Rachel Carson’s 1962 book *Silent Spring* and the ensuing campaign to ban the pesticide DDT created the new prototype. Carson’s book was an alarm call not just about the damage DDT was wreaking on birds’ eggs but about the ecological blind spots of an entire industrial order. The response, though, was narrowly focused, specific and measurable: ten years after the book first hit shelves, DDT’s production and use had been banned in the United States. There soon emerged something like a standard structure to the life cycle of an environmental issue in the years after *Silent Spring*.

A problem would be identified as significantly acute and urgent, often by scientists or environmental groups or both in concert. Public awareness was then raised through protest, publicity stunts, and media campaigns. Government officials were persuaded of the necessity to act. New regulation was proposed, debated, drafted, passed. Affected industries were obliged, often reluctantly, to comply. There was a symmetry to it.

A rogue Greenpeace boat blocks a whaling ship’s harpoons, the subsequent media attention plants “Save the Whales” in the public consciousness, and in due course an international moratorium on commercial whaling is enacted. Industrial phosphates pouring into the Great Lakes are identified as the cause of biodiversity-killing algal blooms, and toxic chemicals known as PCBs are found leaking into waterways. Their use and disposal become tightly controlled. Sulphur dioxide emissions from power plant smokestacks, clear-cut logging, a refrigeration chemical destroying the atmosphere’s vital ozone layer—one after another, specific environmental contaminants and pollution streams are identified, campaigns mounted, and problems reduced, if rarely solved completely. If the ground-level reality of such campaigns was

often much more precarious and complex, the entirety of it was nonetheless fixed in time and place. Environmental crises were discrete phenomena that could be assessed, addressed, contained.

Since World War II, we have been living inside an explosion of synthetic chemicals: from 1 billion pounds in the 1940s to more than 400 billion pounds in the late 1980s. Even these numbers barely hint at the ubiquity of chemicals in our synthetic century. By 2004, the US chemical industry was producing more than 138 billion pounds of seven petrochemicals—ethylene, propylene, butylenes, benzene, toluene, xylenes, and methane—from which companies make tens of thousands of consumer products. Today, industries worldwide generate 300 billion pounds of plastics a year.

It is only in this context—a country bathed in man-made chemicals—that one can understand why the United States is in the midst of a cancer epidemic. The cancer establishment—made up by the National Cancer Institute, the American Cancer Society, trade associations like the Chemical Manufacturers Association, and the chemical industry—has fundamentally misled the American people into searching for a miraculous “cure.” Rather than vigorously examining the myriad poisons we are forced to encounter every day, these groups warn people to be careful about their “lifestyle.” Blame for cancer falls on consumers, not on the poisons that cause illness. From the perspective of the industries that make these chemicals, it’s a brilliant strategy. For the rest of us, it’s a tragedy.

John Quarles, a Nixon man who became a deputy administrator of the EPA in the early 1970s, found industry influence, disinformation, and propaganda against the EPA so insulting he wore his title of ‘bureaucrat’ with pride.

“I am part of the faceless, gray government machine, one of those government officials whom cartoonists make fun of and editorialists stick pins in, who are blasted with criticism by public leaders from Barry Goldwater to Ralph Nader. I am also an environmentalist, a chief official of the United States Environmental Protection Agency since its creation in December 1970, and in that capacity, too, I have been the object of heated criticism. The agency has been the target of the power industry, the steel industry, the auto industry, labor unions, farmers, editorialists, and private citizens. Its actions have been attacked as arbitrary, unreasonable, narrow-minded, impractical, and un-American. Much of this condemnation has been based on misunderstanding.”

What does this industry influence mean in practice? With few exceptions, environmental statutes allow chemicals to be dumped on the market without ever having been tested. In the case of the pesticides law, for instance, the EPA is authorized to demand pre-market health and environmental testing of new products. But in practice, the chemical industry plays a major role in writing those regulations and has a powerful hand in restraining the EPA from enforcing its rules. The chemical industry's allies in Congress and the White House raise no objections. The truth is, most toxic chemicals enter the market without ever being tested for health and environmental effects, and this is just the way the chemical industry likes it. The Occupational Safety and Health Act, the Toxic Substances Control Act, the cosmetic provisions of the Food, Drug, and Cosmetics Act, and all other federal laws require no testing for the chemicals or other products entering the market. Only the pesticides act and the food sections of the Food, Drug, and Cosmetics Act require testing of chemicals likely to enter the food we eat. This does not prevent industry marketers from saying that their products "meet EPA standards."

In almost all cases, these chemicals had been certified by both industry and the EPA as having an "acceptable" impact on the environment, or posing only "acceptable" risks to people. Human beings, we were told, had a "tolerance level" for each of them. As long as we use the chemicals "properly," we would be safe. The EPA uses the term 'tolerance' to describe how much of a certain pesticide will be tolerated in a given amount of food. But there is very little science behind these tolerance levels; their sole purpose is to provide legal cover for the companies who make the chemicals, the farmers who use them, and the manufacturers who process food. As long as the government sets even bogus health standards, companies have legal cover if their products make people sick.

A new principle of toxicology has, it seems, become firmly entrenched in the literature: no matter how lethal a poison may be for all other forms of animal life, if it doesn't kill human beings instantly, it is safe. When nevertheless it unmistakably does kill a human, this was the victim's own fault—either he was "allergic" to it (the uncompensable sin!) or he didn't use it properly.

In 1949, thirteen years before Rachel Carson alerted the world to the unseen dangers of pesticides, A. D. Pickett, a field entomologist in Nova Scotia, Canada, blamed farmers for a chain of deadly ecological reactions. Posterity, he said, would condemn us "as despoilers on account of the indiscriminate dissemination of poisons." Man, he reminded us, is merely one in a vast multitude of species making a living on earth.

“For thousands of years man accepted insects as part of the normal environment over which he had little or no control, and it is only within the last half century that we have actually made any real attempt to reduce their effectiveness as competitors.”

Pickett urged North Americans to return to an agricultural and food system that would render farm chemicals obsolete. We could grow crops primarily for “the purpose of satisfying man’s food requirements and not as a means of making particular human activities commercially profitable regardless of the overall effect on human welfare.”

A foundational myth of industrialized agriculture is that sprays have something to do with increasing the yields of crops. But we have known since for at least forty years that pesticides actually stifle the yield of growing crops, as you would expect from poisons that indiscriminately kill insects, plants, and countless other forms of life. In 1970 a study showed that after dusting the pollen of alfalfa with melipax, a toxaphene-like spray, no more than 10.5 percent of the grains would germinate, compared to 62.1 percent of the pollen left clear of the deadly dust. With only 0.3 percent of fribal emulsion, another poison similar to toxaphene, only 28.2 percent of grains germinated, compared to 81.5 percent of the grains sprouting in the absence of the toxin.

The scientific results are powerful, and clearly counter to the prevailing mythology of agricultural pesticides. But this brand of science has been hard to come by for one simple reason: most academic scientists, when they examine America’s agricultural system, don’t ask the right questions. Their work is funded largely by agribusiness, so—naturally—scientists tend to believe this system is the best in the world, and that pesticides make that system possible. Such delusions become intransigent beliefs, both within and without the government.

It’s hardly a surprise. Resilient agricultural systems are diverse—genetically diverse, and diverse in crops and techniques. And Monsanto already knew that plants could grow resistant to glyphosate because they got the resistant genes from plants growing in an outfall outside a glyphosate factory.

The worst thing is that even in intensive agriculture, the use of general herbicides is largely unnecessary. Years back a friend was doing research on an alternative to a spring spraying of newly planted wheat fields in the UK. They were looking at the alternative of covering the soil with about 50mm (2 inches or so) of low grade mulch to choke out weeds, planting the wheat on the mulch. Not only did it work just as well as a spray, it would have been an excellent way to promote the use of composting as a form of waste

treatment for organic waste, and it would cut down on soil erosion. But the problem seems to have been creating the chain—supporting composters to invest in the facilities, guaranteeing a supply to farmers at the right time. No private business saw this as profitable enough to do, only government could do it. But nobody was interested.

Every year, more land is sealed beneath buildings and roads. And because cities have usually grown from settlements on the most fertile land, vast urban centres are now squatting on some of our best soils.

Monoculture farming has more in common with engineering than with natural systems. And since engineers were redesigning and plumbing the country to water the developing giant farms, Rachel Carson thought of pesticides as crude weapons like “a cave man’s club hurled against the fabric of life.” She connected this violence with the still-fashionable ambition of modern industry to “control nature.” That idea—that modern people could dream of controlling the natural world—made Carson very angry. She lambasted such thinking as hubris. This kind of thinking and ambition, Carson said, mirrored a “Neanderthal age of biology and philosophy, when it was supposed nature exists for the convenience of man.”

“It is our alarming misfortune that so primitive a science has armed itself with the most modern and terrible weapons, and that in turning them against the insects it has also turned them against the earth.”

In its early days, pesticides seemed to represent a triumph of Western science and technology: both a proven weapon to subdue the “undesirable” aspects of nature and an elixir of cleanliness and even health. “The great expectations held for DDT have been realized,” ran an advertisement in *Time* magazine in 1947.

“Exhaustive scientific tests have shown that, when properly used, DDT kills a host of destructive pests, and is a benefactor of all humanity. Today, everyone can enjoy added comfort, health, and safety through the insect-killing powers of DDT products. [DDT] helps to make healthier, more comfortable homes [and] protects your family from dangerous pests. Use DDT powders and spray—then watch the bugs ‘bite the dust.’”

Though you may be forgiven for thinking otherwise, for several decades, honey producers in the United States were worried that protesting the death of their bees would bring down the wrath of industrial farmers, who will either wipe them out with sprays or ruin them by suggesting that honey

and pollen may be full of tiny capsules of nerve gas and numerous other poisons. This explains a depressing catch-22: even as their bees continue to die, honey producers have been largely silent; they are willing to lose some of their hives as a price for the social contract they have with the farmers whose insecticides kill their bees. The Beekeepers Association of Texas, for instance, opposed state regulations creating a buffer zone between sprayed fields and other property. A beekeeper in Corpus Christi, Texas, who supported buffer regulations was nearly wiped out—by farmers who sprayed his hives directly. The farmers wanted to teach him a lesson about whistle-blowing. Beekeepers keep their mouths shut in order to survive, and farmers want to believe their crops are not harming people. No consumer would buy honey with pesticides in it.

The problem is not that we don't know, but that government and industry refuse to do what is best for all of us, and for the natural world. The environment, science, and public health be damned.

Part of the issue is that no one looks at the problems from a broad perspective, such as the overall effect of all these chemicals on crops, the environment, and society at large. Instead, farmers identify a single-level problem—a pest, a fungus—and say: 'This poison solves this problem.' Then, when the pest becomes immune or a new one comes along, there's always another poison to deploy. There is a tragic lack of holistic thinking in the agricultural establishment. The consequences of the industrial scale of agriculture go beyond chemicals, of course. If farmers deplete rivers, they find ways to tap (and then deplete) water from the depths of the earth, as is now happening with the Ogallala Aquifer in the Great Plains or the sinking of parts of the Central Valley in California.

In such a single-minded, convoluted system, one pays attention only to the myriad technical problems of keeping crops and animals alive and multiplying. This eliminates asking complex biological and social questions, much less philosophical ones. What happens when our insecticides kill most insects? What are birds supposed to eat? Herbicides kill the microorganisms responsible for the movement of nutrients to the growing crop. What does this do to the nutritional value of the food we eat? The practitioner of one-crop farming does not ask questions like these. The farmer who has become heavily dependent on herbicides does not see the ecological tragedy taking place in his soil. He is oblivious to the dead fish that float to the surface after rains flush his pesticides into the river. He refuses to acknowledge the danger in the poisoned crops he feeds to animals and people, including, inevitably, his own children.

Farmers and their families often pay a high price for their chemical addiction, suffering an increased frequency of cancers of the stomach, prostate,

bone and connective tissue, blood, lymph tissue, and bone marrow. Compared to non-farmers, Iowa farmers develop these cancers from 40 to 100 percent more frequently. In general, studies show Iowa farmers—and probably all farmers using pesticides—are subject to higher than expected mortality rates from certain types of cancer. In a study of white male Iowa residents dying from 1971 to 1978, for example, it was concluded that farmers had statistically significant elevated mortality rates from the following six cancer types: lip cancer, stomach cancer, prostatic cancer, lymphatic cancer, leukemia, and multiple myeloma. These results were consistent with an Iowa study based on the years 1964–1970 and with studies completed in other states. The more bushels of corn and soybeans the large farmers of Iowa produce, in other words, the more cancer they harvest—and sell to the rest of us.

Pesticides have been linked to various cancers, endocrine problems, and poorer health in general. They are impossible to contain—traces of DDT have been found in animals living in the deep sea and are present in the breast milk of every nursing female animal on Earth, including humans.

Rats and mice exposed to toxin levels similar to those found in groundwater all over the United States suffer measurable damage to their immune, endocrine, and neurological systems. Among other impacts, this damage has made the animals more aggressive. Other studies complement these findings, revealing that children exposed to pesticides in utero or at preschool age turn out to be highly aggressive, with diminished intelligence and decreased stamina. It's cliché at this point but this is the creation of Idiocracy by pesticide exposure coupled with poor culture. RoundUp—it's what plants crave!

A 2007 study reported that premature births and birth defects in the United States peak at the very time (from April through July) when farmers spray and fertilize their crops and the residues of those poisons are at their greatest concentrations in the country's surface water. What we put into the environment can have pandemic effects, harming pregnancy and even the development of the infant and child.

We now know that pesticides injure man's genetic material in precisely the same way that radiation does. And what is so awful about such a genetic injury is that it is permanent—it can't be recalled, corrected, or somehow restricted to the victim, unless you also castrate that individual. So with an ever greater number of pesticide poisons loose in the environment, we as a society are creating a generation of people who will be weak in facing the future. We are then changing, irreversibly, the future itself. The price for that change is—or should be—unacceptable to any people with dignity and respect for themselves and love for their children.

On a global level, a quarter or more of the food produced for human consumption is lost or squandered—left in the field, ruined by poor storage, wrecked in packaging, spoiled in transport, rejected in markets, or simply thrown away by consumers. The exact amount depends on the definition of ‘waste,’ which varies dramatically in different studies, and how it is measured, which also varies. In wealthy places, most of the waste comes from people not eating food they have bought. By contrast, the losses in poor nations are concentrated in the field, storage, and transport. Cutting waste obviously would reduce the need to increase harvests. Unfortunately, it will not be easy. In poor nations it would require significant improvements to agricultural infrastructure—costly investments that are difficult for cash-strapped nations to make. Reducing losses in rich nations would involve changing the behavior of huge numbers of busy people, an equally challenging endeavor.

The tomatoes we get at the supermarket are selected for long-distance travel from California and for long shelf life, unlike the garden variety we grow for good taste. As with wild fruit, the nutrients that make them taste good also cause their rapid spoilage, and our commercial varieties of fruit are selected, like many winter fruits, for longevity.

Net necrosis is a purely cosmetic defect, yet because McDonald’s believes—with good reason—that we don’t like to see brown spots in our french fries, farmers must spray their fields with some of the most toxic chemicals now in use, including an organophosphate called Monitor. Monitor is a deadly chemical, it is known to damage the human nervous system.

“I won’t go into a field for four or five days after it’s been sprayed—not even to fix a broken pivot.”

That is, the farmer would sooner lose a whole circle to drought than expose himself or an employee to this poison.

One farmer is working hard to adjust his fields to the logic of nature, while the other is working even harder to adjust his fields to the logic of monoculture and, standing behind that, the logic of an industrial food chain. One small case in point: when I asked the first what he did about net necrosis, the bane of the other’s potato crop, I was disarmed by the simplicity of his answer:

“That’s only really a problem with Russet Burbanks. So I plant other kinds.”

The industrial farmer can’t do that. He’s part of a food chain—at the far end of which stands a perfect McDonald’s french fry—that demands he grow Russet Burbanks and nothing else.

In 1954, insects destroyed about 10 percent of America's food crops. In 1980—more than twenty-five years and untold tons of pesticides later—insects and disease destroyed nearly four times as much food—some 37 percent, worth about \$85 billion. Without even raising the harrowing questions of environmental and human health, it seems reasonable to ask a simple question: Has it been worth it? If farmers grew food entirely without using pesticides, they would lose about 41 percent of their crops, according to some studies. This would lead to a rise in the price of food of about 5 to 10 percent. Yet when we consider the significant damage done by fully armed chemical farmers, growers, and ranchers, this seems a modest price to pay. A 2003 study calculated the environmental and societal damages from the legal use of pesticides to be about \$12 billion per year.

Is industrialized agriculture as benign—or even as effective—as its industrial patrons seem to think? Or is it just a con game, a successor to the nineteenth-century patent medicine hustle? Another way of asking this question: Have we been duped?

The larger the farm, the more sprays per acre, and the heavier the costs; the smaller the farm, the less pesticide sprayed per acre, and the less cost to the farmer. Farms under 24 acres paid about a third (per acre) of what farms over 50 acres paid for pesticides, yet the largest farms sprayed nearly five times as much as the smallest grower and nearly twice as much as a medium-size grower. Large and medium-size growers used twice as much fungicide as the small farmer. The intensity and level of sprays of the large capital-intensive grower is significant. In the end, if an informed consumer had a choice between eating onions from a large farm (sprayed with 52 different chemicals) and onions from a small farm (sprayed with 11 different chemicals), the owner of the larger farm would probably not be able to sell his onions. At one time farmers knew enough to graze cows next to onion fields. They knew that cow dung provided food parasites that controlled the onion maggot. Once industrial farms insisted on devoting all their fields to a single crop (such as onions), the onion maggot flourished and created an ideal market for toxic sprays.

Totalitarian agriculture was not adopted in our culture out of sheer meanness. It was adopted because, by its very nature, it's more productive than any other style—and there are many other styles. Totalitarian agriculture represents productivity to the max, as Americans like to say. It represents productivity in a form that literally cannot be exceeded. Many styles of agriculture—not all, but many—produce food surpluses. But, not surprisingly, totalitarian agriculture produces larger surpluses than any other style. It produces surpluses to the max. You simply can't outproduce a system designed to convert all the food in the world into human food.

On average, an American farmer today grows enough food each year to feed a hundred people. Yet that achievement—that power over nature—has come at a price. The modern industrial farmer cannot grow that much food without large quantities of chemical fertilizers, pesticides, machinery, and fuel. This expensive set of “inputs,” as they’re called, saddles the farmer with debt, jeopardizes his health, erodes his soil and ruins its fertility, pollutes the groundwater, and compromises the safety of the food we eat. Thus the gain in the farmer’s power has been trailed by a host of new vulnerabilities.

Farmers in the US grow five times as much corn per acre as African smallholders, and synthetic fertilizers are key to this. Their invention altered the nitrogen cycle and changed our planet. More than 100 million tonnes of nitrogen are removed from the atmosphere each year by the fertilizer industry, helping feed half the world’s people. The problem is, only a fraction of this nitrogen ends up in our food. The excess lingers in soils, lakes, and oceans, fertilizing massive blooms of algae that can be toxic and use up the dissolved oxygen, suffocating other species.

In the 1990s Kenya passed Israel to become Europe’s biggest provider of cut flowers, which now exceed coffee as its main source of export income. This fragrant turn of fortune, however, incurs a debt that may keep compounding long after flower lovers are no longer around. A flower, like a human, is two-thirds water. The amount of water a typical floral exporter therefore ships to Europe each year equals the annual needs of a town of 20,000 people. During droughts, flower factories with production quotas stick siphons into Lake Naivasha, a papyrus-lined, freshwater bird and hippo sanctuary just downstream from the Aberdares. Along with water, they suck up entire generations of fish eggs. What trickles back whiffs of the chemical trade-off that keeps the bloom on a rose flawless all the way to Paris. Lake Naivasha, however, doesn’t look quite so alluring. Phosphates and nitrates leached from flower greenhouses have spread mats of oxygen-choking water hyacinth across its surface. As the lake level drops, water hyacinth—a South American perennial that invaded Africa as a potted plant—crawls ashore, beating back the papyrus. The rotting tissues of hippo carcasses reveal the secret to perfect bouquets: DDT and, 40 times more toxic, Dieldrin—pesticides banned in countries whose markets have made Kenya the world’s number-one rose exporter. Long after humans and even animals or roses go, Dieldrin, an ingeniously stable, manufactured molecule, may still be around.

“If man were to faithfully follow the teachings of Miss Carson, we would return to the Dark Ages, and the insects and diseases and vermin would once again inherit the earth.”

“We’ve heard the benefits of pesticides. We have heard a great deal about their safety, but very little about their hazards, very little about their failures, their inefficiencies. And yet the public was being asked to accept these chemicals, was being asked to acquiesce in their use, and did not have the whole picture. So I set about to remedy the balance there.

We still talk in terms of conquest. We still haven’t become mature enough to think of ourselves as only a tiny part of a vast and incredible universe. I think we’re challenged as mankind has never been challenged before, to prove our maturity and our mastery, not of nature, but of ourselves.”

Farmers can only mirror a mismanaged society. They need guidance and direction and appropriate research from the land grant universities, which, sadly, take their cues from pesticide companies and the rest of the agroindustrial complex. Ideally, the EPA, the USDA, and the state governments ought to intervene by teaching farmers how to practice safe agriculture. In reality, the academic-agribusiness complex is rife with cultural arrogance, failing to see that its system cannot continue in a future energy- and chemical-limited environment that is necessary if we are to maintain a viable culture for future generations.

It’s obvious that it costs a lot of money and energy to produce all the food we need to maintain our population at seven billion. But there is an additional, hidden cost that has to be counted in life-forms. Put plainly, in order to maintain the biomass that is tied up in the seven billion of us, we have to gobble up two-hundred species a day—in addition to all the food we produce in the ordinary way. We need the biomass of those two-hundred species to maintain this biomass, the biomass that is in us. And when we’ve gobbled up those species, they’re gone. Extinct. Vanished forever. In other words, maintaining a population of seven billion humans costs the world two-hundred species a day. If this were something that was going to stop next week or next month, that would be okay. But the unfortunate fact is that it’s not. It’s something that’s going to go on happening every day, day after day after day—and that’s what makes it unsustainable, by definition. That kind of cataclysmic destruction cannot be sustained.

Humans kill around 1,600 animals every second for food, and that doesn’t even count the marine life.

Superfarms already exist in Saudi Arabia and the US, housing more than 100,000 live animals.

At the beginning of the twentieth century barely 10 percent of the world’s grain harvest went to animals, mostly horses, mules, and oxen used as farm

labor. By the beginning of the twenty-first century, the figure had risen considerably, though by exactly how much is difficult to calculate: perhaps 40 percent, the great majority of it destined for dairy and meat animals.

Just how much grain is required to produce a pound of beef, pork, or chicken?

Beef farmers in the Midwest buy 650-pound steer that have been raised on pasture and feed them leavings in the form of silage (mowed grass and clover, wheat, and maize plants that are cut after harvest) and distillers' grains (maize, rice, or barley from which the starches have been stripped to make products like beer, ethanol, or high-fructose corn syrup). The feedyards where steer are fattened before slaughter surround ethanol and corn-syrup plants like moons around a planet. As a result, the animals form a critical component of the overall grain industry—but actually eat less grain themselves than one might think. Every uptick in meat consumption is associated with a bump in grain production. But the precise amount of the increase is not straightforward. For beef, it is affected by a host of other factors, including the subsidies for ethanol, the price of corn syrup (and the sugar for which it is a substitute), and the demand for leather, bone, fat (an ingredient in airplane lubricants), keratin (extracted from hooves and used in fire-extinguishing foam), and other meat by-products.

Matters are just as complex for pork, chicken, and farm-raised fish. Almost no matter what the scenario, though, if tomorrow's newly affluent billions are as carnivorous as Westerners today, the task facing tomorrow's farmers will be huge. Between 1961 and 2014, the world's meat production more than quadrupled. Simply reproducing that jump could easily require doubling the world's grain harvest.

It takes around fifteen pounds of grain or soybeans to produce a pound of meat. The United States actually uses 95 percent of its soybean crop (the second largest in the world) as animal food, mostly for pigs. Leaving aside the fact that the soybeans could have fed hungry people much more efficiently, there's another problem: high-input annual crops like soybeans and corn release about 1,000 pounds of CO₂ per acre per year which comes to 144 billion tons of annual carbon emissions in the United States from these two crops alone.

1 pound of beef = 10 pounds of feed, 1,000 gallons of water, 200 square feet of pasture (2 acres per cow)

1 pound of pork = 5 pounds of feed, 600 gallons of water, 175 square feet of pasture (2/3 acre per pig)

1 pound of chicken = 2.5 pounds of feed, 150 gallons of water, 75 square feet of pasture (100 square feet per chicken)

1 pound of fish = 1.5 pounds of fish meal, variable amounts of water

1 pound of insects = 2 pounds of feed, 1 gallon of water, 2 cubic feet of land space

It was not until 2006 that the European Union banned the use of antibiotics in animal feed as performance enhancers. The kind of performance being enhanced here is the ability of an animal to not die of infections in a crowded and dirty pen. Antibiotics are a great way to “enhance” this “performance.” In the United States, the Food and Drug Administration is working on a voluntary plan to phase out the use of some of these antibiotics in regular farming.

Currently, around two-billion people live on a primarily meat-based diet, while three billion are malnourished.

Converting food stocks to fuel is a crime against humanity. What has to be stopped is the growing catastrophe of the massacre by hunger in the world. It takes 510 pounds of corn to make 13 gallons of ethanol, which is enough corn to feed a child for a year in Zambia or Mexico.

In August 2012, after an emergency G20 meeting over food prices, the director general of the United Nations Food and Agriculture programme called on the US government to suspend its biofuels quota for the maize harvest, after a months-long drought and heatwave destroyed much of the crop. Cattle farmers around the world backed the call, fearing costly animal feed over the winter. But what the US feared more was a rise in the gasoline price: so it maintained its biofuels quota. In that year, at least, the battle between hungry people and thirsty cars was won by the latter.

Chapter Twenty

The Origin of Modern Sick

Manufactured Illness

“Every hour wounds. The last one kills.”

When Upton Sinclair was threatened with a lawsuit by J. Ogden Armour, of the meatpacking firm, he replied with a letter to the *New York Times*. Sinclair wrote that he had seen:

“The selling for human food of the carcasses of cattle and swine which have been condemned for tuberculosis, actinomycosis, and gangrene; the converting of such carcasses into sausage and lard; the preserving of spoiled hams with boric and salicylic acid; the coloring of canned and potted meats with aniline dyes; the embalming and adulterating of sausages—all of these things mean the dealing out to hundreds and thousands of men, women, and children of a sudden, horrible, and agonizing death.”

Ever cheeky, Sinclair added:

“One-hundredth part of what I have charged ought, if it is true, to be enough to send the guilty man to the gallows. One-hundredth part of what I have charged ought, if it is false, to be enough to send me to prison.”

“The discovery that tables may groan with food and that we may nevertheless face a form of starvation has driven home the fact that we have applied science and technology none too wisely in the preparation of food.”

—*New York Times Editorial, 1941*

“The boats were shaped like booties, fully enclosed, capsule-like cylinders with benches on both sides long enough to fit 73 110-pound Koreans hip to hip and knee to knee—but they could only fit from 45 to 60 of the much larger Americans, depending on the number of 250-pounders aboard.”

Since the 1970s, American farmers have been producing an overabundance of calories—one of the great unspoken secrets and a major problem for the food industry. The industry’s dilemma is that the average American can eat only so much of that food—about 1,500 pounds per year—and the total number of eaters in this country is growing by only one or two percentage points per year. Yet Wall Street demands that food corporations grow at a considerably faster rate. What to do? Add “value” to cheap raw ingredients by processing them (i.e., transform a few pennies’ worth of grain and sugar into five dollars’ worth of breakfast cereal); spend billions to market these products as aggressively as possible (to children, by using sugar and cartoon characters, and to their parents, by making dubious health claims); use every trick of food science and packaging to induce us to eat more of these products than we should; and then, just to make sure no one tries to interfere with this profitable racket, heavily lobby Congress and nutrition scientists to keep anyone in power from so much as thinking about regulation or officially whispering that maybe we should eat a little less of this stuff. It’s pretty much that simple. Many of the nutritional problems of Americans—not least of them obesity—can be traced to the food industry’s imperative to encourage people to eat more in order to generate sales and increase income.

‘Let’s see what’s on the agenda today.’ For thousands of years the answer to this question remained unchanged. The same three problems preoccupied the people of twentieth-century China, of medieval India, and of ancient Egypt. Famine, plague, and war were always at the top of the list. For generation after generation humans have prayed to every god, angel, and saint, and have invented countless tools, institutions, and social systems—but they continued to die in their millions from starvation, epidemics, and violence. Many thinkers and prophets concluded that famine, plague, and war must be an integral part of God’s cosmic plan or of our imperfect nature, and nothing short of the end of time would free us from them.

In most countries today overeating has become a far worse problem than famine. In the eighteenth century Marie Antoinette allegedly advised the starving masses that if they ran out of bread, they should just eat cake instead. Today, the poor are following this advice to the letter. Whereas the rich residents of Beverly Hills eat lettuce salad and steamed tofu with

quinoa, in the slums and ghettos the poor gorge on Twinkie cakes, Cheetos, hamburgers, and pizza. In 2014 more than 2.1 billion people were overweight, compared to 850 million who suffered from malnutrition. Half of humankind is expected to be overweight by 2030. In 2010 famine and malnutrition combined killed about one-million people, whereas obesity killed three-million.

I would argue that many of the ways in which we get sick today have a corporate, almost capitalist origin. We've also got this bizarre notion that finally came true, that our bodies don't really matter.

The World Health Organization (WHO) pinpoints four factors as the main causes of death before the age of 86:

1. Poor diet
2. High blood pressure
3. Obesity
4. Tobacco use

Three of the four are diet related. The National Research Council and the Institute of Medicine came to the same conclusions, finding that diet and activity patterns—far ahead of tobacco, alcohol, drug abuse, gun violence, and car accidents—are the primary factors behind premature deaths in this country.

No more than 10 percent to 20 percent of risk for the primary causes of death comes from our genes. Only about five percent to ten percent of cancer cases are attributable to genetic defects, with the other 90 percent to 95 percent rooted in lifestyle and environment. Colon cancer, the second most lethal cancer in the country, is the cancer most directly affected by what you eat. According to the WHO, 80 percent of all heart disease, stroke, and Type 2 diabetes can be prevented.

People think heart disease, cancer, and diabetes are inherited, not realizing that what they've actually inherited are the eating habits of their parents and grandparents. People are exposed as children to a certain way of eating that they carry into their adulthood. They pass it on to their children. That's why they develop the same diseases their parents and grandparents may have had before them, but it is not inevitable.

They really want to believe, 'I don't have control over this. This happened to my parents, so just give me the drugs. I don't need to change because it's inevitable.' Think of the Greek Fates, particularly the third goddess, "the inevitable," standing with her shears over the cradle—the thought

of predestination can bring a peculiar comfort to many. It takes away responsibility. The majority of conditions that kill people in this country are completely preventable for most of us. It's up to us to take that responsibility and change—change the culture and the real, actual, deadly epidemics.

“Much of what we know about diet comes from studies going back to rural Africa and rural China in the 1920s, where Westerners set up missionary hospitals. They saw millions of people, and to their surprise, they weren't suffering from Western diseases. There were populations where high blood pressure rates were zero. Heart disease rates were zero. Thousands of autopsies found no heart attacks. It's not like these Western-trained doctors couldn't recognize heart attacks. The diseases weren't present. If you want to avoid them, you have to change your diet. Lifestyle medicine pioneers started asking, ‘What if we put people with advanced chronic disease on the diet followed by these populations that don't get the diseases in the first place? Maybe we could slow it down.’ Instead, something miraculous happened. The diseases started to reverse.”

In the early years of the twenty-first century we live in a brave new world of billion-dollar pharmaceuticals and space-age medical procedures. It's no big deal for surgeons to inflate tiny balloons inside congested blood vessels, leaving behind a stent (a permanent wire mesh to prop an artery open), or harvest an artery from a patient's leg and splice it around the heart. We can also suck fat out of your butt and put it in your lips—now there's medical progress.

And yet our rates of chronic disease are smashing through the roof. In 2012, half the US adult population had at least one chronic health condition. One out of four adults had at least two. Eighty-six percent of health care spending in 2010 covered people with one or more chronic conditions, with \$315 billion allocated to heart disease and stroke. Cancer that same year cost \$157 billion; diabetes, \$245 billion. In 2008, obesity-related causes racked up \$147 billion in medical costs. Drugs, hospitals, and surgeries.

“The doctor of the future will give no medicine, but will instruct his patient in the care of the human frame, in diet, and in the cause and prevention of disease.”

Such a prediction has not come true. Because doctors cannot teach what they do not know. Medicine now is about the use of drugs and surgeries to

suppress symptoms associated with the disease, and they do a brilliant job. It just doesn't have anything to do with health.

Nutrition is the poor sister of medical education. Why? First, nutrition is viewed with disdain. Physicians feel, 'We're practicing real medicine, suturing wounds and fixing fractures. Nutrition? Boring. Send them to the dietitian.' Second, physicians don't want to open that discussion because they don't know much about it. And finally, we have to look at the physician's own diet. That's what really keeps nutrition from being recognized as a keystone of disease treatment. Between these three fortresses—the disdain, the ignorance, and the doctors' own unwillingness to change—nutrition doesn't enter the examination room.

In 2009, only 25 percent of accredited US medical schools required their students to take a single dedicated course in nutrition. The National Academy of Medicine recommended, back in the 1980s, that medical schools provide a minimum of 25 hours of nutrition instruction. Thirty years later, the few schools offering courses on diet and disease provided on average less than 24 hours of nutritional instruction, with most students getting only 11 to 20 hours, out of the thousands of hours spent in medical school. And once students graduate, they don't even get that.

The primary organization responsible for physicians' continuing medical education, the Accreditation Council for Graduate Medical Education (ACGME), has a 37-page booklet outlining the continuing education requirements for cardiologists. They include interpreting a minimum of 3,500 electrocardiograms, and interpreting "a minimum of 100 radionuclide studies to include SPECT myocardial perfusion imaging and ventriculograms." Nutrition education is not mentioned once. ACGME asserts, in its 36 pages of requirements for doctors of internal medicine, that "internal medicine is a discipline encompassing the study and practice of health promotion, disease prevention"—and yet again, not a single nutrition-related requirement is included.

You might be wondering why a carnivorous animal like a cat doesn't get the same cancers that humans get from eating large amounts of meat. One answer may lie in our guts. The human body has a very long digestive tract, with extra surface area to extract nutrients, and process all the fiber in plants. If you eat a high-fiber diet—by which I mean a plant-based diet—fiber will carry out the carcinogens and the excess hormones. An animal like a cat is built for a meat-based diet. They have a very, very short intestinal tract, so the carcinogens don't stick around. It's a completely different system. Cats and other carnivores move food through their intestinal tracts in under 4 hours. But food stays in our human bodies for 18.

Your skin covers about twenty square feet. Your lungs, if you were to

flatten out all the tiny air pockets, could cover hundreds of square feet. And your intestines? Counting all the little folds, some scientists estimate that your gut would blanket thousands of square feet, vastly more expansive than your skin and lungs combined. What you eat may very well be your primary interface with the outside world. That means that regardless of the carcinogens that could be lurking in the environment, your greatest exposure may be through your diet.

Adventists believe god calls on them to care for their bodies, treating them with the respect a divine creation deserves. They exercise regularly and do not smoke, drink alcohol, or take illicit drugs. They advocate:

“A well-balanced vegetarian diet that avoids the consumption of meat coupled with intake of legumes, whole grains, nuts, fruits, and vegetables, along with a source of vitamin B12.”

Loma Linda, a town in Southern California, is home to about nine-thousand Adventists and is one of the world’s five longevity “Blue Zones”—the only one in the United States—where people live notably longer, healthier lives, often past 100. The five Blue Zones are:

- Nicoya, *Costa Rica*
- Ikaria, *Greece*
- Sardinia, *Italy*
- Okinawa, *Japan*
- Loma Linda, *United States*

Residents of all five Blue Zones eat plant-based diets, accented infrequently, if at all, with animal protein. About 50 percent of Adventists are vegetarians, who eat no meat but do eat dairy and eggs. But there are also large numbers of Adventist vegans, who don’t eat any animal protein at all, as well as those who eat small amounts of fish and/or meat. Because they live close together in the same environment, and share the same healthy lifestyle, the dietary distinctions among them take on a special value for researchers.

I’ve known people who try a plant-based diet, but then say:

“I got so weak. I couldn’t get out of bed.”

The insinuation is always that the absence of animal protein—real protein—sapped them. But your body does not use protein for energy. Your

body uses carbohydrates or fat for energy. This idea that a person becomes weak and tired because of protein deficiency is absolutely not true. There's no biochemical explanation for that.

“Most of my patients, in fact, feel fantastic when they shift their diet. I've been doing this for 30 years. I've had 15,000 people on an in-patient basis, and I haven't yet come across someone whose symptoms were caused by a deficiency of dead flesh, coagulated cow pus, or any other animal products. Physically, human beings are able to adopt a plant-based diet and thrive. Psychologically? It might be like an alcoholic saying, 'I can't quit drinking because of my constitution.'”

Not eating enough calories is one of the problems sometimes experienced by people new to a plant-based diet. Whole plant foods are much less calorically dense than animal foods. If your caloric intake suddenly drops, people can feel lousy. So you need to eat more to get the same number of calories. Good news for people who like to eat.

“One of my friends was plant-based for three years, and then felt really weak. She had a sip of bone broth and felt better.”

Come on.

“No, I've heard it a few times: 'I had some chicken and I felt all better.'”

That is crazy psychological placebo nonsense. It's actually not possible. Now, if she said, 'I started eating meat again, and a couple months later I felt much better,' then maybe she was iron-deficient. But there is no disease on the planet where you eat a piece of chicken or a can of tuna, and the clouds part and the sun comes out.

“Or what about people who say, 'I know my body, I just need meat'?”

That's like saying, 'I need meat because I'm a Capricorn.' It makes no biological sense. Are there people who simply can't change their diet? There certainly are. Now, you have to ask, 'Are they given all the information? Are they given all the motivation? Do they have the opportunity and the environment to support this?' Most of the time, when I have a patient who can't change their diet, it's because of their surroundings. Environment is huge. Culture is huge.

Going vegan is a significant dietary change for a lot of people. As with any change, you're probably going to notice some different feelings. But if your idea of a plant-based diet is Oreos, French fries, Diet Coke, and lots of processed meat alternatives, you're not going to feel great. The same would be true if you ate nothing but kale and broccoli, shunning grains, legumes, nuts, and seeds. Both those diets would certainly turn you into a tired, sick vegan. What you need in your meal plan is a dash of knowledge.

“Human beings have evolved to eat meat. Look at our canine teeth!”

Look at the canines on a panda. When your cat yawns you see protruding razor teeth used to kill prey, to scrape hide and pull meat off bones. Our canine teeth are no bigger than our incisors. That happened at least three-and-a-half-million years ago. Our teeth are designed for grinding, which is good for vegetables, fruits, grains, and beans. Not so good for killing and eating a raw animal. Try eating roadkill without tools. Lots of herbivores have canines. The canines in several primates are very long, almost like the canines in carnivores, but they're used for defense and fighting each other. Human canines have become small and rounded. They're useless for ripping anything other than an envelope. With our 30-foot-long gastrointestinal tract, there's no question that humans are herbivores.

What can't you get in a plant-based diet that you can get in meat? Are there any healthy things found only in animal products? Every nutrient from meat, dairy, and eggs can be found, in a form that is as healthy or healthier, in plants. Many people might worry, ‘Will I get the nutrition I need on a plant-based diet?’ The fact is, you're not getting the nutrition you need on a meat-based diet.

Let's look at iron. Iron deficiency is one of the most common nutritional deficiencies in both the United States and the world. People on a plant-based diet are no more likely to be iron deficient than meat eaters. There are two types of dietary iron: heme iron (found in animal tissue like meat) and non-heme iron (found in plants). “Heme” comes from “hemoglobin,” the molecule in red blood cells. An easy way to remember: animals bleed (heme); plants do not (non-heme). Heme iron is more easily absorbed than non-heme iron. Sounds like a good thing, right? The higher bioavailability of iron from muscle tissue and blood, though, is a serious drawback disguised—and often trumpeted—as a benefit. The body will keep absorbing iron from animals, even when no more is needed. Non-heme iron, however, allows the body to control the amount absorbed. If the body has enough iron, the intestines can dial down the absorption of plant iron. If the body needs more, it can

turn up the absorption. Our digestive systems block the intake of plant iron—if we already have a sufficient supply in our bodies—about five times more efficiently than animal iron.

Getting our iron from plants protects us from excess iron, which is a dangerous thing. Once it's absorbed, there are very limited ways to get rid of it. It's trapped in the body. Iron is a pro-oxidant that can damage DNA. Iron from meat has been associated with higher risks of heart disease, stroke, Type 2 diabetes, and even cancer. Scientists can tell, by examining tumors, how much meat the cancer patient has eaten. You can avoid heme iron by getting your iron from sources like lentils, tofu, chickpeas, peas, cashews, soybeans, blackstrap molasses, quinoa and other whole grains, dark leafy vegetables, fortified cereals, and broccoli. You can also boost your iron absorption by up to five times if you eat iron-rich foods along with vitamin C. Delicious iron/vitamin C combos include lentil soup with green peppers; rice and beans with salsa; stir-fried broccoli and tofu; bran cereal topped with strawberries; and hummus with lemon juice. A lot of vegetables, like broccoli and bok choy, are sources of both iron and vitamin C.

All protein is made by plants. I'll state that again for the record: all protein is made by plants. What distinguishes protein from carbs and fats is the presence of nitrogen. Only plants have the ability to take nitrogen from the air, break those molecules apart, incorporate that nitrogen into amino acids, and make protein. Animals eat plants and reprocess those amino acids into their own tissues. All animal protein is simply recycled plant protein. And you really want to get your protein directly from plants, because plant proteins have a much more beneficial effect on our physiology. It is not necessary to eat animal tissue in order to get protein. If anything, we need less protein.

That's nutritional blasphemy. Our nation is obsessed with protein. Protein has what researchers call a "health halo effect," an idolization of the nutrient that doesn't have much to do with science.

"Protein is one of those rare things that has a lot of different meanings to a lot of different people and they are all positive."

People eat protein to lose weight. People eat it to gain weight. People eat it for energy. Most of us believe we should eat as much protein as possible. Just 10 percent to 35 percent of your total calories, however, should come from protein. That's the recommendation from the Food and Nutrition Board, Institute of Medicine, National Academies. According to the American Council on Exercise, a 145-pound person requires 52.7 grams of protein daily, using the Recommended Dietary Allowance figure of 0.8 grams of protein per kilogram of body weight.

American males over the age of 20 eat an average of 98.9 grams of protein a day. American females over the age of 20 eat an average of 68 grams of protein per day. This means that men, on average, are eating enough protein to sustain a 273-pound man. Women are eating enough protein for a 187-pound woman. I know America has issues with obesity, but still, that's a bit much.

