or not the proposed amendment(s) result in a changed, added, or deleted condition of certification or the changes cause noncompliance with any applicable LORS. **It is the project owner's responsibility to contact the CPM to determine if a proposed project change triggers the requirements of section 1769.** Section 1769 details the required contents for a Petition to Amend an Energy Commission Decision. The only change that can be requested by means of a letter to the CPM is a request to change the verification method of a condition of certification.

Implementation of a project modification without first securing Energy Commission, or Energy Commission staff approval, may result in an enforcement action including civil penalties in accordance with section 25534 of the Public Resources Code. If the Energy Commission's rules regarding amendments are revised, the rules in effect at the time the change is requested shall apply.

COM-11: REPORTING OF COMPLAINTS, NOTICES, AND CITATIONS

Prior to the start of construction, the project owner must send a letter to property owners within one (1) mile of the project, notifying them of a telephone number to contact project representatives with questions, complaints, or concerns. If the telephone is not staffed twenty-four (24) hours per day, it must include automatic answering with a date and time stamp recording.

The project owner will respond to all recorded complaints within twenty-four (24) hours. The project site will post the telephone number on-site and make it easily visible to passersby during construction and operation. The project owner will provide the contact information to the CPM who will post it on the Energy Commission's web page at http://www.energy.ca.gov/sitingcases/hydrogen_energy/. The project owner must report any disruption to the contact system or telephone number change to the CPM promptly, to allow the CPM to update the Energy Commission's facility webpage accordingly.

In addition to including all complaints, notices and citations included with the Monthly and Annual Compliance Reports, within ten (10) days of receipt, the project owner must report, and provide copies to the CPM, of all complaints, including noise and lighting complaints, notices of violation, notices of fines, official warnings, and citations. Complaints must be logged and numbered. Noise complaints must be recorded on the form provided in the **Noise and Vibration** conditions of certification. All other complaints shall be recorded on the complaint form (Attachment A) at the end of the Compliance Plan.

COM-12: SITE CONTINGENCY PLAN

No less than sixty (60) days prior to the start of commercial operation, (or other date agreed to by the CPM) the project owner must submit for CPM review and approval, a Site Contingency Plan (Contingency Plan). The Contingency Plan must evidence a facility's coordinated emergency response and recovery preparedness for a series of reasonably foreseeable emergency events. The CPM may require updating of the Contingency Plan over the life of the facility. Contingency Plan elements include, but are not limited to:

1. a site-specific list and direct contact information for persons, agencies, and responders to be notified for an unanticipated event;
2. a detailed and labeled facility map, including all fences and gates, the windsock location (if applicable), the on- and off-site assembly areas, and the main roads and highways near the site;
3. a detailed and labeled map of population centers, sensitive receptors, and the nearest emergency response facilities;
4. a description of the on-site, first response and backup emergency alert and communication systems, site-specific emergency response protocols, and procedures for maintaining the facility's contingency response capabilities, including a detailed map of interior and exterior evacuations route, and the planned location(s) of all permanent safety equipment;
5. an organizational chart including the name, contact information, and first aid/emergency response certification(s) and renewal date(s) for all personnel regularly on-site;
6. a brief description of reasonably foreseeable site-specific incidents and accident sequences (on- and off-site), including response procedures and protocols and site security measures to maintain twenty-four hour site security;
7. procedures for maintaining contingency response capabilities; and
8. the procedures and implementation sequence for the safe and secure shutdown of all non-critical equipment and removal of hazardous materials and waste (see also specific conditions of certification for the technical areas of **Hazardous Materials Management** and **Waste Management**).

COM-13: INCIDENT REPORTING REQUIREMENTS

Within one (1) hour, the project owner must notify the CPM or COM, by telephone and e-mail, of any incident at the power plant or appurtenant facilities that results or could result in any of the following:

1. reduction in the facility's ability to respond to dispatch (excluding forced outages caused by protective equipment or other typically encountered shutdown events);
2. health and safety impacts on the surrounding population;
3. property damage off-site;
4. response by off-site emergency response agencies;
5. serious on-site injury;
6. serious environmental damage; or
7. emergency reporting to any federal, state, or local agency.