Human breast milk is the fluid designed by evolution over millions of years as the perfect food for human babies. It has the lowest protein content in any mammalian milk—rat milk, donkey milk, any milk that's ever been tested. That gives you a sense of human protein requirements. Protein overload is one of the reasons formula is not optimal. One cup of human milk contains 2.5 grams of protein, compared to 7.9 grams in cow's milk, and 8.7 grams in goat's milk.

Here in America, calcium and milk are synonymous, just like protein and meat. It's another nursery school belief, inculcated in us as toddlers and never examined since. What is calcium? It's a mineral. And where are minerals found? In the soil. And why do cows have calcium in their milk? Because they eat the grass. But three out of four cows raised specifically for dairy are not consuming grass, and so that the dairy industry can live up to the marketing claims that it's a high-calcium food, what do they do to the cows' feed? They supplement their feed. You could supplement your feed. We'd skip a lot of problems. Or you could go right to the source and get your calcium from the green leafy vegetables, the highest source of calcium. Cow's milk has 189 mg of calcium in every 100 calories. Kale has 257 mg per 100 calories, tofu 287, collard greens 539, and bok choy has 775 mg. Now sure, that's a shitton of leaves, but nuts, seeds, legumes all contain calcium as well.

If I could flay all the skin off you and boil the flesh off your skeleton, all the bones in your body would weigh about 35 pounds. A bull moose grows a full rack of antlers in three months. They're made of solid bone. A mature bull's antlers weigh 80 pounds, more than twice the amount of your entire skeleton. That moose grows his rack of antlers while eating nothing but green, leafy plant foods.

Eating cheese and other dairy products is also linked to feminization in men. This is ironic, considering that men often refuse soy out of fear it will take the edge off their masculinity. Yet they have no qualms about Philly cheese steaks, whey protein shakes, and three-cheese pizzas, all loaded with the sex steroid hormones of a pregnant bovine mammal. In one experiment, a group of young men ages 19 to 21 were asked to drink a quart of cow's milk in 10 minutes. Within the hour, their estrogen levels shot up 60 percent, while their testosterone levels plummeted dramatically. Another

study was titled, “Dairy Food Intake in Relation to Semen Quality and Reproductive Hormone Levels Among Physically Active Young Men.” The “physically active young men” ate a large amount of cheese in particular, and regardless of their overall dietary patterns, the motility of their sperm declined considerably and the quality of their semen deteriorated.

The egg industry has remarkable parallels with the behavior of the tobacco industry. The egg industry has been slapped on the wrist repeatedly for decades, by institutions such as the USDA, the Federal Trade Commission (FTC), the US Court of Appeals, and the Supreme Court, for “false and misleading advertising that eggs had no harmful effects on health.” In 1977, the National Commission on Egg Nutrition, a major trade group, was convicted of false advertising by the US Court of Appeals and ordered to “cease and desist from disseminating any advertisement” that “represents that there is no scientific evidence that eating eggs increases the risk of heart attacks, heart disease, atherosclerosis, arteriosclerosis, or any attendant condition.”

The FTC has twice brought cases against Eggland’s Best, Inc., in 1994 and 1996, for making “deceptive” advertising claims like:

“Imagine eating delicious, real, whole eggs and not raising your serum cholesterol. People did. In clinical tests of Eggland’s Best eggs. They ate a dozen a week while keeping within the limits of the Surgeon General’s low-fat diet. And... their serum cholesterol didn’t go up.”

The USDA has reminded the egg industry repeatedly that, due to laws against false advertising:

“You can’t couch eggs/egg products as ‘healthy’ or ‘nutritious.’ Nutritious and healthy carry certain connotations, and because eggs have the amount of cholesterol they do, plus the fact that they’re not low in fat, these words are problematic.”

This is a list of advertising claims about eggs that the USDA has told the egg industry they cannot use, because they’re not true:

- “A rich source of protein”
- “Low in saturated fat”
- “Nutritional powerhouse”
- “Eggs contribute nutritionally”
- “Relatively low in calories”
- “Healthful”
- “Relatively low in fat”
- “Eggs contribute healthful components”

See, under the FDA, a food can only be labeled ‘healthy’ if it is low in saturated fat and contains 90 mg or less of cholesterol per serving.

One weekly serving of fish during pregnancy can build up more mercury in your unborn baby than injecting a dozen mercury-containing vaccines straight into their fetal bodies. Fetuses are far more sensitive to mercury than adults. Mercury in the diets of pregnant women is linked to birth defects, intellectual and developmental disabilities, seizures, and cerebral palsy in their babies.

The American Diabetes Association has taken money from, among others:

Kraft Foods Makers of Velveeta processed cheese, Oscar Mayer processed meat, and Lunchables processed kids’ meals

Campbell Soup Company Makers of canned salt water

Cadbury-Schweppes The world’s largest confectioner and producer of foods like the Cadbury Crème Egg and Dr. Pepper

Coca-Cola Makers of sugar water

Hershey’s Makers of candy, sugar milk, frozen sugar milk

Dannon One of the largest dairy yogurt producers

Kroger Processed food supplier

Walgreens Another processed food supplier

Bumble Bee Foods Makers of processed canned meats and dead dolphins

The American Diabetes Association also flirted seriously with Burger King for almost a year, until BK came out with a burger with more fat than had ever been seen on the fast-food market. Now that’s just going too far.

But wait, there’s more. In the ADA’s 2017 “Banting Circle Elite” level of corporate sponsorship, which requires a gift of at least \$1 million, you’ll find:

- AstraZeneca
- Eli Lilly
- Merck
- Novo Nordisk
- Sanofi
- Janssen Pharmaceuticals

In the next tier down, requiring a gift of only \$500,000, is Pfizer and Medtronic. These drug companies are in the booming business of helping people manage the symptoms of their Type 2 diabetes.

“Dr. Ratner at the ADA only wanted to talk about people living longer with diabetes. Once I mentioned eliminating diabetes or prevention, he shut down the conversation. Diet and cure? Whoa, let’s not go there.”

Lets do another one—the American Heart Association. The American Heart Association has received money from:

- Texas Beef Council
- Cargill
- South Dakota Beef Industry Council
- Kentucky Beef Council
- Nebraska Beef Council
- Tyson Foods
- AVA Pork
- Unilever
- Trauth Dairy
- Domino’s Pizza
- Perdue
- Idaho Beef Council
- Bristol-Myers Squibb
- Eli Lilly
- GlaxoSmithKline
- Novartis
- Pfizer
- Sanofi
- Merck
- AstraZeneca

The final members on that list were among fistfuls of pharmaceutical companies which contributed \$21,470 in 2010 to fund an AHA program on “emerging strategies with statins,” and nearly \$100,000 for projects such as “debating controversial topics in cardiovascular disease.” I wonder what controversial topics AstraZeneca had in mind.

One more, the Susan G. Komen breast cancer charity. You’ve got:

- Kentucky Fried Chicken (eat a breast to save a breast?)
- Eggland’s Best
- Yoplait
- Dietz & Watson
- Trident Seafoods
- Walgreens

“I have no doubt that the major health-related organizations have the best intentions of the American public at heart. But once these groups say, ‘The best thing to reduce your risk of cancer, heart disease, and diabetes is to reduce or eliminate your consumption of meat, dairy, and egg products’—that would be the end of their funding. That would bring the entire catastrophe down upon their heads, and they would essentially disappear as organizations. That means you are not going to be hearing the truth, as far as nutrition goes, from these organizations. He that pays the piper calls the tune.”

The Academy of Nutrition and Dietetics (AND) is the nation’s largest trade group for registered dietitians, representing some 75,000 nutrition professionals. One of AND’s major sponsors is the National Dairy Council. They give AND money every year, and they get to have a huge booth at the annual expo. So you walk in, and there’s the National Dairy Council promoting itself to nutritionists who are telling Americans how to eat. They also sponsor scientific sessions, so dietitians can learn why lactose intolerance is no big deal, sponsored by the National Dairy Council. And they offer continuing education units so nutritionists can continue to hear about the wonders of dairy while fulfilling mandated requirements.

It’s not only the National Dairy Council that American nutritionists are getting their information from. McDonald’s sponsored and catered the 2017 annual conference of the California Dietetic Association, an affiliate of AND. AND also publishes “Nutrition Fact Sheets” to help people make healthier choices. Guess who writes those “Fact Sheets”? The food industry. Not only that, but they pay AND \$20,000 per “Fact Sheet.”

“What’s really sad, is that we cannot trust the information from these leading health organizations, because they’re taking money from the very industries that are causing the problems these groups are supposed to be helping to prevent.”

Phytates, a natural compound found in plant seeds—and therefore in all seeds, nuts, beans, and whole grains—have been shown through in vitro studies—ones performed in an environment outside a living being, such as a test tube—to suppress the development of practically all human cancer cells tested, including breast, cervix, colon, liver, pancreas, prostate, and skin cancers. Healthy cells were not affected. Phytates also increase the activity of your body’s natural killer cells that track down and clear out cancer cells.

The connection between vitamin A deficiency and night blindness is now well understood, and has to do with our rods, the cells in our retinas

that allow us to see in low light. Rods contain a pigment called rhodopsin, also known as visual purple for its reddish-purple color, that immediately bleaches when it's exposed to light—similar to what happens if you expose undeveloped photographic film to the sun. This bleaching breaks down the visual purple into new chemicals that translate light waves into nerve signals in the brain that create the images we see. Our bodies need vitamin A to recycle these chemicals back into visual purple so they can be used again. You can actually observe this recycling happening whenever you're blinded by a bright light like a camera flash: the sudden light bleaches the visual purple in your rods, and it takes several moments for your body to “unbleach” it—using vitamin A—so that you can see again. Our bodies are able to recycle most of the vitamin A, but not all of it; every new unbleaching cycle uses up a bit more. If this vitamin A isn't replaced by your diet, you won't be able to replenish your rods' visual purple. And if you can't replenish your rods' visual purple, you won't be able to see in low light. You become night blind.

There have been at least twelve confirmed deaths by water poisoning in sports events and thousands of close calls. Instead of too little to drink, they were dying from too much. They'd gulped so much fluid, they'd diluted their blood sodium concentration and caused their brains to swell. The Sports Drink Giants had been fantastically successful at tricking people into believing that, unlike every other creature on Earth, humans were too stupid to know when to drink. Cows and puppies and infants have it covered, but not you—no, you need to be told. The terrible irony was that by inventing a fake health scare, the Drink Giants had created a real one. They'd scared people into believing they were drinking too little, and fooled them into drinking too much. It was death by marketing. The “Science of Hydration” is propaganda conceived by marketers who wished to turn a collection of kitchen chemicals into a multi-billion dollar industry. To their credit, they succeeded. To their unending shame, they cost the lives of some of those they were pretending to protect.

We've been brainwashed into being repulsed by the mention of the word 'fat' but the real heart danger is sugar. It's a corrosive that damages arterial walls, creating grooves that allow plaque to adhere. Which means the only real solution for cardiovascular disease and global obesity is pure scorched earth. Ten companies produce 80 percent of processed foods in the world, and they're creating billions and billions of dollars in profits by poisoning people. If you don't take addictive foods out of the environment along with improving the societal and environmental conditions which contribute to the addictive behavior, you'll never cure the addiction. Some argue this is going too far.

Whereas in ancient agricultural societies human violence caused about 15 percent of all deaths, during the twentieth century violence caused only five percent of deaths, and in the early twenty-first century it is responsible for about one percent of global mortality. In 2012 about 56 million people died throughout the world; 620,000 of them died due to human violence (war killed 120,000 people, and crime killed another 500,000). In contrast, 800,000 committed suicide, and 1.5 million died of diabetes. Sugar is now more dangerous than gunpowder.

When we speak of sugar, we often mean a particular molecule extracted from sugar beet or sugar cane, but there are more than a hundred different kinds of sugar. If, historically, we had developed a sugar industry based on endive sugar, our sweets would not cause tooth decay. Sweetness is not in itself unhealthy, we simply eat only the most unhealthy kind of sweetness.

With Type 2 diabetes genetics plays a huge role. That risk is brought out by the interaction of diet, exercise, environment, genetic propensity—you need all of that together for the disease to occur. If the disease requires all those factors, then—maybe?—genetics wasn't playing such a “huge” role. For instance, there are two populations of Pima Indians who are virtually genetically identical. The ones in central Mexico are subsistence farmers: thin, with virtually no diabetes. The other group lives on an Arizona Indian reservation. They're obese, with a 50 percent prevalence of diabetes. Another example is the case of first-, second-, and third-generation Japanese, starting in Japan, who move to Hawaii, and then to Seattle. You see a progressive increase in the development of Type 2 diabetes the farther they get from Japan, and as more generations pass.

What's happening in Japan that's different from Seattle? There's no question that lifestyles are different. They're walking more. Their diet is clearly very different. There's no question that the Western-type diet seems to correlate with an increased risk of diabetes.

Almost 40 years ago there was a study published in the *American Journal of Clinical Nutrition*, showing that a plant-based diet slashed the insulin requirements of men with Type 2 diabetes by more than half. Some of the men had been living with diabetes for 20 years, injecting 20 or more units of insulin every day. They were not allowed to lose weight—if the numbers on the scale dropped, they had to eat more (grains, legumes, fruits, and vegetables). And not only did they dramatically reduce their insulin requirement; half of the subjects were able to get off insulin completely. Did I mention how long this took? About 16 days.

In the State Prison of Southern Michigan in the 1970s, there was—quite by accident—an experiment carried out. Because of the way the prison was built, half the prisoners' cells looked out over rolling farmland and trees,

and half looked out onto bare brick walls. An architect studied the medical records for these different groups of prisoners (who didn't differ in any other way), and found that if you were in the group who could see the natural world, you were 24 percent less likely to get physically or mentally sick.

If we had a medication for which preliminary results showed such efficacy, we would be all over researching that medication. Here is a treatment that has very few side effects, is not expensive, doesn't require a trained or licensed professional to prescribe it, and has pretty good evidence of efficacy so far. But the research is very hard to find funding for because a lot of the shape of modern biomedical research has been defined by the pharmaceutical industry, and they're not interested because it's very hard to commercialize nature contact. You can't sell it, so they don't want to know. We'll have to wait for the virtual reality "therapeutic worlds" And just think, then we could do away with prisoners' windows altogether—well the few they've got left anyway.

When a controversial fact is finally absorbed into public consciousness, a revolution happens. What was heresy becomes self-evident. The earth revolves around the sun. Global warming is driven by human activity. Smoking kills. Animal protein kills. Think of all those years in which it was considered rude if you told a guest not to smoke in your house—some of you are going to be far too young for this one. We put up with that crap for a long time before it became acceptable to say no. Nobody wants a smoker in their house, because you're breathing the toxic by-products of their bad habit. But someone else eating a burger doesn't affect you does it?

Diet is not a personal choice. I understand how people think it is, but in reality, our individual food choices affect our nation, our planet, billions of animals, and they affect us as a human species.

"I brought cattle to slaughter when I was a kid. They were scared. You hang them up by their leg and slit their throats. It takes a while to wake up to it. I don't know why it took me so long."

Transglutaminase creates strong bonds between proteins, the company says, and thus "transforms worthless cuts of meat or fish without commercial value into standardized portions with a high added value." Now we're talking a language that everyone can understand.

Speaking for enzyme companies, the European Food Information Council argues that "the concept of acceptable risk is intrinsic to the notion of pushing back the frontiers of science." Of course, the issue for most people is, 'Do I and my family really want to be part of a human experiment at the

cutting edge of enzyme technology?’ Don’t spend too long thinking about that question. You aren’t being consulted on the question, and so, your opinion doesn’t matter.

The idea that women’s choices in the kitchen needed to be “officially” approved by nutritional scientists represented an important perception shift in who could be trusted to decide what Americans should eat—and the insecurity caused by this shift left the public vulnerable to any person or product that claimed to offer answers. But such an idea also hid an even more frightening assumption: that any un-careful homemaker—that is, any woman who didn’t follow the nutritional advice of outside experts—was playing Russian roulette with her family’s health. Like any truly successful health guru knows: You can’t just be a cheerleader, you also need to be a fearmonger.

We have been groomed to see natural, unprocessed food as a seething mass of sinister bacteria that can only be rendered safe by the controlling hand of technology. Case in point, under the tabloid-style headline “Kitchen sink squalor,” NHS Choices warns us that “most people think of the toilet as the most contaminated part of the house, but in fact the kitchen sink typically contains 100,000 times more germs than a bathroom or lavatory.” Scary or what? This is typical of the tone of government food hygiene advice, wherein home cooks are portrayed as dangerously ignorant, exposing their nearest and dearest to life-threatening hazards. In government food hygiene campaigns, no mention is made of the much more extensive food poisoning risks of factory food production, or of how the modern food distribution system can facilitate the spread of a problem to thousands of homes, thousands of miles away, in a matter of hours. The effect of this slanted emphasis on domestic food poisoning risk is to undermine the confidence of home cooks in our ability to prepare safe food. It makes us crave the apparent safety of processed, manufactured food and drink. In the opinion of one Twitter correspondent:

“A factory is what we call a hygienic, efficient place to prepare food. It’s safer than a farmhouse kitchen.”

Such sentiment is widespread amongst generations that have never learned to cook and so are heavily dependent on processed food and takeaway. Bring on those protective additives please!

We buy foods that claim their added vitamins and dietary chemicals will “support a healthy metabolism,” without demanding an explanation of how that has been proved—or what it actually means. We feel reassured when a food or cosmetic has been studied in “clinical trials,” even if the label

provides no information about where or how said trials were conducted, or what they actually found. Instead, inspired by the same joint forces of hope and fear that yeast cakes, thiamin, and war evoked in our predecessors, we continue to believe that if we follow the right experts' advice, we'll be able to stave off sickness and disease; as long as advertisements employ the magic word 'science,' we are willing to accept claims that otherwise might crack under the pressure of common sense.

Enrichment: Replacing micronutrients that processing has destroyed.

Fortification: Adding micronutrients at higher amounts than were originally present or introducing micronutrients to foods that never naturally contained them.

Perhaps this about-face was a recognition of the public relations time bomb that could explode if and when the public learned the truth about vitamins' vulnerabilities during processing; perhaps it was simply an attempt to capitalize on the trendiness of the things. Regardless, one thing is clear: once food companies began to fortify and enrich products—and to recognize the enormous profits that vitamins could help them achieve—they never looked back. In retrospect, food companies' embrace of vitamins occurred at a very fortuitous moment. Like a repentant thief replacing stolen silver before anyone noticed it was gone, manufacturers could replace the vitamins that food processing had removed before most of the public knew they were missing. Rather than being perceived as correcting a flaw, fortification and enrichment could therefore be advertised in purely positive terms, the addition of something good rather than the correction of something bad.

As a result, food companies changed their tune toward vitamin measurement techniques as well. Now they were seen as tools rather than liabilities, able to confirm marketing claims of what nutrients food processing had added instead of revealing what it had destroyed. The serendipity of this timing still affects us, for a reason that is both straightforward and profound: processed-food manufacturers have never had to publicly admit the potential nutritional inferiority of their products. Instead, they were—and are—free to highlight the benefits of enrichment and fortification without acknowledging why the addition of vitamins (or minerals) was necessary to begin with—even arguing, as the president of the Grocery Manufacturers Association did in 1956, that “today's processed foods have a food value at least equal, and often superior to, raw produce.” And indeed, fortified and enriched products are still largely perceived in one of two favorable lights: they're just as good as their unprocessed, unrefined counterparts,

or they're even better. The flip side—that this fortification is necessary because refinement has made the food inferior—is rarely acknowledged or discussed.

In the past, American products, especially medicines, were adulterated so frequently that they carried the same stigma that many Chinese products do today. European countries began embargoes against American food. At one point, adulteration was such a concern that the US Navy's Bureau of Medicine and Surgery stopped buying drugs from domestic pharmaceutical companies and began making them itself.

Consider the case of Elixir Sulfanilamide. The company later claimed not to have been aware that diethylene glycol, which is related to a main ingredient in antifreeze, can cause kidney failure, convulsions, and a painful and prolonged death—even though there is evidence that Massengill had done preliminary safety testing with diethylene glycol ten months earlier and found that a solution containing three percent diethylene glycol caused kidney damage in rats. Elixir Sulfanilamide contained 72 percent. Either way, it didn't take long for the tragedies to begin. By early October, a doctor in Tulsa, Oklahoma, reported that ten of his patients had immediately died after taking the elixir. More quickly followed.

On November 1, 1937, a woman from Tulsa named Marie Nidiffer wrote a heartbreaking, handwritten letter to President Roosevelt about the night her six-year-old daughter, Joan, had died:

“The first time I ever had occasion to call in a doctor for her and she was given the Elixir of Sulfanilamide. Today our little home is bleak and full of despair. . . Even the memory of her is mixed with sorrow for we can see her little body turning to and fro and hear that little voice screaming with pain and it seems as tho it drives me insane.”

Within months of the product's launch, an estimated 107 people, mostly children, had died.

The Generally Regarded as Safe (GRAS) list includes many additives and chemicals that were in use at the time of the list's creation and were grandfathered in without any clinical trials.

“When people are facing health insurance that they can't afford, and treatments for cancer that sometimes result in side effects that are just as awful as the cancer, they're ready for a cure—they're desperate for one. They would like to believe that there is some kind of conspiracy that's keeping them from knowing the true facts that could keep them healthy. What they

didn't understand, though, was that this view was manipulated by people who stood to make a lot of money, and they did make a lot of money—billions of dollars.

Believe me, I appreciate as a physician the appeal of a simple cure. Of course, we would all rather take some miracle pill than undergo more arduous and sometimes uncertain treatments. But, unfortunately, cures don't come packaged as neatly as we hope, and patients, who would forsake therapies that offer some real benefit for the siren song of empty promises, have a lot to lose."

The supplement industry argument wasn't about safety. It wasn't about efficacy. It was about whether rule-obsessed, megalomaniacal bureaucrats should be allowed to limit Americans' right to make decisions about their own health. This argument—that access to vitamins is a matter of personal freedom—was a brilliant tactical move, and it has defined the discussion on supplement regulation ever since. The Proxmire amendment was tacked onto a health bill and passed the Senate with a vote of 81–10. Enacted on April 23, 1976—and still in effect today—the amendment made it illegal for the FDA to ever establish standards for supplements, classify them as drugs, or require that they only contain useful ingredients. It forbade the FDA from ever setting limits on the quantity or combination of vitamins, minerals, or other ingredients that a supplement could contain, unless the FDA could prove (usually after the product was on the market) that the formulation was unsafe—an extremely important shift of responsibility.

Imagine, for example, that penicillin mold—one of the world's first and most important antibiotics—had been sold as a dietary supplement and that contaminated batches had begun to kill people. If that happened today, it's possible that the resulting stigma would prevent penicillin from ever being pursued as a legitimate drug. Also, why would a drug company invest time and money into developing a drug if people could already buy its active ingredient as an over-the-counter supplement?

The industry would hone this tactic into a potent weapon. A specialist in nutrition and food safety at the Congressional Research Service in the Library of Congress, was responsible for answering the hundreds of questions from Congress members that these letters provoked, particularly in regard to the erroneous claim that the FDA wanted to regulate all dietary supplements like prescription drugs. As she recalled:

"When I pointed out to some industry lobbyists that what they were telling people to say in these letters wasn't true, they just shrugged and said, 'It works.'"

Despite the fact that, thanks to the Proxmire amendment, dietary supplements can contain nearly any combination of dietary ingredients in any dosage, today's supplement manufacturers do not have to prove that their products are safe or effective before selling them. Instead, the burden of proof is on the FDA to demonstrate that supplement products are unsafe after the products are already on the market. Thanks to DSHEA and all the consumers, industry representatives, and politicians who supported it, America's supplements have largely been made exempt from nearly a century's worth of tighter regulation for food and drugs.

Indeed, it's so difficult to do so that the FDA has banned only one dietary ingredient since the 1994 passage of DSHEA: ephedra—or, more precisely, ephedrine alkaloids—a dangerous stimulant often obtained from the plant *ma huang*. Despite overwhelming evidence of its dangers—it's thought to have contributed to the deaths of more than a hundred people—it took more than a decade of legal struggles and the highly publicized ephedra-related death of Steve Bechler, a twenty-three-year-old pitcher for the Baltimore Orioles, before the FDA succeeded. However, even today you can still find products being sold online that contain forms of ephedra. The whole experience was so difficult and so costly that, in the words of the Government Accountability Office in 2009, banning further dietary ingredients—even though there are several definitively known to be dangerous—“is not a very viable option.”

While it can be difficult to quantify the precise effects of a particular law, in the case of DSHEA, several figures stand out. The tightened regulations in the amended 1938 Food, Drug, and Cosmetic Act greatly decreased the number of medications on the market—it was largely responsible for Smith Kline's decision in the 1950s to discontinue all but 60 of its 15,000 therapeutic products. In contrast, when DSHEA was passed, America's supplement market contained about 4,000 dietary supplement products. Today, there are more than 85,000. Consider this chilling description of the state of America's drug market after the passage of the 1906 Pure Food and Drug Act:

“The law still permitted, as muckrakers vehemently pointed out, that the human population of the United States be guinea pigs for all experiments with medicinal drugs. No testing was required before the drugs were sold, and if the federal government was concerned about any drug, it had to prove in court that the drug was harmful to a substantial number of people before removing it from the market. If the danger was subtle, a cumulative effect over a long period, or if it affected, say, only

one in a thousand people, the damage would likely continue indefinitely.”

It’s now more than a hundred years later. But, thanks to DSHEA, you could be forgiven for thinking that he is describing the state of America’s supplement regulation today.

The supplement industry readily acknowledges its dependence on DSHEA. The Council for Responsible Nutrition, a major industry trade association, states in a Q&A about supplement regulation on its website:

“If dietary supplements were regulated like drugs, there would likely be no dietary supplement industry.”

They go on to claim that if supplements were regulated as drugs, “supplements would cost what drugs cost.” That is highly debatable, since few people argue that dietary supplements should be regulated as prescription drugs. It is also debatable given the massive mark-ups involved in prescription pharmaceuticals. A better comparison might be over-the-counter drugs, which include not just obvious things like Tylenol but products with drug-like attributes, such as toothpaste with fluoride, deodorants with antiperspirant, and anti-dandruff shampoo, all of which are technically considered drugs by the FDA (they all have Drug Facts panels on their boxes) but are certainly not prohibitively expensive.

Originally, the industry had wanted supplement labels to be allowed to claim the product would treat, cure, or prevent a disease. When FDA officials and lawmakers refused—that is, after all, the definition of a drug—the politicians created structure/function claims as a compromise. Structure/function claims do not have to be pre-approved; a manufacturer must simply alert the FDA to the structure/function claim within thirty days after marketing the product and have some sort of substantiation for the claim on hand that hypothetically could be used to demonstrate that it is “truthful and not misleading.” Perhaps these loose standards are part of the reason why, in a late-night concession to the FDA, the supplement industry agreed to one other requirement: when a supplement uses a structure/function claim, its label must include a statement, set off by an asterisk, that will be familiar to anyone who has bothered to read the box:

“These statements have not been evaluated by the Food and Drug Administration. This product is not intended to diagnose, treat, cure, or prevent any disease.”

The compromise enabled the bill to be released from committee and passed. But while structure/function claims will hold up in court, they’re

also, from a commonsense perspective, fundamentally absurd. Why would you take a supplement, after all, if you didn't think it could treat, cure, or prevent something? Are there really people who would buy a product that "improves regularity" without hoping it might also treat constipation? Structure/function statements—which are now nearly ubiquitous on dietary supplement labels—allow companies to make far more assertions than they're permitted to in the more strictly regulated category of food health claims, and few consumers know the difference. Nor do consumers realize the circular process some companies use to create them. As an employee in the supplement industry once explained it:

“We use focus groups to decide what to say in claims. We hear what people want, and then we put that on the label.”

Even vitamins come with caveats, though they're rarely divulged unless it's required. For example, prescription prenatal vitamins—which are standard multivitamins with some extra folic acid and iron—come with a “patient prescription information” sheet that's mandatory for all drugs. It includes a long list of possible side effects and interactions, including how the tablets could potentially reduce the absorption of other drugs like common antibiotics and thyroid medications, or mask the signs of a vitamin B12 deficiency. The sheet also lists possible side effects (diarrhea, constipation, upset stomach), tells you what to do if you have signs of a serious allergic reaction, and suggests that you tell your doctor or pharmacist about any other medications or nutritional supplements you are taking at the same time in case there might be additional interactions. The same formulation as an over-the-counter supplement would not require this information or warning.

A 2007 paper published in the *Archives of Internal Medicine* suggested that many doctors might not recognize the need to put supplements under special scrutiny, since they are just as clueless about supplement regulation as their patients. Of 335 residents and attending physicians at fifteen different internal medicine residency programs, the study found that “one third of physicians were unaware that dietary supplements did not require FDA approval or submission of safety and efficacy data before being marketed,” a similar percentage believed there were regulations to ensure supplement quality (at the time there were not), and “most physicians” were unaware that serious adverse events due to the use of supplements should be reported to the FDA.

Many of our most common assumptions about food and health come from data sets whose foundations, if we dig into the details, look more like sand than cement.

But solving the mysteries of human nutrition is a bit like peeling an onion: the more layers you pull back, the more layers you find underneath. As the limitations of MREs and the continued uncertainties over the RDAs themselves demonstrate, even a hundred years after the failure of purified diets and the discovery of vitamins, we still don't know how to reverse engineer perfect food. Nature is simply too complex. Indeed, it might well be an impossible goal—for how could we ever be confident that we weren't missing something? This question applies not just to MREs but to infant formula, fortified breakfast cereals, meal replacement shakes, multivitamins, and every other human-designed food we come into contact with each day. Indeed, the very idea that we might know precisely which chemicals each of our bodies needs (and in which quantities and combinations) brings to mind the innocence—and arrogance—of chemists at the turn of the twentieth century whose artificial foods failed because they didn't know about vitamins. Like our predecessors, we, too, are likely leaving out compounds whose importance we don't yet recognize or understand. The story of vitamins is definitely one of scientific triumph, but it's also a cautionary tale, a reminder that the most important issue in nutrition isn't just what we know; it's what we don't.

For-Profit Shitheads

Some might argue that most doctors contribute very little to human health or happiness but are mainly just dispensers of placebos. This may or may not be the case; frankly, I don't have the competence to say; but if nothing else, the oft-cited fact that the overwhelming majority of improvement in longevity since 1900 is really due to hygiene, nutrition, and other public health improvements and not to improvements in medical treatment, suggests a case could be made that the very poorly paid nurses and cleaners employed in a hospital are actually more responsible for positive health outcomes than the hospital's very highly paid physicians.

“And then also the little-mentioned advantage to being destitute and in possession of a Health Card that's expired and not even in your name: hospitals show you a kind of inverted respect; the place bows to your will not to stay; they all of a sudden defer to your subjective diagnostic knowledge of your own condition, which post-seizure condition you feel has turned the corner toward improvement: they bow to your quixotic will: it's unfortunately not a free hospital but it is a free country: they honor your wishes and compliment your mambo and say Go with God. It's a good thing you can't see what you look like, though.”

The United States has 2.6 physicians per 1,000 people, compared with 2.8 in the United Kingdom, 3.3 in France, and 4.0 in Germany. But the relatively low density in the United States is a matter of deliberate policy. In 1997, the Accreditation Council on Graduate Medical Education decided to limit medical school enrollments in the United States, which had previously been growing more or less in step with population growth. More importantly, the federal government caps the number of residency slots that Medicare supports, which is an effective limit on the number of residents in the United States. Since a US residency is a requirement for practicing medicine in the United States, the cap on Medicare-supported residency positions effectively limited the number of practicing physicians in the country.

US limits for residents stands at eighty hours per week, including twenty-four-hour shifts. By comparison, Europe limits weekly hours to forty-eight,

On her first day as an intern, a three-year-old died after an accident. When she cried as the parents were informed of the death, she was scolded by the chief resident as unprofessional. She learned the lesson so well that years later, she delivered the news of an infant's death to grieving parents

with perfect composure and stoic distance. The father felt compelled to apologize for falling apart, and for the first time, she saw the consequence of that distance: she wasn't a comforter, but a strangely chastising burden to the grief-stricken.

“The America I know and love is not one in which my parents or my baby with Down Syndrome will have to stand in front of Obama’s ‘death panel’ so his bureaucrats can decide, based on a subjective judgment of their ‘level of productivity in society,’ whether they are worthy of health care. Such a system is downright evil.”

—Sarah Palin, August 2009

The ironic thing about Palin’s message was that so-called death panels are actually a very real thing in America. Every single day, death panels at for-profit health insurance corporations determine whether or not it’s worth paying out a certain claim or signing on to a certain lifesaving medical procedure. In those cases, a “subjective judgment” is made on how a cancer patient’s chemotherapy will affect the corporation’s bottom line.

I wish I could read this stuff without becoming almost paralyzed with rage. We the people need single payer. It is the only thing that will work. We need it now. The politicians do not offer single payer as an option because it is the one thing we know we want. They are protecting both the insurance and pharmaceutical companies. It is a disgrace. Insurance and pharma must serve us. We have no goddam obligation to serve them. They do not know how to function rationally. Balance billing? Great business skillz.

While stock repurchasing is also common in other industries to achieve corporate goals, the health insurance industry has been especially rife with share buybacks. Among the top 50 share repurchasers for 2000 to 2008 were the two largest corporate health insurers: UnitedHealth Group at number 23 with \$23.7 billion in buybacks, and WellPoint at number 39, with \$14.9 billion. For each of these companies, repurchases represented 104 percent of net income for 2000–2008. Over this period, repurchases by the third largest insurer, Aetna, were \$9.7 billion, or 137 percent of net income, and the fifth largest, CIGNA, \$9.8 billion, or 125 percent of net income. Meanwhile, the top executives of these companies typically reaped millions of dollars, and in many years tens of millions of dollars, in gains from exercising stock options. A serious attempt at health care reform would seek to eliminate the profits of these health insurers, given that these profits are used solely to manipulate stock prices and enrich a small number of people at the top.

From 2000 to 2008, the ten largest for-profit health insurers paid their CEOs a total of \$690.7 million, according to corporate filings with the Securities and Exchange Commission. As outsized as the CEO pay is, it doesn't capture the full extent of the health insurance industry's wasteful overhead. In 2009, WellPoint employed thirty-nine executives who each collected total compensation exceeding \$1 million, according to company documents gathered by the House Energy and Commerce Committee. And WellPoint spent more than \$27 million on retreats for its staff at resorts in such destinations as Hawaii and Arizona in 2007 and 2008, the documents showed. Compare this lavish executive compensation to that of the administrator of the Center for Medicare and Medicaid Services, who manages the health care of forty-four-million elderly and disabled Americans on Medicare and about fifty-nine-million low-income and disabled recipients on Medicaid. This administrator's pay tops out at \$176,000 a year.

It's not that we can't have a good, workable, affordable system—millions of people in other countries have it, so we know it can be done—it's just that we're the exceptional country that places money and profit as a higher priority than the health of our people.

It's profit-taking from the sick and poor—the most evil behavior imaginable—and the imposition of fierce burdens on those at death's door, simply fighting to survive. Our health care system is inhumane, unethical, and serves only to line the pockets of the rich.

We can't all immigrate to Ecuador for health care. We have to build the nation we need where we are. In ancient Rome the Christian faith began to spread through the empire partly because of the charitable works of the Christians. They believed in and practiced radical poverty, charity to the poor, care of the sick. At church service they distributed food. As capitalism inflicts repeated wounds on the public body maybe we should look back to those practices for inspiration, perhaps not for religious reasons but in service of radical morality.

In the past, the benefits of modern medical science have not been enjoyed by our citizens with any degree of equality. Nor are they today. Nor will they be in the future—unless government is bold enough to do something about it. We should resolve now that the health of this nation is a national concern; that financial barriers in the way of attaining health shall be removed; that the health of all its citizens deserves the help of all the nation.

If we want genuinely good societies, which produce genuinely healthy people, both physically and psychologically, we need to figure out a way to run our society which involves much less coercion and precarity. The whip of hunger; the fear of losing one's job and with it any life worth having, are the ruling fears of our age, and they produce real and genuine ills.

One of the duties of the state is that of caring for those of its citizens who find themselves the victims of such adverse circumstances as makes them unable to obtain even the necessities for mere existence without the aid of others. That responsibility is recognized by every civilized nation. To these unfortunate citizens aid must be extended by government—not as a matter of charity but as a matter of social duty.

The irony today of detractors calling national health care “socialist” must certainly have Bismarck spinning in his grave. It is no paradox that he and those who followed in his footsteps established European health systems as extremely conservative anti-socialists—they were catering to the working classes as leverage against their joining true socialist and labor movements of the day. Strong conservative governments in Europe called this “turning benevolence into power”—a strategy generally credited with creating the social welfare measures that actually kept Communism from becoming a dominant force.

For the second time in the life of many Americans, military action in Europe put an end to any real talk about national health insurance—except for tax exemptions allowed for health benefits so that companies could attract and maintain private-sector workers during the war years. Many employers took advantage of the exemptions, bolstering the nonprofit Blue Cross-type coverages already in the market and leading to the uniquely American employer-based health insurance system.

In 1943, at the height of World War II, when the American armies and industries needed every troop or worker they could find, the Internal Revenue Service tweaked the tax code, granting tax-free status to employer-based health insurance. This didn’t seem to be a big deal, certainly nothing to rival the headlines about the German surrender in Stalingrad or Allied landings on Sicily. At the time, only about nine percent of American workers received private health coverage as a job benefit. But with the new tax-free status, businesses set about attracting scarce workers by offering health insurance. Within ten years, 65 percent of Americans would come under their employers’ systems. Companies already exerted great control over our finances. But in that one decade, they gained a measure of control—whether they wanted it or not—over our bodies. Seventy-five years later, health care costs have metastasized and now consume \$3 trillion per year. Nearly one dollar of every five we earn feeds the vast health care industry.

“No longer will older Americans be denied the healing miracle of modern medicine. No longer will illness crush and destroy the savings that they have so carefully put away over a lifetime so that they might enjoy dignity in their later years. No longer

will young families see their own incomes, and their own hopes, eaten away simply because they are carrying out their deep moral obligations to their parents, and to their uncles, and their aunts.”

—Lyndon Johnson

Attitudes toward HMOs began to change for the worse when the big for-profit insurers began to take over. These insurers knew that the more HMO members they had in a given market, the more leverage they would have over local doctors and hospitals. Not only could the insurers demand deep discounts from doctors once they acquired significant market share, but they could also influence—through their reimbursement policies and coverage guidelines—how the doctors practiced medicine.

It was at that moment that I realized how much was at stake with the industry’s transition from managed care to consumerism. The business model based on managed care had failed, and the only way the insurers could continue to meet shareholders’ expectations was to find a new way to avoid paying for health care. The means now available to them was to shift costs to policyholders.

Although Wall Street constantly pressures companies to reduce their MLRs, this imperative for the first time would collide with national standards, as established by the Obama’s health care reform law. Insurers are mandated now to spend at least 80 percent of premiums on medical care for the individual and small-group market (one-hundred enrollees or fewer) and at least 85 percent for the large-group market. One might think that these new requirements will benefit health care providers and patients, but you can count on insurers to game the system.

They’ve already tried. Within days of Obama’s signing the law, WellPoint told Wall Street analysts that it had decided to “reclassify” certain categories of costs that it had previously counted as administrative expenses and move them to the medical-spending side of the equation, effectively raising its ratios without making any actual changes in behavior. When low MLRs were needed to impress Wall Street investors, insurance companies excluded the cost of nurse hotlines, medical reviews, and disease-management programs from medical costs. Now that the government is demanding minimum MLRs, the insurers want regulators to consider those expenses as medical costs, a clear-cut signal to investors that they will resist efforts to get them to trim profit margins.

From 2007 to mid-2009, insurance and HMO political contributions and lobbying expenses totaled a jaw-dropping \$586 million, according to Public

Campaign. At the height of the battle, the industries were spending nearly \$700,000 a day to influence the political process.

“I started questioning whether for-profit insurers really did play a constructive role in our health care system, as I insisted publicly. But it was all self-talk. I never told anyone I was having doubts. I found that alcohol helped to keep those thoughts at bay, so I drank more than I ever had—although never at work—to keep from dealing with recurring thoughts that I had sold out. As part of my rationalization, I told myself that at least I was occasionally able to make a positive difference in a few people’s lives.

One of my responsibilities, when a health-plan member complained to the media about a treatment or procedure that CIGNA had refused to cover, was to make sure the company’s executives understood what the PR consequences could be if the company didn’t pay. While medical directors always said they would never change a coverage decision based on what the media might or might not do, denials that attracted media attention were often reversed. Whenever that happened, I took some satisfaction in thinking that I might have helped save someone’s life.

I came to realize that many of my fellow employees engaged in the same kind of self-talk to get through the day. They were good people who had families and needed to keep their jobs just as much as I needed to keep mine. We told ourselves that for every horror story we heard, there were many more success stories, many more cases in which CIGNA paid hundreds of thousands of dollars for urgently needed care. And, we reminded ourselves, the media cover the few big wrecks on the freeway, not the thousands of people who make it home safely every day.”

The bad news is that companies are obligated to provide the cost of the benefit only when the patient survives long enough to receive it. If the patient dies before receiving the treatment, the insurer or HMO pays nothing. Because there is no meaningful penalty for denying medically necessary treatment, there is no incentive to approve costly care. Imagine that the penalty for bank robbery was limited to giving back the stolen money. No jail time, no fines, just pay the money back—and only if you are caught. To top it off, the repaid money would be interest free. Would bank robbery increase under such circumstances? That’s the situation HMOs and insurers enjoy under ERISA.

It's clear that voters were frightened away by the specter—conjured up by the insurance industry and its business and political allies—of government bureaucrats coming between them and their doctors. What Americans got instead was private insurance companies doing exactly the same thing.

Hearing Voices

In the 50s researchers found a patient at Bellevue who'd been committed for the first time to the psychiatric ward for hearing voices. The patient was a machinist whose psychiatric medical profile was completely normal other than a sudden audio aberration. Before the voices appeared, the machinist had displayed no symptoms of insanity. Whereas many a 1950s doctor would have written the man off as crazy, the researchers had another theory to pursue. They believed the man might be hearing voices that were traveling on a radio wave, that the machinist was somehow "tuned in" to a specific radio frequency that other individuals could not hear.

"We found out that his job was the key to the diagnosis."

In the machine shop where the man worked, the machinist's daily routine was grinding metal casings against carborundum wheels for hours at a time. When the research team gave the man a dental examination, it showed that his metal fillings were coated with carborundum dust, or silicon carbide, a semiconductor. The carborundum behaved like the crystal rectifier in the old crystal radio sets of the 1920s. When the subject was placed inside the Faraday Cage, all electrical and radio signals were eliminated. The voices ceased. His teeth were cleaned and he was cured of the 'psychiatric' problem. The man was never crazy to begin with.

"Rather, we found that he was precisely tuned to radio station WOR in New York City."

What is that voice in your head? The one you hear when you're slicing carrots in the kitchen, waiting for a bus, clicking through your emails, or grappling with a dilemma. Is it you speaking to you, or are you the thing that is endlessly spun by that conversation? In which case, where do you go when the voice stops? Does it ever stop? Who is the 'me' or 'you' to whom a young child speaks aloud, and who is the speaker—especially in the stage when that fragile self is still in the process of being formed? Who speaks to the novelist in her study, or to the psychiatric patient in his hospital room? To the church-goer, praying silently in her pew, or to the ordinary voice-hearer, listening in to the transmissions of a fractured self? What are the tattered, dissociated fragments that auditory verbal hallucinations bring into being, protect against and help us to understand?

I sit in my study, typing these words. I hear the next sentence resonating in my head, and a voice repeats it back at me as I watch it taking shape on the screen. I stop, listening to the winter wind howling outside. I look out

of the window at the bright February afternoon. The voice is quiet now, a shadow of the urgent chatter of a moment ago, but it is still there. I mutter aloud to myself, sounding out the sentences I am grappling with. Am I in my head, a product of my restless brain, or am I the echoes of what I hear coming back at me, part of the process by which all of this—my self, these words, this reality—is constructed? There's a brief silence; I've been working hard and I am very tired. But I know that it will start up again before too long: softly, inconspicuously, intimately familiar. The voice in my head will not frighten or demean me, although it will occasionally chastise me and urge me to do better. It will tell me things I didn't know. It will surprise me and make me laugh, and above all it will remind me of who I am. I have heard it before.

Novelists use two main methods for depicting what characters say in their stories. They can present exactly what the character said, usually marking it with speech marks—what is known as direct speech. Or they can report the utterance at second hand, in so-called reported (or indirect) speech. It's the difference between writing:

1. Mary said, "The game was interesting"
2. Mary said that the game was interesting.

Psychologists have shown that direct speech is generally perceived as more vivid than reported speech. One study asked participants to report a conversation that some other people had had, and were instructed either to make the account entertaining or simply to make it informative. When participants were trying to entertain rather than simply convey information, they were more likely to choose direct speech as their medium.

Other researchers have asked what goes on in the brain when people read the two kinds of speech. They began with the hypothesis that, when we read reported speech, we only process the meaning; when we read direct speech we go so far as to sound the speaker's words out in our heads. In line with their predictions, they found differences in brain activation in participants listening to direct versus reported speech. Specifically, listening to direct speech led to greater activation in areas of the right auditory cortex (housed in the temporal lobe), which is known to be particularly important for processing voices. This wouldn't be expected if both kinds of speech led to processing the depicted speech at the same level. The findings provide a neural basis for the observation that direct speech is experienced more vividly than reported speech, because it activates areas of the brain that represent the qualities of voices.

To date, there have been no experimental investigations of whether readers' processing of this kind of depiction of inner speech leads to the voice taking on life in the mind in the way that direct speech does. But there's no doubt that mixing characters' inner speech with a regular authorial voice is one of the ways in which novelists make their prose come alive. Writers can also have a lot of fun with the fact that people often say things that are the opposite of what they're thinking. Fictional characters can go about their internal lives safe in the knowledge that their thoughts will not be overheard by the characters they are conversing with. Eavesdropping on those contradictory messages is one of the pleasures of reading fiction.

But voices can get out of hand. For some individuals, fictional voices can make audible what we would rather remained silent. Voices on the page transport the self beyond its safely policed boundaries, showing us the precarious harmony that is the polyphony of consciousness. They remind us that we are not one, but many.

You sit alone, with no capacity for movement, in a dimly lit place whose dimensions you cannot verify. You know that your eyes are open because of the tears that stream from them endlessly. You are seated with your hands on your knees and no support for your spine, and you are speaking. Without ceasing. It's pretty much all you can do. The voice that you hear sounds alien, and yet it can only be you who is producing it. Sometimes there is more than one voice. Singular or plural, it seems to be able to impose its will on you, giving you no choice but to listen. And yet it is your mouth that is uttering it. You are listening to yourself, but what you are listening to is not 'you.'

A solitary mind is actually a chorus. We can go so far as to say that minds are riddled with different voices because they are never really solitary. They emerge in the context of social relationships, and they are shaped by the dynamics of those relationships. Other people's words get into our heads. This is more than the currently fashionable formulation that we have "social brains," wired up to engage with others from the first days of life (although that is also true). It's saying that our thinking is social. Our minds contain multitudes just as a work of fiction contains the voices of different characters with distinct perspectives. Thinking is a dialogue, and human cognition retains many of the powers of a conversation between different points of view.

Consider creative partnerships such as the one between John Lennon and Paul McCartney. Some kind of internalized creative dialogue must surely be a major part of any such partnership—how otherwise would anything get done? Lennon was not limited to being a musical genius only when McCartney was in the room, and vice versa. Creative partnerships—of which

the history of various art forms is littered with examples—may come to have their power at least in part because the artist recreates an internalized version of the actual dialogue that would have taken place over cups of tea and cigarette breaks. I would go further and say that, once established, the inner dialogue develops to a point where it no longer needs the other contributor.

In whichever form we do it, there are good psychological reasons why conducting dialogues on the page might benefit the creative process. If I'm doing my thinking in writing, as opposed to silently in my head, it will have the benefit of reducing my processing costs, particularly the demand on working memory. For one thing, if I've written my question down, I don't have to divert mental resources towards holding it in memory while I think of how to answer it. The notebook page becomes an external version of the 'open slot' in which we park a perspective while generating a response to it. Giving our thoughts a material, external form helps to cut down the amount of work we need to do to process them.

Something similar happens when we think out loud in private speech. Rather than having to hold a perspective silently in my head, I can voice it out loud and know that it will resonate for a while in my auditory memory. Speaking our thoughts aloud, like writing them down, appears to be a handy way of cutting down the resource costs of doing it all in inner speech. That issue of processing cost may be the secret to understanding the power of dialogic thinking. Creativity involves bringing bits of information to bear on a problem that may not be obviously relevant (thinking about a tack box as a candle-holder, for example). As soon as you express one perspective in words, you drastically constrain the range of possible dialogic responses to it. Conversations have to be about the same thing, or they are not really conversations. To illustrate this, answer this simple question: Have you ever danced with a movie star? To answer this question, you don't have to run through a list of every single person you have ever danced with, and check to see whether any of them are Hollywood A-listers. You simply have to put the idea out there, in a question aimed at yourself, and then answer it, through relatively effortless and automatic reasoning processes.

In sixteenth-century Spain, St. John of the Cross presented an explanation for how divine voices could arise as a result of misattributed inner speech. Building on his predecessor St. Thomas Aquinas's view of thinking as "the interior word," St. John noted how novices at meditation could have the experience of a divine voice when in fact "it is for the most part they who are saying these things to themselves." From its origins in European theology, this view later became established in the medical literature. In his 1886 book *Natural Causes and Supernatural Seemings*, the British psychiatrist Henry

Maudsley wrote of “a vividly conceived idea which is so intense. . . that it is projected outwards into what seems an actual perception. . . in the case of hearing, an idea so intense as to become a voice.”

A century later, in the late 1970s, Irwin Feinberg proposed that auditory verbal hallucinations might arise as a result of a disorder to the brain systems that usually monitor which actions are self-produced. Like all good ideas, Feinberg’s notion is at its heart a simple one. An individual generates an utterance in inner speech—the kind of ordinary internal conversation we’re all familiar with—but for some reason fails to recognize it as their own work. There are words in the head, but they don’t feel like the words of the self. The individual experiences them as an utterance from without: a heard voice.

There are dangers, though, in trying to work with historical accounts of private, subjective experiences like voice-hearing. Mass literacy is an invention of the modern world, and many of the people whose experiences we might be most interested in would have been unable to read or write. Their testimonies are therefore usually filtered through the belief system and sensibility of someone who could do those things: usually a holy man, like a monk or a priest. These accounts were often highly distorted and fictionalized. We are naturally also limited to artifacts that have survived and can now be interpreted, which, as we go further and further back in time, represent a dwindling number.

Language processing in deaf people seems to be based in very similar regions to those activated in hearing individuals, and covert signing in the deaf seems to recruit a classic “inner speech” network. This suggests that our brains code information about communication in a way that is not specific to any particular sensory channel. That would explain why deaf people who report hearing voices often report a mix of experiences, and it also fits with observations that voices in hearing people are often accompanied by experiences in other senses.

Some have argued that felt presence should be properly understood as a delusion, because it seems not to involve any sensory perception, phantom or genuine. But a more useful way of thinking about it is as a hallucination of a social agent with communicative intentions. When you sense the presence of your baby in your bed, or feel that your deceased partner is in the room with you, you are effectively hallucinating a person: not their voice or their face, but their entire being. The reason might be that there is, or was, a real person there whose presence you have been tracking, just as a shopkeeper might track the movements of a suspicious-looking customer, or a parent might track the whereabouts of her inquisitive toddler. Research in developmental psychology has shown that the ability to keep track of

social agents develops very early in babyhood, or may even be innate. In the case of bereavement, a person whose presence you have been monitoring for a long time, perhaps for decades, is suddenly not there any more. But your brain keeps on expecting their presence and filling in the gap that they have left. It's no wonder that hearing voices is so common in people who have recently lost a loved one.

“I often hear voices. I realize that drops me in the crazy category but I don't much care. If you believe, as I do, that the mind wants to heal itself, and that the psyche seeks coherence not disintegration, then it isn't hard to conclude that the mind will manifest whatever is necessary to work on the job.”

Dissociation refers to the phenomenon whereby thoughts, feelings, and experiences are not integrated into consciousness in the usual way. The connection with hearing voices comes through the finding that people who live through horrific events often describe themselves dissociating during the trauma. Splitting itself into separate parts is one of the most powerful of the mind's defense mechanisms. It is as though there is some drastic attempt by the psyche to remove itself from the horror that is unfolding: drastic because it effectively involves the psyche cleaving itself into pieces.

Dissociation makes sense as a natural reaction to horrific events:

“Some of the most dramatic memories of dissociation I have are acute ones, during actual trauma exposure—the sense of seeing myself on the floor, as if I was just floating above the horror happening below, completely separate from it. It's like your mind knows that the time has come when it's better to lose touch with what's happening to your body and simply breaks free: mental flight.”

Voices may not be memories in the literal sense, but we can learn much about methods for dealing with them by looking at how people learn to live with memories of horrible events. Therapy for traumatic memories, such as those that characterize post-traumatic stress disorder, involves encouraging the sufferer not so much to try to forget the event as to remember it more accurately. That means fitting it into a network of memories in such a way that it can become less intrusive, distorted, and autonomous.

Rumination refers to an obsessive dwelling on the reasons for distress or unhappiness, and it has been associated with several psychiatric symptoms including hallucinations. There have been almost no attempts to investigate whether rumination is a specifically verbal phenomenon, although it seems

likely that it will be in many cases. The auditory modality might be a particularly suitable channel for dwelling on miserable things. You can have a self-sustaining dialogue with an auditory representation, for one thing—particularly one that takes the form of a characterful, agentic ‘other’—in a way that would be difficult with a visual image. Verbal rumination might therefore be the dismal counterpart to creative, open-ended inner dialogue. Perhaps this is even a way of understanding the perspective that voices are a safety mechanism. If negative emotions are channeled into the auditory modality, it might make them slightly easier to deal with. Voices and negative ruminations might be unpleasant, but at least they can be engaged with. In which case, the dominance of inner speech might ultimately reflect its evolved role in making the organism resilient to distress. In a similar way to avatar therapy, giving the troublesome thought a material, external form may make it easier for the sufferer to engage with it, thus reducing the unhappiness it can cause.

Another way of attaining that distance is to understand the voice as coming from a non-physical entity. More people make sense of their voice-hearing experiences within a spiritual framework than they do within any other, whether neuroscientific, trauma-related, or anything else. Given how the feeling of a communicating agency seems so central to voice-hearing, a spiritual interpretation would seem to flow naturally. I am not a religious person, but it seems plausible to me that many believers would see some of their ordinary thoughts as having a supernatural origin, without necessarily describing them in terms of voice-hearing.

Ultimately a heard voice is something that communicates, and an entity that communicates can be represented separately from its actual utterances. If I’m on the phone to someone and there’s a pause in the conversation, I can still represent my interlocutor mentally even though I’m not hearing her voice. Voices are more than fragments of sensory perception or intrusions from memory—they’re kind of like people, really. And the communicative agents that are experienced or hallucinated have intentions—they want things which don’t necessarily map on to what the voice-hearer wants. Something similar can happen with imaginary companions, and with the fictional creations that a novelist comes up with.

When we talk to and listen to ourselves in our own ordinary voices, do we sense the presence of a social agent? Could our multi-voiced inner speech even be one of the ways in which we represent such agents for ourselves, as we fill our minds with the voices of the people we carry with us? Is that ‘you’ in your head really like a person who is communicating with you? If so, what does that mean for what you know of yourself, and for the challenge of keeping track of who you are? One way into this question is to ask whether

our inner speech has a tone of voice, or any of the other qualities that make a voice into something like an agent, capable of expressing emotions and intentions. Try, for example, asking whether your inner speech can ever be sarcastic or insincere. I for one am fairly sure I've said to myself things like 'Today is going really well' when I actually meant the exact opposite. Can you lie to yourself in inner speech, or say to yourself something that you don't really mean? The evidence on the dialogicality of ordinary inner speech certainly suggests that our speaking selves have that multiplicity. And yet these selves don't feel alien; we don't feel that we have been colonized, inhabited, or taken over, as many voice-hearers do. What makes our speaking selves seem like 'us' in the typical case? Whatever it is, its disturbance makes for a thoroughly disorienting experience.

Under the right kinds of stresses and expectations, people can quite readily perceive communicative intentions in signals such as mobile phone ringtones or pager beeps. One recent study showed that it is not uncommon for nursing mothers to hear voices and other sounds in the noise of their breast pumps, such as a repeated, alarming utterance like 'Snap my arm.'

Hallucinations are shaped by the intellectual, emotional, and imaginative powers of the individual, and by the beliefs and style of the culture in which he is embedded. Cultural beliefs will exert top-down effects on hallucinatory experiences in varied ways. An individual's cultural (including religious) background will affect what counts as reality, shape how a hallucination is experienced, and influence the meaning that is attributed to it. For example, a study showed that voice-hearing patients in Ghana and India were more likely than a Californian comparison group to identify their voices as people they knew and to engage them in conversation—a finding that is difficult to reconcile with the view that hallucinations can be entirely explained in terms of biological mechanisms. We need to learn much more about how particular languages confer specific properties on inner speech, and how they might even open up patterns of thought that would not be possible in other languages.

What can we conclude, then, about the importance of these conversations in our heads? We can fairly easily reject the idea that you need language in order to be intelligent. There is an agonizingly complicated philosophical literature on whether thinking depends on language, and my own view should now be plain. For a start, we can't have that conversation unless we are willing to be much clearer on what we mean by thinking. For many of the activities we call thinking, the use of self-directed language is a massive boost, but it is by no means essential. Inner speech is the way in which humans happen to do much of it, but it is by no means the only way. We also need to be clear on what we mean by language.

Some argue words function as psychological tools, capable of enhancing the range of things that can be done with one's mental capacities. But that role can be fulfilled by any sufficiently sophisticated system of signs, and is certainly not restricted to the verbal or auditory. Deafness affects language use in many ways, but there is no reason why deaf people could not do their internal communication in sign language. Many deaf people are in fact bilingual, and bilingualism in all its forms raises profound questions about our inner conversations. In a group, a trick is to ask if anyone speaks two languages. Then ask: 'So what language do you think in?' People always respond to this inquiry in delightful and varied ways, but for me the interesting thing is that the question makes sense. If thinking was not verbal, people would presumably respond to that question with a look of bafflement.

Examples of thinking in the absence of any language are a bit more complicated. In cases of aphasia, people typically lose their language functions (through brain damage or disease) after they have learned to speak—and thus presumably after they have had a chance to learn to talk to themselves. Studying cognitive functions in aphasia is thus not a critical test of the model, because the structures necessary for dialogic thinking will have developed during the period in which language was intact. Developmental disorders such as autism are different again. We don't know much about inner speech in autism, partly because the disorder is defined in terms of problems with language and communication, meaning that getting autistic people to describe their inner experience is going to be difficult. The little evidence that we have suggests that people with autism do use inner speech, but that it appears not to have the dialogic, self-communicative qualities that it has in neurotypicals. That might be a function of how the disorder limits autistic children's opportunities for social interaction as they are growing up. If you are not participating in social dialogues, you cannot really internalize them.

One view is that inner speech has a role in pulling together the plentiful different things that the brain does. A brain that has evolved to fulfill many varied functions will require some way of integrating these different information-processing systems. According to some scholars, language became involved in human cognition (ultimately, in the form of mental voices) because it was able to bind together the outputs of separate, autonomous brain systems. To switch the metaphor, think of inner speech as the thread of a necklace. Different experiences flow through our consciousness: visual images, sounds, music, feelings. But it is inner speech that strings them all together, allowing distinct neural systems to talk to each other by virtue of the way that the internal language network plugs flexibly and selectively

into other systems.

If inner speech has this kind of usefulness, then it is bound to be a boon. If it can actually have a survival function—as suggested by the voice-hearing experiences of those in extreme situations—then there is even more reason for thinking that it will stick around in the face of natural selection. Many voice-hearers can link their experiences to specific episodes of trauma.

“My voices saved my life. I could have just said, ‘It’s not worth living, my dad tried to kill me, nobody cares, better to die.’ And, you know, I could have committed suicide. What my voices did was protect me. I couldn’t look at the truth directly at the time, so voices helped me not to do that.”

Voices have a dual role, as tormentors and protectors. The experience is both an attack on personal identity and an attempt to keep it intact. If we insist on telling people that their voices are neural junk, then a profound part of the experience, and a possible route to relief from its distress, are lost. Our inner voices can help to keep us safe. Doing that internal speaking silently will also have clear evolutionary benefits. Talking to ourselves won’t be much good if it betrays our position to a predator, enemy, or prey. The pressures to keep a lid on our inner conversation might be social as well as evolutionary. One reason why private speech goes underground in middle childhood is probably that talking to yourself out loud is rarely sanctioned in Western schools. There is a growing recognition, though, that audible self-talk remains valuable well into adulthood, which is certainly a change from the way grown-up private speech was perceived in the past.

I suspect that inner speech will turn out to have a substantial role in memory. Verbal rehearsal of material is an important part of the human working memory system (think of that shopping list you recite to yourself as you walk around the supermarket). On a much longer timescale, talking to ourselves might be a big part of how we keep a grip on the past. Children’s development of autobiographical memory is known to be influenced by the kinds of conversation that parents have with them about past events. If children are exposed to talk in which adults elaborate on details, such as the emotions and feelings of the protagonists in the events, they go on to produce richer autobiographical narratives of their own. A study using the Tower of London task found that children who produced more self-regulatory private speech also produced more sophisticated autobiographical narratives. There is also evidence that the memories of adults are mediated by inner speech. Bilingual people find it easier to recall events if they are asked about them in the language they spoke at the time of the event, as compared with

a language they might have learned more recently. This fits with the idea that we code memories verbally, so that they are sensitive to the kind of language with which they are probed.

Such a prominent role for internal language would arguably give it a role in how we become aware of our own selves. Our inner speech is at least faithful to us. It is reassuringly or irritatingly there on tap. It offers us the unfailing if ambiguous company of a guest who does not plan to leave. People who talk to themselves more frequently also score more highly on measures of self-awareness and self-evaluation. Supporting the idea that the narratives we spin about ourselves have a role in anchoring those selves, the study of aphasia has shown that the condition can be accompanied by a diminution of the sense of who one is. An individual, for example, who temporarily lost her ability to speak following a stroke, wrote of “the dramatic silence that had taken residency inside my head,” which accompanied the dwindling of her sense of individuality and ability to retrieve autobiographical memories. When we lose the ability to talk to ourselves, we might also lose something of the sense of who we are.

Human Shoes

Suicide is painless
It brings on many changes

Through early morning fog I see
Visions of the things to be
The pains that are withheld for me
I realize and I can see...

That suicide is painless
It brings on many changes

And I can take or leave it if I please
I try to find a way to make
All our little joys relate
Without that ever-present hate
But now I know that it's too late, and...

That suicide is painless
It brings on many changes

The game of life is hard to play
I'm gonna lose it anyway
The losing card I'll someday lay
So this is all I have to say:

That suicide is painless
It brings on many changes

The only way to win is cheat
And lay it down before I'm beat
And to another give my seat
For that's the only painless feat

That suicide is painless
It brings on many changes

The sword of time will pierce our skins
It doesn't hurt when it begins
But as it works its way on in
The pain grows stronger
Watch it grin, but...

That suicide is painless
It brings on many changes

A brave man once requested me
To answer questions that are key
Is it to be or not to be
And I replied “oh why ask me?”

That suicide is painless
It brings on many changes

Cause suicide is painless
It brings on many changes
And I can take or leave it if I please.
And you can do the same thing if you please.

Why do so many people who experience violence in childhood feel the same way? Why does it lead many of them to self-destructive behavior, like obesity, or hardcore addiction, or suicide? I have spent a lot of time thinking about this. When you're a child, you have very little power to change your environment. You can't move away, or force somebody to stop hurting you. So you have two choices. You can admit to yourself that you are powerless—that at any moment, you could be badly hurt, and there's simply nothing you can do about it. Or you can tell yourself it's your fault. If you do that, you actually gain some power—at least in your own mind. If it's your fault, then there's something you can do that might make it different. You aren't a pinball being smacked around a pinball machine. You're the person controlling the machine. You have your hands on the dangerous levers. In this way, just like obesity protected those women from the men they feared would rape them, blaming yourself for your childhood traumas protects you from seeing how vulnerable you were and are. You can become the powerful one. If it's your fault, it's under your control. But that comes at a cost. If you were responsible for being hurt, then at some level, you have to think you deserved it. A person who thinks they deserved to be injured as a child isn't going to think they deserve much as an adult, either. This is no way to live. But it's a misfiring of the thing that made it possible for you to survive at an earlier point in your life.

Many undesirable outcomes in life arrive incrementally.

“My life can be summed up as dull, miserable, demeaning, undignified, and intolerable. It is a misery created by the accumulation of lots of things which are minor in themselves but,

taken together, ruin what's left of my life. Things like constant dribbling; having to be hoisted everywhere; loss of independence, particularly toileting and washing, in fact all bodily functions (by far the hardest thing to get used to); having to forgo favourite foods having to wait until 10:30 to go to the toilet. In extreme circumstances I have gone in the chair, and have sat there until the carers arrived at the normal time.”

Over one-million people every year take their own lives, more than are murdered or killed in wars. And which countries are leading the way, with rates of depression and anxiety that are unrivaled in the rest of the developed world? America and Japan—perhaps the most technologically advanced societies on the planet, and among the richest. Clearly, technology and affluence alone don't make people happy.

Human endurance is like shoe leather. It can walk over only so much pain and terror before the souls are worn through.

It's time to stop pulling drowning kids out of the river and start heading upstream to see who is pushing them in.

Edgar Allen Poe dealt with impulses such as suicide in an essay called “The Imp of the Perverse.” Poe noted that the impulse could increase to a wish, then to a desire, then to an uncontrollable longing.

“There is no passion in nature so demonically impatient as that of him who, shuddering upon the edge of a precipice, thus meditates a plunge.”

Those who commit suicide are powerless souls. The suicider's world is an interior pain that is almost indescribable. What is foremost to these actors is the stage inside the mind upon which they enact life's loneliest agony. The torment that ultimately plunges a suicider into death is uniquely personal, with tentacles that then touch the rest of us.

Because none of us could have consented to being brought into existence, it is especially important that each one of us at least have the option of ceasing to exist if he or she would rather not endure the hardships that life presents. After all, it is very likely that the high value we attach to life is at least significantly influenced by a brute biological life drive, a strong instinct of self-preservation that is pre-rational, shared with other animals, and then, in the case of humans, rationalized.

Maybe one reason why suicide is often seen as a tragedy is because it pierces the bubble of our shared self-perpetuating reality—our grand collective illusion—that life is worth living. Suicide is an indirect claim that life is purposeless, absurd, not worth living. Suicide pierces this transcendent

collective reality. Suicides somehow violate the unspoken covenant we all have with each other to affirm life, even when there may be little left to affirm.

The suicider does not play the game, does not observe the rules. He leaves the party too soon, and leaves the other guests painfully uncomfortable.

“Joe seemed like one of us ducks floating down the river. We just didn’t realize he was paddling so furiously under the water. Eventually Joe got tired of paddling.”

Things all look the same on the surface, but just below, the substrate is deteriorating. We’re all ducks like Joe Stack desperately paddling to stay afloat. And day by day more and more of us are sinking. Joe Stack thought he was doing what needed to be done. As he wrote in his suicide letter:

“I can only hope that the numbers quickly get too big to be whitewashed and ignored and that the American zombies wake up and revolt. It will take nothing less.”

Sorry, Joe, turns out no one gives a shit. But have you heard about those 5,000 Wuhan Flu deaths—oh, of course not, you’re dead. Due to something far less exploitable by wealthy, powerful narrative-makers—you should see the viewer numbers on the latest episode of Fredo’s Fever Dreams. But, one should not be surprised, after all, it is their owners who are driving people like poor Joe here to take their leave.

“I’ve lived for thirty years (badly), some will say it was too short a life. But these people can not determine the limits of patience and tolerability, for these limits are subjective, not objective.

I tried to be a good person. I’ve made mistakes. I started many new experiments. I have tried to make sense of my life and to set myself a goal, using my abilities. I tried to make an art out of the discomfort.

But the questions never stop and I am tired of having to bear them. I am also sorry to ask these questions. I am tired of my efforts failing to bear fruit. I am tired of having to suffer criticism. I am tired of running to senseless job interviews for a job as a graphic artist.

I am tired of wasting feelings and desires for the other sex that obviously does not need me. I’m tired of being envious. I’m tired of asking myself how it feels to be on the winners’ side.

I am tired of having to justify my existence without having determined it myself. I am tired of meeting the expectations of others, although my own expectations have never been fulfilled. I am tired of making a good face to the evil game, pretending to disappoint myself, to be taken on the arm, to be sorted out and to hear myself say that sensitivity is a particularly great character.

All lies. If sensitivity is really a great character property, researchers would have recognized that by now. But she never was and never will be, because that is the wrong reality.

A reality in which comfort counts, talents and alternatives are not valued; the ambitions ridiculed and dreams as well as everything else that does not fit in the so-called normality, are destroyed. This reality I can not accept as mine.

No one can make any claims to this reality. You can not ask for a job, you can not hope for love, you can not expect recognition, you can not ask for security, and you can not ask for a stable environment.

As for the last point, you will experience your blue wonder in the future, because soon you will not even be able to ask for more food, electricity, or running water, but of course that will not be my problem anymore. The future will be a disaster to which I do not want to contribute my part and not want to be part of it. I wish all those who are ready to face this future good luck.

This is by no means the world in which I should live, and no one can force me to continue to be part of this world. It is a nightmare full of problems, without any identity, without collateral, without clues and meanwhile also without prospects.

There are no prerequisites for me to get through this world, and I do not have the means to create these conditions. I can not look back at what I see, and I do not see any meaning in it: I have nothing to do with all this.

I can not spend the rest of my life struggling just to survive. To fight for the place I need, or for what I am legally entitled to do with the best of the worst in order to get along with as little as possible. I do not care about the minimum, I wanted the maximum, but this is unfortunately not available to me.

With the answer 'No' one can not live but die, and in this world there was never room for what I wanted, so I really did not really exist.

The general state of things is unacceptable to me, and I no longer intend to accept things. I think it is right if someone occasionally reminds the others that we are free, that there is an alternative to suffering: we can stop.

If life can not be a pleasure, it can not become a duty and I have understood that. I am aware that I am hurting you with great pain, but my anger is now so great that it only gets worse if I do not carry out my plan, and I can not bear any more hate.

As a free man, I have come into this world, and as a free man I leave this world, for in this world I have not fallen in the least.

Stop the hypocrisy.

I'm not letting myself be blackmailed by the fact that this is the only one Possibility. My individual model does not work. You are the ones who settle with me, not me with you.

I have always been a nonconformist and have the right to say what I think; to make my own decisions, no matter what price. There is nothing that can not be separated, death is only the means to it. The free will obeys the individual and not the comforts of others.

I know you'll be like a madness, but that's not it. It's just disappointment. I have no more desire: not here and not now.

I can not assert my existence, but my absence is already, and the absolute nothing is still better than a whole, in which you can not be happy if you bow down to your fate.

Mom, Daddy, please forgive me if you can, but I'm back home now. I'm fine.

There was no chaos in my mind. There was order within my mind. This generation takes revenge for a robbery, the robbery of happiness.

I ask all my friends to forgive me. Please do not hate me. I thank you for the wonderful moments we spent together. You are all better than me. This is not an abuse of my origin, but an accusation of treason.

I've been through as long as I could."

Maybe he was tired, like me, of all the fighting, and saw there was no need for fighting. Or if we fought and won there would be more fighting against us. And on and on. Because as a culture, humans have not learned that doing nothing is the greatest common denominator. That doing—and being—*nothing* would bring peace. But the influence for us to be and do is just too much in the Facebook generation.

What that man performed was the ultimate boycott. He will no longer need to buy food, clothes, and shelter from these multinational companies that are raping the earth and exploiting everyone. But until we get the middle class to boycott these companies, people like him and I will suffer. And there is a limit to human pain and suffering.

I found that for people of my circle there were four ways out of the terrible position in which we are all placed. The first was that of ignorance. It consists in not knowing, not understanding, that life is an evil and an absurdity. From people of this sort I had nothing to learn—one cannot cease to know what one does know.

The second way out is epicureanism. It consists, while knowing the hopelessness of life, in making use meanwhile of the advantages one has, disregarding the dragon and the mice, and licking the honey in the best way, especially if there is much of it within reach. That is the way in which the majority of people of our circle make life possible for themselves. Their circumstances furnish them with more of welfare than of hardship, and their moral dullness makes it possible for them to forget that the advantage of their position is accidental and that the accident that has today made me a Solomon may tomorrow make me a Solomon's slave. The dullness of these people's imagination enables them to forget the things that gave Buddha no peace—the inevitability of sickness, old age, and death, which today or tomorrow will destroy all these pleasures.

The third escape is that of strength and energy. It consists in destroying life, when one has understood that it is an evil and an absurdity. A few exceptionally strong and consistent people act so. Having understood the stupidity of the joke that has been played on them, and having understood that it is better to be dead than to be alive, and that it is best of all not to exist, they act accordingly and promptly end this stupid joke, since there are means: a rope round one's neck, water, a knife to stick into one's heart, a bottle of pills, a gun, or the trains on the railways; and the number of those of our circle who act in this way becomes greater and greater, and for the most part they act so at the best time of their life, when the strength of their mind is in full bloom and few habits degrading to the mind have as yet been acquired.

The fourth way out is that of weakness. It consists in seeing the truth of the situation and yet clinging to life, knowing in advance that nothing can come of it. People of this kind know that death is better than life, but not having the strength to act rationally—to end the deception quickly and kill themselves—they seem to wait for something. This is the escape of weakness, for if I know what is best and it is within my power, why not yield to what is best? The fourth way was to live like Solomon and

Schopenhauer—knowing that life is a stupid joke played upon us, and still to go on living, washing oneself, dressing, dining, talking, and even writing books. This was to me repulsive and tormenting, but I remained in that position.

Perhaps the greatest power our minds possess is the ability to cope with pain. Classic thinking teaches us of the four doors of the mind, which everyone moves through according to their need.

First is the door of sleep. Sleeping can be a form of emotional escape and can with sustained effort be abused. Sleep offers us a retreat from the world and all its pain. Sleep marks passing time, giving us distance from the things that have hurt us. When a person is wounded they will often fall unconscious. Similarly, someone who hears traumatic news will often swoon or faint. This is the mind's way of protecting itself from pain by stepping through the first door.

Second is the door of forgetting. Some wounds are too deep to heal, or too deep to heal quickly. In addition, many memories are simply painful, and there is no healing to be done. The saying 'time heals all wounds' is false. Time heals most wounds. The rest are hidden behind this door.

Third is the door of madness. There are times when the mind is dealt such a blow it hides itself in insanity. While this may not seem beneficial, it is. There are times when reality is nothing but pain, and to escape that pain the mind must leave reality behind.

Last is the door of death. The final resort. Nothing can hurt us after we are dead, or so we have been told.

This is very important: time does not heal all wounds—the proverb is fucking bullshit. Time may soften the pain, but it does not erase the memories. Time may separate the past from the present, but it does not mend what has been broken. Time may heal physical wounds, but it does not repair the violation of trust.

Certain actions lead to destruction and loss in a manner and on a scale that forbid correction and amends, that on some occasions we can only accept the certainty of negative consequences that cannot be avoided. Human beings may be capable of remarkable, even wondrous achievement, but limits are inherent in existence itself. Sometimes those limits mean that wounds will never heal, that the pain will never end.

A clinically depressed person cannot even perceive any other person or thing as independent of the universal pain that is digesting her cell by cell. Everything is part of the problem, there is no solution. It is a hell for one.

“Some boy I hardly knew in the room below mine heard me staggering around whimpering at the top of my lungs. He came

up and sat up with me until it went away. It took most of the night. We didn't converse; he didn't try to comfort me. He spoke very little, just sat up with me. We didn't become friends. By graduation I'd forgotten his name and major. But on that night he seemed to be the piece of string by which I hung suspended over hell itself.

I understood the term 'hell' as of that summer day and that night in the sophomore dormitory. I understood what people meant by hell. They did not mean the black sail. They meant the associated feelings. Or the corner it came up out of, inside, if they mean a place. From that day, whether I could articulate it satisfactorily or not, I understood on an intuitive level why people killed themselves. If I had to go for any length of time with that feeling I'd surely kill myself."

Jokes and sarcasm are often too pregnant and fertile with clinical significance not to be taken seriously: sarcasm and jokes are often the bottle in which clinical depressives send out their most plangent screams for someone to care and help them.

"I didn't want to especially hurt myself. Or like punish. I don't hate myself. I just wanted out. I didn't want to play anymore is all. I wanted to just stop being conscious. I'm a whole different type. I wanted to stop feeling this way. If I could have just put myself in a really long coma I would have done that. Or given myself shock I would have done that. Instead.

The last thing more I'd want is hurt. I just didn't want to feel this way anymore. I don't... I didn't believe this feeling would ever go away. I don't. I still don't. I'd rather feel nothing than this. The feeling is why I want to. The feeling is the reason I want to die. I'm here because I want to die. That's why I'm in a room without windows and with cages over the lightbulbs and no lock on the toilet door. Why they took my shoelaces and my belt. But I notice they don't take away the feeling do they."

The so-called 'psychotically depressed' person who tries to kill herself doesn't do so out of hopelessness or any abstract conviction that life's assets and debits do not square. And surely not because death seems suddenly appealing. The person in whom its invisible agony reaches a certain unendurable level will kill herself the same way a trapped person will eventually jump from the window of a burning high-rise. Make no mistake

about people who leap from burning windows: their terror of falling from a great height is still just as great as it would be for you or me standing speculatively at the same window just checking out the view; the fear of falling remains a constant. The variable here is the other terror, the fire's flames: when the flames get close enough, falling to death becomes the slightly less terrible of two terrors. It's not desiring the fall; it's terror of the flames. And yet nobody down on the sidewalk, looking up and yelling 'Don't!' and 'Hang on!,' can understand the jump. Not really. You'd have to have personally been trapped and felt flames to really understand a terror way beyond falling.

So the idea of a person in the grip of It being bound by a 'Suicide Contract' some well-meaning substance-abuse halfway house makes her sign is simply absurd. Because such a contract will constrain such a person only until the exact psychic circumstances that made the contract necessary in the first place assert themselves, invisibly and indescribably. That the well-meaning halfway-house staff does not understand Its overriding terror will only make the depressed resident feel more alone.

"Because I can't stand feeling like this another second, and the seconds keep coming on and on. I don't want to work, or go out, or read, or watch TV, or go out, or stay in, or either do anything or not do anything, I don't want anything except for the feeling to go away. But it doesn't. Part of the feeling is being like willing to do anything to make it go away. Understand that. Anything. Do you understand? It's not wanting to hurt myself it's wanting to not hurt."

When you're out of your skull with desperation and ready to end your struggle and they tell you how it'll all get better and better as you abstain and recover: they somehow omit to mention that the way it gets better and you get better is through pain. Not around pain, or in spite of it. They're telling you remember the pointless pain of active addiction and telling you that at least this sober pain now has a purpose. At least this pain means you're going somewhere, they say, instead of the repetitive gerbil-wheel of addictive pain.

"I think this is my life now, ending one minute at a time and there is no escape."

Whenever people talk about their personal bouts of depression in the abstract, there are two obstructions I hear more than any other: The possibility that one's life is not important, and the mundane predictability of

day-to-day existence. Talk to a depressed person—particularly one who’s nearing midlife—and one (or both) of these problems will inevitably be described. Since the end of World War II, every generation of American children has been endlessly conditioned to believe that their lives are supposed to be great—a meaningful life is not just possible, but required. Part of the reason forward-thinking media networks like Twitter succeed is because people want to believe that every immaterial thing they do is pertinent by default; it’s interesting because it happened to them, which translates as interesting to all. At the same time, we concede that a compelling life is supposed to be spontaneous and unpredictable—any artistic depiction of someone who does the same thing every day portrays that character as tragically imprisoned—January Jones on *Mad Men*, Ron Livingston in *Office Space*, the lyrics to “Eleanor Rigby,” all novels set in affluent suburbs. If you know exactly what’s going to happen tomorrow, the voltage of that experience is immediately mitigated.

Yet most lives are the same, 95 percent of the time. And most lives aren’t extrinsically meaningful, unless you’re delusionally self-absorbed or authentically *Born Again*. So here’s where we find the creeping melancholy of modernity: The one thing all people are supposed to inherently deserve—a daily subsistence that’s both meaningful and unpredictable—tends to be an incredibly rare commodity. If it’s not already there, we cannot manufacture it.

Overmedicalizing human emotions can lead to pathologizing normal reactions.

Critical thinking and intelligence—especially in a world gone mad—is the prerequisite of depression and anxiety. Being well adjusted to a sick, maladjusted society is the antithesis of being well adjusted.

Recent advances in neurobiology focus attention away from human suffering and feelings and toward drugs that influence brain circuits and neurotransmitters. Psychiatry has been famously described by Thomas Szasz as mechanomorphic, treating patients like “defective machines” rather than feeling human beings.

Doctors ignored her complicated inner life, focusing instead on the mechanical details of neurochemistry and medication. Rather than simulating her experiences, her doctors simply relied on their explicit theories about her condition.

“The moment the psych-unit doors locked behind me, I was stripped of my identity as wife, mother, teacher, and writer and transformed into patient, room number, and diagnosis.”

In 1851, a US physician published a paper in the *New Orleans Medical and Surgical Journal* in which he described a new disorder. “In noticing a disease that, therefore, is hitherto classed among the long list of maladies that man is subject to, it was necessary to have a new term to express it,” wrote Cartwright, and named the new syndrome drapetomania. Drapetomania was a disease of slaves that caused them to run away. Early symptoms included slaves becoming “sulky and dissatisfied without cause.” Treatment to stop further development of the disease at this point called for “whipping the devil out of them” as a “preventative measure.” Cartwright’s analysis of the “disease” that would make a slave want to run away is similar to our modern tendency to diagnose and medicate depression in those who work long days doing menial tasks in a windowless cubicle.

It is certainly no accident that anti-authoritarian psychiatrists and psychologists are rare. Mainstream psychiatry and psychology meet the needs of the ruling power structure by pathologizing anger and depoliticizing malaise so as to maintain the status quo. In contrast, anti-authoritarians model and validate resisting illegitimate authority, and so anti-authoritarian professionals—be they teachers, clergy, psychiatrists, or psychologists—are not viewed kindly by the ruling power structure.

“Depression is more seductive. Its tool is: ‘Wouldn’t it be way more comfortable to stay inside and not deal with people?’ Grief is an attack on life. It’s not a seducer. It’s an ambush or worse. It stands right out there and says: ‘The minute you try something, I’m waiting for you.’”

Prolonged grief is likely to be medicated as abnormal rather than openly acknowledged as an inevitable part of life.

For most of recorded medical history, clinical and common understanding saw sadness with a cause and sadness without a cause as very different things. One constituted “normal” grief and the other an “abnormal” condition. The second condition was called melancholy. By the eighteenth and nineteenth centuries, this melancholy had begun to take on an identity, and even a literal face. Etienne Esquirol, a French psychiatrist at the turn of the nineteenth century, had a series of drawings made to illustrate these features. This kind of physical documentation proliferated, but was, unfortunately, rather vague. Western medicine has—for more than a century—created new classifications, and all the while distinguished between the two kinds of sadness. But in the twenty-first century, and in the very DSM diagnostic criteria, that isn’t necessarily the case. According to the diagnostic manual, grief becomes diagnosable as depression if the symptoms are felt without cause—or with

cause, but for too long. How long is too long? For bereavement, the DSM defines a normal period of sadness to be two months.

The grief exception revealed something that the authors of the DSM—the distillation of mainstream psychiatric thinking—were deeply uncomfortable with. They had been forced to admit, in their own official manual, that it's reasonable—and perhaps even necessary—to show the symptoms of depression, in one set of circumstances. But once you've conceded that, it invites an obvious follow-up question. Why is a death the only event that can happen in life where depression is a reasonable response? Why not if your husband has left you after thirty years of marriage? Why not if you are trapped for the next thirty years in a meaningless job you hate? Why not if you have ended up homeless and you are living under a bridge? If it's reasonable in one set of circumstances, could there also be other circumstances where it is also reasonable?

The problem lies in the concept of 'normal.' Medical knowledge is frequently privileged as more accurate and more important than other forms of understanding or experience. This is especially true in the US, though also of the UK and much of Western Europe. When medical authorities tell us that two weeks or two months is sufficient, it creates a cultural expectation that grieving is, firstly, a short process with recognizable steps, and secondly, something that we must get over in order to return to normal.

The period after World War II was called an "Age of Anxiety" in response to the horrors of warfare. An entire generation reeled, suffering what was considered a natural response to circumstance. Our present age, by contrast, might be called an 'Age of Depression,' and the substitution of that single word makes all the difference. The anxiety of the early twentieth century had been considered normal, in the light of external events, whereas depression in the twenty-first century is understood as a diagnosable condition, an illness, a sickness of soul that should be (and often is) medicated. Screening for depression is ubiquitous in the West.

Instead of saying our pain is an irrational spasm to be taken away with drugs, we should start to listen to it and figure out what it is telling us. In most cases we would have to stop talking about "mental health"—which conjures pictures of brain scans and defective synapses—and start talking about 'emotional health.' Why do we call it mental health? Because we want to make it sound scientific. But it's our emotions.

Our approach today is like putting a Band-Aid on an amputated limb. When you have a person with extreme human distress, we need to stop treating the symptoms. The symptoms are a messenger of a deeper problem. Let's get to the deeper problem. What if depression is, in fact, a form of grief—for our own lives not being as they should? What if it is a form of

grief for the connections we have lost, yet still need?