The notice must describe the circumstances, status, and expected duration of the incident. If warranted, as soon as it is safe and feasible, the project owner must implement the safe shutdown of any non-critical equipment and removal of any hazardous materials and waste that pose a threat to public health and safety and to environmental quality (also, see specific conditions of certification for the technical areas of **Hazardous Materials Management** and **Waste Management**).

Within one (1) week of the incident, the project owner must submit to the CPM a detailed incident report, which includes, as appropriate, the following information:

1. a brief description of the incident, including its date, time, and location;
2. a description of cause of the incident, or likely causes if it is still under investigation;
3. the location of any off-site impacts;
4. description of any resultant impacts;
5. a description of emergency response actions associated with the incident;
6. identification of responding agencies;
7. identification of emergency notifications made to other federal, state, and/or local agencies;
8. identification of any hazardous materials released and an estimate of the quantity released;
9. a description of any injuries, fatalities, or property damage that occurred as a result of the incident;
10. fines or violations assessed or being processed by other agencies;

    name, phone number, and e-mail address of the appropriate facility contact person having knowledge of the event; and

11. corrective actions to prevent a recurrence of the incident.

The project owner must maintain all incident report records for the life of the project, including closure. After the submittal of the initial report for any incident, the project owner shall submit to the CPM copies of incident reports within twenty-four (24) hours of a request.

COM-14: NON-OPERATION

If the facility ceases operation temporarily, either planned or unplanned, for longer than one (1) week (or other CPM-approved date), but less than three (3) months (or other CPM-approved date), the project owner must notify the CPM, interested agencies and nearby property owners. Notice of planned non-operation must be at least two (2) weeks prior to the scheduled date. Notice of unplanned non-operation must be provided no later than one (1) week after non-operation begins.

For any non-operation, a Repair/Restoration Plan for conducting the activities necessary to restore the facility to availability and reliable and/or improved performance shall be submitted to the CPM within one (1) week after notice of non-operation is given. If non-operation is due to an unplanned incident, temporary repairs and/or corrective actions may be undertaken before the Repair/Restoration Plan is submitted. The Repair/Restoration Plan shall include:

1. identification of operational and non-operational components of the plant;
2. a detailed description of the repair or restoration activities;
3. a proposed schedule for completing the repair or restoration activities;
4. an assessment of whether or not the proposed activities would require changing, adding, or deleting any conditions of certification or would cause noncompliance with any applicable LORS; and
5. planned activities during non-operation, including any measures to ensure continued compliance with all conditions of certification and LORS;.

Written updates to the CPM for non-operational periods, until operation resumes, shall include:

1. progress relative to the schedule;
2. developments that delayed or advanced progress or that may delay or advance future progress;
3. any public, agency or media comments or complaints; and
4. projected date for the resumption of operation.

During non-operation, all applicable conditions of certification and reporting requirements remain in effect. If, after one (1) year from the date of the project owner's last report of productive Repair/Restoration Plan work, the facility does not resume operation or does not provide a plan to resume operation, the Executive Director may assign suspended status to the facility and recommend commencement of permanent closure activities. Within ninety (90) days of the Executive Director's determination, the project owner shall do one of the following:

1. If the facility has a closure plan, the project owner shall update, submit for CPM approval, and initiate the closure activities in the approved plan.
2. If the facility does not have a closure plan, the project owner shall submit one consistent with the requirements in this Compliance Plan, for CPM review and approval.

COM-15: FACILITY CLOSURE PLANS

To ensure that a facility's closure and long-term maintenance do not pose a threat to public health and safety or to environmental quality, the project owner must coordinate with the Energy Commission to plan and prepare for eventual permanent closure.