“We’re such an utterly disconnected culture, we just don’t get human suffering.”

Most substance-addicted and/or depressed people are also addicted to thinking, meaning they have a compulsive and unhealthy relationship with their own thinking. 99% of compulsive thinkers’ thinking is about themselves; that 99% of this self-directed thinking consists of imagining and then getting ready for things that are going to happen to them; and then, weirdly, that if they stop to think about it, that 100% of the things they spend 99% of their time and energy imagining and trying to prepare for all the contingencies and consequences of are never good. Then that this connects interestingly with the early-sobriety urge to pray for the literal loss of one’s mind. In short that 99% of the head’s thinking activity consists of trying to scare the everliving shit out of itself.

“Sarge, no one commits suicide because of what happened to ‘em. They commit suicide because they thought about it too much.”

Like most clinically depressed patients, she appeared to function better in focused activity than in stasis. Their normal paralyzed stasis allowed these patients’ own minds to chew them apart. But it was always a titanic struggle to get them to do anything to help them focus.

We do bad things in our lives that have painful consequences, but most of us don’t spend every day thinking about the worst things we have done. We deal with them at the time, and our lives go on; we have opportunities to try to do better; we create new memories. But a prisoner’s world can be frozen on what is likely the very worst day of their entire life, and every day after it is just a reminder of how they failed—maybe not just because they had committed a crime and feel remorseful, but because they got caught or were unfairly convicted. Whatever the perspective, if they’re in prison, they failed. They are left with nothing to do but recycle the events that got them there, to ruminate endlessly.

Rumination is the practice of turning over negative events in your mind again and again, usually adding layer after layer of self-blame. It is agonizing. It leads to serious negative health consequences like increased stress, depression (which it makes more severe, longer-lasting, and more difficult to treat), anxiety, negative or dysfunctional coping mechanisms, and an overwhelming feeling of being stuck.

Most Americans go to great lengths to escape the monsters that are our own thoughts and imaginations. A study from the University of Virginia found that most people would rather be doing something bad—including hurting themselves by administering shocks—than sitting alone with their thoughts. Is it that when the external stimulation stops, our thoughts come rushing in, and we don't know how to handle it?

“So then at forty-six years of age I came here to learn to live by clichés. To turn my will and life over to the care of clichés. One day at a time. Easy does it. First things first. Courage is fear that has said its prayers. Ask for help. Thy will not mine be done. It works if you work it. Grow or go. Keep coming back.

The thing is that the clichéd directives are a lot more deep and hard to actually do. To try and live by instead of just say. Even if they are just clichés, clichés are (a) soothing, and (b) remind you of common sense, and (c) license the universal assent that drowns out silence; and (d) silence is deadly, pure Spider-food, if you've got the Disease.”

Suicide is an individual act and flows from specific circumstances and a particular state of mind. Generalizations miss the subtleties of each desperate cry. Some suicides are spontaneous acts, spur of the moment decisions—as is often the case in Asian countries, where poison is the most common method of suicide—others may be drawn out over years, in the case of the alcoholic, for example, punctuated perhaps by times of relief and optimism, only to collapse under the weight of life's intense demands once more.

So what can we say about the vast numbers of people who commit slow suicide by a series of acts and inactions that last a long lifetime and render them the living dead, those whom Thoreau so famously said were the mass of people who “lead lives of quiet desperation”? Is the meaning of life for them simply the habit of living they fell into at the start of life before they thought or wondered what's it all about? Or is it the habit they embraced after shrinking back in fear from the disturbing revelations thinking once brought them? Or did they ever seriously question their place in the lethal fraud that is organized society, what Tolstoy called the Social Lie? Why do so many people kill their authentic selves and their consciences that could awaken them to break through the social habits of thought, speech, and action that lead them to live ‘jiffy-lube’ lives, periodically oiled and greased to smoothly roll down the conventional highway of getting and spending and refusing to resist the murderous actions of their government?

If you have a why to live, you can bear almost any how. A meaningful life can be extremely satisfying even in the midst of hardship, whereas a meaningless life is a terrible ordeal no matter how comfortable it is.

“There was a long time in my life where I thought the only thing to do with my self was to destroy it.”

People think others who threaten suicide aren't serious. It's literally a call for help. If they can't get help they will drown in their sorrow. This is another thing that people don't understand, they call all drug users pathetic. When in reality they are just wanting to feel happy and normal like the others.

The truth is we live in a world where we don't listen to people anymore. So often we're just waiting for the next opening to respond. What we need to realize is that sometimes people don't need advice. Sometimes people just need to be heard. Sometimes the greatest gift we can give someone is just to keep our mouths shut and let them empty themselves into our hands. When they're finished, we don't need to do anything with what they've given us. We just need to show them that we're holding it for them till they can catch their breath.

I don't like the phrase 'A cry for help.' I just don't like how it sounds. When somebody says to me, 'I'm thinking about suicide, I have a plan; I just need a reason not to do it,' the last thing I see is helplessness.

I think: Your depression has been beating you up for years. It's called you ugly, and stupid, and pathetic, and a failure, for so long that you've forgotten that it's wrong. You don't see good in yourself, and you don't have any hope.

But still, here you are; you've come over to me, banged on my door, and said, 'HEY! Staying alive is REALLY HARD right now! Just give me something to fight with! I don't care if it's a stick! Give me a stick and I can stay alive!'

How is that helpless? I think that's incredible. You're like a marine: Trapped for years behind enemy lines, your gun has been taken away, you're out of ammo, you're malnourished, and you've probably caught some kind of jungle virus that's making you hallucinate giant spiders.

And you're still just going 'Give me a stick! I'm not dying out here!'

'A cry for help' makes it sound like I'm supposed to take pity on you. But you don't need my pity. This isn't pathetic. This is the will to survive. With *no* hope, running on *nothing*, you're ready to cut through a hundred miles of hostile jungle with nothing but a stick, if that's what it takes to get to safety.

All I'm doing is handing out sticks. You're the one staying alive

If you want to destroy your lives, at least find a new way of doing it. Don't destroy yourselves in the same ways people have done it for thousands of years. A life spent repeating the known follies of the past isn't just tragic, it's embarrassing.

Here is the advice I give everyone I can about this. If you well and truly, absolutely must die then do it through life itself. Run away. You have crippling debt, can't make ends meet, have an abusive spouse, are depressed, et cetera. Leave it all behind. Grab your jacket, some cash, whatever food you might be able to hold onto and just walk out the door. Jump on the back of a freight train or something and just go around. Find where you can be happy or make yourself so busy surviving actual fight-or-flight threats that you don't have time to be bothered by whatever ailed you. Maybe start a revolution and end the source of all this bullshit. What do you really have to lose with this? Anything you might stand to lose, you were already throwing away with death. So change the equation. Experience the world, as many things as you can at any level you can. Who knows? You might find somewhere or something that just makes it all right. You might help create somewhere or something. Worst case? You die in the attempt but if that was the plan at the start then is it really something to hold you back? Good luck with whatever you choose.

All my life I've been so lonesome
 If happiness came, I missed the call
 All my dreams have died and vanished
 And now, I'm so tired of it all

In life and love, I've been a failure
 Too many tears through it all
 Too many broken vows and promises
 And now, I'm so tired of it all

Everything I loved, I lost dear
 Too many times I've watched my castles fall
 My life is full of regretting
 And now, I'm so tired of it all

From this world I'll soon be going
 No one will miss me, after all
 Up there, I pray I'll find contentment
 But now, I'm so tired of it all

“I’m not brave. I was fearless. Fearlessness isn’t a virtue, bravery is. Bravery is doing what you know needs done, despite your fears. Fearlessness is just a lack of fear. Fearless people are those who just don’t care anymore. Fearlessness is a kind of depression, a mental illness.”

“If you feel like crying just let it out. If you try to hold it in it’s just going to tear you up inside.”

Told to me by a policeman when I was 8 or 9. My parents were in a brutal custody battle and my mom had basically kidnapped me and convinced me horrible things would happen if I went back to my dad, which was a lie. On our way back to her house she had the great idea to have me get out of the car and walk to the house, because police would be waiting and she’d get in trouble if I was with her, and they’d take me back to my dad’s house. I reluctantly agreed and walked, in the dark, along a busy road with no sidewalk.

When I got to her house I saw police in the driveway. I tried to go around the woods on the side of the house but they saw me and came and got me. An older policeman took me off to the side and sat me down until my dad could get there to pick me up. He was talking to me and basically trying to make me feel better. I was so scared and confused. I wanted to cry, but I didn’t want to show it. I felt embarrassed. And that’s when he told me: “If you feel like crying just let it out. If you try to hold it in it’s just going to tear you up inside.”

I cried, and I’ll never forget what he told me. Crying is something meant for others to see, so that the people who truly care can offer you support. If you try to hold it in you will just feel worse.

According to Buddhism, the root of suffering is neither the feeling of pain nor of sadness nor even of meaninglessness. Rather, the real root of suffering is this never-ending and pointless pursuit of ephemeral feelings, which causes us to be in a constant state of tension, restlessness, and dissatisfaction. Due to this pursuit, the mind is never satisfied. Even when experiencing pleasure, it is not content, because it fears this feeling might soon disappear, and craves that this feeling should stay and intensify. People are liberated from suffering not when they experience this or that fleeting pleasure, but rather when they understand the impermanent nature of all their feelings, and stop craving them. This is the aim of Buddhist meditation practices. In meditation, you are supposed to closely observe your mind and body, witness the ceaseless arising and passing of all your feelings, and realize how

pointless it is to pursue them. When the pursuit stops, the mind becomes very relaxed, clear, and satisfied. All kinds of feelings go on arising and passing—joy, anger, boredom, lust—but once you stop craving particular feelings, you can just accept them for what they are. You live in the present moment instead of fantasizing about what might have been.

This idea is so alien to modern liberal culture that when Western New Age movements encountered Buddhist insights, they translated them into liberal terms, thereby turning them on their head. New Age cults frequently argue: ‘Happiness does not depend on external conditions. It depends only on what we feel inside. People should stop pursuing external achievements such as wealth and status, and connect instead with their inner feelings.’ Or more succinctly, ‘Happiness Begins Within.’ This is exactly what biologists argue, but more or less the opposite of what Buddha said.

Before the “mental health revolution” beginning in the early 1990s, people with schizophrenia often had a place in society, typically in churches. Tribes were collectivist. In these tribes, the only thing that gets you kicked out, or ostracized, is a major crime like murder or infidelity that threatens the solidarity or culture of the group. Last I heard, schizophrenia is a disease, not a crime.

Locking people away for who they are is social ostracism. Victims of schizophrenia were, for whatever unfair circumstance, born different, had different experiences, and developed a disease that said:

“You see that society that you’ve been experiencing normally like everyone else? Let me fuck up your thoughts and perceptions so they don’t accept you anymore.”

Studies show that ostracism and loneliness have negative physiological effects on the human body. Lonely people are sick more often, take longer to recover, and have unhealthier resting vitals. They have less social support, poorer social skills, lower self-esteem, lower optimism, and more anger, anxiety, and fear of negative evaluation.

So yeah, when we isolate individuals from the larger part of society by sticking them and their stigmas in an under-funded hellhole together until they’re “safe” or have “found the right treatment plan” (because they need to think like the rest of us do), we might not be treating them as well as we could be.

Real mental health disorders do exist, of course. But I wonder if many of our so-called dysfunctions are really just the appropriate and completely sane reaction to a set of insane circumstances. After all—why would I not feel a deep sense of tragedy when confronted by the fact that my country is

dragging our ecosystem into a chasm of irreversible climate change? And should people not be kept up at night by anxiety or vague, urgent, instincts that something is deeply wrong with how all of us are expected to get up, clock in at work, come home, watch TV, drink, consume, and repeat? Is a person truly “sick” because they become convinced this is not at all how it is supposed to be or that their reality is being shaped by irrational forces beyond their knowledge and control?

“Very interesting. I believe I’ve spent most of my life post-childhood (now in my early 30s) in a state of feeling detached from life, as a passive observer. To me, the people and events around me seem more like characters and scenarios from a novel than they do reality. Rationally, I understand reality is in fact reality, but my default mental state seems to reject that notion. An example: I remember when 9/11 was live on TV, I just shrugged and went to watch something else while eating lunch.

I spend the majority of my time in fantasies, imagining myself elsewhere, or doing something else, or how I could have done something differently. Fantasies of vindictive revenge feature often, even though I’m a passive and peaceful man in ‘the real world.’ I spend a great deal of time distracting myself with story books or story-driven video games, or the occasional TV series. I just have no interest in dealing with reality at all.

That, combined with gradually worsening anhedonia, an inability to motivate myself to initiate activities, no career ambitions, a lack of empathy for people (but enormous empathy for animals) leads me to believe I’m a type of schizoid (perhaps the ‘secret’ subtype given my learned ability to socialize well as needed).

Perhaps I’m something different entirely, since I have no trouble feeling emotions, which I understand to be an issue for many schizoids. I’m also married, which I understand to be odd, although I wouldn’t say I love my wife or feel my relationship is all that beneficial.

Still, what you said about how many people suddenly realize their reality and become detached is fascinating. I generally assume most people, when I bother to think about them, are well-grounded in reality, but I suppose that can’t be true given the lengths many go to in order to pursue uncertainties.”

It takes a lot of heart, self-confidence and energy to find that value in yourself when you have none of the things that society values most. I've been single and without a job for a very long time, mostly due to health issues. After all is said and done, I think that it made me a stronger and more balanced person than I was before.

Still, it wasn't easy. It still isn't always easy. I can see how it would break people, especially if you don't have a support structure. I've actually seen it break people who were in a similar situation even if it was only for a little while. I think that this is really troubling. Especially considering my suspicion that jobs will become even more scarce in the future and the fact that marriage is less of a given these days.

To many people, the judgment of society is essential to their self-worth. I don't have that issue, but many do and it's not their fault nor something they can easily remedy. So this society risks ruining the mental state of so many worthwhile individuals as long as it's prime indicator of value is one's wealth, relationship status, or employment.

Not only is the present rendered irrelevant, but it becomes impossible to shape a better future because your capacity to hope is so diminished. So you just keep on spinning around and round doing the same shit that isn't making you happy and you're not doing anything to become happy.

It may be what in the old days was called a spiritual crisis or whatever. It's just the feeling as though the entire—every axiom of your life turned out to be false, and there was actually nothing, and you were nothing, and it was all a delusion. And that you were better than everyone else because you saw that it was a delusion, and yet you were worse because you couldn't function.

If we consider that the nature of being extreme translates into both big risks and big rewards, then perhaps "mental illness" is one of nature's ways of making a risky bet and hoping it will pay off.

It's like Mother Nature waltzes into the casino every now and then and bellies up to the roulette table to lay all of her money down on double-zero. If she hits it, the payout is big—with someone like an Isaac Newton, who ironically, never married or had kids, but increased the reproductive fitness of humanity for centuries after he lived. But if she comes up with nothing, then she ends up broke and looking to sneak into the all-you-can-eat buffet without being noticed.

Some tendencies of mental illness, in certain situations, may have been beneficial in the roving tribes of our ancestors.

A psychopath obviously poses a big risk, particularly to those who get close to him, but his psychopathic qualities might make him a shrewd leader, even if he's a ruthless one. If it just so happens that a tribe needs a

shrewd, ruthless leader to guide them through an unpredictable and unstable environment, the psychopath might be their best option.

A schizotypal member of the tribe might have been delusional, but he could also be a source of a few hair-brained ideas that ended up paying off in a big way for everyone. Maybe he hallucinates a burning bush telling him to round people up and mass-migrate them to more fertile land. Maybe he hallucinates ten commandments and carves them in stone and declares him and his friends God's chosen people. Maybe this ends up being the beginning of all Abrahamic religions and most of Western civilization.

Paradoxically, the same things that should cause these disorders to fall out of the gene pool are the ones that keep them in it. Their biggest handicap is also their biggest advantage. And the same extremes that hinder individuals could be what provides the "tincture of madness" for their genius and creativity. And, in many ways, we all benefit from it.

Let's look at some strategies and tactics used as part of a three phase process by many psychopaths. Note that this process is a natural outgrowth of their personality and that often it will be more automatic than consciously planned out. First, they assess the value of individuals to their needs, and identify their psychological strengths and weaknesses. Second, they manipulate the individuals (now potential victims) by feeding them carefully crafted messages, while constantly using feedback from them to build and maintain control. Not only is this an effective approach to take with most people, it also allows psychopaths to talk their way around and out of any difficulty quickly and effectively if confronted or challenged. Third, they leave the drained and bewildered victims when they are bored or otherwise through with them.

Recent theory and research in evolutionary psychology suggests that there are genetic reasons for such attitudes and behaviors. In this model, psychopathy is a heritable, adaptive life strategy in which the goal—reflected in the early emergence of aggressive sexuality—is to provide genetic continuity. Passing on one's gene pool can be accomplished in a number of ways, including the careful nurturance of a small number of offspring. The psychopathic pattern appears to be quite different, but equally (or even more) successful: the production of a large number of children, with little or no emotional and physical investment in their well-being. This pattern involves the use of a persistent and callous pattern of deception and manipulation to attract potential mates, a readiness to abandon them and their offspring, and the need to move on to fresh mating grounds.

One of the biggest and most painful mistakes we make is to assume that everyone has much the same capacity as we do for emotional experiences. Because we have little difficulty in putting ourselves in the emotional shoes

of another person, we are surprised at the callous indifference some people appear to show to the pain and suffering of others. What we often fail to realize is that there are some individuals, including psychopaths, whose own emotional life is so shallow that they cannot construct an accurate emotional facsimile of those around them.

Asking one teenager with conduct disorder to identify the emotional state of someone who appeared distressed and afraid, the teenager said:

“I don’t know what that expression is called, but I know it’s what people look like right before I stab them.”

Even when it’s incident-free, living in a constant state of fear—whether it be a violent neighborhood, a war zone, or an abusive household—is draining. The body is always in its hyper-vigilant, ‘ready to run’ mode, which is physically, emotionally, and cognitively exhausting. You are constantly processing excess cortisol and adrenaline, which disrupts your other systems. Among the effects are a weakened immune system, digestive problems (such as ulcers and irritable bowel syndrome), decreased fertility, heart disease, weight gain, metabolic syndrome (sometimes called “prediabetes”), sleep problems, fatigue, memory problems (the hippocampus shrinks), a slowing of cognitive processing, difficulty concentrating and controlling impulses, and depression.

If you believe, or in this case feel, something is true, it has real consequences. It doesn’t matter if there is no monster under your kid’s bed. He’s going to end up shaking, crying, and sleeping with you.

Microscopic Worlds

Consider the Parasite

The Voyager wasn't a hunter. Not an expert and dedicated one, anyway. He had other skills. He was a fisherman. He lived not in a forest clearing like the one at Mambele but in a fishing village along the Ngoko River. He was a river boy from childhood. He knew the water; he knew boats. He owned a canoe, a good one, sturdy and long, made from a mahogany log with his own hands, and he spent his days in it. He was a young man with no wife, no children, and just a bit of an appetite for adventure. He had fallen away from his natal community at an early age, becoming a loner, because his father died and the village came to despise his mother, suspecting her of sorcery based on a piece of bad luck and a grudge. He took this as a deep personal bruise; he despised the villagers in return, screw them, and went his own way. It suited him to be alone. He was not an observant Bakwele. He never got circumcised.

The Voyager ate fish. He ate little else, in fact, besides fish and bananas—and sometimes manioc, which he didn't plant or process himself but which was easily bought with fish. He liked the taste and he loved the idea of fish, and there was always enough. He knew where to find fish, how to catch them, their varied types and names. He drank the river. That was enough. He didn't make palm wine or buy it. He was self-sufficient and contained within his small world. He provided fish to his mother and her two younger children. His mother still lived at the fringe of the old village. His surplus catch he dried on racks, or in wet season smoked over a fire, at his solitary riverbank camp.

Occasionally he made considerable journeys, paddling miles upstream or drifting downstream, to sell a boatload of fish in one of the market villages. In this way, he had tasted the empowerment of dealing for cash. Brass rods were the prevailing currency, or cowrie shells, and sometimes he may even have seen deutschmarks. He bought some steel hooks and one spool of manufactured line, which had come all the way from Marseille. The line was

disappointing. The hooks were excellent. Once he had floated downstream as far as the confluence with the Sangha, a much larger river, powerful, twice as wide as the Ngoko, and had ridden its current for a day—a heady and fearful experience. On the right bank he had seen a town, which he knew to be Ouesso, vast and notorious; he gave it a wide berth, holding himself at midriver until he was past. At day's end he stopped, slept on the bank, and next day reversed, having tested himself enough. It took him four days of anxious effort to paddle back up, hugging the bank (except again at Ouesso), climbing through eddies, but the Voyager made it, relieved when he regained his own world, the little Ngoko River, and swollen with new confidence by the time he beached at his camp. This might have occurred, let's say, in the long dry season of 1916.

On another occasion, he paddled upstream as far as Ngbala, a river town some miles above Moloundou. It was during his return from that journey that he stopped at Moloundou and there, in his boat, where it was tied for the night in a shaded cove just below town, had sex with a woman. She wasn't his first but she was different from village girls. She was a river trader herself, a Buy 'em-Sell 'em, several years older than he was and considerably more experienced. She traveled up and down the Ngoko and the Sangha, making a living with her wits and her wares and sometimes her body. The Voyager didn't know her name. Never heard it. She was outgoing and flirtatious, almost pretty. He didn't think much about pretty. She wore a print dress of bright calico, manufactured, not local raffia. She must have liked him, or at least liked his performance, because she returned to his boat in the shadows the next night and they coupled again, three times. She seemed healthy; she laughed merrily and she was strong.

He considered himself lucky that night—lucky to have met her, to have impressed her, to have gotten at no cost what other men paid for. But he wasn't lucky. He had a small open wound on his penis, barely more than a scratch, where he'd been caught by a thorny vine while stepping ashore from a river bath. No one can know, not even in this imagined scenario, whether the lack of circumcision was crucial to his susceptibility, or the little thorn wound, or neither. He gave the woman some smoked fish. She gave him the virus. It was no act of malice or irresponsibility on her part. Despite swollen and aching armpits, she had no idea she was carrying it herself.

Scientists think that each of the twelve groups (eight of HIV-2, four of HIV-1) reflects an independent instance of cross-species transmission. Twelve spillovers. In other words, HIV hasn't happened to humanity just once. It has happened at least a dozen times—a dozen that we know of, and probably many more times in earlier history. Therefore it wasn't a highly improbable event. It wasn't a singular piece of vastly unlikely

bad luck, striking humankind with devastating results—like a comet come knuckleballing across the infinitude of space to smack planet Earth and extinguish the dinosaurs. No. The arrival of HIV in human bloodstreams was, on the contrary, part of a small trend. Due to the nature of our interactions with African primates, it seems to occur pretty often.

Of the diseases shared by humans and their domesticated animals, twenty-six are found in chickens, forty-two in pigs, forty-six in sheep and goats, and fifty in cattle. Most of the worst scourges of human health until the advent of vaccination in the eighteenth century were imports from our farm animals, including measles, tuberculosis, smallpox, and influenza. Bubonic plague was transmitted to us by fleas from rats living in human settlements. As far as we can tell from the archaeological record, none of these so-called zoonotic diseases (from the Greek *zoon*, for animal, and *nosos*, for disease) afflicted our Paleolithic ancestors—all seem to have arisen in the Neolithic with the spread of farming. Many of the plagues described in the Bible may coincide with the explosion of zoonotic diseases during the emergence of the urban civilizations of the Neolithic, Bronze, and Iron Ages.

“These are the constraints within which a molecular biologist studying wild animals labors: the relative availability and other parameters of blood, shit, and piss.”

Humanity is a kind of animal, inextricably connected with other animals: in origin and in descent, in sickness and in health. About 60 percent of all human infectious diseases currently known either cross routinely or have recently crossed between other animals and us.

A zoonosis is an animal infection transmissible to humans. The animal hideaway is known as a reservoir host. The event of transmission, from one species into another, is called spillover.

Zoonoses by definition involve events beyond the ordinary, and the scope of their consequences can be extraordinary too. Every spillover is like a sweepstakes ticket, bought by the pathogen, for the prize of a new and more grandiose existence. It's a long-shot chance to transcend the dead end. To go where it hasn't gone and be what it hasn't been. Sometimes the bettor wins big. Think of HIV.

If you look at the world from the point of view of a hungry virus, or even a bacterium—we offer a magnificent feeding ground with all our billions of human bodies, where, in the very recent past, there were only half as many people. A marvelous target for any organism that can adapt itself to invading us.

Infectious disease is a conflict between man and his parasites which, in a constant environment, would tend to result in a virtual equilibrium, a climax state, in which both species would survive indefinitely. Man, however, lives in an environment constantly being changed by his own activities, and few of his diseases have attained such an equilibrium.

Think of a BSL-4 laboratory—not necessarily AA-5 at USAMRIID but any among a handful around the world in which Ebola is studied. Think of the proximity, the orderliness, and the certitude. Ebola virus is in these mice, replicating, flooding their bloodstreams. Ebola virus is in that tube, frozen solid. Ebola virus is in the petri dish, forming plaques among human cells. Ebola virus is in the syringe; beware its needle. Now think of a forest in northeastern Gabon, just west of the upper Ivindo River. Ebola virus is everywhere and nowhere. Ebola virus is present but unaccounted for. Ebola virus is near, probably, but no one can tell you which insect or mammal or bird or plant is its secret repository. Ebola virus is not in your habitat. You are in its.

Until recently, scientists underestimated the sophistication of parasites. Over most of the past century, the complicated life cycles of these organisms, coupled with their puny size and concealment inside the body, made them exceedingly difficult to study. Largely out of researchers' ignorance, parasites were presumed to be backward, degenerative life forms. Their inability to survive as independent, free-living creatures was seized as proof of their primitive status. The very notion that hosts high up the evolutionary ladder might be jerked around like marionettes by such simpletons—many lacking even a nervous system—seemed absurd. Until the tail end of the twentieth century, our behavioral defenses against parasites were also assumed to be rudimentary. Indeed, the subtlest of these adaptations—manifested as automatic thoughts and feelings—were overlooked almost entirely, probably because they occur at the periphery of our awareness. Scientists are no more cognizant of subconscious impulses than the rest of us, so this subterranean realm appears to have gone uncharted simply because no one thought to look for it.

Though lions, bears, sharks, and weapon-wielding humans may populate our nightmares, parasites have always been our worst enemy. In medieval times, one-third of Europe's population was decimated by the bubonic plague. More people died in the 1918 Spanish flu epidemic than were killed in the trenches of World War I. Malaria, presently among the most deadly infectious agents on the planet, is arguably the greatest mass murderer of all time. Experts estimate the disease has killed half of all people who have roamed the planet since the Stone Age.

Animals traveling in large packs, shoals, or flocks are assumed to do

so for their own benefit—for example, to find mates, deter predators from attacking, or enhance foraging strategies. Maybe it's time to reexamine that assumption in some cases. Perhaps far more often than we realize, parasites might be herding their current hosts straight into the jaws of their next hosts.

Researchers have now discovered that many interactions between predators and prey were not what they appeared to be but rather were “rigged” by parasites. Biologists, who couldn't see what was happening out of view, had been hoodwinked. What's more, parasites were not just swinging a sledgehammer, directly killing and sickening hosts, but also bringing ill upon them by subtly changing their behavior—the ecological implications were enormous. It meant that these tiny organisms were taking animals out of one habitat and putting them in another, with unknown effects that would ripple through the food chain.

Predators may not always be the supreme hunters nature documentaries suggest they are. A significant portion of their catch of the day may be low-hanging fruit brought within their reach courtesy of parasites. Why, after all, work hard for a meal when it will come to you? Perhaps the most heretical notion is simply that one should not assume animals are always acting of their own volition. Numerous crustaceans, mollusks, fish, and truckloads of insects are behaving weirdly because of parasites. Mammals like ourselves appear to be less common victims of their manipulations, but that belief may derive from ignorance. This much is certain: An undiscovered universe of animal behavior will yet be traced to parasites. Their meddling is just harder to prove in some species than others.

Perhaps our biggest handicap is that we're imprisoned by our senses. Quite simply, we rely too heavily on our eyes for our understanding of the world.

The worm is producing a raft of neurochemicals that closely mimicked ones normally found in the cricket. If we don't speak the same language, we can't communicate. So if I'm the worm, I want to talk to you in the same language. Natural selection favors worms that make molecules the cricket can recognize, facilitating “crosstalk” between them. In this way, the parasite can tell the cricket what it wants the insect to do.

Compared to healthy controls, the stricken insects have higher amounts of a protein involved in sight, possibly altering their visual perception. This revelation prompted researchers to explore whether crickets harboring the parasite are attracted to light. Indeed they were, whereas the healthy insects preferred the dark. If you're a cricket that lives in the forest, what in your surroundings is brightest of all at night? An open area filled with water—an excellent reflector of moonlight. By tinkering with the settings

of the cricket's visual system the worm mesmerizes its host. It's effectively whispering to the insect, 'Go toward the light.'

Like most fish, killifish are dark on top and light on the belly. When they roll over on their sides, you see this bright flash—this silver glint. It's almost like someone shining a rescue mirror in your face. The fish that are infected are every bit as healthy as the uninfected fish. They just swim up to the surface and wave hello to the birds that come down and eat them. To figure out how the parasite could coax its host into acting so imprudently researchers analyzed the neurochemistry of infected fish. They found that the parasite was disrupting the regulation of serotonin, a neurotransmitter that influences the anxiety level of many animals, including humans (the popular antidepressant Prozac alters the metabolism of serotonin). Following that lead, the scientists traumatized healthy and infected fish by plucking them out of the water for several seconds at a time. Afterward, the healthy fish showed increased activity in serotonin circuits—a sign that they were under acute stress. In stark contrast, the infected fish had a muted response in those brain circuits. The more parasites the fish had, the less stressed-out the fish. This suggests it's so mellow that it doesn't get anxious in a situation that should make the animal fearful. It's less risk averse, like a fish on Prozac. Which they might also be on given the number of pharmaceuticals in our waterways.

A female jewel wasp performs neurosurgery on a roach. The procedure robs the roach of free will, so when the wasp pulls on one of its antennae, off it trots to her burrow, where it will nourish her offspring.

With the goal of understanding how the wasp dominates her much larger host, mad scientists fed the wasp a radioactive compound that was incorporated into her venom. When the wasp stung a roach, the researchers could then track where the poison went. They discovered that the venom knocked out a vital neural center for decision-making. Basically, information from the roach's eyes and other sensory organs is relayed to this nexus, and after processing these inputs, the insect chooses what to do next. Roaches aren't automatons that react to stimuli in the same way every time. Just like us, they can be unpredictable. They think before acting, which is why they're so good at escaping humans chasing after them with rolled-up newspapers. So when the venom knocks out that central command module, the creature is effectively robbed of free will. Instead of running for its life, it's frozen by indecision. All it takes is a little tug by the wasp to get it over its inertia, and off it trots to its death.

The yellow sac on the underside of this crab holds the young of a parasitic barnacle. It has also infiltrated the inside of the crab and controls it like an amphibious robot.

A human—who loses the battle with toxoplasmosis gondii typically ends up with two-hundred to five-hundred cysts in the brain. And each is more than just a potential dopamine factory. Every cyst also triggers a local immune response that further disrupts the balance of neurotransmitters in the surrounding area. Basically, the body tries to starve the parasite of a chemical it requires to awaken from its dormant state, but that very same chemical is needed by the brain for normal mental functioning, so the containment strategy may come at a cost to the host. The parasite is going to be altering dopamine, GABA, glutamate, and other key neurotransmitters at two-hundred different places in the brain so it's not surprising it's going to be subtly influencing human behavior—or, if the cysts happen to cluster in certain regions, even contributing to psychiatric disease. It's certainly plausible that the organism could exacerbate an underlying mental condition. For instance, we may all exist on a schizophrenic spectrum. Someone without the parasite might already be showing mild symptoms of schizophrenia, but then they get the parasite and their symptoms worsen. The variation from individual to individual in the distribution of the cysts might also explain reports of infected people experiencing personality changes, increased impulsivity, and less fear or poor judgment in potentially dangerous situations such as when to speed up and pass a car.

If the latent infection predisposes you to psychiatric illnesses, should it be treated as a preexisting condition? Should car insurance companies hike your rates on the grounds that you're more likely to get into a crash?

Textbooks today still make silly statements that schizophrenia has always been around, it's about the same incidence all over the world, and it's existed since time immemorial. The epidemiological data contradicts that completely. Save for the ancient Egyptians, virtually no one kept cats as pets until the latter part of the 1700s. The first people to embrace the practice were poets—avant-garde, left-wing types in Paris and London, and it just came to be the thing to do. They called it the “cat craze,” and coinciding with it, the incidence of schizophrenia rose sharply. The disease is so striking in its full manifestations that it should be seen as extraordinary that it wasn't described clearly in the medical literature before 1806, when it was simultaneously described both in England and France. Most compelling, people with schizophrenia are two to three times more likely to have antibodies against the parasite than those who don't have the disorder.

Human genome findings clearly show that schizophrenia has a heavy hereditary component, a discovery that would appear to clash with this position—but perhaps we shouldn't see it this way. So far, the genes that have been most consistently linked to schizophrenia are those that control

how the immune system defends against infectious agents. In families with a high incidence of the mental illness, they say, it may be that the risk factor being passed down is an ineffective immune response to the parasite.

The main problem facing a parasite over the long-term is the issue of transmission: how to spread its offspring from one individual host to another. Various methods and traits have developed toward that simple end, ranging from massive replication, airborne dispersal, environmentally resistant life-history stages (like the small form of *C. burnetii*), direct transfer in blood and other bodily fluids, behavioral influence on the host (as exerted by the rabies virus, for instance, causing infected animals to bite), passage through intermediate or amplifier hosts, and the use of insect and arachnid vectors as means of transportation and injection. It is clear however that no matter by what method a parasite passes from host to host, an increased density of the susceptible population will facilitate its spread from infected to uninfected individuals. Crowded hosts allow pathogens to thrive.

The first rule of a successful parasite? Myxoma's success in Australia suggests something different from that nugget of conventional wisdom. It's not: Don't kill your host. It's: Don't burn your bridges until after you've crossed them.

The parasites responsible for malaria possess wondrously complicated life histories, encompassing multiple metamorphoses and different forms in series: an asexual stage known as the sporozoite, which enters the human skin during a mosquito bite and migrates to the human liver; another asexual stage known as the merozoite, which emerges from the liver and reproduces in red blood cells; a stage known as the trophozoite, feeding and growing inside the blood cells, each of which fattens as a schizont and then bursts, releasing more merozoites to further multiply in the blood, and causing a spike of fever; a sexual stage known as the gametocyte, differentiated into male and female versions, which emerge from a later round of infected red blood cells, enter the bloodstream en masse, and are taken up within a blood meal by the next mosquito; a fertilized sexual stage known as the ookinete, which lodges in the gut lining of the mosquito, each ookinete ripening into a sort of egg sac filled with sporozoites; and then come the sporozoites again, bursting out of the egg sac and migrating to the mosquito's salivary glands, where they lurk, ready to surge down the mosquito's proboscis into another host.

If you've followed all that, at a quick reading, you have a future in biology. This elaborate concatenation of life-forms and sequential strategies is highly adaptive and, so far as mosquitoes and hosts are concerned, difficult to resist. It shows evolution's power, over great lengths of time, to produce structures, tactics, and transformations of majestic intricacy. Alternatively,

anyone who favors Intelligent Design in lieu of evolution might pause to wonder why God devoted so much of His intelligence to designing malarial parasites.

The different attributes of DNA and RNA account for one of the most crucial differences among viruses: rate of mutation. DNA is a double-stranded molecule, the famed double helix, and because its two strands fit together by way of those very specific relationships between pairs of nucleotide bases (adenine linking only with thymine, cytosine only with guanine), it generally repairs mistakes in the placement of bases as it replicates itself. This repair work is performed by DNA polymerase, the enzyme that helps catalyze construction of new DNA from single strands. If an adenine is mistakenly set in place to become linked with a guanine (not its correct partner), the polymerase recognizes that mistake, backtracks by one pair, fixes the mismatch, and then moves on. So the rate of mutation in most DNA viruses is relatively low. RNA viruses, coded by a single-strand molecule with no such corrective arrangement, no such buddy-buddy system, no such proofreading polymerase, sustain rates of mutation that may be thousands of times higher.

Influenza is caused by three types of viruses, of which the most worrisome and widespread is influenza A. Viruses of that type all share certain genetic traits: a single-stranded RNA genome, which is partitioned into eight segments, which serve as templates for eleven different proteins. In other words, they have eight discrete stretches of RNA coding, linked together like eight railroad cars, with eleven different deliverable cargoes. The eleven deliverables are the molecules that comprise the structure and functional machinery of the virus. They are what the genes make.

Two of those molecules become spiky protuberances from the outer surface of the viral envelope: hemagglutinin and neuraminidase. Those two, recognizable by an immune system, and crucial for penetrating and exiting cells of a host, give the various subtypes of influenza A their definitive labels: H5N1, H1N1, and so on. The term 'H5N1' indicates a virus featuring subtype 5 of the hemagglutinin protein combined with subtype 1 of the neuraminidase protein. Sixteen different kinds of hemagglutinin, plus nine kinds of neuraminidase, have been detected in the natural world. Hemagglutinin is the key that unlocks a cell membrane so that the virus can get in, and neuraminidase is the key for getting back out.

One of the things that makes influenza so problematic is its propensity to change. First of all there's the high rate of mutation, as in any RNA virus. No quality control as it replicates. Continual copying errors at the level of individual letters of code. But that's not the half of it. Even more important is the reassortment—the accidental swapping of entire genomic segments

between virions of two different subtypes. It's similar to recombination, as occurs sometimes between crossed chromosomes in dividing cells, except that reassortment is somewhat more easy and orderly. It happens often among influenza viruses because the segmentation allows their RNA to snap apart neatly at the points of demarcation between genes: those eight railroad cars in a switching yard. Sixteen available kinds of hemagglutinin, nine kinds of neuraminidase—you can do the math—144 possible pairings.

The changes are random and most yield bad combinations, making the virus less viable. But random changes do constitute variation, and variation is the exploration of possibilities. It's the raw material of natural selection, adaptation, evolution. That's why influenza is such a protean sort of bug, always full of surprises, full of newness, full of menace: so much mutation and reassortment. The steady incidence of mutations yields incremental change in how the virus looks and behaves. Ergo you need another flu shot every autumn: This year's version of flu is different enough from last year's. Reassortment yields big changes. Such major innovations by reassortment, introducing new subtypes, which may be infectious but unfamiliar to the human population, are what generally lead to pandemics.

The flu virus is most transmissible in the two to three days after a person's exposure to it but prior to the onset of symptoms. Viral shedding peaks during that narrow window of time. Put another way, if you go to a party and wake up the next morning with a sore throat and runny nose, don't assume the people you hugged or shook hands with the night before gave you the bug. Quite likely just the opposite happened: you gave it to them.

But it's not all about human disease. Different subtypes have their affinities for different species of host. H7N7 does well among horses. Dead terns in South Africa, back in 1961, had been infected with H5N3. Only subtypes bearing H1, H2, or H3 as their hemagglutinin cause human flu epidemics, because only those spread readily from person to person. Pigs offer conditions intermediate between what a flu virus finds in people and what it finds in birds; therefore pigs get infected with both human subtypes and bird subtypes. When an individual pig is infected simultaneously with two viruses—one adapted to humans, one adapted to birds—the opportunity exists for reassortment between those two.

Although wild aquatic birds are now known to be the ultimate origin of all influenzas, the viruses reassort themselves in pigs and elsewhere (quail also serve as mixing bowls), and by the time they get into humans, they have generally been assembled from H1, H2, or H3 plus the ten other necessary proteins, some of those in forms borrowed from this or that bird flu or pig flu virus. Other subtypes, featuring H7 and H5, have occasionally tried on

the prospect of targeting people and in all cases so far, the fit has been bad. They infect humans but they haven't acquired transmissibility. They don't pass from person to person. They may kill a lot of poultry, spreading through entire flocks, but they don't travel on human sneezes. Influenza among birds is primarily an infection of the gastrointestinal tract, with transmission occurring by the fecal-oral route; a sick bird shits the virus onto the floor of its coop, or onto the ground of a barnyard, or into the water of a lake or an estuary, and another bird picks it up while pecking or dabbling for food. So you've got to handle a hen, or butcher a duck, to get infected.

Still, with such a variable group of viruses, always mutating, continually reassorting, the next try on could be different. Consequently there's not a hope in hell, at this time, of predicting just what the next pandemic will be. But we can try.

The first criterion is the most obvious: recent pandemics in human history. That would point to the orthomyxoviruses (including the influenzas) and the retroviruses (including the HIVs), among others. The second criterion is proven ability to cause major epidemics in non-human animal populations. This would again spotlight the orthomyxoviruses, but also the family of paramyxoviruses, such as Hendra and Nipah, and the coronaviruses, such as that virus later known as SARS-CoV and of course the latest out of Wuhan (Biolabs?). The third criterion is intrinsic evolvability—readiness to mutate and to recombine (or reassort)—which confers on a virus the potential to emerge into and to cause pandemics in human populations. Examples would be retroviruses, orthomyxoviruses, and coronaviruses. Some of these viruses, coronaviruses in particular, could pose serious threats to human health. These are viruses with high evolvability and proven ability to cause epidemics in animal populations.

In 1996, Reston virus reentered the United States by way of another shipment of Philippine macaques. Sent from the same export house near Manila that had shipped the original sick monkeys to Reston, Virginia, these went to a commercial quarantine facility in Alice, Texas, near Corpus Christi. One animal died and, after it tested positive for Reston virus, forty-nine others housed in the same room were euthanized as a precaution. Most of those, tested posthumously, were negative. Ten employees who had helped unload and handle the monkeys were also screened for infection, and they also tested negative, but none of them were euthanized.

Pigs were left starving in their pens. Some broke out to roam the roadways like feral dogs, foraging for food. Malaysia at that time contained 2.35 million pigs, half of them from Nipah-affected farms, so this could have become an almost medieval problem, like a scene from the Black Death:

herds of infected pigs stampeding ravenously through empty villages. A phalanx of cullers, including soldiers from the army as well as police and veterinary officers, moved into the countryside wearing protective suits, gloves, masks, and goggles. Their assigned task was to shoot, bury, or otherwise dispose of more than a million animals, and to do it quickly, without splashing virus everywhere. Despite all precautions, at least half a dozen soldiers did get infected. There's no easy way to kill a million pigs. Later it was found out to be 1.1 million pigs. The difference might seem like just a rounding error, but if you ever had to kill an "extra" hundred-thousand pigs and dispose of their bodies in bulldozed pits, you'd remember the difference as significant.

Bats come in many, many forms. The order Chiroptera (the "hand-wing" creatures) encompasses 1,116 species, which amounts to 25 percent of all the recognized species of mammals. To say again: One in every four species of mammal is a bat. Such diversity might suggest that bats don't harbor more than their share of viruses; it could be, instead, that their viral burden is proportional to their share of all mammal diversity, and thus just seems surprisingly large. Maybe their virus-per-bat ratio is no higher than ratios among other mammals. Then again, maybe it is higher.

Besides being diverse, bats are very abundant and very social. Many kinds roost in huge aggregations that can include millions of individuals at close quarters. They are also a very old lineage, having evolved to roughly their present form about 50 million years ago. Their ancientness provides scope for a long history of associations between viruses and bats, and those intimate associations may have contributed to viral diversity. When a bat lineage split into two new species, their passenger viruses may have split with them, yielding more kinds of virus as well as more kinds of bat. And the abundance of bats, as they gather to roost or to hibernate, may help viruses to persist in such populations, despite acquired immunity in many older individuals.

Remember the concept of critical community size? Remember measles, circulating endemically in cities of five-hundred-thousand people or more? Bats probably meet the critical community size standard more consistently than most other mammals. Their communities are often huge and usually large, offering a steady supply of susceptible newborns to become infected and maintain the viral presence.

That scenario assumes a virus that infects each bat only briefly, leaving recovered individuals with lifelong immunity, as measles does in humans. An alternative scenario involves a virus capable of causing chronic, persistent infection, lasting months or even years within a single bat. If the infection can persist, then the long average lifespan of a bat becomes advantageous

for the virus. Some of the smaller, insectivorous bats live twenty or twenty-five years. Such longevity, if the bat is infected and shedding virus, vastly increases the sum of opportunities over time for passing the virus to other bats. In the language of the mathematicians: R_0 increases with the lifespan of a persistently infected bat. And a bigger R_0 , as you know, is always good for the pathogen.

Social intimacy helps too, and many kinds of bat seem to love crowding, at least when they hibernate or roost. Mexican free-tailed bats in Carlsbad Caverns, for instance, snuggle together at about three-hundred individuals per square foot. Not even lab mice in an overloaded cage would tolerate that. If a virus can be passed by direct contact, bodily fluids, or tiny droplets sprayed through the air, crowding improves its chances. Under conditions like those in Carlsbad even rabies has been known to achieve airborne transmission.

Speaking of airborne: It's not insignificant that bats fly. An individual fruit bat may travel dozens of miles each night, searching for food, and hundreds of miles in a season as it moves among roosting sites. Some insectivorous bats migrate as much as eight-hundred miles between their summer and winter roosts. Rodents don't make such journeys, and not many larger mammals do. Furthermore, bats move in three dimensions across the landscape, not just two; they fly high, they swoop low, they cruise in between, inhabiting a far greater volume of space than most animals. The breadth and the depth of their sheer presence are large. Does that increase the likelihood that they, or the viruses they carry, will come in contact with humans? Maybe.

Then there's bat immunology—little is known by anyone. Is it possible that the cold temperatures endured by hibernating bats suppress their immune responses, allowing viruses to persist in bat blood? Is it possible that antibodies, which would neutralize a virus, don't last as long in bats as in other mammals? What about the ancientness of the bat lineage? Did that lineage diverge from other mammals before the mammalian immune system had been well honed by evolution, reaching the level of effectiveness seen in rodents and primates? Do bats have a different 'set point' for their immune responses, allowing a virus to replicate freely so long as it doesn't do the animal any harm?

The much darker story remains to be told, probably not about this virus but about another. When the Next Big One comes, we can guess, it will likely conform to the same perverse pattern, high infectivity preceding notable symptoms. That will help it to move through cities and airports like an angel of death.

Moral: If you're a thriving population, living at high density but exposed

to new bugs, it's just a matter of time until the NBO arrives.

During the early twentieth century, disease scientists from the Rockefeller Foundation and other institutions conceived the ambitious goal of eradicating some infectious diseases entirely. They tried hard with yellow fever, spending millions of dollars and many years of effort, and failed. They tried with malaria, and failed. They tried later with smallpox, and succeeded. Why?

The differences among those three diseases are many and complex, but probably the most crucial one is that smallpox resided neither in a reservoir host nor in a vector. Its ecology was simple. It existed in humans—in humans only—and was therefore much easier to eradicate. The campaign to eradicate polio, begun in 1988 by WHO and other institutions, is a realistic effort for the same reason: Polio isn't zoonotic.

And malaria is now targeted again. The Bill and Melinda Gates Foundation announced, in 2007, a new long-term initiative to eradicate that disease. It's an admirable goal, a generously imaginative dream, but a person is left to wonder how Mr. and Mrs. Gates and their scientific advisers propose to deal with *Plasmodium knowlesi*. Do you exterminate the parasite by killing off its reservoir hosts, or do you somehow apply your therapeutics to those hosts, curing every macaque in the forests of Borneo?

That's the salubrious thing about zoonotic diseases: They remind us, as St. Francis did, that we humans are inseparable from the natural world. In fact, there is no "natural world," it's a bad and artificial phrase. There is only the world. Humankind is part of that world, as are the ebolaviruses, as are the influenzas and the HIVs, as are Nipah and Hendra and SARS and the Wuhan Flu, as are chimpanzees and bats and palm civets and bar-headed geese, as is the next murderous virus—the one we haven't yet detected.

A Dover newspaper explained confidently:

"The higher the number of deer in an area, the higher the chances are of spreading Lyme disease to humans."

Well, actually, no. That simple formula is as false as the notion that swamp vapors bring malaria. The premise behind such civic efforts is that the landscapes in question contain "too many" deer and that their overabundance accounts for the emergence of Lyme disease since 1975. And it's true enough that there are lots of deer out there. Populations in the northeastern United States have rebounded robustly—because of forest regrowth, absence of big predators, lessened hunting by meat-hungry humans, and other factors—since the hard times of the eighteenth and nineteenth centuries. There might be more deer in Connecticut today than at the time of the Pequot War in 1637. But that abundance of whitetails is

probably irrelevant to the chances you'll catch Lyme disease during a stroll in, say, Cockaponset State Forest. Why? Any infectious disease is inherently an ecological system. And ecology is complicated.

A practical question: Say you're a parent with young children, living here in your Millbrook, Connecticut dream house on three acres of beautiful lawn and shrubbery—what do you want for protection against Lyme disease? There might be a whole range of desperate options. Pesticide spraying by the county? Deer eradication by the state? Thousands of mousetraps deployed in the forest and baited with cheese, snapping away like brushfire? Do you pave your yard and ring it with an oil-filled moat? Do you put flea-and-tick collars on your kids' ankles before they go out to play? No, none of those.

You should feel a lot more comfortable if you know that the landscape would support healthy populations of owls, foxes, hawks, weasels, squirrels of various kinds—the components of the community that could regulate mouse populations. In other words, biological diversity. Risk of Lyme disease seems to go up as the roster of native animals, in a given area, goes down.

Although it's an intricate system, certain points about Lyme disease emerge plainly. We know that walking into a small woodlot is riskier than walking into a nearby large, extensive forest. We know that hiking in the oak woods two summers after a big acorn year is much riskier than hiking in those same woods after an acorn failure. We know that forests that house many kinds of mammals and birds are safer than those that support fewer kinds. We know that the more opossums and squirrels there are in the woods, the lower the risk of Lyme disease, and we suspect that the same is true of owls, hawks, and weasels. As for white-tailed deer: They're involved, yes, but far from paramount, so don't believe everything you've heard.

Dirty Wars

Microbes make up 90 percent of our bodies, so zapping every germ in your path is in a sense anti-human.

Our microbial cells—or selves, for each of us is in reality a super-organism—defy easy classification. A number of strains labeled pathogens actually inhabit us all the time, causing trouble only when we're run-down or when unusual conditions favor their growth. The same species of bacteria may be a helper (a symbiont), a harmless freeloader (a commensal), or a hurter (a parasite), depending on circumstances that are constantly in flux.

It's clear, however, that animals' behavior changes markedly with the composition of their gut microbiota. The most striking proof of this comes from germ-free mice—that is, animals specially reared under sterile conditions to be devoid of gut microbes. A normal healthy mouse with its intestinal microbiota intact is a quick and eager learner. Show it a new object like a napkin ring and it will circle and sniff it with great interest. If placed in a maze, it's keen to explore new passages.

Germ-free mice demonstrate none of this natural curiosity. It's as if they have no recollection of objects and places they've recently explored, for they're just as likely to favor what's familiar over what's new, exciting, or different. These rodents are also oddly fearless. They boldly venture where mice with normal microbiota know not to go. Bright lights and open spaces that scream danger to the average mouse don't deter them in the least. In fact, they're so immune to anxiety that they show no signs of distress even when separated from their mothers at birth for three hours a day—a trauma that would normally lead to lifelong skittishness and social maladjustment. In addition, germ-free mice scurry about their enclosures more than those with normal microbiota. Just as in the case of mice with autism-like features, transferring healthy gut microbiota into the germ-free animals can normalize many of these behaviors—for example, they become more cautious and less active—but only if done before they are four weeks of age. After that, the transplant has no effect, suggesting that microbiota at the start of life shape the very wiring of the brain.

We must assume that such findings are being considered to determine how they can be used to exert control over societies.

Scientists examined how probiotic-fed mice responded to a test widely used by the pharmacological industry to assess the efficacy of medicines used for anxiety and depression. The animals were placed in a small tank of water and forced to swim with no escape route. Panicked, they eventually gave in to despair and became immobile. Untreated animals went only two minutes

before they lost their will to survive. In contrast, mice fed probiotics before the test swam a full forty seconds longer. They behaved as if they were already treated with an antidepressant.

So folks, this is a great example of how antidepressants are not designed to help you. The medication just makes you more able to deal with despair and hopelessness. Also: holy fucking shit you sadistic fucking scientists—fuck you. Throw cats in a bag and toss it in a river: labeled a potential serial killer; toss mice into a tank of despair: maybe get a Nobel.

Scientists gave young mice brief, high-dose pulses of antibiotics to mimic human treatment. When the rodents grew up, they not only weighed more but also had considerably more fatty tissue than their untreated counterparts. And if the animals were fed calorie-rich fare instead of normal chow, weight gain was even more dramatic. This synergistic interaction between the foods we eat and our microbiomes may go a long way toward explaining why the incidence of obesity in the United States is greatest in the South, which combines a love for deep-fried foods with the highest usage of antibiotics in the nation.

Why did gut bacteria evolve to direct our behavior? Here we are on shaky ground, but I offer this educated guess: We humans use our brains to create music, understand mathematics, and ponder the fate of the universe, so we tend to think of the gut as serving the brain rather than the other way around. But when bacteria began to colonize animals, some eight-hundred-million years ago, brains were not so sophisticated. Earthworms are believed to be among the first creatures to harbor gut bacteria, and each wriggling form basically consists of one long digestive tract surrounded by nerve fibers—what we now refer to as the second brain—to coordinate digestion. The main function of the brain in its head—if two tiny clumps of cells can be called that—is to obey orders from below like ‘Eat, eat, eat!’ so as to keep the bacteria teeming inside its tube of a body well fed. The brain above may even have evolved as an outpost of the gut’s nerve network, in which case the second brain came first.

So from the start, gut bacteria have been in very close communication with the brain upstairs and maybe even quite dictatorial in their demands. After all, they greatly outnumber the rest of the cells in the body and clearly have a stake in the safety and welfare of their vessel. And as that vessel has evolved and its range of behavior grown more complex, its microbial inhabitants have, with the ever pressing need of nourishment, been compelled to extend their control beyond simple appetites to the realms of emotion and cognition. Which is why without them an animal can seem rudderless, listless, or downright reckless. Germ-free mice don’t learn very well or remember where they’ve been. They don’t avoid predators. They don’t

become distressed or protest when separated from their mothers, whose nurturance and protection is critical for their survival. But if you colonize them with the normal microbiome for that strain, they calm down and behave in a much more appropriate, cautious manner. You could say that it's in the bacteria's best interest that the host survives and takes fewer risks.

Compared to microbes selected for virulence, they live life at a more leisurely pace and are less intrusive, spreading much more slowly—in a bead of spittle when a mother kisses her child or by a handshake, especially if the owner of one of those hands forgot to wash it after going to the bathroom. They have traded a life of piracy and murder for a more settled existence—a roof over their heads, a warm meal they can count on. Still, like their hosts, they can be opportunistic. If they sense they can get away with it, they may gnaw their way into the stomach or inflict other kinds of harm. And they are at the mercy of monsters like rabies, microbes that have no intention of getting along with any living thing and attack the brain directly, manipulating the host far more effectively, to their and our loss—though, when we die, gut microbes get to eat us. In short, gut bacteria are no more altruistic than parasitic manipulators—it's just that their survival strategy tends to be more closely allied with our own. And because they usually want us to act in ways that promote our well-being, they typically draw less attention to themselves than malicious microbes do. But make no mistake: Their influence on our behavior is dramatic. In fact, I'm not sure we will ever truly be able to separate their motives from our own.

Bathing as a way of keeping the body clean was a privilege of the rich even up to the beginning of the twentieth century. It was around that time that dermatologists in Germany began to call for “a bath a week for every German!” Large companies built bathhouses for their employees and encouraged personal hygiene by issuing them with free towels and soap. The tradition of the weekly bath did not really take hold until the 1950s. Then, typical families took their bath on a Saturday evening, one after another in the same bathwater, and hard-working Dad often got to go in the tub first. Originally, personal cleanliness meant ridding the body of unpleasant smells and visible dirt. As time went on, this concept became increasingly abstract. It's hard for us today to imagine this once-a-week family bathing routine. We spend money on disinfectants to get rid of things we can't even see. The surface in question looks exactly the same after cleaning as it did before—yet just knowing it is clean is extremely important to us.

The higher the hygiene standards in a country, the higher that nation's incidence of allergies and autoimmune diseases. The more sterile a household is, the more its members will suffer from allergies and autoimmune diseases.

Thirty years ago, about one person in ten had an allergy. Today that figure is one in three. At the same time, the number of infections has not fallen significantly. This is not smart hygiene.

If you dilute the bacteria on your plates, cutlery, and cutting board nicely with water, then wipe them over with a kitchen sponge before putting them away, you may as well have licked them clean with your tongue. Kitchen sponges offer the perfect home for any passing microbe—nice and warm, moist, and full of food.

Which is more shocking, to talk about shit, or the fact that kids are dying because we don't talk about shit? Poo is taboo precisely because it's a pile of germs. Were that not the case, we might not mind its scent and would be happy to talk about it.

Surprisingly, most people can't explain their revulsion to these things. A typical answer is: "I don't know. It's just yucky!" The question is trickier than it may seem. That's because what disgusts humans is a really weird mixed bag of filthy, slimy, smelly, sticky, wriggling things. While some of them—for example, rancid meat, curdled milk, and vomit—are easy to link to illness, in many other cases, the connection is far from obvious. Acne, for example. It's not contagious, so why is it disgusting? The likely answer is that pimples resemble the pustules associated with diseases like smallpox, measles, and chickenpox. Rats, cockroaches, snails, and seaweed are widely viewed as disgusting yet none are parasites. They make it onto the list because they can transmit viral and bacterial infections, gastrointestinal bugs, parasitic worms, and cholera, respectively. Earthworms are harmless, but lots of people can't stand to touch them. What makes them repugnant, perhaps, is that they look a lot like parasitic worms in fish and meat that, if swallowed, can burrow into our intestines.

Even those who care for the sick or who have unsavory jobs like cleaning toilets or sewers are frequently stigmatized. Worse, they themselves may develop post-traumatic stress disorder when called upon to perform particularly nasty chores—for example, retrieving the corpses of neglected old people who've been left to rot in their homes. I think it's terribly important we talk about this because it's no good saying, 'Oh, you're being irrational and illogical. Of course nobody thinks you're disgusting because you're sick.' But I'm afraid we do. And we're not going to make much progress unless you acknowledge it and deal with the emotional labor involved in having to overcome disgust.

Infectious diseases spread with alarming efficiency when there are a large number of hosts living near one another, especially under unsanitary circumstances. The advance of agriculture created these very conditions. The first farmers could barely eke out an existence, being one crop failure

away from disaster. Their grain-heavy diet was deficient in many nutrients and overabundant in others (the bacteria that cause cavities thrived on all those carbohydrates, triggering dental woes unknown to hunter-gatherers). Hunger and malnourishment combined to weaken their immune systems, making them more vulnerable to infection. As they became more successful at farming, ironically, their health problems only worsened. Their grain stores attracted insects and vermin that spread disease. With human settlement came piles of human waste and a greater danger that the water people drank was polluted with fecal contaminants. And the chickens, pigs, and other animals that they domesticated brought them in contact with new pathogens for which they had no natural resistance. As these risks mounted, early farmers fell prey to wave upon wave of diseases—many unheard-of in prehistoric times—including mumps, influenza, smallpox, whooping cough, measles, and dysentery, to mention just a few.

This didn't happen overnight. It took thousands of years for agriculture to take off. Few cities in the Middle East had more than fifty-thousand inhabitants prior to biblical times. So the perfect storm was slow to gather, but when it hit, a health crisis of unimaginable disruption and trauma ensued. These new diseases were far more lethal and terrifying than the versions manifested in the untreated and unvaccinated today. We are the heirs of exceptionally hardy people who were unusual in having immune systems that could repel these virulent germs.

It was exactly at this critical juncture that our forefathers went from being not particularly spiritual to embracing religion—and not just passing fads, but some of the most widely followed faiths in the world today, faiths whose gods promised to reward the good and punish the evil. Hunter-gatherers, at least today, sometimes believe that spirits can influence the weather or other events, but these mystical beings are rarely concerned about whether humans behave in a moral fashion. One of the oldest of these enduring belief systems is Judaism, whose most hallowed prophet, Moses, is equally revered in Christianity and in Islam (in the Koran, he goes by the name Musa and is referred to more times than Muhammad). Half the world's population follows religions derived from Mosaic Law—that is, God's commandments as communicated to Moses.

Not surprisingly, given its vintage, Mosaic Law is obsessed with matters related to cleanliness and lifestyle factors that we now know play a key role in the spread of disease. Just as villages in the Fertile Crescent were giving rise to filthy, crowded cities, and outbreaks of illness were becoming an everyday horror, Mosaic Law decreed that Jewish priests should wash their hands—to this day, one of the most effective public-health measures known to science. The Torah contains much more medical wisdom—and by that I

don't mean merely its famous admonishments to avoid eating pork (a source of trichinosis, a parasitic disease caused by a roundworm) and shellfish (filter feeders that concentrate contaminants) and to circumcise sons (this one seems to be debunked by modern research, but such knowledge has not found its way into mainstream views yet). Jews were instructed to bathe on the Sabbath (every Saturday); cover their wells (a good idea, as it kept out vermin and insects); engage in cleansing rituals if exposed to bodily fluids like blood, feces, pus, and semen; quarantine people with leprosy and other skin diseases and, if infection persisted in the community, burn their clothes; bury the dead quickly before corpses decomposed; submerge dishes and eating utensils in boiling water after use; never consume the flesh of an animal that had died of natural causes (a sign that it might have been felled by illness) or eat meat more than two days old (likely on the verge of turning rancid).

When it came time for divvying up the spoils of war, Jewish doctrine required any metal booty that could withstand intense heat—objects made of gold, silver, bronze, or tin—to “be put through fire” (sterilized by high temperatures). What could not endure fire was to be washed with “purifying water”: a mixture of water, ash, and animal fat, basically an early recipe for soap. Equally prescient from the standpoint of modern disease control, Mosaic Law has numerous injunctions specifically related to sex. Parents were admonished not to allow their daughters to become prostitutes, and premarital sex, adultery, male homosexuality, and bestiality were all discouraged, if not banned outright. Religion is an ideal enforcer of good public health, for many of the behaviors most relevant to disease propagation occur behind closed doors, outside of public view. There's simply no way of getting around an omnipresent, all-seeing God ever on the lookout for those who defy His will. Lest His flock be tempted to stray from the fold, the Torah makes clear that there will be a steep health cost. The Lord, it warns, will punish the disobedient with “severe burning fever,” “the boils of Egypt,” “with the scab, and with the itch,” “with madness and blindness”—and, if all that fails, the sword.

Contrary to common assumption, human brains didn't stop changing once people submitted to divine authority and became civilized. They kept on changing—especially, perhaps, in the very regions involved in processing disgust. Admittedly, that's conjecture. But discoveries from the forefront of genetics support this thinking. One of the most surprising findings to emerge from human gene-sequencing data in the past decade is that human evolution has been speeding up in recent times. In fact, adaptive mutations in our species' genome have accumulated a hundred times more quickly since farming got under way than at any other period in human history,

and the closer we move to the present, the quicker the adaptive mutations pile up. Scientists were initially puzzled by this unexpected finding until it finally dawned on them that the catalyst behind this change was ourselves. Humans were radically transforming their environment by taking up the plow, and their bodies and behavior had to adjust to the rapidly shifting landscape. In an evolutionary eyeblink, they had to adapt to new diets and very different lifestyles. Our species' cooperative spirit—our ingenuity and ability to work together—forced us into evolution's fast lane. The quickest-changing sections of the human genome regulate the functioning of the immune system and the brain. Given disgust's role in coordinating our physical and behavioral defenses against infection, it stands to reason that the parts of the brain that the emotion engages could have undergone significant remodeling with the rise of civilization.

That argument is even more convincing when you consider that large segments of populations were decimated by plague and pestilence over that very period. Natural selection would have strongly favored people who believed in God or who, at the very least, were conscientious in obeying religious doctrine that served to protect their health. Most important, it would have favored the survival of people with a punitive streak—that is, those prone to stiffly penalize anyone who broke society's rules. And as agriculture gave way to industry, causing a massive migration from farms to factories and concentrating more people than ever before into sprawling squalid slums, these pressures surely would only have intensified.

Some thinkers have come to view disgust as God's gift to us. They counsel that we should heed the wisdom of repugnance. This voice that wells up inside us warns when a moral boundary has been crossed. They call for people to listen to its outrage at acts like human cloning, abortion, incest, and bestiality.

“Repugnance, speaks up to defend the central core of our humanity. Shallow are the souls who have forgotten how to shudder.”

Needless to say, this is a less rosy view of disgust—and not without cause. As we've seen, it can make prejudice feel right, justifying the stigmatization of immigrants, homosexuals, the homeless, the obese, and other vulnerable groups. Moreover, our natural revulsion to disease has fed into the notion that sickness is God's punishment for sin—a view that still persists around the world even as modern medicine has dramatically advanced.

For example, Orthodox Jews are prohibited from sitting on a chair that a menstruating woman has occupied. Even in more secular pockets of the

world, many couples—both men and women—believe it is wrong to have sex when a woman has her period. Owing to how disgust affects our thinking, it's all too easy for women to be viewed as both polluting and morally offensive and thus deserving of fewer rights than men.

While people may not be able to suppress their moral intuitions, they should challenge these sentiments with reason and logic. It may take long and arduous intellectual work to reach an ethical decision—for example, that slavery should be abolished or it's cruel to eat animals—but with the passage of time our new values can become automatic and intuitive. If more people favored reason tempered with emotion over emotion tempered with reason in making moral decisions, would politics be less polarized? We think of ethical views as wildly different across individuals and across cultures, but the truth is that there's a ton of agreement. Most people think that murder, rape, stealing, lying, and cheating are wrong. What's interesting is where they diverge. Those differences have become a hotbed of political rhetoric and abuse. Where people clash predominantly relates to sexual mores and other social values highly pertinent to the transmission of disease. Which potentially implies something radical: it's parasites that have divided us! So if we could eradicate the worst of them and tamp down our disgust, perhaps people's attitudes would change and political debates would not be so rancorous. Of course, that's absurdly simplistic.

Religious scholars have been very interested in religious commitment, but they can't predict which countries will be religious based on current paradigms. Their theories are not very sophisticated—for example, you learn your religion from your parents. In contrast epidemiological data is a very good indicator of where religious fervor will burn brightest. And the more baroque a religion's sacred rituals and the greater the demands on its adherents, the better it is at keeping the congregation tightly bound together and separate from the members of other sects and their parasites.

In areas that have historically endured a high incidence of infection, people are more likely to be introverted and less prone to seek out novel experiences. Women, and to a lesser extent men, in these regions also report having restricted sexual lifestyles—that is, they have fewer partners over their lifespans and believe sex should be reserved for stable, committed relationships. In short, they don't mingle readily and they tend to follow traditional codes of conduct that might serve as a buffer against disease—for example, washing before prayer, bowing instead of shaking hands, and marrying only within their religious groups. Their traits seemed to be part of a broader package of values—namely, collectivism. An adherence to convention and distrust of foreign ways of doing things are well-known characteristics of collectivist societies. Could disease avoidance be an overlooked function

of that belief system?

Of course not every individual in the US is individualistic and not everyone in China is collectivistic. There's tremendous variation within any given population on these traits. We're just talking about relative prevalence—mean or average values—where you'll see differences between nations. The pattern detected on an international scale holds up within the United States. Americans are the most collectivistic in the very states—mostly in the Deep South—where CDC figures indicate infectious disease was highest. In the early decades of the twentieth century, southerners were considered far less productive than northerners, a sluggishness that was eventually traced to epidemic levels of hookworm that had rendered a large sector of the population anemic. The South in that era was also plagued by malaria, a problem that “required” the draining of swamps and other major efforts to bring it under control. Those combined factors may explain why the region even today remains more clannish than the rest of the country.

The most common criticism is that a correlation between parasite stress and collectivism does not prove that one caused the other. Especially with something as complex and multifaceted as culture, it can be very tricky to control for unrecognized factors that might be behind the association. The theory's progenitors are well aware of that hazard, and though there's no simple solution to the problem, they have found ways to subject their ideas to more rigorous scrutiny. Based on their model, for example, they've generated numerous new predictions and tested them against voluminous bodies of data gathered from many different sectors of the social sciences. So far, they report, their theory has held up well to this barrage of tests. Not only that, but their latest findings lead them to think its explanatory powers are considerably broader than they'd initially proposed. Do you live in a democracy or under a brutal dictatorship? Are you deeply religious? Do women in your country have the same rights as men? Is war frequently erupting around you? Some scientists believe parasite stress has direct bearing on all those questions.

People in those regions are well adapted to coexisting with only some of those strains. So if they move very far away from their own locale, they may encounter novel strains that could sicken or kill them. If a foreigner were to insinuate himself into their group, his germs could be lethal to them and vice versa. That foreigner's genes, should one of them decide to mate with him, would produce children whose immune systems would be less adept at fighting off local scourges. For these reasons people in parasitic hot zones should be reluctant to marry outside their own community. And they should develop all kinds of idiosyncratic markers of communal identity—unique dialects, religious practices, culinary customs, modes of dress, jewelry, music,

and so forth—that allow each group to tell ‘them’ from ‘us.’ In short, the theory predicts that regions teeming with parasites should produce homebodies and a Balkanized social landscape—that is, divided by religions and languages, among other social barriers. Indeed, that’s what was found. Researchers also discovered that people in these zones are more fervent about their faith, as measured by the number of times they pray per week, how often they attend services, and many other indices tracked by ethnographers. Atheism, by contrast, flourishes where there are very low parasite loads.

Although there are now a lot of different pieces of evidence linking pathogen prevalence to various kinds of cultural differences, parasite stress clearly is not the only thing that plays a role in shaping society. If there’s one thing we know in cognitive behavioral sciences, it’s this: Everything is multi-determined. For example, it would be grossly simplistic to conclude that religion is simply a parasite defense. Even if that’s a function it serves, that in no way implies that religion arose to serve that purpose alone or that it continues to exist for that one reason. Similarly, linguistic diversity, types of governance, and outbreaks of violence are no doubt the products of numerous geographic and historical factors, not parasite stress alone.

How parasite stress gets translated into attitudes and personality traits will also need to be clarified. There may have been differential selection for different personality traits in different cultures. There may be different frequencies of alleles (gene variants) for neurotransmitter pathways related to mood and temperament. The brain may sense when the immune system is in overdrive due to chronic infections and in response switch an individual’s mental outlook into a defensive mode manifested by collectivistic thinking.

Humans may even have evolved the ability to read levels of antibodies circulating in other people’s blood, which would tell them whether those around them were harboring lots of parasites. Are we talking about a sixth sense? Why not? Hell, there could be seven to five-hundred senses that allow the brain to detect antibody titers and the duration of immune system activation. When you look at a person, you’re assessing information about their age, all the hormone markers, the symmetry of the face and movement of the person—all this stuff ties to the health stats of an individual. Body odor might also provide information about a person’s immune status. There could be multiple things the brain is reading. We say certain animals have all kinds of abilities to sense things we can’t—but do they know everything they’re doing? What if we don’t know what we are actually perceiving?

Cultural anthropologists have begun to weigh in with their own opinions, and while facets of the model seem feasible to many of them, they also find flaws in its logic. For example, proselytizers regularly come into contact with strangers, and some religious practices—such as ritual bloodletting—

promote, rather than impede, the transmission of disease. Although no theory—especially not one that purports to account for cultural variation—can always make spot-on predictions, these counterexamples still raise troubling questions, and if enough of them accumulate, the theory could crumble under their weight.

Even creatures with no knowledge of the germ theory of disease have an instinct for healing and staying well. Good hygiene, vaccination, therapeutic interventions—these are the pillars of modern medicine. Yet animals of almost every stripe engage in these practices, as did early humans. Indeed, were it not for these evolved defenses, the immune system would quickly be overwhelmed. One of the most familiar but widely misinterpreted examples of this phenomenon is what scientists call sickness behavior. When you're ill, you spike a fever, lose your appetite, and become depressed and listless. Contrary to popular belief, these symptoms don't mean that the disease agent is weakening you but just the opposite—they demonstrate that the brain, in conjunction with the immune system, is mounting a multi-pronged campaign against the invader.

Infectious organisms typically can live only within a narrow temperature range, so fever kills them in droves basically by boiling them—a brilliant defensive tactic, but one that requires a vast amount of energy. To turn up the body's thermostat just one degree Celsius requires roughly the same number of calories that an average adult would expend walking forty kilometers. To funnel that much energy to the battlefield, the brain begins snapping orders: Stop moving about! Stop looking for a mate! Stop foraging for food and spending precious energy digesting it! Stop everything and go to bed! And so you fall into a feverish sleep—Fredo knows what we're talking about. Fever is so important for slaying germs that animals that cannot regulate their own body temperature—for example, locusts, baby rabbits, and cold-blooded creatures like lizards—have found alternative means to cook pathogens: They sunbathe.

Lest anyone doubt that sickness behavior is a defense against pathogens, scientists can induce it without exposing animals to a single germ. They manage this simply by injecting healthy rodents with immune components called cytokines. The once-frisky animals refuse to eat or drink and lose their passion for running in their wheels. Up go their temperatures and down go their heads. They act and feel sick even though they're healthy.

Given that nature's creatures don't come into the world equipped with microscopes or medicine cabinets, how are they so successful at warding off infection? One of their many tricks is to avail themselves of the medicine cabinet in their mouth. When injured by a bite, gash, or scrape, numerous species—among them primates, felines, canines, and rodents—use their

tongue like an antiseptic wipe to clean wounds. Saliva is rich in antimicrobial agents, immune-boosting substances, fungicides, and growth factors for stimulating healing of both skin and nerves. In laboratory experiments, the removal of rodents' salivary glands retarded the healing of their skin wounds. In another study, a sheet of human cells grown in culture was punctured to simulate a wound. The addition of saliva to the petri dish prompted cells in the area of the injury to grow much more quickly than those not so treated. In the right situation the old saying 'go lick your wounds' is very good advice.

Like primates today, our ancestors probably licked their wounds too. Modern humans may continue the tradition, albeit perhaps unknowingly. How many have, after nicking a finger, begun sucking on the cut?

Saliva can prevent germs from entering the body through other routes. After copulating, male rodents, cats, and dogs will furiously lick their penises for several minutes. The liberal application of saliva kills several pathogens that are leading causes of STDs in these species. Their habit also benefits females because it prevents males from passing on infections to their next mates. Interestingly, cattle and horses, which can't lick their own penises, are much more prone to STDs—one of the reasons they're bred by artificial insemination. Humans are also very susceptible to STDs, possibly owing to similar anatomical limitations—a limitation many a teenage boy has tried to defy. Lactating females of many mammalian species have found still another healthful purpose for saliva. They use their tongues to sponge away germs on their nipples before allowing their young to nurse. Rodent pups may even refuse to attach to a tit unless it has first been washed with her saliva.

Chimpanzees have—in Jane Goodall's words—"an almost instinctive horror of being soiled with excrement." When they accidentally come in contact with feces, they grab fistfuls of leaves and vigorously wipe it off. Even sex can quickly lose its appeal if excrement enters into the picture. Goodall reported that when a female chimp signaled her eagerness to copulate by raising her rump to a male, he initially seemed game until he spotted a diarrhea smear on her fur, whereupon he opted to abstain. Another male, no doubt with fewer prospects, eventually took her up on her offer, but not before first meticulously wiping off the offending spot with leaves.

Other animals are equally fastidious when it comes to feces. Mole rats and other small mammals that live inside burrows build underground latrines that are separated from their living quarters and larders. Lemurs in Madagascar have their own version of an outhouse—mounds aboveground, which they visit only to relieve themselves. Cows, sheep, and horses don't graze near fresh dung heaps no matter how lush the grass is in the vicinity of those piles.

Animals that lack our ability to preserve and cook food must of course adopt other behaviors to prevent food-borne infections. For dogs and cats, one such behavior is eating grass. They do so to flush intestinal worms out of their systems. The animals usually can't know if they have intestinal worms so they occasionally eat grass as a form of prophylaxis. Puppies and kittens do this most often because their small size makes them particularly vulnerable to the energy-draining effects of parasites. Our pets inherited this behavior from their wild ancestors. Wolves and cougars, for example, regularly eat grass, which is found in about two to four percent of their scat, sometimes along with worms they've expelled. The consumption of leaves may serve the same function in chimps, bonobos, and lowland gorillas. The leaves they choose always are covered in indigestible hairs, and the animals never chew them, as they would food, but rather swallow the leaves whole—sometimes as many as a hundred at a time. All that roughage dramatically accelerates the movement of food through the GI tract, purging them of at least two species of parasitic worms.

Wild Kodiak and brown bears dig up osha roots (*Ligusticum wallichii* and *L. porteri*), chew on them to release their volatile oils, and then work the paste deep into their pelts. Hinting at the root's medicinal value, the Navajo people use it as an antibacterial and anesthetic salve, and according to their legend, the burly beasts taught them about its healing power.

Wedge-capped capuchin monkeys in Venezuela roll their bodies over millipedes to stimulate the insects to release defensive toxins and then frenetically apply the chemicals to their fur with a liberal quantity of their own drool. The millipedes evolved the toxins to repel their insect enemies, so the monkeys are, in effect, stealing their bug spray. Birds—some two-hundred species of them—use a similar strategy. They crush ants with their beaks, causing them to release their own version of insect repellent, then rub the bugs through their feathers.

We think of vaccines as a sophisticated tool of modern medicine, but animals and humans without MDs have also figured out ways to vaccinate. When an ant gets a deadly fungus, for example, another member of its colony will rush up and lick it, thereby exposing the insect to a tiny dose of the disease agent. This method of inoculation is not without perils—two percent of ants perish. But the vast majority develop heightened immunity to the infection,

A technique for vaccinating against smallpox was used by people in northern Africa long before an eighteenth-century English physician named Edward Jenner received credit for inventing the world's first vaccine against the disease. In this ancient practice, a scab from someone with smallpox was rubbed into a tiny cut on the skin of a healthy person. And just as in

the case of inoculated ants, two percent of those people died. The custom, however, appears to have averted far more tragedies than it caused, lowering the mortality rate from smallpox by 25 percent.

We resort to separating the world into natural and unnatural only because our threadbare cultural inheritance provides us no better rules for making sense of the frightening mysteries all around us. The real problem with vaccines is not their unnaturalness, but the reaction they create when combined with culture: They reveal tremendous failures in our system of sharing knowledge. Unlike the Yolngu, where the elder women are trusted to sort the poisonous seeds from the healthy, in the United States there are few bonds of trust connecting the public to the oracles of our accumulated cultural—and therefore medical—knowledge.

“There are 500,000 people in the United States who can’t be vaccinated. They can’t be vaccinated because they’re on cancer chemotherapy, or they’ve had a bone marrow transplant, or a solid organ transplant, or they’re receiving steroids because they have severe asthma. They depend on those around them being vaccinated.”

In a country of over 320 million, the numbers we are discussing are less than 1% of the population. Such facts are often obscured in the popular arguments for vaccination and how it protects the vulnerable. And of course by foregoing vaccination you are not definitively condemning these others to death, and even from an indirect perspective there are far worse killers. Even from a preventable perspective you won’t find yourself in the top-ten.

So the question is, what level of risk to oneself outweighs the risk to others? The answers are not as black and white as they are presented in mainstream discourse. Especially now that “DNA vaccines” are being toyed with. These vaccines, rather than containing the pathogen, are instead composed of synthetic RNA designed to enter your cells and cause them to produce proteins that mimic the pathogen resulting in an immune response—hijacking the cell processes of your body, what could go wrong? No vaccines of this nature are currently approved for human use, but two recent instances of human testing are telling. In 2016 a Zika vaccine was trialed and in 2020 a Wuhan Flu vaccine began trials. As is often the case, irrational public fear, often stirred up by those in power and positions of authority, allow actions to be taken which, under normal conditions, would be opposed by the general public. How many of you, after months or maybe years of fearmongering, are going to rush to get the shot? After all, think of all those vulnerable people still alive, and think of how many we lost, how could you even think

of being so irresponsible?! Maybe you shouldn't even have a choice in the matter. After all:

“If it looks like you're overreacting, you're probably doing the right thing.”

The Making of a Plague

Are you interested in talking about... things? You know, the kind of things that we're not allowed to talk about anymore? You know, since the The Event?

You are? Great. So, allow me to voice some thought-crimes of my own. But be forewarned: I assure you that you will find at least some of my ideas to be offensive. You will disagree with them strongly. You will become irate. The real question is: What are you going to do to those voicing opinions you disagree with? Engage in dialogue with them? Or demand that agents of the state scrub their speech from the internet and lock them in a cage for their thought-crime?

Well, either way, I've already committed thought-crime numerous times, I might as well share them with you. Are you ready? Let's go.

The monumental importance of the measures taken around the world in the fight for control of the current Wuhan Flu pandemic during the past few weeks motivated us to express through this text a few considerations and comments on this hugely important topic.

"I have never seen anything like this. I am not talking about the pandemic, because I have seen 30 of them, one every year. But I have never seen this reaction, and I am trying to understand why."

We do too, and wish to share our thoughts through these lines.

"History suggests that we are actually at much greater risk of exaggerated fears and misplaced priorities"

Even in the midst of the Wuhan Flu panic, the Millionaire Socialist still barely touches radicality. What is his proposed \$2,000 going to do? It's going to act as a backdoor bailout to the corporations; to the 10%, but mainly the 1%. It's basically a textbook example of the criticism of UBI: absent a complete restructuring of the ownership and production of survival needs, any payments are funneled into the hands of the wealthy, for they control access to survival needs. This is why even Republicans propose such things. It's 2020 after all, you can't just chuck giant sackfuls of money at the rich while the poors suffer—and this time those desperate dirty poors might even give the rich some disease, can't have that.

Plus, it seems quite obvious that given its universal nature, the effect it is likely to have on at least some percentage of the top-30% is to help increase

stock prices, as the few Americans with retirement accounts depleted by the latest crash use the infusions to purchase more financial instruments. This, combined with the nearly free money being pumped out by the Fed are designed to reflate the bubble, the illusion of prosperity and stability.

For others, it will simply be used to pay off debts, funneled to the banks in other words. Or it will be saved.

And of course, he's all for the nationalization of coordinating the medical response, but not the nationalization of the providers. Combined with the pledge to provide all Wuhan Flu treatment for free, this stance acts as a giant government gift to the medical industry. All this is thinly papered over with nice sounding claims about limiting the profiting off of such things.

With nationalization of a clearly key industry off the table, he ignores the solution which would mitigate the issues raised about \$2,000 payments and potentially make them far less needed. Much of the worry faced by individuals currently out of work is the inability to pay rent, utilities, loans, and so on. Were the utilities nationalized, rent simply paid into community housing co-op funds, loans restricted to businesses because all other needs (e.g. education loans) would have been met for free, food provided by community grocery co-ops, and so on, then much of the current stress would not exist.

And if you want to be outraged at someone over Trump's briefly floated plan to "open the country by Easter," you should be outraged at Bernie. If only he had not been such a lazy and/or ignorant piece of shit in the four years since his 2016 sheepdogging. Bernie's continuation of the myth of money will kill more people than Donald Trump.

"Two categories of propaganda must be distinguished. The first strives to create a permanent disposition in its objects and constantly needs to be reinforced. Its goal is to make the masses 'available,' by working spells upon them and exercising a kind of fascination. The second category involves the creation of a sort of temporary impulsiveness in its objects. It operates by simple pressure and is often contradictory (since contradictory mass movements are sometimes necessary)."

The French-Algerian writer Albert Camus' great 1947 novel, *The Plague*, is a warning to us today, but a warning in disguise. When he died sixty years ago at the young age of forty-six, he had already written *The Stranger*, *The Fall*, and *The Plague*, and had won the Nobel Prize for Literature.

The outward story of *The Plague* revolves around a malignant disease that breaks out in a town that is quarantined when the authorities issue a

state of emergency. After first denying that they have a problem, the people gradually panic and feel painfully isolated.

Death fear runs rampant, much like today with the Wuhan Flu. The authorities declare martial law as they warn that the situation is dire, people must be careful of associating, especially in groups, and they better obey orders or very many will die. So the town is cordoned off.

Before this happens and the first signs that something is amiss emerge, the citizens of the town of Oran, Algeria, remain oblivious, for they “work hard, but solely with the object of getting rich.” Bored by their habits, heavily drugging themselves with drink, and watching many movies to distract themselves, they failed to grasp the significance of “the squelchy roundness of a still-warm body” of the plague-bearing rats that emerge from their underworld to die in their streets.

“It was as if the earth on which our houses stood were being purged of their secret humors; thrusting up to the surface the abscesses and pus-clots that had been forming in its entrails.”

To them the plague is “unthinkable,” an abstraction, until all their denials are swept aside as the truth emerges from the sewers and their neighbors and families die from the disease.

“Stupidity has a way of getting its way;” the narrator, Dr. Rieux tells us, “as we should see if we were not always so wrapped up in ourselves, plagues and wars take people equally by surprise.” The American people are wrapped up in themselves. Nor do they recognize the true rats. They are easily surprised; fooled would be a better word.

Camus uses a physical plague to disguise his real subject, which is the way people react when they are physically trapped by human rats who demand they obey orders and stay physically and mentally compliant as their freedom is taken from them.

The Plague is an allegorical depiction of the German occupation of France during World War II. Camus had lived through that experience as a member of the French Resistance. He was a writer and editor of the underground Resistance newspaper *Combat*, and with his artist’s touch he later made *The Plague* a revelatory read for today, especially for citizens of the United States, the greatest purveyor of the plague of violence in the world.

We are all infected with the soul-destroying evil that our leaders have loosed upon the world, a plague of killing that is now hidden behind the Wuhan Flu panic that is being used to institute tight government controls

that many will come to rue in the months ahead, just as happened after the attacks of September 11, 2001.