A. Provisional Closure Plan and Estimate of Permanent Closure Costs

To assure satisfactory permanent closure and long-term site maintenance activities for "the whole of a project," the project owner must submit a Provisional Closure Plan and Cost Estimate (Provisional Plan), for CPM review and approval. The project owner must submit the Provisional Plan within sixty (60) days after the start of commercial operation. The Provisional Plan must consider applicable final closure plan requirements, including long-term, post-closure site maintenance costs, and reflect:

1. facility closure costs at a time in the facility's projected life span when the mode and scope of facility operation would make permanent closure the most expensive;
2. the use of an independent third party to carry out the permanent closure; and
3. no use of salvage value to offset closure costs.

A closure/decommissioning services consultant should prepare the Provisional Plan, and must provide for a phased closure process, including but not be limited to:

1. comprehensive scope of work and itemized budget;
2. closure plan development costs;
3. dismantling and demolition;
4. recycling and site clean-up;
5. mitigation and monitoring direct, indirect, and cumulative impacts;
6. site remediation and/or restoration;
7. post-closure monitoring and maintenance, including long-term equipment replacement costs; and
8. contingencies.

The project owner must include an updated Provisional Plan in every fifth-year Annual Compliance Report for CPM review and approval. Each Provisional Plan update must reflect the most current regulatory standards, best management practices, and applicable LORS.

B. Final Closure Plan

Three (3) years prior to initiating a permanent facility closure, the project owner must submit for CPM review and approval, a Final Closure Plan (Final Plan), which includes any long-term, post-closure site maintenance and monitoring. Final Plan contents include, but are not limited to:

1. a statement of specific Final Closure Plan objectives;
2. a statement of qualifications and resumes of the technical experts proposed to conduct the closure activities, with detailed descriptions of previous power plant closure experience;
3. identification of any facility-related installations not part of the Energy Commission license, designation of who is responsible for these, and an explanation of what will be done with them after closure;
4. a comprehensive scope of work and itemized budget for permanent plant closure and long-term site maintenance activities, with a description and explanation of methods to be used, broken down by phases, including, but not limited to:
    a. dismantling and demolition;
    b. recycling and site clean-up;
    c. impact mitigation and monitoring;
    d. site remediation and/or restoration;
    e. post-closure maintenance; and
    f. contingencies.
5. a revised/updated Cost Estimate for all closure activities, by phases, including long-term, post-closure site monitoring and maintenance costs, and replacement of long-term post-closure equipments;
6. a schedule projecting all phases of closure activities for the power plant site and all apurtenances constructed as part of the Energy Commission-licensed project;
7. an electronic submittal package of all relevant plans, drawings, risk assessments, and maintenance schedules and/or reports, including an above- and below-ground infrastructure inventory map and registered engineer's or delegate CBO's assessment of demolishing the facility; additionally, for any facility that permanently ceased operation prior to submitting a Final Closure Plan and for which only minimal or no maintenance has been done since, a comprehensive condition report focused on identifying potential hazards;
8. all information additionally required by the facility's conditions of certification applicable to plant closure;
9. an equipment disposition plan, including:
    a. recycling and disposal methods for equipment and materials; and
    b. identification and justification for any equipment and materials that will remain on-site after closure;

10. a site disposition plan, including but not limited to:
    a. proposed rehabilitation, restoration, and/or remediation procedures, as required by the conditions of certification and applicable LORS,
    b. long-term site maintenance activities, and
    c. anticipated future land-use options after closure;
11. identification and assessment of all potential direct, indirect, and cumulative impacts and proposal of mitigation measures to reduce significant adverse impacts to a less-than-significant level; potential impacts to be considered shall include, but not be limited to:
    a. traffic
    b. noise and vibration
    c. soil erosion
    d. air quality degradation
    e. solid waste
    f. hazardous materials
    g. waste water discharges
    h. contaminated soil
12. identification of all current conditions of certification, LORS, federal, state, regional and local planning efforts applicable to the facility, and proposed strategies for achieving and maintaining compliance during closure;
13. updated mailing list or listserv of all responsible agencies, potentially interested parties, and property owners within one (1) mile of the facility;
14. identification of alternatives to plant closure and assessment of the feasibility and environmental impacts of these; and
15. description of and schedule for security measures and safe shutdown of all non-critical equipment and removal of hazardous materials and waste (see conditions of certification for **Hazardous Materials Management** and **Waste Management**).