The Wuhan Flu is a perfect cover-story for the occupation of the public's mind by a propaganda apparatus that has grown even more devious over the past nineteen years.

Ask yourself: Where is the news about US military operations in Syria, Afghanistan, Yemen, Iraq, eastern Europe, Africa, Latin America, Asia, et cetera? There is none in the corporate mainstream media, and little in the alternative media as well. Have those operations ceased? Of course not. It's just that the news about them, little that it was, has disappeared. Now it is all about us and the Wuhan Flu. It is about how many of us might die. It is about stocking toilet paper. For the rich, it is about getting to their second or third houses where they can isolate themselves in splendor.

As I write, 50,000 or so Americans are claimed to have died of the Wuhan Flu, and by the time you will read this the number will have climbed, but the number will be minuscule compared to the number of people in the USA and those numbers will be full of contradictions that few comprehend unless, rather than reacting in fear, they did some comprehensive research. But arguments are quite useless in a time of panic when people are consumed with fear and just react.

For we live in plague time, and the plague lives in us. But to most Americans, the Wuhan Flu is the plague, because the government and media have said it is. Like the inhabitants of Oran, the United States is "peopled with sleep walkers," pseudo-innocents, who are "chiefly aware of what ruffled the normal tenor of their lives or affected their interests." That their own government, no matter what political party is in power—both working for deep-state, elite interests led by the organized criminals of the CIA—is the disseminator of a world-wide plague of virulent violence, must be denied and divorced from consensus reality.

When it comes to the plague-stricken deaths visited on millions around the world for decades by the American government, this must be denied by diverting attention to partisan presidential politics, and now the Wuhan Flu that engenders fear, loathing, and a child-like tendency to believe Big Brother. The true plague, the bedrock of a nation continually waging wars through various means—i.e. bombs and economic and medical sanctions, et cetera—against the world, disappears from consciousness. As the US Secretary of State said to 60 Minutes' Lesley Stahl in 1996 when asked if the US sanctions on Iraq that had resulted in the death of 500,000 Iraqi children were worth it:

"We think the price is worth it."

For “decent folks must be allowed to sleep at night,” says the character Tarrou sarcastically; he is a man who has lost his ability to “sleep well” since he witnessed a man’s execution where the “bullets make a hole into which you could thrust your fist.” He awakens to the realization that he “had an indirect hand in the deaths of thousands of people.” He loses any peace he had and vows to resist the plague in every way he can.

“For many years I’ve been ashamed, mortally ashamed, of having been, even with the best intentions, even at many removes, a murderer in my turn.”

The rats are dying in the streets. They are our rats, diseased by us. They have emerged from the underworld of a nation plagued by its denial. Unconscious evil bubbles up. We are an infected people. Worry and irritation—“these are not feelings with which to confront plague.” But we don’t seem ashamed of our complicity in our government’s crimes around the world. For decades we have elected leaders who have killed millions, while business went on as usual. The killing didn’t touch us. As Camus said:

“We fornicated and read the papers.”

He knew better. He warned us:

“It’s a wearying business being plague-stricken. But it’s still more wearying to refuse to be it. That’s why everybody in the world looks so tired; everyone is more or less sick of plague. But that is why some of us, those who want to get the plague out of their systems, feel such desperate weariness.”

Yet the fight against the plague must go on. Tarrou puts it thus:

“All I maintain is that on this earth there are pestilences and there are victims, and it’s up to us, as far possible, not to join forces with the pestilences. That may sound simple to the point of childishness; I can’t judge if it’s simple, but I know it’s true.

You see, I’d heard such quantities of arguments, which very nearly turned my head, and turned other people’s heads enough to make them approve of murder; and I’d come to realize that all our troubles spring from our failure to use plain, clear-cut language. So I resolved always to speak—and to act—quite clearly, as this was the only way of setting myself on the right track.”

These days, I keep thinking of an incident that occurred when I was a young investigator of sexually transmitted diseases, working for the US Department of Health, Education, and Welfare through the Public Health Service as an epidemiologist. My job was to track down sexually transmitted diseases by finding links of sexual contacts.

One day I went to interview and take a blood sample from a poor woman who had been named as a sexual contact. I knocked on her door on the third or fourth floor of a walk-up apartment building. She looked through the peep hole and asked who it was and I told her my name and what government agency I represented. I could tell she was very wary, but she opened the door. She stood there naked, a very heavy woman of perhaps 300 pounds. She nonchalantly welcomed me in and I followed her as she padded down the hall where she took a housecoat off a hook and put it on.

There is, as you know, an old tale by Hans Christian Anderson called “The Emperor’s New Clothes.” Although the emperor parades around naked, the adults make believe he is clothed. Only a child sees the obvious. I was a 23-years-old naïve young man at the time of this unforgettable incident, but it echoes in my mind as a reminder to myself that perhaps that woman was unconsciously teaching me a lesson in disguise.

The year was 1967, and when I went out to get into my government car with federal license plates—a white man in a white shirt in a white car in a poor black neighborhood—a hail of bricks rained down toward me and the car from the roof opposite. I quickly jumped in and fled as the ghettos were exploding. Soon the National Guard would be called out to occupy them.

Intuition tells me that although the emperor has no clothes and a vast psyops occupation is now underway, too many are too grown-up to see it. It’s an old story continually updated. Like *The Plague*.

CNN recently trotted out Hollywood actor Sean Penn to give the nation expert advice on how to deal with the Wuhan Flu. Did they do this because we live in a meaningless, godless universe where madness reigns and everything is chaos? Close, but no. They wanted Penn to explain to the public that it would be wonderful if the US military were deployed inside US borders to deal with the Wuhan Flu panic, because the US military is the greatest humanitarian force on planet Earth.

“There is no greater humanitarian force on the planet than the United States military. The logistical skills, commitment to service, their care for the people. It’s really time to give the military the full breadth command and control of this operation. I wouldn’t blink, I would have put command and control in their hands a month ago, certainly today.”

The US military is in fact one of the least humanitarian forces on this planet, second only to malaria-laden mosquitoes—and even that’s debatable. No other force is circling the globe murdering people in countless undeclared military entanglements and bullying the world into complying with the interests of a nationless alliance of plutocrats and opaque government agencies at the expense of ordinary humans everywhere. They are the exact opposite of a humanitarian force on this planet.

Medical staff are a force for humanitarianism on this planet right now. Grocery store clerks are a force for humanitarianism on this planet. The US military are the armed thugs of a metastatic globe-sprawling empire run by sociopaths.

Don’t say ‘Thank you for your service’ to veterans whose only contribution to humanity has been helping to murder people for imperialist fossil fuel control agendas and Raytheon profit margins. Say ‘Thank you for your service’ to your local cashier. To do the former is to participate in a cruel collective propaganda operation which only encourages more young people to hurl their bodies into the gears of the US war machine in search of the respect and honor you’re displaying, while to do the latter is to thank someone for actually providing a crucial service to human beings.

The malfunction in Penn’s mind is the result of many malignant factors, but among them is the fact that people who rise to fame and fortune naturally experience a gravitational pull toward elitist echo chambers which cultivate narratives that favor the status quo which gave rise to their fame and fortune. You have a hard time hanging out with normal people because most of them don’t treat you normally anymore, so you find yourself spending time with other rich and famous people, and with people who have a vested interest in the rich and famous.

This dynamic naturally fosters an environment where celebrities are eager to believe positive stories about the system which favors them, and where narrative managers are eager to circulate those stories among influential voices. This is why, with very few exceptions, the closest you’ll ever get to seeing a Hollywood celebrity express an anti-establishment opinion is one of them saying “Fuck Trump” at the Tony Awards. It’s also why every few weeks you’ll see some celebrity tweet something disgusting and then go into a meltdown when thousands of ordinary people react with revulsion; they don’t have ordinary people in their lives giving them feedback on what’s normal anymore, all they have is the elitist echo chamber.

This echo chamber is what led a group of self-quarantining celebrities to believe it would be an awesome idea to share a video compilation where they all badly sing lines from John Lennon’s “Imagine” from inside their mansions with a world full of people who’ve been laid off from their jobs and

are terrified for their futures. The figuratively and literally tone-deaf video was universally panned and people have been mocking it on social media ever since its release, which probably would have come as a surprise to the celebrities themselves since nothing in their insulated day-to-day lives would have told them they could all be collectively rejected with such disgust.

The celebrity “Imagine” project was spearheaded by Israeli actress Gal Gadot, who as an IDF veteran would not have required any Hollywood echo chambering to have undergone deep psychological programming in favor of the empire. Gadot, who famously came under fire for publicly cheerleading the 2014 Gaza massacre, first shared the video on Instagram with the caption “We are in this together, we will get through it together. Let’s imagine together. Sing with us.” Memesters have of course been having fun with this.

Then you’ve got celebrities like Rob Reiner:

“No more fucking around. We’re standing on a precipice. Time to consider a Federal lockdown.”

Reiner is one of the more ham-fisted of the right-wing Democrats who we first saw promoting Russia hysteria, and are now promoting drastic totalitarian measures from their high-profile platforms. If you still hadn’t seen these people for what they are yet, you should definitely be seeing them now.

It is an absolute guarantee that powerful people will use this panic to advance authoritarian measures which they have no intention of rolling back once the Wuhan Flu news cycle is over. They are working to do this currently. This is not a possibility, this is an absolute certainty. We need to make sure we slam on the brakes long before we yield any more ground to the authoritarians than they’ve already shored up over the years. And we need to loudly shout down any celebrities who try to tell us otherwise.

Hollywood is a giant propaganda mill which when it isn’t cranking out movies which are literally funded and controlled by the US war machine is putting on spectacular ninety-minute ‘The global world order is perfectly sane and capitalism is totally working’ infomercial presentations. It is an arm of cultural control which is unrivaled by anything else in this world, so of course it has powerful forces at work within it ensuring status quo loyalism.

Whoever controls the narrative controls the world, and Hollywood celebrities are psyops wrapped in human skin. May our collective disgust with them continue to grow.

The problem is, when this is all said and done, what narrative-mongers seem so often to ignore, likely because they never pay any real price, is that

everything they do has consequences. Words have power, framing has power; they know this, that is why they write and speak the way they do. To use that power so frivolously, carelessly, manipulatively—it's unacceptable.

When the Wuhan Flu panic has finally been exposed for what it is, what remains is the terror, the stress, the fear, manufactured by you sniveling scyphantic propagandists. And you'll all rush to defend your actions, not a fucking one of you will admit that you were wrong—the type of wrong where you just go the fuck away for awhile and reflect on what you've done. No, you'll spin, you'll blame, 'how could we have known?' There were voices telling you, in real time, from the start, how wrong you were. You silenced, marginalized, mocked those voices. That was you. You did that, this is your fault. Your one job is to ensure full understanding of issues, not just an understanding that furthers your own agenda. You can have an agenda—we certainly do—but show some fucking humility for fucks sake.

The common cold, as its name indicates, is the most common human infectious disease and affects people all over the globe. Adults have typically two to three infections per year, and children even more. Rates of symptomatic infections increase in the elderly due to reduced defense mechanisms. Over 200 virus types are implicated, the main ones being rhino-, corona-, adeno- and entero-viruses as well as influenza, parainfluenza, human respiratory syncytial and metapneumoviruses.

Studies out of different countries were reviewed, showing that coronaviruses are present year after year in 7–15% of winter respiratory tract infections (RTI). Every year indeed, these common cold viruses invade the planet in wintertime of the northern hemisphere and mutate to get entry into our organisms, and reproduction inside our cells. We are thus dealing with a cyclic viral planetary invasion with high contagious capacity, in this sense a pandemic, which, because it is so well known and most of the time benign, activates no significant fears in the population and most of the time low interest from microbiologists.

Like SARS of 2002–2003 and the MERS virus of 2012, the Wuhan Flu is a coronavirus which is thought to have mutated from an animal. The next essential characteristic of a virus, after its contagiousness, is its lethality for the human population. A study just published finds that common (i.e. pre-Wuhan Flu mutation) coronaviruses had in France an estimated mortality of 0.8% in 2016. They analyzed, in addition, four common coronavirus strains between 2013 and 2020, which had mortalities between 0.36% and 2.7% (381 other corona strains diagnosed before 2017 were not assigned to this study). The Wuhan Flu displays no higher mortality than its older companions. It must be realized, however, that viral RTIs can be threatening to old, sick, and weakened human beings. The mortality rate of the common cold can

go as high as 8% in elderly nursing homes.

We have at the time no idea of the presence (prevalence) of the Wuhan Flu in the human population. The journal *Le Monde* published a detailed review of 26 countries showing on average 10% of tests being positive, and others cite values between 10–15%. Recall that the presence of common cold coronaviruses in yearly RTIs worldwide is 7–15%. Common cold viruses display a high contagiousness level, due among other factors to the fact that a large majority of their infections, estimated between 80% and 99.5%, are non- or mildly-symptomatic.

As around 20–40% of the population get an RTI in winter, we are led to the conclusion that a very large proportion of the population must harbor common cold viruses including the Wuhan Flu corona strain. Confirming this line of thought, some studies are suggesting that a large part of the population has already been infected by the Wuhan Flu, going through a mild or an asymptomatic infection.

Stress has been shown to be at the source of cell losses in the limbic (behavioral) brain of animals. It is in position to activate excitotoxic, oxidative, immunological, inflammatory, endocrine and vegetative mechanisms, and to cause in certain conditions the potentially fatal failure of multiple organs. One such situation has been described by ethnologists in the context of a ritual performed by the “kurdaitcha man.” It is called “pointing the bone” and causes the so-called “self-willed death,” or “bone-pointing syndrome.” A ritual bone is pointed at the victim, which activates the effect of a “spear of thought” and kills the cursed person over days to weeks, without great suffering. This ritual may have served kurdaitcha men over the millennia when a member of their community would become dangerous. The power of an idea and its related emotion, i.e. fear, is exemplified here in a most impressive and definitive way.

We propose to consider the possibility, in the context of the Wuhan Flu crisis, that a planetary ‘spear of thought’ loaded with fear and capable to kill is active now and threatens the whole of mankind, inducing among other things the development of alveolar and interstitial pneumopathy (AIP) and provoking fear-based chain reactions all over the world. Pre-existing and facilitating factors may be the threat of human extinction by a killer virus as shown impressively in disaster movies, and a current feeling of a doomed and dismal planetary state due to pollution. Images have been displayed all over the world of bad science fiction scenes, with human silhouettes installed in beds surrounded by alien-looking fully masked and dressed-up doctors and nurses, dead streets swept with gross disinfectant systems, the close-up picture of the initiating Chinese doctor with panicky eyes over a ventilation device, “state of war” declarations to the virus by politicians, faked Italian

(but just like all capitalist propaganda, we're sure they've adapted this trope to whatever country you reside in) messages as the one from a mother wanting to convince her child to stay home, emergency military tents filled with persons waiting for the verdict of their test, et cetera.

In addition, it is interesting to consider that both SARS in 2003 and the MERS in 2012 were coronaviruses: they may have paved the way toward a sensitivity of the human environment to a respiratory threat. They were rated as dangerous because they had a high mortality, although their propagation was very limited with a death toll of 770 (SARS) and 850 (MERS) patients worldwide.

The elements for panic generation were in place: death by a killer virus, economic failure and chaos, loss of familial and social support, loss of freedom and isolation due to lockdown measures, helplessness, uncertain future for the human civilization, and the overwhelming fear of losing a loved one without being able to say goodbye. Like the man cursed by the pointing of the bone of the kurdaitcha, the current spear of thought seems to be able to hit different body targets and induce multiple organ failure: for example, cardiomyopathy is described in the high percentage of 33% of Italian patients. Fear and anxiety are felt typically at the cardio-respiratory level, with dyspnea (choking feeling) and heart palpitations.

Let us imagine a person, for example in the north of Italy in February 2020, breathing in some of the most dirty air in the country, coughing and unwell from an RTI. An immediate fear of getting infected by the Wuhan Flu virus arises and dominates his mind. Of course, I take here the example of a man, as the infection risk is higher for males—or so they say! He heard, announced the day before by the WHO, that this virus kills more than the flu (against which he is vaccinated, being 70 years old). He knows that policemen closed the village where he lives, forbidding entry and exit. Being a good citizen, he announces that he suspects a Wuhan flu infection and is taken to the local hospital. At arrival, he is placed in a probably uncomfortable and cold tent, in the middle of other fearful citizens, and his Wuhan Flu test is performed. Other people cough around him, and he waits for the sentence. His heart beats hard and it seems that he cannot breathe well.

His test being positive, he is taken into the hospital by an efficient but stressed medical team, and gets surrounded by masked nurses. He realizes that he is now no longer free to leave this whole nightmare, to get back home. Panic raises its dreadful head, and his defense mechanisms fall down, opening the way to a full-blown—and at his age threatening—viral infection. In this state, our patient may experience one of the three following scenarios:

1. He keeps an upper RTI, with a bit of fever, a solid cough through bronchitis, some difficulty to swallow, and a full nose. He is kept isolated in the hospital, the staff remains efficient but stressed, very busy and distant, and he stays alone with his fears to get full-blown choking feelings leading so many to the intensive care unit and ventilator. He cannot get visits from his family and he stays sick with a solid RTI for the next two weeks. Most probably, this experience will stay imprinted forever in his emotional brain.
2. His age, his long-standing suboptimal pulmonary function, his significant obesity, precipitate a bronchopneumonia with combined viral development and bacterial secondary infection by nosocomial germs, leading to death in a few days. He dies without a last contact with his wife and children.
3. The viral attack on his pulmonary system is moderate and the tissues there begin to recover in the proper manner over a week. He keeps a deep feeling of fear and doom, dyspnea arises, a scan is performed showing the presence of an AIP, and he is taken to the intensive care unit. Over the next few days, the 'spear of thought' proceeds flying, his pre-existing suboptimal health state limits his resources to overcome the reanimation phase, secondary infections arise, heart failure and failure of other organs develop and he dies, far away from his family.

No matter what, around him and at home, other patients suffering from other health problems are treated suboptimally, all energy, material and staff being concentrated on the Wuhan Flu crisis. It is easy to understand how hospital staffs will be submitted to a huge overload:

1. Worried people flow into hospitals, increasing the workload of the medical and nursing teams.
2. Teams are reduced by the absence of burned-out collaborators, by the quarantine of others, and in some situations by the ones kept away by the closing of borders. Again stress and panic develop and create the pervasive impression of exceptional and uncontrollable chaos.

The existence of SARS and MERS episodes in 2003 and 2012 could point to the possibility of mutations of the Wuhan Flu toward a particular pulmonary affinity. Three same or similar, allegedly random mutations are however not likely, and we favor in this context the hypothesis mentioned above of sensitivity of the human environment to a respiratory threat, a spear of thought loaded with fear and threatening the whole human planet.

Of course, you run something through thousands of weasels enough times and who knows what comes out the other side. . .

A dominant characteristic of fear is to always favor information that maintains or amplifies it and repress information which does not. Could it be the reason why the Scandinavian experience is rarely mentioned and if yes, qualified as being nonethical, without discussion of the pros and cons and the risk/benefit ratio of the confinement approach? Fear does not allow good science to be performed, and we badly need good science, now and tomorrow.

We have been given a very clear narrative about the declared Wuhan Flu pandemic. The UK State has passed legislation, in the form of the Coronavirus Act, to compel people to self isolate and practice social distancing in order to delay the spread of the Wuhan Flu. We are told this “lockdown,” a common prison term, is essential. The mainstream media (MSM) have been leading the charge to cast anyone who questions the State’s Wuhan Flu narrative as putting lives at risk. The claim being that questioning what we are told by the State, its officials, and the MSM undermines the lockdown. The lockdown is, we are told, essential to save lives.

It is, however, possible both to support the precautionary principle and question the lockdown. Questioning the scientific and statistical evidence base, supposedly justifying the complete removal of our civil liberties, does not mean those doing so care nothing for their fellow citizens. On the contrary, many of us are extremely concerned about the impact of the lockdown on everyone. It is desperately sad to see people blindly support their own house arrest while attacking anyone who questions the necessity for it. The knee jerk reaction—assuming any questioning of the lockdown demonstrates a cavalier, uncaring disregard—is puerile. Grown adults shouldn’t simply believe everything they are told like mindless idiots. Critical thinking and asking questions is never ‘bad’ under any circumstances whatsoever.

If a system cannot withstand questioning it suggests it is built upon shaky foundations and probably not worth maintaining. Yet perhaps it is what we are not told that is more telling. Among the many things we are not told is how many lives the lockdown will ruin and end prematurely. Are these lives irrelevant? Where are the flashy models and the virtuous tweets and the think-pieces and the outraged questioning by media during press briefings? We are not told that the numbers of deaths reportedly caused by the Wuhan Flu is statistically vague, seemingly deliberately so; we are not told that these deaths are within the normal range of excess winter mortality; we are not told that in previous years excess winter deaths have been higher than they are now. We didn’t need to destroy the economy in response to those periods of loss so why do we need to do so for this?

Before we address what we are not being told, it's worth looking at how the MSM is spreading disinformation. On February 22nd one rag printed a story which absurdly alleged, without a shred of evidence, that Russia was somehow deliberately spreading disinformation about the Wuhan Flu. It reported this uncritically, questioning nothing. Their opening paragraph read:

“Thousands of Russian-linked social media accounts have launched a coordinated effort to spread misinformation and alarm about the Wuhan Flu, disrupting global efforts to fight the epidemic, US officials have said.”

On March 10th the same rag reported another story about disinformation in which it was noted:

“Disinformation experts say, there remains little evidence of concerted efforts to spread falsehoods about the virus, suggesting that the misleading information in circulation is spread primarily through grassroots chatter.”

The irony shouldn't be overlooked. Directly contradicting their own previous disinformation, this MSM pulp assumes we are all so stupid we won't notice their perpetual spin and evidence-free claims. The UK's national broadcaster—the BBC—is perhaps the worst of all the disinformation propagandists. The sheer volume of disinformation they are pumping out is quite breathtaking.

The United Nations Universal Declaration of Human Rights spells out what freedom of expression means. All human beings are born free with equal dignity and rights. All are afforded these rights without any distinction at all. Article 19 states:

“Everyone has the right to freedom of opinion and expression; this right includes freedom to hold opinions without interference and to seek, receive and impart information and ideas through any media and regardless of frontiers.”

The BBC, who obviously couldn't care less about human rights, gleefully supported the censorship of so called conspiracy theorist David Icke. They did so by spreading disinformation. Icke raised concerns about the possible link between 5G and the spread of the Wuhan Flu. He did not incite violence, as suggested in the BBC's disinformation. The BBC misled the public utterly when they stated:

“Conspiracy theories linking 5G signals to the Wuhan Flu pandemic continue to spread despite there being no evidence the mobile phone signals pose a health risk.”

While I agree with the BBC that there is no evidence of a link between 5G and the Wuhan Flu, we certainly can't rule it out. Because the second half of their statement, that there is no evidence that mobile signals pose a health risk, was a mendacious deceit. There is a wealth of evidence of that risk. The leading medical journal *The Lancet* noted these risks in 2018:

“... mounting scientific evidence suggests that prolonged exposure to radiofrequency electromagnetic radiation has serious biological and health effects.”

Why are the BBC so willing to mislead the public and expose them to unnecessary health harms? Is it deliberate or are they just shoddy journalists? Either way, quite clearly they are habitual peddlers of disinformation. They appear to no better than the worst clickbait sites that have proliferated over recent years. The MSM is responsible for the majority of misinformation and disinformation circulating at the moment. We must diligently verify every claim they make and check the evidence ourselves. They are not to be trusted. As the BBC quite rightly points out:

1. Stop Before You Share
2. Check Your Sources
3. Pause if You Feel Emotional

Some additional tips: If it's the MSM check to see if they offer any evidence at all or if it's just their opinion. If it's their opinion, ignore it. It's almost certainly unfounded. And, if you do feel emotional you have probably just been manipulated by the MSM.

I don't know about you, but I remain unconvinced by the evidence I've seen so far. I have no doubt that there is a health crisis and excess seasonal deaths, but I have seen no evidence at all that the numbers are unprecedented or unusual in any way. I accept that we should exercise the precautionary principle and take steps to limit the risks to the most vulnerable but I do not accept that the lockdown is the best way to go about it. Nor do I see any necessity at all for all the other dictatorial clauses in the Coronavirus Act. I do not consent.

If you think this will all be over soon and won't get worse, I'm afraid you may be disappointed. The UK state have based this lockdown on the scientific rubbish spewed out by ICL. Here's one of the ICL's recommendations:

“The major challenge of suppression is that this type of intensive intervention package—or something equivalently effective at reducing transmission—will need to be maintained until a vaccine becomes available (potentially 18 months or more).”

There is nothing to suggest this isn't the intention of the State. Certainly voices in the US are already indicating their desire for an 18-month lockdown—apparently taking their cue directly from the discredited ICL report and steadfastly ignoring everything else. Nor should we assume the draconian powers seized by the state won't get worse.

Most of this response is being driven by globalist policy emanating, on this occasion, from the World Health Organization. Speaking at the daily WHO press briefing Dr. Michael Ryan, Executive Director of the WHO Health Emergencies Programme, said:

“Lockdowns and shutdowns really should just be part of an overall comprehensive strategy. Most of the transmission that's actually happening in many countries now is happening in the household at family level. Now we need to go and look in families to find those people who may be sick and remove them and isolate them in a safe and dignified manner.”

Given that we now live in a de facto dictatorship there's no reason to believe that states across the globe won't use this as justification to start removing people from their homes. My hope is that sense will prevail and, as it becomes clear the pandemic is waning, public pressure will mount to repeal this dictatorial legislation. However, given some of the comments I have seen on social media over the last two weeks, the panic buying, and attacks upon anyone questioning the State's narrative, it seems many people are so frightened they desperately need to believe the State is trying to save them.

This fear is based upon apparent ignorance of the economic severity of the lockdown and the monumental health risk it poses. People don't seem to want to know there is considerable doubt the Coronavirus Act is even legal in international law. There is also doubt that the Wuhan Flu is an identifiable virus and the statistics we are given may well be based upon tests that can't identify it anyway. There is evidence that the statistics we have been given have been deliberately manipulated to exaggerate the health risk and there is no evidence these excess deaths are “unprecedented.”

Effectively, a small group of policy decision makers have placed an estimated 3.5 billion people under house arrest. It is only possible for them to do so with our consent. Consent is carefully cultivated by controlling the

information we are given. For the vast majority their only source of information is the corporate mainstream media and the public announcements of the State. Evidence strongly suggests the State and the MSM, adhering to a globalist agenda, have colluded to mislead the public into believing the Wuhan Flu threat is far greater than it actually is.

The Wuhan Flu can be fatal for those with pre-existing comorbidities, and possibly even some without, as can other forms of pneumonia and influenza-like respiratory illness. However, while every Wuhan Flu death has been reported, none of the far greater number of people who have died in this year from other respiratory infections have even been mentioned.

Systems have been created to ensure the Wuhan Flu statistics are as terrifying as possible. Their statistical product is so vague it borders upon meaningless. It seems we have been inculcated with misplaced fear to justify the lockdown regime, to convince us to accept it and prepare us for what is to come.

The World Health Organization (WHO) is financed through a combination of assessed and voluntary contributions. Assessed contributions are paid by nation states for WHO membership and figures are released quarterly. Voluntary contributions are additional contributions from member states and “other partners.” For some reason these figures haven’t been reported for more than three years. About 80% of the WHO’s finances come from voluntary contributions. In its most recent 2017 voluntary contribution report the WHO accounted for the \$2.1 billion it received from private foundations and global corporations. This compared to just over \$1 billion voluntarily provided by governments. Contributors included GlaxoSmithKline, Bayer AG, Sanofi, Merck and Gilead Sciences whose drug remdesivir is currently being trialed, alongside the off-patent hydroxychloroquine, as a possible preventative treatment for the Wuhan Flu. The remdesivir trial is part of the WHO’s SOLIDARITY trials. The third-largest single contributor in 2017 was GAVI. Formerly called the Global Alliance for Vaccines and Immunization, they contributed nearly \$134 million. GAVI are partnered with the WHO, UNICEF, the Gates Foundation and the World Bank to sell vaccines globally. The World Bank contributed nearly \$146 million themselves and the largest individual payment, by some margin, at nearly \$325 million came from the Bill & Melinda Gates Foundation. Though like many other foundations and corporations, through their various networks of interlinked partnerships, their overall contribution was much higher.

Among other beneficiaries of the Gates Foundation’s generosity are the Vaccine Impact Modeling Consortium (VIMC) led by Professor Neil Ferguson. They are based at Imperial College London and are directly funded by the Gates Foundation and GAVI. Their objective is to provide

statistical data analysis for the Gates Foundation and GAVI in order for them to sell more vaccines. Ferguson not only led the team who created the hopelessly inaccurate prediction which the US and UK governments based their lockdown regimes upon, he also co-founded the MRC Centre for Outbreak Analysis and Modeling which worked with the WHO in 2009 to create ridiculous computer models predicting the H1N1 pandemic.

In 2009 the world went crazy after the WHO declared the H1N1 influenza pandemic. This resulted in billions being spent on very expensive H1N1 vaccines and antiviral treatments although it turned out the pandemic was indistinguishable from seasonal flu. The only people who benefited from pointless vaccines and unnecessary medication were the manufacturers GlaxoSmithKline, Roche, and Novartis. Each of these pharmaceutical corporations were among the largest voluntary contributors to the WHO in FY2008–2009. With an \$84 million investment, the Swiss pharmaceutical giant Roche were the largest single contributor into the WHO's coffers that year. Luckily, as it turned out, they could afford it because sales of their unnecessary Tamiflu H1N1 medication rocketed to more than £3 billion following the WHO's declared H1N1 pandemic. Which was just a coincidence. The whole debacle resulted in the Parliamentary Assembly of the Council of Europe (PACE) launching an investigation into the WHO to look into the issue of a "falsified pandemic."

"The WHO basically held the trigger for the pandemic preparedness plans, they had a key role to play in deciding on the pandemic. Around 18 billion dollars was spent on this pandemic worldwide. Millions were vaccinated for no good reason. It is not even clear that the vaccine had a positive effect, because it was not clinically tested."

"A number of scientists and others are questioning the decision of the WHO to declare an international pandemic. The H1N1 virus is not a new virus, but has been known to us for decades. In Germany, about 10,000 deaths are attributed to seasonal 'flu,' especially among older and frail people. Only a very small number of deaths, namely 187, can be attributed to the H1N1 virus in Germany—and many of those are dubious."

Of course nothing came of it because PACE were making allegations against the World Health Organization. The WHO don't break the rules, they make the rules. Amazingly, probably because no one ever learns anything from history—with the help of a for-profit media which fails

consistently to provide actual informative context—we all believed the WHO this time.

To imagine these huge investments made by pharmaceutical corporations and private foundations don't buy influence is so naive it barely warrants mention. The WHO is essentially a policy lobby group for the powerful globalists who own it. Why an organization with such significant and clear conflicts of financial interests should be considered a global health authority is anyone's guess.

“WHO continues to call on all countries to implement a comprehensive approach with the aim of slowing down transmission and flattening the curve. This approach is saving lives and buying time for the development of vaccines and treatments. As you know, the first vaccine trial has begun. This virus is presenting us with an unprecedented threat”

The Wuhan Flu is not an unprecedented threat.

Everyday, for weeks, the MSM has reported every single UK death which was supposedly due to the Wuhan Flu. This has been central to their effort to convince us of the severity of the pandemic. The reporting always supports the State's narrative that the lockdown is necessary.

Under normal circumstances, when someone dies, a person who knows them well, such as a family member, or someone who was physically close to the person at the time of death, is the qualified informant who can notify the registrar of the circumstances and non-medical details of the death. That is not true for suspected the Wuhan Flu patients. For them a funeral director, who has almost certainly never met the deceased, can be the qualified informant. This places far more emphasis on the Medical Certificate of Cause of Death (MCCD) as registration can take place without any input from family or anyone else familiar with the circumstances of the death.

When an MCCD is completed the medical causes are listed sequentially with the immediate cause of death at the top and the underlying cause of death at the bottom of the list. For example, heart failure caused by pneumonia stemming from influenza would list the immediate cause of death as a 'heart attack' and the underlying cause as 'influenza.' That underlying cause is usually diagnosed through positive test results. It is crucial to understand that for the Wuhan Flu to be recorded on the MCCD as the underlying cause of death, there does not need to be any test-based diagnosis of the syndrome. Diagnosis can simply be from observation of symptoms or CT scans.

Even when a sample test is undertaken to identify the Wuhan Flu, questions remain. The RT-PCR test commonly used to test for the Wuhan Flu does not appear to be very reliable, nor is it designed as a diagnostic tool for identifying viruses. A study found wild variations in RT-PCR accuracy. It was found to be between 22–80% reliable depending on how it was applied. This general unreliability has been confirmed by other studies. Further studies show clear discrepancies between RT-PCR test results and clinical indication from CT scans.

Most of these studies indicate RT-PCR failure to detect the Wuhan Flu in symptomatic patients, so-called “false negative” tests. When Chinese researchers conducted data analysis of the RT-PCR tests of asymptomatic patients they also found an 80% false positive rate. Having passed peer review and publication, the paper was subsequently withdrawn for what seem quite bizarre reasons. It was removed from the scientific literature because it “depended on theoretical deduction.” The paper was not testing an experimental hypothesis, it was an epidemiological analysis of the available statistical data. All such statistical analysis relies upon theoretical deduction. The claimed reason for withdrawal suggests that all data analysis is now considered to be completely useless. It seems scientific claims that the Wuhan Flu numbers are underestimated are fine, claims they are overestimated are not. Either way, whether false negative or false positive, there is plenty of evidence to question the reliability of the RT-PCR test for diagnosing the Wuhan Flu.

The MSM has suggested that enhanced RT-PCR testing can detect the virus and, in particular, the amount of it in the patient’s system, the viral load. This is disinformation.

“Quantitative PCR is an oxymoron. PCR is intended to identify substances qualitatively, but by its very nature is unsuited for estimating viral load. These tests cannot detect free, infectious viruses at all. The tests can detect genetic sequences of viruses, but not viruses themselves.”

Reported Wuhan Flu deaths can be registered without a test clearly diagnosing any coronavirus, let alone the Wuhan Flu. The death can be signed off by a doctor who has never seen the patient and can then be registered by someone who has never met the deceased and was nowhere near them when they died. Further provisions then allow for the body to be cremated, potentially against the family’s wishes, ensuring a confirmatory autopsy is impossible, though it is unlikely one will be conducted anyway.

To say this raises questions about the official reported statistics is an understatement. Questions in no way allege either medical malpractice or

negligence. Neither are required for significant confusion to occur because the potential for widespread misreporting of causes of death seems to be a core element of the Wuhan Flu MCCD process the State has constructed.

As I write, the UK is said to have 93,873 cases with 12,107 deaths attributed to the Wuhan Flu. Both the infection and mortality rates are showing a declining trend. Coupled with the data which shows unusually low hospital admissions, with little to no evidence of the widely anticipated “surge,” justification for the State’s lockdown of society and the economy appears painfully thin. The evidence base does not improve when we look at the official data.

The Office of National Statistics (ONS) have released analysis of the Wuhan Flu deaths that occurred during March 2020. In total 3,912 deaths were recorded of which 3,372 (86%) listed the Wuhan Flu as the underlying cause of death. Of these, 38 (1%) were cases where the Wuhan Flu was only suspected as the underlying cause, meaning neither a test nor any clear clinical presentation was observed. The problem is that the RT-PCR test, supposedly confirming the Wuhan Flu, doesn’t tell us much either. Of the 3,372 deaths recorded with underlying the Wuhan Flu, approximately 3,068 had at least one comorbidity with the majority having more than two. Not only does the RT-PCR test fail to provide any reliable proof that these people even had the Wuhan Flu, the existence of other comorbidities provides further reason to question if the Wuhan Flu was a contributory factor. Of the 3,912 people who died, 540 of them merely mentioned the Wuhan Flu on the MCCD with no indication that it contributed to the deaths. With at least 91% of patients having comorbidities, there is very little evidence that the people who died with a Wuhan Flu infection wouldn’t have died without. The age profile of the deceased is practically identical to standard all cause mortality in the UK. If the Wuhan Flu is a viral pandemic it is one that behaves like normal mortality.

And yet, despite all this, the MSM reported every one of them to the public as confirmed Wuhan Flu deaths.

Another, perhaps even more alarming possibility has arisen. While heart disease accounts for 14% of the Wuhan Flu comorbidities, reported deaths from heart disease have mysteriously dropped by the corresponding amount during the same period. This clearly indicates that patients dying from other causes, such as heart failure, are being recorded, and certainly reported by the MSM, as dying from the Wuhan Flu. This illustrates a far more complex picture than we have been given to believe. Why have the State and the MSM made so many alarming claims about people dying from the Wuhan Flu when the evidence supporting those claims is, at best, questionable?

None of this is the fault of medical practitioners or bodies like the Office

of National Statistics (ONS). The ONS system has been both reliable and informative for many years. Yet once again, in the case of Wuhan Flu deaths, the State felt it was necessary to make some changes. On March 30th the MSM reported that the UK State had instructed the ONS to change the way they record Wuhan Flu deaths. This habit of states deciding to change the Wuhan Flu mortality data, by adding in people who are assumed to have died from it, appears to be a global policy. The China CDC did the same and the US have added a significant number to their statistics.

In every case the revision increases and never decreases the fatality statistics. Why do states around the world feel the need to do this? Is it because they are concerned about statistical rigour or are they more concerned about justifying their lockdown regimes?

The ONS reported all cause mortality for week 14 ending April 3rd. They recorded 16,387 deaths which was 6,082 higher than the ONS 5-year average. They stated that 21.2% of total deaths “mentioned” the Wuhan Flu. The MSM immediately pounced on this claiming this meant the Wuhan Flu had pushed up the death toll to unprecedented levels. This was outrageous disinformation. That is not what the data showed.

The ONS stated that of the 6,082 excess deaths 3,475 “mentioned” the Wuhan Flu. Of those 1,466 also mentioned influenza and pneumonia. Consequently, while registered deaths are 6,082 above the 5-year average, only 2,009 of those solely mentioned the Wuhan Flu with 4,073 mentioning other underlying causes. It is worth remembering only the Wuhan Flu deaths can be ‘mentioned’ without a clear positive test result.

Therefore, at least 67% of that excess mortality is being caused by other unknown factors that no one seems to care about. The MSM have absolutely no interests at all in this more severe health crisis. Why not? Once again they have completely misled the public and deny the existence of another, more significant reason for concern. Perhaps anticipating this the ONS stated:

“‘Influenza and Pneumonia’ has been included for comparison, as a well-understood cause of death involving respiratory infection that is likely to have somewhat similar risk factors to the Wuhan Flu.”

For the year to date, the ONS showed a comparison of the deaths mentioning the Wuhan Flu and deaths mentioning pneumonia and Influenza. Deaths this year from pneumonia and influenza appear to stand at around 30,000. Quite clearly, according to the ONS, other respiratory infections, like pneumonia and influenza, currently pose a significantly greater threat to

life than the Wuhan Flu. Something is certainly pushing up mortality in the UK but, at the very most, only 33% of that increase is vaguely attributable to the Wuhan Flu. Short of openly stating that the Wuhan Flu is no more deadly than any other pneumonia like illnesses, the ONS appear to be trying to get a message across. Perhaps they can't say it directly.

As the so called pandemic has progressed, more in-depth studies have begun to emerge. Initial findings from Chinese scientists indicate that the Wuhan Flu has an "infection fatality rate" (IFR) of between 0.04% and 0.12%. which is comparable to flu pandemics with an estimated IFR of 0.1%. None of these have required a lockdown regime. Further studies have highlighted the overestimated risk allegedly presented by the Wuhan Flu.

The MSM have recently started floating the idea that the lockdown regime could become "the new normal." According to the State it may be necessary to go in and out of various levels of the regime from time to time, depending on the State's threat assessment. This is based on scientific research bought and paid for by pharmaceutical corporations and private foundations including GlaxoSmithKline (Wellcome Trust). Seeing as it is increasingly evident that the Wuhan Flu threat has been massively overhyped, why would the State and its globalist partners want the economic destruction to continue? Because it delivers on a number of long held globalist objectives: a cashless society, mandatory vaccination, universal basic income, a surveillance state, restricted freedom of movement, and a complete restructuring of the global economy have already been touted as necessary following the pandemic. All of these ambitions and economic realities existed before the pandemic first emerged in China.

The State and Big Tech have already moved towards censoring anyone who questions vaccines. It is vital to understand that the canard of the antivaxxer is a meaningless trope. It is entirely possible to accept that vaccines can contribute towards effective preventative public health programs while, at the same time, questioning the efficacy and purpose of some vaccines. Vaccines are not all the same. The State's and the MSM's insistence that anyone who question any vaccines is some sort of whacked out, new age, science Luddite is total nonsense. No one will be permitted to question vaccines, and that fact alone should be sufficient to raise anyone's suspicion.

From GAVI to the WHO and from the Gates Foundation to Imperial College the response to the Wuhan Flu pandemic has been driven by foundations and pharmaceutical corporations with considerable investments in vaccine development. Of course they would like to see global mandatory vaccination. To just ignore this, because you've been told by the MSM that questioning any vaccine is a "conspiracy theory," not only evidences a lack of critical thinking, it demonstrates a degree of brainwashing.

Global financial institutions, such as the IMF, have been advocating the cashless society for years. A cashless society will allow central banks to control every aspect of your life. Everything you buy can be tracked and your purchases could easily be limited to exclude certain items. Although there is very little evidence that handling cash presents any increased threat of infection, that hasn't stopped the MSM from selling the idea.

In a cashless society, people who don't behave in accordance with State regulations, could be punished financially. Instant fines will be commonplace. We are already seeing how that control can be deployed within a surveillance society as the State and its compliant MSM put the idea of immunity passports into the public imagination. The link between this and mandatory vaccination is obvious. This proposed policy comes straight from the heart of the globalist think tanks.

ID2020 is a globalist initiative which intends to provide everyone on earth with an authorized identity. GAVI, Microsoft, the Gates Foundation, and the Rockefeller Foundation are among the happy ID2020 alliance who will decide who you are allowed to be. Biometric ID controlled by your friendly ID2020 globalists—Because they care! Comically they claim that proving who you are to the State is somehow a human right. This is utter bullshit. I don't know about you, but I know who I am and so do the people I care about. I couldn't care less who the State thinks I am. Like everyone else on Earth, you were born with inalienable human rights. The State doesn't define what they are, they just choose to ignore them. ID2020 is in no way objective. Your digital biometric ID can be 'good' which means it can also be 'bad.'

“With a 'good' digital identity you can enjoy your rights to privacy, security, and choice.”

Which means you can't if its 'bad.' As long as you are a good citizen, do as you are told, get your mandatory vaccinations and don't step out of line, you can have your rights because megalomaniacs think they are gods who have the power to allow or deny them. Your digital ID will control the information you are allowed to access and your immunity passport will almost certainly be part of your State authorized identity as we move towards something indistinguishable from China's social credit system.

It will be used to monitor your behaviour. Your immunity passport status will depend upon where you go and who with. The State has decided that we all need contact tracing apps to regulate who we meet and limit our freedom of movement. If you meet the wrong person or go to the wrong

area, or perhaps fail to produce your authorization Q-code on demand, then you will be locked down, and maybe tased or beaten.