If a CPM-approved Final Closure Plan is not implemented within one (1) year of its approval date, it must be updated and re-submitted to the CPM for supplementary review and approval. If a project owner initiates but then suspends closure activities, and the suspension continues for longer than one (1) year, or subsequently abandons the facility, the Energy Commission may access the required financial assurance funds to complete the closure. The project owner remains liable for all costs of contingency planning and closure.

COM-16: FINANCIAL ASSURANCE FOR CLOSURE AND POST CLOSURE CARE

The project owner must provide financial assurances guaranteeing adequate and readily available funds to ensure facility closure and post-closure compliance. Within thirty (30) days following Provisional or Final Plan and Cost Estimate approval (whichever is most recent), the project owner must submit, for CPM review and approval, a financial assurance mechanism, such as a closure trust fund or surety bond, for no less than the amount provided in the approved Plan and Cost Estimate.

Provisions from the California Bond and Undertaking Law, as well as other statutory and case law may be applicable, consult an attorney if needed. Upon request, the CPM can provide examples of acceptable cost estimation techniques and financial assurance mechanisms.

Key Events List

PROJECT: ______________________________

DOCKET #: ______________________________

COMPLIANCE PROJECT MANAGER: ______________________________

EVENT DESCRIPTION	DATE
Certification Date	
Obtain Site Control	
On-line Date	
POWER PLANT SITE ACTIVITIES	
Start Site Assessment/Pre-construction	
Start Site Mobilization/Construction	
Begin Pouring Major Foundation Concrete	
Begin Installation of Major Equipment	
Completion of Installation of Major Equipment	
First Combustion of Gas Turbine	
Obtain Building Occupation Permit	
Start Commercial Operation	
Complete All Construction	
TRANSMISSION LINE ACTIVITIES	
Start T/L Construction	
Synchronization with Grid and Interconnection	
Complete T/L Construction	
FUEL SUPPLY LINE ACTIVITIES	
Start Gas Pipeline Construction and Interconnection	
Complete Gas Pipeline Construction	
WATER SUPPLY LINE ACTIVITIES	
Start Water Supply Line Construction	
Complete Water Supply Line Construction	

Compliance Table1
Summary of Compliance Conditions of Certification

CONDITION NUMBER	SUBJECT	DESCRIPTION
COM-1	Unrestricted Access	The project owner shall grant Energy Commission staff and delegate agencies or consultants unrestricted access to the power plant site.
COM-2	Compliance Record	The project owner shall maintain project files on-site. Energy Commission staff and delegate agencies shall be given unrestricted access to the files.
COM-3	Compliance Verification Submittals	The project owner is responsible for the delivery and content of all verification submittals to the CPM, whether such condition was satisfied by work performed or the project owner or his agent.
COM-4	Pre-construction Matrix and Tasks Prior to Start of Construction	Construction shall not commence until the all of the following activities/submittals have been completed: • Notify property owners • Submit pre-construction matrix identifying conditions to be fulfilled before the start of construction • Completed all pre-construction conditions • CPM has issued a letter to the project owner authorizing construction
COM-5	Compliance Matrix	The project owner shall submit a compliance matrix (in a spreadsheet format) with each monthly and Annual Compliance Report, which includes the status of all compliance conditions of certification.
COM-6	Monthly Compliance Report and Key Events List	During construction, the project owner shall submit Monthly Compliance Reports (MCRs) which include specific information. The first MCR is due the month following the Energy Commission business meeting date on which the project was approved and shall include an initial list of dates for each of the events identified on the Key Events List.
COM-7	Annual Compliance Reports	After construction ends and throughout the life of the project, the project owner shall submit Annual Compliance Reports instead of Monthly Compliance Reports.
COM-8	Confidential Information	Any information the project owner deems confidential shall be submitted to the Energy Commission's Executive Director with a request for confidentiality.
COM-9	Annual fees	Payment of the Annual Energy Facility Compliance Fee.
COM-10	Amendments, Ownership Changes, Staff-Approved Project Modifications, and Verification Changes	The project owner must petition the Energy Commission to delete or change a condition of certification, modify the project design or operational requirements and/or transfer ownership or operational control of the facility.