Perhaps the biggest deception of all is yet to come as the State maneuvers to blame the Wuhan Flu for the economic collapse. The impact of the lockdown regime across the globe has already had a devastating economic impact. All the indicators are that the regime will throw the global economy into a deep depression. The longer it continues the worse it will get. The tendency of some to claim this doesn't matter because saving life is the only concern is hopelessly myopic. The link between poverty and significantly increased mortality is beyond dispute. The cure will definitely be far worse than the disease. As millions are forced into unemployment the outlook isn't good. However, while the State will undoubtedly claim that unemployment has been caused by the Wuhan Flu crisis, in truth the imminent economic collapse was already driving up unemployment before the crisis began.

It isn't the Wuhan Flu but rather the lockdown regime that has sped up destruction of the economy—but that destruction was inevitable anyway. The 2008 credit crunch was a failure of the banks. They speculated in the markets and lost. As a result we have endured a decade of austerity to bail them out. Socialism only applies to those who can afford it. Austerity has reduced essential public services to rubble, and now, when we supposedly need them most, we've all been placed under house arrest to stop us using them while many of the most vulnerable have been ignored. The irony is laughable.

While we've all suffered austerity, the central banks have been printing funny money, blowing up the debt bubble to unimaginable proportions. The result has been increasing consumer debt, staggering levels of corporate borrowing and, though monetarily non-sovereign government deficits have reduced, government debt is off the charts, even in comparison to 2010 levels. This kind of debt-based economy was never sustainable and global financiers have known it for years.

What the globalists needed was a reason to reset the economy without losing power. Perhaps it is another coincidence that the Wuhan Flu lockdown regime just happens to deliver both the mechanism and the excuse to press that global reset button. That it also ushers in all the globalist's desires is just another in a very long line of remarkable coincidences.

Now that global terrorism is no longer a daily threat and global warming has been put on the back burner, the new normal of the ever shifting threat from pandemic seems to be the novel war on terror. Training, funding, and equipping terrorist groups has served the State well in the first two decades of the 21st century but now it is ready to move on to the next phase by exploiting a terror closer to the heart of every home: Disease.

In their totality, for those willing to look, it is transparent that these response measures have coalesced to create the framework for a totalitarian dictatorship. One rolling out at pace in the UK. Similar draconian diktats have sprung up across the globe. A coordinated global effort like this doesn't just happen. It takes years of training and planning. The only people who can't see it are those who, for whatever reason, choose not to.

As if it was planned in advance, billions of people around the globe are being forced step by rapid step into a radically different way of life, one that involves far less personal, physical, and financial freedom and agency. Here is the template for rolling this out.

Step 1: A new virus starts to spread around the world. The World Health Organization (WHO) declares a pandemic. International agencies, public-health officials, politicians, media and other influential voices fan fear by focusing almost exclusively on the contagiousness of the virus and the rising numbers of cases, and by characterizing the virus as extremely dangerous. Within a few days governments at national and local levels also declare states of emergency. At lightning speed they impose lockdown measures that confine most people to their homes—starting with closing schools—and shut down much of the global economy. World markets implode.

The stunned, fearful and credulous public—convinced over the previous few years that their bodies do not have the natural ability to react to pathogens by producing antibodies that confer long-lasting immunity—largely complies willingly.

The first weekly virtual class on local emergency and crisis responses to the Wuhan Flu is held for mayors and other city officials around the world. Coordinated by a handful of American organizations in the academic, medical, financial, political, and transportation spheres, the classes feature guests ranging from Barack Obama to Bill Gates.

Step 2: National, state/provincial, and municipal leaders, as well as public-health officials, start daily press briefings. They use them to pump out frightening statistics and modeling asserting the virus has the potential to kill many millions. Most of this information is hard to decipher and sheds little real light on the natural course of the virus's spread through each geographic area. Officials and media downplay or distort inconveniently low death tolls from the virus and instead focus on alarming statistics produced by compliant academics, social-media influencers, and high-profile organizations. The main message is that this is a war and many lives are at stake unless virtually everybody

stays at home. Mainstream media amplify the trope that the world is at the mercy of the virus.

Simultaneously, central banks and governments hand out massive amounts of cash, largely to benefit the big banks. And they bring in giant private-sector financial firms to manage the process despite these global companies' very poor track record in the 2008–2009 crash. Governments also rapidly start to create trillions of dollars worth of programs that include compensating businesses and workers for their shutdown-related losses.

Step 3: There is a concerted effort by all levels of government and public health to very rapidly ramp up testing for viral RNA, along with production of personal protective equipment. They push aside the need for regulation—including quality standards and independent verification of tests' rates of accuracy—by insisting that fast approval and roll-out are imperative for saving lives.

Models are released that predict snowballing of numbers of cases, hospitalizations, and deaths even under best-case scenarios. At about the same time, public-health officials significantly loosen the criteria for viral infections, outbreaks, and deaths, particularly for the oldest members of society. That increases the numbers of cases and deaths ascribed to the new pathogen.

The media continue to clamour for more testing and for severe punishment of people who aren't completely compliant with the lockdown measures. As a result, there's little backlash as police and military with sweeping new powers enforce these measures and give stiff penalties or even jail terms to those who disobey orders. States also monitor with impunity massive numbers of people's movements via their cell-phones. Vast human resources are focused on tracking down people who have had contact with a virus-positive individual and confining them to their homes. Thus the portion of the public exposed to the virus remains relatively small. It also contributes to social isolation. Among many effects, this enables those in control to even further erase individual and collective choices, voices, and power.

Step 4: When the numbers of cases and deaths start to plateau, local officials claim it's too early to tell whether the virus has finished passing through their population and therefore, restrictive measures must continue. An alternative narrative is that if such measures aren't kept in place there will be a resurgence of cases and deaths. Yet another

is that the continuing climb in elderly persons' deaths means all bets are off for the time being. They admit that initial models incorrectly predicted there would be a tsunami of cases, ICU admissions, and deaths. However, they assert more time is needed before it can be determined whether it's safe to loosen some of the restrictions and let children return to school or adults go back to work. Officials do not try to calculate the overall skyrocketing cost to their populations and economies of the shut-downs and other measures against, nor do they discuss what cost level may be too high.

They and powerful media organizations also push for the massive virus-testing over-capacity to be used to surveil the general population for viral DNA in their bodies. At the same time, the roll-out begins of widespread blood testing for antibodies to the virus.

Meanwhile, new data are published showing the virus has a high capacity to mutate. Scientists and officials interpret this as meaning a larger medical arsenal will be needed to combat it.

Step 5: About two or three weeks later, the dramatic increase in testing for viral DNA produces the desired goal of a significant upsurge in the number of people found positive for the virus. Public-health officials add jet fuel to the surge by adding to their case and death tallies the large number of people who are only suspected—and not lab-test-confirmed—to have had an infection. Politicians and public-health officials tell the populace this means they cannot return to their jobs or other activities outside the home for the time being.

Governments work with public-health agencies, academics, industry, the WHO and other organizations to start to design and implement immunity-passport systems for using the results of the widespread antibody testing to determine who can be released from the lockdowns. This is one of many goals of the seven steps. Meanwhile, government leaders continue to highlight the importance of vaccines for besting the virus.

Step 6: Large-scale human testing of many different types of antivirals and vaccines begins, thanks to a concerted push from the WHO, Bill Gates and his collaborators, pharmaceutical and biotech companies, governments and universities. Large swaths of the population don't have the antibodies to the virus because they've been kept from being exposed to it; they eagerly accept these medications even though they've been rushed to market with inadequate safety testing. They

believe these medical products offer the only hope for escaping the virus's clutches.

Step 7: Soon the new virus starts another cycle around the globe—just as influenza and other viruses have every year for millennia. Officials again fan the flames of fear by positing the potential for millions of deaths among people not yet protected from the virus. They rapidly roll out virus and antibody testing again, while companies sell billions more doses of antivirals and booster vaccines.

Governments simultaneously cede control of all remaining public assets to global companies. This is because local and national governments' tax bases were decimated during Step 1 and they're virtually bankrupt from their unprecedented spending in the war against the virus in the other steps.

The overall result is complete medicalization of the response to the virus, which on a population level is no more harmful than influenza. This is coupled with the creation of permanent totalitarianism controlled by global companies and a 24/7 invasive-surveillance police state supported by widespread blossoming of "smart" technology.

The key players repeat the cycle of hysteria and massive administration of antivirals and booster shots every few months. And they implement a variation of steps 1 to 7 when another new pathogen appears on the planet.

Sounds far-fetched? Unfortunately, it's not. With the arrival of the Wuhan Flu many countries quickly completed Steps 1, 2 and 3. Step 4 is well under way in a large number of jurisdictions. Step 5 is on track to start in early May.

It is fascinating, if you can, to watch the swirling narratives interact, influence, reinforce, break down. The Wuhan Flu panic is full of such displays. The first, and perhaps most important, is how well capitalism's storytelling has prepared people to overreact to such things. The latest updates become the newest chapter released for an unfinished book, and like a Game of Thrones fan desperately hoovering up every little trickle out of or about George R. R. Martin, the people search and scroll and read, desperately trying to figure out what comes next. So much of what they encounter, given the absolute infestation of Hollywood ideology into the mainstream culture, will mimic the somber, serious, dramatic tones and backdrops of 'leaders' they see in films and shows. They've got an endless array of little Aaron Sorkin wannabes churning out fanfic to choose from. Anyone straying from this narrative will be heckled, smeared, shouted down,

called a selfish narcissistic murderer—the fucking irony here is not lost on us, dear reader, as we expect it is not lost on you.

People imagine that when the boots-on-the-ground tyranny arrives, it will be enforced by the police or the military. Newsflash: the boots-on-the-ground tyranny is here, and it is being enforced by your neighbors, Joe Sixpack and Jane Soccermom. Need proof? How about all the new “snitch lines” that are opening up in city after city and state after state all around the globe to help good citizens tattle on neighbors who aren’t practicing proper social distancing?

That’s right. It’s not just guys yelling out their windows in Brooklyn anymore. Now whenever you see someone within two meters of someone else it is your duty as a loyal citizen of the Brave New World Order to actively report them to the authorities so that they can be dealt with by Big Brother. Rest assured, a score card is being compiled for each jurisdiction, and the powers-that-shouldn’t-be are keeping a list of who’s being naughty or nice (Good job, Minnesota!).

Still, while we can all unequivocally and universally agree 100% with the idea that anyone who physically approaches another human being in this Year of the Virus deserves to be charged with manslaughter for their heinous act, maybe, just maybe—and I’m just spit-balling, so forgive me if this seems brash—we’re heading into dangerous territory here. You know, what with the social distancing Stasi becoming the enforcers of our new police state nightmare and all. Call me crazy.

When 9/11 happened, there was a marked and notable intensification in the propaganda glorifying the American military. Not that such propaganda didn’t exist before, but it was nothing like what we’ve seen since “the day that changed everything.” Yes, the hero worship of veterans is one of the hallmarks of the Age of Terror that 9/11 ushered in. So if this pandemic is the new 9/11, what’s the new hero worship? Well, it should be obvious by now: Doctors are the new soldiers. Now we must dutifully show our appreciation for the brave medical workers on the front lines of this new war—or face yet more social castigation. The militarized mindset creeps into ever more crevices of daily life.

You may have noticed the interesting phenomenon making its way around the world. I call it ‘The Totally Spontaneous Balcony Applause Phenomenon.’ Yes, completely out of the blue, all the people under lockdown have decided to show their appreciation for the valiant doctors and nurses in this heroic struggle by going to their balcony at a pre-appointed time and applauding. And no, this totally spontaneous phenomenon is not just occurring in one or two countries. Or three or four countries. But in seemingly every country around the globe. Just like that. Just out of the blue. Must be something

in the zeitgeist, I guess.

Now you'll forgive me for being out of the loop, so I don't know exactly how people decide on the right time to go to their balcony to applaud. Is it done by vote? What if I'm a few minutes late? Will people think I'm clapping for something else? What exactly is the etiquette here? And what if you don't have a balcony? Aren't balconies a bit elitist?

Here's another thought-crime: I find these displays creepy and off-putting. I find the glorification of doctors and nurses unsettling. Not because I think they are all quacks. Not because I think they are all evil. Not because I am not grateful for the work that (some) doctors do (some of the time). Not because I don't recognize the enormous stress that these doctors and nurses are under right now. But because this socially engineered adoration is going to be used to push an agenda exactly like the glorification of veterans was used to push the militarism agenda of the post-9/11 years. This time, we are being asked to glorify doctors and nurses because these are the same trusted experts whose authority cannot be questioned who are going to be giving you the vaccine. You know, The Vaccine.

“We don't want to have a lot of recovered people. To be clear, we're trying—through the shutdown in the United States—to not get to one percent of the population infected. We're well below that today, but with exponentiation, you could get past that three-million people, or approximately one percent of the U.S. population, being infected with Wuhan Flu and the vast majority recovering. I believe we will be able to avoid that with having this economic pain.”

It appears that rather than let the population be exposed to the virus and have most develop antibodies that give them natural, long-lasting immunity to the Wuhan Flu, Gates and his colleagues far prefer to create a vast, hugely expensive, new system of manufacturing and selling billions of test kits, and in parallel very quickly developing and selling billions of antivirals and vaccines.

And then, when the virus comes back again a few months later and most of the population is unexposed and therefore vulnerable, selling billions more test kits and medical interventions.

Pay for success finance deals will be well served by the global vaccine market that is being advanced through Gates's outfit GAVI. Vaccine doses are readily quantifiable, and the economic costs of many illnesses are straightforward to calculate. With a few strategic grants awarded to prestigious universities and think tanks, I anticipate suitable equations framing out a

healthy ROI (return on investment) will be devised to meet global market demands shortly.

Over the past month, the gaze of investigative researchers has been fixed on GAVI, Bill Gates, Gates's associates like Fauci, and the over-size influence they are having on public health policy around the Wuhan Flu. The members of the 2012 Development Impact Bond (DIB) Working Group Report are of particular interest, since DIBs are being considered as a way to finance vaccination campaigns. Among them:

Toby Eccles founder of Social Finance and developer of the social Impact Bond

Owen Barder former Economic Aide to Tony Blair, UK AID

Elizabeth Littlefield JP Morgan, World Bank, OPIC, US Impact Investing Alliance

Vineet Bewtra Lehman Brothers, Deutsche Bank, Omidyar Network

Bob Annibale CitiGroup Community Development

Chris Egerton Warburton Goldman Sachs, Lions Head Partners

Rebecca Endean UK Research and Innovation

Kippy Joseph Rockefeller Foundation, International Development Innovation Alliance

Oliver Sabot Absolute Return On Kids (ARK, UK Charter School), The Global Fund

Steven Pierce USAID

Public health is a servant of bond markets and financiers. A glance at the participants in this working group makes it clear: doses and people and death and suffering are just going to be part of their market analysis. For too many people, openly discussing concerns about vaccines remains a third-rail. But we *do* have to learn how to talk about this to one another, because the stakes are too damn high to shy away from it. I also believe these campaigns and the tracking systems associated with them have been structured as an imperial enterprise and should be treated with profound caution.

The World Bank started promoting the use of a blockchain to track vaccine supplies as early as 2017, the same year they got into the pandemic

bond business. There is an elegant, if twisted, logic in melding vaccine supply chain tracking with blockchain digital identity/health passports. Not unlike Palantir's "philanthropic" endeavors around human trafficking. The ultimate goal of the cloud bosses is to be able to track everyone all the time—Tolkien's all-seeing eye. To be able to lay down the infrastructure of digital oppression while being lauded for humanitarian efforts will be quite a coup if they pull it off. So you have the vaccine tracked on blockchain. You have the quantum dot tattoos (health data bar codes) ready to go. You have the capacity to pressure people into setting up digital health passports linked to their electronic health record (thanks Obama). It makes perfect sense that it would all be linked together.

Total quality management, systems engineering, where the cellular structures of entire communities are unlocked and remade for profit. When I was doing my work into ed-tech, I described the process of data-mining as fracking the minds of children. This is the same thing, but in a medical context—fracking our DNA. Creating an immutable record of doses linked to specific individuals, means investors can assess the 'impact' of inoculations they fund and take their profit. This will be made possible using MIT's Enigma software, which protects "privacy" even as it mines cellular structure for "impact" and turns people into GMOs. Something I've had growing concerns about in recent weeks is knowing the Gates-backed initiatives involve the use of mRNA platforms. Moderna is one of them, and they tout their vaccine system as the "software of life."

So we know that pay for success relies on *measurable* change. We also know these platforms use synthetic biology to re-engineer humans at the molecular level. Precision medicine, while a valuable tool to use against inoperable tumors, could become a huge problem if tweaking our biomes at the population level to suit the whims of global financial markets is normalized. Genetic engineering tied to quarterly returns—now that would be grotesque.

Besides, our country has a nasty history of eugenics and unethical scientific experimentation. What protections are in place to keep "pay for performance" contracts and vaccines from being used to justify 'fixing' people that the market deems 'sub-standard' from a human capital investment point of view? It is not such a jump from taking an impact payment for preventing a projected future illness to genetic modification for more insidious purposes.

We are being conditioned to accept that there will be repeated campaigns of vaccination tied to future outbreaks. Remember, this is meant to be a "permanent crisis." Pay for success demands it. It is the crisis framework that legitimizes intrusive surveillance framed as a public benefit. In this way social systems can be regulated to conform to the expectations of global

technocrats.

Gates also funded the development of quantum dot vaccine tattoos by MIT, which act as health data bar codes viewable under certain lighting conditions. This nanotechnology is used for such diverse purposes as solar power and device displays. One of the companies developing electronic health records that are compatible with quantum dot data tattoo systems is Quantum Materials out of San Marcos, Texas. Their system runs on Azure, Microsoft's cloud computing system.

Now imagine Gates-affiliated entities profiting first from vaccine bonds, then from vaccine development, from the cloud computing software tracking the data and documenting the impact, and finally from returns on the pay for success deals. Meanwhile, the public, those who are actually supposed to be served by health policy, are instead used to generate impact data. This results in healthcare services being platformed, automated, and dehumanized. People will start to lose their humanity, seen only as data, veering into transhumanist territory after repeated system upgrades.

As I write, we can see the mounting toll of the pandemic panic as hospital systems have started to furlough workers. As a consequence, I expect we will soon see human staff reductions, and the roll out of tele-presence medical robots, and more and more doctors on screens where they can operate at a 'safe' distance, never needing a mask or to even touch their patient. It is hard to believe this is where we have arrived in the world. And yet, here we undoubtedly are.

Vaccines will be the bread and butter for impact investors; but then factor in the crushing human and economic costs of global pandemic, and suddenly you're talking real money. Imagine tallying up all the costs associated with the lockdown. That is going to create one *enormous* cost offset for investors moving forward. The longer the lockdown, the bigger the cost offset they will be able to use in "pay for success" pandemic deals. For this first round there is a certain sick market logic in making the situation as dire as possible. Future profits are riding on calculations of harm that are being tallied now.

Many have already looked into Event 201, the coronavirus table-top game Gates funded in partnership with the World Economic Forum and the Johns Hopkins Center For Health Security last October. Another funder was Open Philanthropy, started by Facebook Employee #3, Dustin Markovitz. I highly recommend checking out the videos, especially the highlight reel and the communication and finance sessions. I've seen comments dismissing concern over this event, because the tabletop game wasn't actually the Wuhan Flu, but rather a generic coronavirus. Evidently because authorities had been anticipating a pandemic event, we should just shrug off the fact that a coronavirus outbreak occurred mere months after participants checked

out of the luxury Pierre Hotel with their souvenir virus plushies. Watch the videos—the event was a spectacle. Certainly not a serious strategic venture. Even the program for the prior year’s game, Clade-X was much more buttoned-up and serious.

While the event was held in New York, there were also participants representing Australia, Canada, Switzerland, China, and the United Nations. A glance over the participant list shows high-level executives from Edelman (public relations) and NBC Universal; George Gao, director of the Chinese Center for Disease Control and Prevention; as well as a number of groups, including Johnson and Johnson and GAVI, that have a stake in vaccine trials underway.

Given Gao’s presence at this event and his participation in the WHO and World Bank’s Global Preparedness Monitoring Board, one wonders at the apparent disintegration of communication channels after the game was over. If Gates, the World Economic Forum, and Johns Hopkins set up Event 201 with the goal of fostering the creation of an integrated global pandemic response strategy, the aftermath of the Wuhan outbreaks and lack of information sharing shows it to have been a spectacular failure. But perhaps the first round was supposed to be a spectacular failure so that it would be easier to show improvement during future outbreaks.

What?! You still question the vaccines? You still dare to defy the authority of these brave doctors and nurses who risked their lives for us? You can’t say that, you disgusting conspiracy mongering thought-criminal, you!

Vaccination is probably the most deceptive tool of imperialism that even anti-imperialists often fail to recognize. It displays a humanitarian face but has the soul of a beast. Its true character is that of a deceptive agent of imperialism. The romanticism of western medicine has masked the true nature and ethos of vaccination. However, a diligent and deeper study of the history of vaccination and the socio-political and cultural context of that history would reveal the true character of vaccination.

Vaccination is the process of introducing a vaccine into the body to produce immunity to a specific infectious organism. It is not the same as immunization—which has been mistakenly used interchangeably with vaccination—which is the process of conferring immunity, not necessarily through vaccination. Immunity is the capacity of the body to protect itself from the development of a disease due to exposure to an infectious organism.

Imperialism is usually defined as expansion of economic activities, especially investment, sales, extraction of raw materials, and use of labor to produce commodities and services beyond national boundaries, as well as the social, political, and economic effects of this expansion. I would define

Imperialism as: Intervention of Monopolistic Power Exploiting the Resources of Impoverished Areas Leading to Increased Social Misery.

If we look carefully into the history of vaccination, we will find that the development of vaccination coincided with the development of imperialism. Medicine and public health have played important roles in imperialism. With the emergence of the United States as an imperial power in the early twentieth century, interlinkages between imperialism, the business elite, public health, and health institutions were forged through several key mediating institutions. Philanthropic organizations sought to use public health initiatives to address several challenges faced by expanding capitalist enterprises: labor productivity, safety for investors and managers, and the costs of care.

In the early 1900s, the capitalist magnate Rockefeller already had a hand in the development of smallpox vaccine. Rockefeller's pioneering virologist Tom Rivers undertook to develop a safer vaccine by growing the virus in tissue culture. The result was an attenuated strain of virus that was better than the earlier vaccines produced in England. It was the first vaccine used in humans to be grown in tissue culture. Rivers' interaction with Rockefeller Foundation scientists, who were then working to make a yellow fever vaccine in Foundation laboratories on the Rockefeller Institute campus, influenced Max Theiler to create an attenuated virus vaccine. Theiler later won a Nobel Prize for this work. Parke-Davis also was a pioneer in vaccine production. The company set up shop in 1907 in Rochester hills, Michigan, pitching a circus tent to house horses and constructing a vaccine-propagating building, a sterilizing room, and a water tank. Parke-Davis was once America's oldest and largest drug maker. It was acquired by Warner Lambert company in 1970, which in turn was acquired in 2000 by Pfizer, which is now the largest pharmaceutical company in the world. Pfizer claims that it was involved in the commercial production of a smallpox vaccine in the early 1900s, that it was the first to develop a heat-stable, freeze-dried smallpox vaccine as well as the bifurcated needle, the first to introduce a combined vaccine for preventing diphtheria, pertussis and tetanus, and had produced more than 600 million doses of the first live trivalent oral poliovirus vaccine. These medical advances coincided with the emergence of what has been called "New Imperialism"—when European states established vast empires mainly in Africa, Asia and the Middle East and almost at the same period, the United States colonized the Philippines, Guam, Puerto Rico, the Kingdom of Hawaii, American Samoa, the Northern Mariana Islands, and for short periods, Haiti, the Dominican Republic, Nicaragua and Cuba.

Imperialism is driven by the pressure of capital for external fields of investment. The recurrent crises of overproduction and subsequent diminu-

tion of profits and stagnation of capital leads to ever-increasing pressure to expand markets and territories. The tendency for investors to work towards the political annexation of countries which contain their more speculative investments is very powerful. Imperialism is seen as a necessity by the capitalists so they can continue to accumulate wealth. Capitalist greed was hidden behind the curtain of Manifest Destiny and a “mission to civilize colonized people.” It was the Robber Barons of the time, the likes of Rockefeller, Morgan, Carnegie, Cooke, Shwab, Fisk, Harriman and their ilk who actually needed Imperialism and who were fastening it upon the shoulders of the government. They used the public resources of their country for their capitalist expansion. Imperialism, therefore, was adopted as a political policy and practice by the government which was controlled by the business elite. The Government and private corporations sought ways to maximize profits. Economic expansion demanded cheap labor, access to or control of markets to sell or buy products, and extraction of natural resources. They met these demands through plunder and tyrannical rule.

However, the imperialists experienced excess diseases and deaths among their troops, civil servants and traders. They had to do something about it. With the advent of the “Germ Theory” of disease, it was believed that these diseases and deaths were caused by infectious organisms. This belief led to the development of drugs and vaccines that the colonial powers wholeheartedly embraced. That was the beginning of Big Pharma. Initially the advances in medicine were introduced for the protection of colonial troops and civil servants, then for the local people working for the colonial power, and eventually for the whole population. Improved health care was also included with the provision of hospitals and, as for the other measures, these were initially for the military, then for expatriates, and finally for the local people. The pioneer pharmaceutical companies of that time and the financial elite clearly saw the huge profits to be made from vaccination and the provision of pharmaceuticals. Among the most cited justification for colonial rule is the introduction of “modern health care” to the subjugated people. Thus, health became an instrument of pacification of the oppressed and the people were made to believe that colonialism was good for them. However, the introduction of health care technologies like vaccines and drugs are really not out of altruistic intentions of the colonial power but more for the satisfaction of the imperialist’s plunderous desires. In fact, systematic public health regimes originated as military programs in support of imperialist expansion. Private charities entered the field as colonial conquests were consolidated. The colonizer was more concerned with maximizing the exploitation of imperialized labor and extraction of the natural resources of the conquered people.

Since then, the elimination or control of disease in tropical countries became a driving force for all colonial powers. In the colonized world, public health measures encouraged by Rockefeller's International Health Commission yielded increases in profit extraction, as each worker could now be paid less per unit of work, "but with increased strength was able to work harder and longer and received more money in his pay envelope." Rockefeller's research programs promised greater scope for future US military adventures in the Global South, where occupying armies had often been hamstrung by tropical diseases. The Rockefeller programs did not concern themselves with workers' physical productivity alone. They were also intended to reduce the cultural resistance of "backward" and "uncivilized" peoples to the domination of their lives and societies by industrial capitalism. The Rockefeller Foundation discovered that medicine was an almost irresistible force in the colonization of non-industrialized countries. During the US occupation of the Philippines, Rockefeller Foundation president George Vincent was quite frank in saying:

"Dispensaries and physicians have of late been peacefully penetrating areas of the Philippine Islands and demonstrating the fact that for purposes of placating primitive and suspicious peoples medicine has some advantages over machine guns."

Mass vaccination emerged as a major imperialist program, notwithstanding the erroneous, reductionist concept behind it and despite the utter lack of proper safety and efficacy studies. Vaccination was hailed as the savior of colonized people from infectious disease despite clear evidence of adverse effects worse than the original disease. Many of these forced mass vaccination campaigns resulted in disastrous results. For example, in the Philippines, prior to US takeover in 1905, case mortality from smallpox was about 10%. In 1905, following the commencement of systematic vaccination enforced by the US government, an epidemic occurred where the case mortality ranged from 25% to 50% in different parts of the islands. In 1918–1919 with over 95 percent of the population vaccinated, the worst epidemic in the Philippines' history occurred resulting in a case mortality of 65 percent. The lowest percentage occurred in Mindanao, the least vaccinated place owing to religious prejudices. Dr. V. de Jesus, Director of Health, stated that the 1918–1919 smallpox epidemic resulted in 60,855 deaths. In Japan, after compulsory vaccination was mandated, there were 171,611 smallpox cases with 47,919 deaths recorded between 1889 and 1908, a case mortality of 30 percent, exceeding the smallpox death rate of the pre-vaccination period. At about the same time, Australia, one of the least-vaccinated countries in the

world for smallpox, had only three smallpox cases in 15 years. In England and Wales, between 1934 and 1961, not one death from natural smallpox infection was recorded, and yet during this same period, 115 children under 5 years of age died as a result of the smallpox vaccination. The situation was just as bad in the USA where 300 children died from the complications of smallpox vaccine from 1948 to 1969. Yet during that same period there was not one reported case of smallpox in the country.

Similar disastrous results also happened with the polio vaccine. The majority of polio cases actually do not cause symptoms in those who are infected. Symptoms occur in only approximately 5 percent of infections with a case fatality rate of only about 0.4%. Even during the peak epidemics, poliovirus infection resulting in long-term paralysis, was a low-incidence disease that was falsely represented as a rampant and violent paralytic disease by fundraising advertising campaigns to fast track development and approval and release of the Salk vaccine with Rockefeller as the key supporter. Because of outside pressure, the US licensing committee in charge of approving the vaccine did so after deliberating for only two hours without first having read the full research. This hasty approval led to the infamous “Cutter disaster,” the poliomyelitis epidemic that was initiated by the use of the Salk vaccine produced by Cutter vaccine company. In the end, at least 220,000 people were infected with live polio virus contained in the Cutter’s vaccine; 70,000 developed muscle weakness, 164 were severely paralyzed, 10 were killed. Seventy-five percent of Cutter’s victims were paralyzed for the rest of their lives.

When national immunization campaigns were initiated in the 1950s, the number of reported cases of polio following mass inoculations with the killed-virus vaccine was significantly greater than before mass inoculations and may have more than doubled in the US as a whole. Wyeth was also found much later to have produced a paralyzing vaccine. All other manufacturers’ vaccines released in the 1950s were sold and injected into America’s children and millions of vaccines were also exported all around the world.

The “eradication” of smallpox and the seemingly dramatic decline of polio cannot be largely attributed to the vaccines. There never was valid scientific study that supported the claim that the vaccines caused the decline of the disease. The combined effects of social and environmental determinants of what was poliomyelitis at that time were the most likely reasons for the decline. The polio vaccine was propelled more into widespread use by economic, political, and personal interests of imperialists rather than by science and public health interests. It is well established scientifically that the decline in mortality rates of infectious diseases was due largely to socio-economic determinants—improved nutrition, hygiene and sanitation,

et cetera—and the strengthening of natural immunity. Medical intervention using vaccines and antibiotics was late in coming and whatever contribution it made in the overall decline of mortality over time was minuscule at best.

In fact, there is a large body of scientific and narrative evidence that the vaccines cause various acute and chronic adverse effects and likely resulted in delaying the decline of infectious diseases to a relatively insignificant and naturally manageable health problem. Vaccination, an invasive and un-natural induction of immune response, which was largely inappropriate, did not really help but instead, created more problems, among which is the emergence of highly virulent strains of microorganisms. One un-anticipated potentially disastrous adverse effect of vaccination is the disruption of natural immunity among the people in communities. Nevertheless, despite overwhelming contrary scientific evidence, the overwhelming power of the ruling elite successfully implanted the entrenched belief that vaccination had eradicated smallpox and dramatically reduced deaths from polio and other infectious diseases. This widely held belief allowed the global ruling class to hide behind humanitarian posturing and mask their true agenda of global dominance and maximizing profits for Big Business.

After World War II, public health philanthropy became closely aligned with US foreign policy as neocolonialism thrust “development” on Third World nations. The major foundations collaborated with USAID and allied agencies in support of interventions aimed at increasing production of raw materials while creating new markets for Western manufactured goods. The concept of “global health governance” (GHG) arose in the early 1990s, reflecting US confidence that the fall of the Soviet Union would usher in a unipolar world dominated by American interests. This was a vision of diffuse, omnipresent power to be exercised collaboratively by the institutions of global capitalism and guaranteed, in the last resort, by the US military. The Alma Ata principles became moot as structural adjustment programs decimated Third World government investments in public health. Corporate globalization intensified with neoliberal imposition of liberalization, deregulation, and privatization. The new global health governance regime systematically bypassed or compromised national health ministries via “public-private partnerships” and similar schemes.

To soften the resistance against imperialist interventions in health, “emerging infections” were hyped as inevitable and potentially catastrophic and the global health governance scheme was framed within the larger discourse of “security” that arose in the wake of 9/11. Worldwide alarm about bioterrorism provided an opportunity to link together health and national/international security. Not only would health-care workers open the funds for a medical front in the War on Terror, but also military forces

would routinely be mobilized as a response to health disasters. Imperial interventions in the health field began to be justified in the same terms as recent “humanitarian” military interventions. Some analysts denounced the militarization of public health as worryingly authoritarian and strategically counterproductive, but to Bill Gates, the world’s second richest man, it was a welcome development. Gates’ endorsement was especially significant because his foundation had become the leading exemplar of philanthropy in the era of global health governance.

The Bill & Melinda Gates Foundation is now by far the world’s largest private foundation; with more than \$50 billion in assets. The bulk of its activities are directed at the people of the imperialized world, where its ostensible mission involves providing birth control and combating infectious diseases. The Gates Foundation exercises power not only by means of its own spending but also through steering an elaborate network of “partner organizations” including nonprofits, government agencies, and private corporations. As the second largest donor to the UN’s World Health Organization (WHO), it is a dominant player in the formation of global health policy. It orchestrates elaborate public-private partnerships and is the chief funder and prime mover behind the Vaccine Alliance, a public-private partnership between the World Health Organization and the vaccine industry. The chief beneficiary of the Gates Foundation’s activities is not the people of the Global South but the Western pharmaceutical industry. The Gates Foundation’s ties with the pharmaceutical- and vaccine-making industry are intimate, complex, and long-standing. Soon after its founding, the Gates Foundation invested \$205 million to purchase stakes in major pharmaceutical companies, including Merck, Pfizer, Johnson & Johnson, and GlaxoSmithKline. The Gates Foundation’s interventions are designed to create lucrative markets for surplus pharmaceutical products, especially vaccines.

The vaccine producing companies belong to the largest interlocking corporations controlled directly or indirectly by a few highly secretive business and power elite who effectively rule the world and impose imperialist policies. Large corporations have become more and more interrelated through shared directors and common institutional investors. In 2004, a team of Swiss systems theorists, utilizing a database of 37 million companies and investors worldwide, studied the share ownerships linking over 43,000 transnational corporations. They found that a core 1,318 companies, representing 20 percent of global operating revenues, “appeared to collectively own through their shares the majority of the world’s large blue chip and manufacturing firms—the ‘real’ economy—representing a further 60 percent of global revenues.” When the team further untangled the web of ownership, it found much of it tracked back to a “super-entity” of 147 even more tightly knit

companies—all of their ownership was held by other members of the super-entity—that controlled 40 percent of the total wealth in the network. In effect, less than 1 percent of the companies were able to control 40 percent of the entire network. Most were financial institutions. The top-20 included Barclays Bank, JPMorgan Chase, and The Goldman Sachs Group.

This business elite is intimately linked to the Council of Foreign Relations (CFR). The CFR, founded in 1921, is a United States think tank specializing in US foreign policy and international affairs. The CFR runs the Rockefeller Studies Program and convenes government officials, global business leaders and prominent members of the intelligence and foreign-policy community to discuss international issues and make recommendations to the presidential administration and the diplomatic community. Some critics and political analysts have called the Council for Foreign Relations the “Shadow Government” that is pulling the strings behind the scene.

The Vaccination Trojan Horse of Imperialism in recent years has become much bigger with the growing power of Bill and Melinda Gates Foundation which is the main driver of global health policy. Bill Gates is the first private individual to keynote WHO’s general assembly of member countries. One delegate remarked:

“He is treated liked a head of state, not only at the WHO, but also at the G20.”

Oh Billy, you’re going to be so sad once we take it all—you’ll be begging for Lizzie.

The Gates Foundation has been compared to “a massive, vertically integrated multinational corporation (MNC), controlling every step in a supply chain that reaches from its Seattle-based boardroom, through various stages of procurement, production, and distribution, to millions of nameless, impoverished ‘end-users’ in the villages of Africa and South Asia.” It has a functional monopoly in the field of public health. In the words of one NGO official:

“You can’t cough, scratch your head, or sneeze in health without coming to the Gates Foundation.”

With his unprecedented power, Bill Gates was able to initiate an elaborate neoliberal financing scheme for vaccines that inevitably transfers public funds to private coffers. Ostensibly, the scheme is designed to help developing countries to fund their vaccination programs but in reality, these countries are caught in a debt-trap. This so-called “innovative development financing” is a debt-based mechanism that taps capital markets to subsidize vaccine

buyers and manufacturers through an intermediary, the International Finance Facility for Immunization (IFFIm). GAVI floats bonds which are secured by the promise of government donors to buy millions of doses of vaccines at a set price over periods as long as 20 years. Capitalists take a cut at every stage of the value chain while poor countries are supposed to benefit from access to vaccines that might not otherwise be affordable. Bondholders receive a tax-free guaranteed return on investment, suited to an era of ultra-low interest rates. Pharmaceutical firms, meanwhile, are able to peddle expensive vaccines at subsidized prices in a cash-poor but vast and risk-free market. By creating a predictable demand pull, IFFIm addresses a major constraint to immunization scale-up: the scarcity of stable, predictable, and coordinated cash flows for an extended period. Recent Gates Foundation/GAVI activities in Sri Lanka offer a virtual case study in what has been called “pharmaceutical colonialism.” GAVI targeted the country in 2002, offering to subsidize a high priced, patented pentavalent DtwP-hepB-Hib vaccine. In exchange for GAVI’s support, the country agreed to add the vaccine to its national immunization schedule. Within three months of the vaccine’s introduction, twenty-four adverse reactions including four deaths were reported, leading Sri Lanka to suspend use of the vaccine. Subsequently, twenty-one infants died from adverse reactions in India.

The real underlying cause of deaths in epidemics is the dysfunctional health care system brought about by chronic socio-economic underdevelopment characteristic of a semi-feudal and semi-colonial society victimized by imperialism. Corporate hijacking of the health care system with the complicity of government, international institutions, and mainstream medicine deprived the people of their right to health. Profit has become the primary driving factor in addressing a public health problem, not public welfare. Deregulation, privatization and liberalization, the hallmarks of corporate globalization, the new face of imperialism, have practically wiped-out whatever remaining affordable basic needs and social services—especially health services—are available to the majority of the population. Worse, under the guise of economic development, big business juggernauts in mining, plantations, coal, dams and other environmentally destructive and socially disruptive mega-projects have devastated community-empowering and truly sustainable, poverty-alleviating, health-promoting and climate resilient initiatives. The concomitant and worsening assaults—including extrajudicial killings—on fundamental human rights have subjected marginalized people to extreme physical, biological, psychological, and social stress and they have repeatedly been forced to be displaced from their land, homes, crops, and other means of survival. Under these circumstances, infectious disease

epidemics and other serious health problems are bound to arise and worsen. The root cause of epidemics in this country is imperialism. Liberation is the answer, not vaccination.

“Eventually what we’ll have to have is certificates of who’s a recovered person, who’s a vaccinated person. Because you don’t want people moving around the world where you’ll have some countries that won’t have it under control, sadly. You don’t want to completely block off the ability for people to go there and come back and move around. So eventually there will be this digital immunity proof that will help facilitate the global reopening up.”

Be honest, you know that this push is coming. And they are getting the public to sign on with all these ‘spontaneous’ balcony applause sessions. So perhaps you’ll forgive me for not joining in.

It is also interesting to see workers, who previously were underpaid, undervalued, and overworked, be deemed essential workers in critical roles. So, if stocking shelves, manufacturing medical equipment, being a nurse, if all these things are vital to society, why weren’t they being valued and taken care of before? And who doubts once the next crisis du jour springs up and attracts mainstream attention that we will forget these individuals once more?

Our demons now come in the form of graphs, charts. We treat the outputs of models as if they were the word of god, rather than guesses based on incomplete and inaccurate data. And we act as if we’ve progressed quite far from the days where some fuckwad would use his ‘infinite wisdom’ to decide, forgetting that the fuckwad is now some asshole obscured and filtered through some lines of code. I also might add: holy shit, if the media had latched on and fearmongered this hard about climate change models, we’d be well on our way to a greener future—I mean it’s still not good that Anderson Cooper would be acting like a manipulative little fuckboy, but at least then he might be useful for something other than sucking corporate cock.

I am still baffled by the attention that otherwise sane human beings are giving to the latest reported numbers from this or that health agency about the scourge of the Wuhan Flu. People are throwing around CFRs and R0s like they’ve been studying epidemiology their whole lives. In truth, they’re just regurgitating whatever they saw on CNN or were told in the latest Cuomo press conference—it really is convenient to have the pandemic “epicenter” in the media capital of the world.

So what do we make of the baffling discrepancy in death rates from the Wuhan Flu between different countries? Why is Italy's death rate from the disease a staggering 10% while China's is more like 4%? And what does that mean for the 70% of humanity that 'experts' warn will be infected by this virus? And while we're at it, why don't we ask some equally meaningful questions, like: What color is the Easter Bunny? How many angels can dance on the head of a pin? And just how tasty is the cheese that the moon is made of, anyway?

Methods for diagnosing this disease vary so widely from country to country that making comparisons between countries isn't even like comparing apples and oranges. It's like comparing apples and aardvarks. And diagnosing a particular type of viral infection via CT scan? How can we possibly trust the infection numbers that are being generated by such methods? All of that would make the calculation of mortality rates for this disease problematic enough. But, to make matters worse, we don't even have an accurate tally of the number of people who have died from the Wuhan Flu. Take the infamous Italian example, for instance. We're told that the staggering death rates in Italy (roughly 10% if we go by the official numbers at press time) are a sign of just how deadly this new virus can be.

But there's some problems with those numbers:

“The way in which we code deaths in our country is very generous in the sense that all the people who die in hospitals with the Wuhan Flu are deemed to be dying of the Wuhan Flu.”

So how many of the people who are reported as “Wuhan Flu deaths” in Italy actually had ‘Wuhan Flu’ listed as their cause of death? Just 12 percent. What's more, according to the Italian government's own report, half of those who died had three or more other diseases at the time of the death. Nearly 80 percent had at least two other diseases that they were fighting when they died. Only 1.7 percent of those who died had no other disease.

But why listen to me, a conspiracy theorist.

“The data collected so far on how many people are infected and how the epidemic is evolving are utterly unreliable. Given the limited testing to date, some deaths and probably the vast majority of infections due to the Wuhan Flu are being missed. We don't know if we are failing to capture infections by a factor of three or 300. Three months after the outbreak emerged, most countries, including the US, lack the ability to test a large number of people and no countries have reliable data on the

prevalence of the virus in a representative random sample of the general population.”

You cannot honestly present confirmed Wuhan Flu case numbers because due to the nature—and common understanding—of numbers, this will lead most to reach incorrect conclusions. Reporting the death rates alongside the number of confirmed cases is much, much worse than ‘screaming fire in a crowded theater.’ The number of infected is higher—how much unknown—than the “confirmed cases.” No matter how much you test, you will never know this number with certainty. These are the situations where math and statistics most often mislead. We as humans cannot comprehend large numbers, and given a population of over seven billion, most any illness is bound to affect millions. But we deal with multiple of these every year, going about our lives, not grinding everything to a halt.