Compliance Table1
Summary of Compliance Conditions of Certification

CONDITION NUMBER	SUBJECT	DESCRIPTION
COM-11	Reporting of Complaints, Notices, and Citations	Prior to the start of construction, the project owner must provide all property owners within a one (1) mile radius a telephone number to contact project representatives with questions, complaints or concerns. Within ten (10) days of receipt, the project owner shall report to the CPM all notices, complaints, violations, and citations.
COM-12	Site Contingency Plan	No less than sixty (60) days prior to the start of commercial operation the project owner must submit an on-site contingency plan to ensure public and environmental health and safety are protected while responding to an unanticipated event or emergency.
COM-13	Incident Reporting Requirements	The project owner shall notify the CPM within one (1) hour of an incident and submit a detailed incident report within thirty (thirty) days, maintain records of incident report, and submit public health and safety documents with employee training provisions.
COM-14	Non-Operation	No later than two (2) weeks prior to a facility's planned non-operation, or no later than two (2) weeks after the start of unplanned non-operation, the project owner must notify the CPM, interested agencies and nearby property owners of this status. During non-operation, the project owner must provide written updates.
COM-15	Facility Closure Plans	One (1) year after initiating commercial operation, the project owner must submit a Provisional Closure Plan and Cost Estimate for permanent closure. Three (3) years prior to closing, the project owner must submit a Final Closure Plan.
COM-16	Financial Assurance for Closure	Within 120 days of initiating commercial operation, the project owner must establish a CPM approved closure financial assurance mechanism to ensure the necessary funds to adequate perform a facility closure and provide post closure care, as necessary.

PREPARATION TEAM

Executive Summary ....John Heiser

Introduction ....

Project Description..John Heiser

Environmental Assessment

Air Quality .... William Walters, P.E. / Nancy Fletcher

Biological Resources ....Amy Golden

Carbon Sequestration and Greenhouse Gas Emissions ....William Walters, PE / David Vidaver
Abdel-Karim Abulaban, Ph.D, PE / Tad Patzek, Ph.D

Cultural Resources ....Gabriel Roark, M.A. / Thomas Gates Ph.D.
Melissa Mourkas, M.A., ASLA / Elizabeth A. Bagwell, Ph.D

Hazardous Materials Management ....Alvin Greenberg, Ph.D.

Land Use...Jonathan Fong

Noise and Vibration...Edward Brady / Shahad Khoshmashrab

Public Health..Alvin Greenberg, Ph.D.

Socioeconomics...Lisa Worrall / Amanda Stennick

Soils and Surface Water .... Marylou Taylor, PE

Traffic and Transportation.. John Hope

Transmission Line Safety and Nuisance...Obed Odoemelam, Ph.D

Visual Resources .... Elliott Lum

Waste Management...Ellie Townsend-Hough

Water Supply ....Mike Conway, PG / John Fio / Steve Deverel, PG

Worker Safety and Fire Protection ....Alvin Greenberg, Ph.D.

Engineering Assessment

Facility Design... Shahab Khoshmashrab

Geology and Paleontology...Casey Weaver, C. E. G.

Power Plant Efficiency .... Edward Brady

Power Plant Reliability .... Edward Brady

Transmission System Engineering .... Sudath Edirisuriya / Mark Hesters

Alternatives ....Negar Vahidi / Scott Debauche

General Conditions .... Joseph Douglas

Project Assistant .... Diane L. Scott