Recall how quickly the global population has been doubling in recent years, recall how much greater it is than in 1918. Many, many, many more people than died in 1918 need to die in order for this to be comparable in magnitude. More people means more people get infected, more people die, that’s the kind of basic common number sense that’s missing.

OK, so you still insist on taking these phony baloney numbers seriously? Then let’s take another look at that Italian report on those dying with (not of) the Wuhan Flu. The report tells us that the median age of those who have been pronounced dead with (not of) the Wuhan Flu is 78. To put that number in perspective, the average life expectancy in Italy is 82.8.

That means those who are dying with (not of) the disease are within years of reaching the average life expectancy—and, let’s not forget, they are also suffering in the vast majority of cases from at least two other diseases. I venture to say that a similar panic could be raised about just about any viral disease in circulation if it was being reported in the same way as this Wuhan Flu is being reported. After this current madness passes, people will view the public’s blind acceptance of these practices in the same way that we look at the public’s blind acceptance of bloodletting and other methods of medical chicanery from times past.

Since we’re committing thought-crimes here, let’s be blunt: ‘Elderly Patient With Multiple Complications Dies After Contracting Respiratory Illness’ is not a news story. It’s a daily fact of life. But in fact, it is a news story. I have been keeping tabs on how the Canadian MSM have been covering the pandemic panic and saw a segment on one of the national news broadcasts about a woman whose 91-year-old mother died in a nursing home. It was implied that this 91-year-old woman’s life was tragically cut short by the Wuhan Flu and, to make matters worse, her daughter was unable to

hold a funeral or service for her mother because Canada is currently under lockdown. I don't know if I have lost touch with reality or everyone else has, but let me reiterate: This is *not* a news story.

Don't get me wrong: Any such death is doubtless a tragedy for the family involved. My heart genuinely goes out to all those who lose their relatives in such circumstances. But this is not something that we upend our entire civilization over. We do not stop all productive human activity on the planet; institute lockdowns; and begin talking about mandatory vaccinations, internal passports and other abrogations of essential human freedoms on such a basis. In fact, if I were to be dying at the age of 78 due to some viral respiratory illness along with my other 78-year old cohorts, I can guarantee that I would be outraged that the powers-that-shouldn't-be were using my death to upend the liberties that I had spent my life attempting to defend. It is disgusting.

'But what about the young people who die of the disease?' you ask. Fair enough. Again, according to the official reports—which, let me remind you, should not be trusted—there are people under the age of 78 who are dying from the disease as well, albeit in much smaller numbers. And, according to the models from the experts—who, let's remember, are right about everything—there could be hundreds of thousands more deaths before this pandemic runs its course.

Well, that brings me to my ultimate thought-crime: People die.

Sometimes they die of car accidents. Sometimes they die of work-related mishaps. Sometimes they die of old age. Sometimes they die under extremely questionable circumstances while trying to shed light on information that is uncomfortable for the deep state. And, yes, sometimes they die of respiratory illnesses during viral pandemics. I'll go one step further: Our mortality makes us who we are. Humans are blessed and cursed with a knowledge of our own fate. No one makes it out of this life alive. And so the question of what we do with our lives becomes paramount.

But more and more, death is being removed from life. Our elderly are shipped off to nursing homes to wither away so that we don't have to face aging. The funerary industry is neat and anti-septic. Death has become an abstraction. Something that happens somewhere out there, to other people. Not to us, though, surely.

This is what seems to be most at the heart of the Wuhan Flu panic, why the medical establishment is so vocal. They are some of the truest believers in achieving immortality; death, to them, is preventable, often. Look at the efforts so often made to prolong life, long past the point of being worth living. That inclination is then applied to any new threats faced. It has of course been attempted with old threats, the measles anti-vax shaming,

Swine Flu, Ebola—I think there’s one in between these last two, maybe SARS, but who can remember—though they didn’t have the PR agency the Wuhan Flu does. But it never works as well, it’s far easier for people to say: ‘Well, we’ve always lived with this, it’s not so bad, I don’t even think about it really.’ So you need something, might we say, novel.

This entire pandemic madness seems to be predicated on the notion that disease and death are somehow avoidable. That we have conquered such things. Or, at least, that no new disease could ever possibly arise (bioengineered or not) to upset our perfect balance with nature. I mean, yes, many people die of the flu every year, but that doesn’t count. That’s not new.

This is not to say that we shouldn’t work to cure diseases and improve our health. Quite the contrary. It’s just that this current bout of hysteria seems almost anti-human; as if we should be able to transcend our mortal humanity.

“We can’t let these Russian dissension sowers, neo-Nazi accelerationists, and Wuhan Flu-sympathizers confuse us. They want to convince us that Death is, yes, scary, and sad, but inevitable, and natural. How utterly heartless and insane is that?!

No, we need to close our minds to that nonsense. People are dying! This is not normal! Death is our enemy! We have to defeat it! We need to hunt down and neutralize Death! Root it out if its hidey-hole and hang it like we did with Saddam”

We do not understand how common death is, every single day. Around one percent of the world’s population dies every year. Nearly a million die of suicide each year—a number likely to increase as a result of economic devastation, fear, stress, and so on as a result of the panic. Two-hundred-thousand, that’s the average number of deaths due to medical error in the US every year; that’s about five-hundred a day. Where’s the war on that? Well there’s been a war there, but it’s been a war on tort, on making it easier for the medical industry to harm you and not be harmed itself. And in panic we are allowing them to make us guinea pigs once again. You thought the measles vaccine shaming was bad? Just wait until even more decline to be part of the first widescale human trials of so-called “third generation vaccines.” We’re a long way from ants licking ants folks.

“Never let a good crisis go to waste.”

This is religion for the right, the center, the neoliberals. But the ‘left’? Well it just wouldn’t be proper to take advantage of a crisis. Bernie, do us

all on the real left a favour: Get the Wuhan Flu and fucking die. I mean, you probably won't, even if you get it, because you're a prominent millionaire who playacts as a socialist revolutionary; but hey, we can dream can't we?

We allow our oppressors to herd us into their desired pens once again, letting them practice their skills at tracking, cordoning off, isolating, suppressing, experimenting with things they have so little understanding of. Is this really our endless fate? Can we not finally end this awful cycle?

I don't know anymore. Perhaps I'm off my rocker. All I know is that the room to express dissent on these topics is fast disappearing. It's time for those of us who can tolerate thought-crime to circle the wagons. The Thought Police are closing in. So maybe you disagree with me. Maybe you're offended by what I say. Maybe you have your own thought-crimes that you're afraid to express. But if we don't engage in dialogue about these ideas now, what are the chances that this information will be easier to share in the future?

So, what's your thought-crime?

Chapter Twenty-two

Death, Dying, The End

We, only, can see death; the free animal
has its decline in back of it, forever,
and God in front, and when it moves, it moves
already in eternity, like a fountain.

“What are we to make, of a creation in which the routine activity is for organisms to be tearing others apart with teeth of all types—biting, grinding flesh, plant stalks, bones between molars, pushing the pulp greedily down the gullet with delight, incorporating its essence into one’s own organization, and then excreting with foul stench and gasses the residue. Everyone reaching out to incorporate others who are edible to him.”

It is a deathly business, being alive, being an animal.

Fox was here first, and his brother was the wolf. Fox said, people will live forever. If they die they will not die for long. Wolf said, no, people will die, people must die, all things that live must die, or they will spread and cover the world, and eat all the salmon and the caribou and the buffalo, eat all the squash and all the corn. Now one day Wolf died, and he said to the fox, quick, bring me back to life. And Fox said, No, the dead must stay dead. You convinced me. And he wept as he said this. But he said it, and it was final. Now Wolf rules the world of the dead and Fox lives always under the sun and the moon, and he still mourns his brother.

The greatest lie ever told was that there is a mystical afterlife. This lie has been used for millennia to steel the courage of young men before sending them to kill and die in wars. Even worse, most people lie to themselves when confronting suffering and loss, with stories of a better life after this one, despite there being no credible evidence for any such thing. But why is it so damaging to share and believe pleasant fantasies of an afterlife, when nonexistence is both inevitable and too horrific to confront? It is damaging because it leads to bad decisions in this life, the only one we have. Knowing that our lives are so short makes each moment and each interaction more

precious. The happiness and love we find and make in life are all we get. The fact that there is no supernatural being in the universe that cares about us makes it that much more important that we care about one another.

A republic of suffering is made of infinite islands of mourning; we form the archipelago afterward, and only in our minds.

Death is where our distinctions between science, self, and sanctity most often break down.

We don't get it right in this country, we may get it more wrong than any other country in the entire world. The problem isn't necessarily the kind of funeral that takes place, but all that happens (or doesn't happen) after it. After the funeral we are supposed to move on, except of course we can't. It's a slammed door which you cannot reopen, and it's a huge door. So we do get it wrong. We don't have the traditions in place.

My best friend's mother, a breast cancer patient, tried repeatedly to talk about the looming possibility of her own death, only to be told that she should not speak of it. It is a strange irony: the last thing we are supposed (or allowed) to do when preparing to meet death is talk about death. Can you imagine the inverse? We would not plan for the birth of a child without addressing the subject of labour. Major events demand adequate preparation—more than that, they require solemnity, significance. These make up our cultural rituals, and rituals have enormous power.

A useful example of the power of stories as rituals comes from trauma treatment. In March 2012, *Culture, Medicine, and Psychiatry* published the work of Wozniak and Allen about a shelter for abused women in Montana. Care workers had trouble helping their patients to move beyond the trauma they had experienced. Despite extensive counseling, the women frequently found themselves returning to their abusers or moving on to new partners who were similarly abusive. Confounded and frustrated, the shelter psychologists decided to incorporate rites of passage (similar to those practiced by Native Americans) into therapy. Women participated in several ceremonies, one of which had them writing down their weaknesses, their "old selves," and then dropping them into a swift-flowing river. Using this and other rituals, the women let their trauma go symbolically, and one by one they were able to move on with their lives. The women did not necessarily believe in an indigenous worldview, but they did not have to. The rituals themselves had the power to heal.

We decided witches lived in the woods to the west, and that a demon might haunt the woods to the south. Most children believe in monsters. I may have been slightly unusual in that I wrote all of ours down, crafting them into stories that we rehearsed and revised. As we came across new things—new ideas, new monsters—we incorporated them. Children can be

remarkably teleological; our system was fluid but sensibly interested in cause and effect. Dead trees lined the western wood: of course they did, because the witches lived there. One of the trees fell over and crushed a thorn bush. Naturally, the witches were trying to get out, or hoping we would go in. No one told us otherwise. So why not? There may have been trauma in my childhood, but there was also enormous freedom. As I've listened in on the games of other children—my nieces and nephews, and the children of friends—I've noticed the same open, broad thinking. I suspect that most children, given the opportunity to play, will construct equally malleable and magical worlds. Why don't we make new rituals? We did; we have; we do. The trick is to retain their essence later, when we no longer see the world lit up with magic and possibility.

We find ourselves today in a culture of opposites: bent on living forever, but committed to the disposable nature of absolutely everything else. Looking to find meaning isn't an arbitrary quest: it is the human condition, and rituals are human events that help us find that meaning. While the word itself suggests imagery from religious practice, ritual really refers to behaviour—actions performed with intention and significance. They may be as simple as a handshake or as complex as a rite of passage, but they stand for so much more. Rituals are the fabric of our cultural identities and they enable us to proceed through life's great moments.

Our medical establishment is primarily concerned with prolonging life, not with preparing us for death. Death has become the enemy of medicine, to be fought at all costs, regardless of the situation.

An elderly patient suffers a stroke; the news is bad—and it must be delivered. And so the dilemma begins:

“If I'm lucky, the family will recognize that their loved one's life is nearing its end. But I'm not always lucky. The family may ask me to use my physician superpowers to push the patient's tired body further down the road, with little thought as to whether the additional suffering to get there will be worth it.”

No doctor actually possesses these magical powers, of course, and yet many have come to view death as a medical failure rather than life's natural conclusion.

Medicine began as the enemy of sickness and evolved instead to fight off encroachments of death for the adult, regardless of age. When all else fails, medicine aims to deliver the body from the pain of death, if not from death itself, and finally even to take away the pain of grief through psychiatric medicine.

Has modern medicine given us the illusion of immortality?

We usually cannot get outside our own heads to see with fresh eyes; and even if we feel that we don't have the right tools with which to mourn our dead, we certainly don't have time to wrestle with new tools in the moment. This is why multicultural and historical perspectives are so valuable. They unmoor us so that we can look back from a distance and see more of the picture,

Sometimes one's own traditions can seem hollow, smaller, and less vibrant than those taking place elsewhere, but often that is only because we are too near them to see properly. Sometimes the unfamiliar sparkles only because it seems new; we may find that our collective past holds the key to rituals that are richer than we thought. If we have, in fact, lost something that other cultures have retained, perhaps it is the meaning-making process of really thinking about and taking part in ritual.

Though separated by culture, context, and chronicity, all humans must face the coming of death in a way distinct from our nearest mammal cousins. When we witness death, we must grapple with its finality, but also with our own mortality and the knowledge that one day we too will die. Whereas once this was understood as the natural order of things, we now find ourselves conflicted and less willing to see death as natural. If anything, death breaks into our lives as an unexpected surprise.

We know we will one day die, and yet we live. Animals know death when they see it; they even express grief or go looking for their deceased litter-mates, housemates, or masters when they are gone. However, animals largely recognize the event of death rather than the process of expecting death. A mare witnessed her colt being lost to a swollen river. The mother horse ran back and forth along the bank, frantically whinnying. She had witnessed it being buried, but she never expressed any interest in the grave, only in the river. Death happens in a moment, and it's the river she fears, not mortality itself.

To those in terminal pain, who are looking at death in all its faceless ambiguity, it seems perverse that anyone else would try to, and perhaps wrong that they should presume to do so. That moment is so personal, so intimate, so crushing, so full of mixed hopes and despair, it is little wonder most people want to avoid thinking or talking about it. But let us consider again—dying is a process carried out by the living. It is, in fact, the most challenging and daunting experience of life.

Death, like birth, will happen on its own—but a midwife can make it far less painful and protracted.

The "survivor narrative" so frequently forced upon the cancer patient paints them as a victim who is expected to put on a bold face in the midst

of their vulnerability. The metaphor of hard-fought battle has become so usual that rarely do we see an obituary of a cancer patient that doesn't mention their lost "battle" against the disease. But of course, many do die—and if they feel obliged to avoid speaking about death for fear of giving quarter to the enemy, or to remain upbeat in the face of increasingly long odds, that can make the finality of death all the more crushing. Humanity distinguishes itself by expecting death, and yet it still comes unexpected. Contemporary Western culture is built on denial and fear of death rather than acceptance of and preparation for it. But this view is actually rather recent. Most westerners, for most of our history, did not share it. They were not caught between eternal and disposable; they were able to hold those two ideas, event and process, easily in their minds at once. Our ancestors, who did not have the luxury—or burden—of being able to deny death, instead lived with the acceptance of it.

Social historians note that, in some ways, we've arrived at the inverse of our ancestors' beliefs. No longer a "place" and no longer a "journey," the event of death represents a void, a nothingness or a kind of sweet release. By contrast, the process of dying frightens us with its dead ends, dangers, pain, suffering, and confusion. The journey is all on our side of life. Knowledge of the impending death may be uncertain and as a result the journey is characterized by an unsettling, tiresome back-and-forth trajectory that is both wearing on all the participants and even, at times, shameful for everyone.

How could it be shameful? The type of death, of course, has something to do with it—the stigma, for instance, of HIV may still unfairly haunt the dying and their loved ones, while Alzheimer's robs the memory, the dignity, and even the individuality of its sufferers before the end. Most people are treated in the hospital, and so the clinical setting mediates and blurs the decline of the body. But one day, the patient simply does not bounce back. And it's here that we find the shame-faced abandonment that can plague final hours, here where even the most faithful of friends and family might turn away from the wreck of a body once beloved.

The fear of Alzheimer's is the fear of losing your identity while your healthy body walks on into oblivion. It is the fear of becoming a ghost.

I had seen this in our first border collie, when she was sixteen. She'd wake my husband and me in the night, crying and frightened, as if she couldn't remember where she was or who we were. I'd lie on the floor with her and stroke her and kiss her till the light came back into her intense brown eyes, as if her soul had returned from a journey. In all these cases, a piece of these individuals' minds had gone missing.

When she died my dad was at her bedside. He said at that point she

didn't know who he was. But she sat up suddenly and looked straight into his eyes with so much hurt. And so much love. And recognition. And then she laid back down. And that was it.

If we in the West could expand our definition of death to encompass life, we could experience death as part of life and perhaps face death with something other than fear.

The Black Death may not be the start of European history, but in terms of death-preparation, it was the 're-start.' Nothing would ever be the same. Their attempts to grapple with the immensity of loss remains at the heart of Western tradition—and the Western approach to death was remade and reborn through it.

There were no clear targets to blame for the horror and nowhere to go for escape or solace. When tragedy and change on such a scale happens in a single generation, it necessarily shakes the idea that traditions are permanent and immutable.

Corpse Roads were built to allow peasants from afar to bring their dead to the churchyard, which was consecrated by a bishop to make it "holy." No one wanted rotting bodies hauled through their front yards, so the roads were set up on windswept hills and overgrown pastures where no one wanted to go. These coffin-paths still remain in parts of the Netherlands and the UK.

The plague era, the Great Mortality, a time of unremitting death from which Europe emerged cleansed and renewed. But consider: the ubiquity of death had enormous influence on perceptions of death, as well. The rituals of prayers and wakes for the dead had all but been obliterated at the worst of it; in addition, the largely Christian, largely Catholic religious systems had broken down and seeds of doubt about sovereignty had been sown. Many priests died, and those that survived often refused to visit the dying and perform last rites. There are tales of great charity during the time of plague, but also of horrific treatment of minority groups—up to and including vicious massacres. Those who lived through the horrors had to come to terms with the enormity of the disaster. The popularity of *Ars Moriendi*, or *The Art of Dying*—Latin texts that advised the reader how to die a good Christian death—in 1415 attests to how heavily mortality weighed on people's minds, but was also revolutionary in its own right: those texts gave people stewardship over death, dying, and even last rites, allowing people to perform them without need of the Church. This self-stewardship over life's final moments, which would have been unthinkable before the Black Death, marks one of the first major shifts in European grief culture coming out of the middle ages: death traditions began slowly to shift towards individual experience, instead of religious authority.

Of course the funeral cannot really mark the conclusion of the grieving process. It is frequently only the beginning.

It is often said—more often than one might imagine—that nineteenth-century people, because they suffered so many more child deaths than we do, felt them less, or differently, than we might think—or made less of a fetish of them or, because they sometimes photographed bodies, had a set of expectations and rituals for child death radically different from our own. As is seen in the case of the Darwins' mourning, there is no evidence for this at all—just the opposite, actually. Their loss was as complete as ours would be, and their grief as deep. If anything, their grief was deeper, because their shock was less. There was no surprise to buffer it, no sense of a million-to-one shot to place it in the realm of things that never happen. It was not a brick that fell on your head from a skyscraper but the one thing you had always actively dreaded. Parents during the polio era would resonate with that same emotion.

Nothing really prepares us for the too soon loss of someone we love. It is like watching someone sink straight down into the waves, who will never return and never be recovered, while life continues on the surface. This sense, of the ongoing life of the world suddenly cut off irretrievably, of a life going on of which they no longer know a thing, and in which their absence is absolute and permanent, is true grief—no memory can help it; no promise of meeting after can alter it. King Lear's "never's" are the horrible truth; once they was here, and they will never be again.

That feeling of longing—for a person, a place—could smack you, wavelike, delivering actual, physical, pain. It could sneak up on you as a tiny catch somewhere near the middle of your throat. Or it could tug at you with the force of gravity, like a magnetic attraction that was impossible to shake off.

We often say that our world changes after a death like that. But it does not only change; it rocks, it heaves, it shatters. It breaks and bends and twists. The bereaved is like a shaken leaf on roiling waters, and there is nothing at all you can do about it, nothing you can change. A thousand questions may crowd your mind at a time like this: why did we come here? Why wasn't I standing there? Or more drastically world-shifting questions: why did we choose this career? Why did we have to travel? Why didn't we stay safe at home? There is a human desire for someone to be at fault. Sometimes we blame the victim. Sometimes we blame ourselves. But the horrid wound gapes and pulls all the while.

It has been said, "time heals all wounds." I do not agree. The wounds remain. In time, the mind, protecting its sanity, covers them with scar tissue and the pain lessens. But it is never gone.

In ancient Egypt death was not considered enough of a sexual deterrent

for royal embalmers. In the event of a princess dying they were not permitted to begin embalming for at least three days, to make it less likely that they would fornicate with her corpse. There is an obviously gendered element to these early considerations, with women's bodies often the focus of anxiety; even in death, it seems, women have historically been viewed as objects.

The question of defining human life in utero is hopelessly vexed. That is, given our best present medical and philosophical understandings of what makes something not just a living organism but a person, there is no way to establish at just what point during gestation a fertilized ovum becomes a human being. This conundrum, together with the basically inarguable soundness of the principle 'When in irresolvable doubt about whether something is a human being or not, it is better not to kill it,' appears to me to require any reasonable American to be Pro-Life.

At the same time, however, the principle 'When in irresolvable doubt about something, I have neither the legal nor the moral right to tell another person what to do about it, especially if that person feels that s/he is not in doubt' is an unassailable part of the Democratic pact we Americans all make with one another, a pact in which each adult citizen gets to be an autonomous moral agent; and this principle appears to me to require any reasonable American to be Pro-Choice.

Questions of mind at the beginning of life can sometimes continue even after birth, such as in the horrible case of anencephaly, where normal-looking babies are born missing all of their brain except for the brain stem—allowing them to stay biologically alive despite no other mental functioning. Bioethicists suggest that the most ethical choice in anencephaly is to harvest these babies' organs to save the lives of other infants who need them (of children under the age of two who need organ transplants, 30 percent to 50 percent die before receiving them). Of course, it is incredibly difficult to not see a full human mind within your perfect-looking child, even when their lack of brain proves otherwise.

There are many who will think that the existence of twenty-two cases of infant euthanasia over seven years at one hospital in the Netherlands shows that it is a society that has less respect for human life than the United States. But I'd suggest that they take a look at the difference in infant mortality rates between the two countries. The CIA World Factbook shows that the United States has an infant mortality rate of 6.63 per 1,000 live births, the Netherlands 5.11. If the US had infant mortality rates as low as the Netherlands, there would be 6,296 fewer infant deaths nationwide each year. Building a healthcare system in the United States as good as that in the Netherlands—as measured by infant mortality—is far more worthy of the attention of those who value human life than the deaths of twenty-two

tragically afflicted infants.

“No, we don’t bury the bodies or burn them. We leave them out in the open in a sacred place, near a baobab tree, and let the animals eat them. Usually it is the hyena. There is a small ceremony performed by the elders, and we leave food for the passage to the afterlife. We return a few months later to find the bones, and then hide them in the bush. The land we live in is full of the remains of our ancestors, and it connects us to them.”

The entirety of the Hadzabes’ land is a burial ground, with no separate place for the dead to spend their afterlives. They continue on in the landscape after they are dead, and this is part of the reason that the Hadzabe feel such a close connection to their territory. Land, to the Hadzabe, is not just about something that provides subsistence, though of course that is important—it’s also a tangible connection with their ancestors. The land and the people are inseparable, and this connection is the essence of their mythos. To attempt to separate them or to exploit the land in some way would be an insult to the entire Hadzabe worldview. It was and is unthinkable.

Why wash a body before putting it in the dirt? Why sit awake with someone now permanently asleep? Even the practice of embalming the body (which prevents decay) before interring it in the ground (where it is supposed to decay) struck me as a very strange thing to do. With only a minor leap of morbid imagination, care of the newly dead began to resemble care of the newly born.

Called the “Dead Body Bill,” the “Dissecting Bill” and the “Blood-stained Anatomy Act,” it allowed the unclaimed bodies of paupers to be given to the anatomy schools. The 1834 Poor Law that followed added to the unease for the labouring poor in Britain. An article for the *Spectator* published in 1838 claims:

“If they were poor they imprisoned them, then starved them to death, and after they were dead they butchered them.”

Across the pond, the means of securing specimens may seem barbaric now, but could be very workmanlike; a good resurrectionist would have an extensive network that included undertakers, graveyard workers and even other doctors who might be called to the deathbed of a patient and so provide first notification. Details from the notes of a prolific Nashville resurrectionist: The process required three men and a wagon, and took about an hour in good weather; the coffin would be uncovered and the top broken to allow access to the body, which would be drawn forth by a rope tied

around the neck. The bodies were stripped of incriminating identification and the dirt, flowers, and other grave arrangements were replaced to disguise interference. In good times the resurrectionist would take ‘standing orders,’ and in the US, an active interstate trade commenced—furnished almost completely by ‘black bodies disinterred from southern graves.’

In Britain, the practice was largely the same, though the at-risk population was the white poor. The graves of paupers were not deep and a single one might have as many as four bodies stacked on one another. Resurrectionists in urban areas worked late at night, using wooden shovels to avoid the tell-tale ‘clank’ of digging.

In a sky burial the undertaker will unwrap the body while ritual prayers are spoken or sung from afar. While this is going on, vultures and birds of prey gather in the sky, circling and waiting for the ritual dissection. The body will, by these means, be broken down for easier consumption by the birds, whose lives will be enriched by the person’s flesh and blood. Scarcely anything will be left, and nothing wasted. The soul has moved on to the next stage, awaiting rebirth; the body—as a vessel—has been made to serve a new purpose.

The Wari live in the rainforests of Brazil. Until as late as 1960, they disposed of dead bodies primarily through mortuary cannibalism. To the Wari, this practice symbolized their deep respect and honour of their loved ones—but it also allowed them to deal with the loss. The funeral engages the whole community; the dead man lies on a mat, painted red and starting to bloat in the heat. Mourners walk round and round, wailing in sorrow and also to frighten unfriendly spirits away. They are not going to bury this body, however. The body is about to be dismembered and roasted for consumption.

An anthropologist describes the scene as reaching a “fevered pitch” before the body is first cut open. Mourners pile together, struggling to hold the body or to press themselves to it in grief for the coming separation. The men of the village begin dismemberment, removing organs first and then severing the head and cutting the joints before placing limbs upon the roasting rack (inedibles, like hair and entrails, are burned). The elders of the village explain that only the cutting of the body is emotionally difficult—to eat the remains, on the other hand, is good and right. The meat is not eaten from bones, but cut up, almost ritually, and placed on clean mats. Only relatives (but not immediate relations—spouses or children) eat the body, usually the dead person’s in-laws. They eat slowly, weeping while eating. They must consume all or most of the body. Not being able to do so would be offensive; if the body had decayed too much to stomach, eaters would swallow parts and then cremate the rest at dawn the next day. When the

rest of the body had been cremated, the ashes would be buried and the area swept clean. As with the sky burial, nothing remains of the funeral rites or the body. Why consume the dead? The living Wari explain that they would rather be incorporated into the living bodies of their kin than rot in the cold, wet ground.

A most unusual and alarming tradition of the Ilongot concerns “grief rage.” After a death, men in the village felt compelled—irresistibly driven—to headhunt. The hunters endure hunger, thirst, and deprivation in the weeks it takes to set up an ambush; because they must wait for their prey to happen along, the process is lengthy and non-specific. When at last they have attacked, killed, and beheaded the hapless victim, the Ilongot do not keep the head as a trophy or bring it back home. They throw it away.

How could any of this help in the grieving process? How could death be mitigated by more death? When asked what drove them to the practice, they claimed that severing and throwing away a head was the same as throwing away the anger at death. The head becomes something to carry their anger away, a vessel for grief-born rage. This description didn’t really solve the problem, though; or not at first. What caused the rage to begin with? Was it life-for-life? The description given by the Ilongot seemed too simple, or even naïve. Trying different questions, prying further into their cultural traditions, came up with the same thing each time. Rage was born of grief, said the headhunters. Death literally gave birth to the practice.

Problematically for the Ilongot, however, the government outlawed head-hunting. The traditional ways had been blocked, few avenues remained. One describes the painful position of a man who lost his seventh child, a six-month-old baby. Shortly after the death, the father converted to evangelical Christianity, which was being introduced to the area by missionaries. What the man sought wasn’t denial of death (the typical Western response), but a means of coping with death’s reality. What he needed was a ritual, for his own had been taken away. He needed a new means of carrying his rage away before it destroyed him.

The Ilongot had a custom that recognized rage and gave it a place and a temporality—that is, a beginning and an end. This tradition was taken from them. The anger at abandonment is irreducible in that nothing at a deeper level explains it. Death births rage because at some fundamental, wordless level, rage is the gut-wrenching passion of the soul, gnashing its teeth in the dark.

Ideally all death rituals should serve equally to quell the rage and disperse the grief, making death more approachable by making it familiar once more.

Some Buddhist priests practiced an extreme form of asceticism that would lead to their deaths, and yet also establish them as “living Buddhas.”

In addition to practicing rigorous exercise to rid the body of fat, they consumed only nuts, berries, tree bark and pine needles while gradually reducing the amount they ate. The practitioner would starve to death within ten years when the practice was successful. The priest would also drink a poisonous tea made from the urushi tree, causing loss of bodily fluids (a kind of pre-drying). Finally, he would lock himself into a tomb connected to a bamboo breathing tube. The tombs would be opened after three years, and, if the mummification was successful, the remains would be dressed in robes and worshiped by their loyal followers.

The story of Kūkai (also known as Kōbō Daishi): When he was seventy-two, he sealed himself in a mountain cave and meditated until his death. According to tradition, his hair continued to grow, so his followers returned every few years to trim it and provide new robes. As ‘living Buddha,’ Kōbō Daishi had removed himself from the cycle of life and of need, achieving nirvana but also existing between life and death, between familiar and unfamiliar, in a stasis that required and permitted no change.

Look at the patient, stoic, pained expression of the mother as she hovers over a dead infant and consider: why would this be something you might wish to capture and display? Is this public display of grief appropriate or desirable? The answer, for the Victorians, was yes. All grief was public grief. When Queen Victoria’s husband Albert died, she wore black “weeds” for the rest of her life and was, in many respects, defined by her grief. It has been argued that the responsibility for making mourning “fashionable” lies with her—by the height of the Victorian period, widows were living memorials to their husband’s death, and while grieving lasted for shorter periods following the loss of wives or children, it was still always something you displayed to the world.

These relics were embellishments on a costume of grief, and the primary function of mourning wear was to identify the bereaved. In 1840, Basil Montagu records that “in the mourning dress, the outward sign of sorrow, we call for the solace of compassion, for the kind words and looks of friends and for the chastened mirth of strangers, who, unacquainted with the deceased, respect our grief.”

Mourning dress created a culture where grief for the dead was public; something that, in the US and UK at least, is no longer the case. Yet I imagine many today might find the idea appealing. If you have ever been through personal tragedy, you may well have felt hurt and offended by the world around you, which doesn’t slow down or take any notice of your suffering. Haven’t you ever longed for a space of even a few days where people—friends and strangers alike—paused respectfully to consider your loss? Today’s relentless pace demands that most of us schlep along as before,

with little time available to stop and really reflect on, or live with, our grief—ultimately the best way to help us pass through it. The cost and time of making or wearing mourning clothing and mourning jewelry forced a pause, and created space for grief (both private and public). When the mourner was ready to move from black to gray, they were actually performing a rite of passage.

The immortality provided by algorithms can't approximate a personality yet, but we make greater strides every year in that direction. Will we see a resurgence of ancestor worship? That is, will we continue to visit the shrines of the now-deceased on Facebook or other media, consulting them, asking their advice? Stranger still will we begin to see a new emotion arise—one of mourning for a loved one mixed with joy and affection toward a machine housing that loved one's digital resurrection? It might seem improbable, but psychologists take such things seriously. Many suggest that mourning periods will extend as a result, lasting perhaps for years. Once again, though, the Victorians did that long before us.

Owning Ideas

There is one group of people not shocked by the entertainment industry's policy of suing randomly chosen file sharers: historians of copyright. They already know what everyone else is slowly finding out: that copyright was never primarily about paying artists for their work, and that far from being designed to support creators, copyright was designed by and for distributors—that is, publishers, which today includes record companies, movie studios, streaming platforms, and more. But now that the Internet has given us a world without distribution costs or delays, it no longer makes any sense to restrict sharing in order to pay for centralized distribution. Abandoning copyright is now not only possible, but desirable. Both artists and audiences would benefit, financially and aesthetically. In place of corporate gatekeepers determining what can and can't be distributed, a much finer-grained filtering process would allow works to spread based on their merit alone. We would see a return to an older and richer cosmology of creativity, one in which copying and borrowing openly from others' works is simply a normal part of the creative process, a way of acknowledging one's sources and of improving on what has come before. And the old canard that artists need copyright to earn a living would be revealed as the pretense it has always been.

None of this will happen, however, if the industry has its way. For three centuries, the publishing industry has been working very hard to obscure copyright's true origins, and to promote the myth that it was invented by writers and artists. Even today, they continue to campaign for ever stronger laws against sharing, for international treaties that compel all nations to conform to the copyright policies of the strictest, and most of all to make sure the public never asks exactly who this system is meant to help. The reward for these efforts can be seen in the public's reaction to the file-sharing lawsuits. While many people agree that this time the industry went too far, the error is mainly treated as one of degree—as if the companies had a valid point, but had merely resorted to excessive force in making it.

To read the true history of copyright is to understand just how completely this reaction plays into the industry's hands. The companies don't really care whether they win or lose these lawsuits. In the long-run, they don't

even expect to eliminate file sharing. What they're fighting for is much bigger. They're fighting to maintain a state of mind, an attitude toward creative work that says someone ought to own products of the mind, and control who can copy them. And by positioning the issue as a contest between the Beleaguered Artist, who supposedly needs copyright to pay the rent, and Evil Pirates, who would rather copy a song or a story off the Internet than pay a fair price, the industry has been astonishingly successful. They have managed to substitute the loaded terms 'piracy' and 'theft' for the more accurate 'copying'—as if there were no difference between stealing your bicycle (now you have no bicycle) and copying your song (now we both have it). Most importantly, industry propaganda has made it a commonplace belief that copyright is how most creators earn a living—that without copyright, the engines of intellectual production would grind to a halt, and artists would have neither means nor motivation to produce new works.

Yet a close look at history shows that copyright has never been a major factor in allowing creativity to flourish. Copyright is an outgrowth of the privatization of government censorship in sixteenth-century England. There was no uprising of authors suddenly demanding the right to prevent other people from copying their works; far from viewing copying as theft, authors generally regarded it as flattery. The bulk of creative work has always depended, then and now, on a diversity of funding sources: commissions, teaching jobs, grants or stipends, patronage, et cetera. The introduction of copyright did not change this situation. What it did was allow a particular business model—mass pressings with centralized distribution—to make a few lucky works available to a wider audience, at considerable profit to the distributors.

The arrival of the Internet, with its instantaneous, cost-free sharing, has made that business model obsolete—not just obsolete, but an obstacle to the very benefits copyright was alleged to bring society in the first place. Prohibiting people from freely sharing information serves no one's interests but the publishers'. Although the industry would like us to believe that prohibiting sharing is somehow related to enabling artists to make a living, their claim does not stand up to even mild scrutiny. For the vast majority of artists, copyright brings no economic benefits. True, there are a few stars—some quite talented—whose works are backed by the industry; these receive the lion's share of distribution investment, and generate a correspondingly greater profit, which is shared with the artist on better than usual terms because the artist's negotiating position is stronger. Not coincidentally, these stars are who the industry always holds up as examples of the benefits of copyright. (Fun Fact: The NCAA recently did something similar with

allowing their athletes to accept endorsements, effectively buying off those with the biggest platforms that might otherwise be used to complain about the NCAA's continued exploitation.)

But to treat this small group as representative would be to confuse marketing with reality. Most artists' lives look nothing like theirs, and never will, under the current spoils system. That is why the stereotype of the impoverished artist remains alive and well after three-hundred years. The publishing industry's campaign to preserve copyright is waged out of pure self-interest, but it forces on us a clear choice. We can watch as most of our cultural heritage is stuffed into a vending machine and sold back to us dollar by dollar—or we can reexamine the copyright myth and find an alternative.

The first copyright law was a censorship law. It was not about protecting the rights of authors, or encouraging them to produce new works. Authors' rights were in little danger in sixteenth-century England, and the recent arrival of the printing press (the world's first copying machine) was if anything energizing to writers. So energizing, in fact, that the English government grew concerned about too many works being produced, not too few. The new technology was making seditious reading material widely available for the first time, and the government urgently needed to control the flood of printed matter, censorship being as legitimate an administrative function then as building roads.

The method the government chose was to establish a guild of private-sector censors, the London Company of Stationers, whose profits would depend on how well they performed their function. The Stationers were granted a royal monopoly over all printing in England, old works as well as new, in return for keeping a strict eye on what was printed. Their charter gave them not only exclusive right to print, but also the right to search out and confiscate unauthorized presses and books, and even to burn illegally printed books. No book could be printed until it was entered in the company's Register, and no work could be added to the Register until it had passed the crown's censor, or had been self-censored by the Stationers. The Company of Stationers became, in effect, the government's private, for-profit information police force. The system was quite openly designed to serve booksellers and the government, not authors. New books were entered in the Company's Register under a Company member's name, not the author's name. By convention, the member who registered the entry held the "copyright," the exclusive right to publish that book, over other members of the Company, and the Company's Court of Assistants resolved infringement disputes.

This was not simply the latest manifestation of some preexisting form of copyright. It's not as though authors had formerly had copyrights, which

were now to be taken away and given to the Stationers. The Stationers' right was a new right, though one based on a long tradition of granting monopolies to guilds as a means of control. Before this moment, copyright—that is, a privately held, generic right to prevent others from copying—did not exist. People routinely printed works they admired when they had the chance, an activity which is responsible for the survival of many of those works to the present day. One could, of course, be enjoined from distributing a specific document because of its potentially libelous effect, or because it was a private communication, or because the government considered it dangerous and seditious. But these reasons are about public safety or damage to reputation, not about property ownership. There had also been, in some cases, special privileges—then called “patents”—allowing exclusive printing of certain types of books. But until the Company of Stationers, there had not been a blanket injunction against printing in general, nor a conception of copyright as a legal property that could be owned by a private party.

For awhile this partnership worked well for the government and for the Stationers. The Stationers profited from their monopoly, and through the Stationers, the government exercised control over the spread of information. Around the end of the seventeenth century, however, owing to larger political changes, the government relaxed its censorship policies, and allowed the Stationers' monopoly to expire. This meant that printing would return to its former anarchical state, and was of course a direct economic threat to the members of the Company of Stationers, accustomed as they were to having exclusive license to manufacture books. Dissolution of the monopoly might have been good news for long-suppressed authors and independent printers, but it spelled disaster for the Stationers, and they quickly crafted a strategy to retain their position in the newly liberal political climate.

The Stationers based their strategy on a crucial realization, one that has stayed with publishing conglomerates ever since: authors do not have the means to distribute their own works. Writing a book requires only pen, paper, and time. But distributing a book requires printing presses, transportation networks, and an up-front investment in materials and typesetting. Thus, the Stationers reasoned, people who write would always need a publisher's cooperation to make their work generally available. Their strategy used this fact to maximum advantage. They went before Parliament and offered the then-novel argument that authors had a natural and inherent right of ownership in what they wrote, and that furthermore, such ownership could be transferred to other parties by contract, like any other form of property.

Their argument succeeded in persuading Parliament. The Stationers had managed to avoid the odium of censorship, as the new copyrights would originate with the author, but they knew that authors would have little

choice but to sign those rights back over to a publisher for distribution. There was some judicial and political wrangling over the details, but in the end both halves of the Stationers' argument survived essentially intact, and became part of English statutory law. The first recognizably modern copyright, the Statute of Anne, was passed in 1709 and took effect in 1710.

The Statute of Anne is often held up by champions of copyright as the moment when authors were finally given the protection they had long deserved. Even today, it continues to be referenced both in legal arguments and in press releases from the publishing industry. But to interpret it as an authors' victory flies in the face of both common sense and historical fact. Authors, having never had copyright, saw no reason now to suddenly demand the rather paradoxical power to prevent the spread of their own works, and did not do so. The only people threatened by the dissolution of the Stationers' monopoly were the Stationers themselves, and the Statute of Anne was the direct result of their lobbying and campaigning. In the memorable words of the contemporary Lord Camden, the Stationers "... came up to Parliament in the form of petitioners, with tears in their eyes, hopeless and forlorn; they brought with them their wives and children to excite compassion, and induce Parliament to grant them a statutory security." To make their argument more palatable, they had proposed that copyright would originate with the author, as a form of property that could be sold to anyone—anticipating, correctly, that it would most often be sold to a printer.

This proposal was a shrewd tactical move, because one of Parliament's concerns was to prevent the re-establishment of a centralized monopoly in the book trade, with its attendant potential for a renewal of censorship by the crown.

"The stationers made the case that they could not produce the fragile commodities called books, and thus encourage learned men to write them, without protection against piracy. There is an apparent tracing of rights to an ultimate source in the fact of authorship, but before attaching large importance to this we have to note that if printing as a trade was not to be put back into the hands of a few as subject of monopoly—if the statute was indeed to be a kind of 'universal patent'—a legal draftsman would naturally be led to express himself in terms of rights in books and hence to initial rights in authors. A draftsman would anyway be aware that rights would usually pass immediately to publishers by assignment, that is, by purchase of the manuscripts as in the past. I think it nearer the truth to say that publishers saw the tactical advantage of putting forward authors' interests

together with their own, and this tactic produced some effect on the tone of the statute.”

The Statute of Anne, taken in historical context, is the smoking gun of copyright law. In it we can see the entire apparatus of modern copyright, but in still-undisguised form. There is the notion of copyright as property, yet the property is really intended for publishers, not authors. There is the notion of benefiting society, by encouraging people to write books, but no evidence was offered to show that they would not write books without copyright. Rather, the Stationers’ argument was that publishers could not afford to print books without protection from competition, and furthermore that printers could not be depended to reproduce works faithfully if given unfettered freedom to print. The corollary, they implied, was that without the prospect of reliable distribution, authors would produce fewer new works.

Their argument was not unreasonable, given the technology of the time. Making a perfect copy of a printed work required access to the original press and compositor, anyway; if reliable reproduction were to be encouraged, then a single-holder copyright system had a certain logic to it. And the publishers would now be effectively forced to pay authors in return for exclusive printing rights (although in fact the Stationers had sometimes paid authors even before, simply to guarantee the completion and delivery of a work). The authors who succeeded in selling this new right to printers had no particular motivation to complain—and naturally, we don’t hear very much about the authors not so favored. The consolidation of author’s copyright probably contributed to the decline of patronage as a source of income for writers, and even allowed some authors, though always a small minority, to support themselves solely from the royalties their publishers shared with them. The fact that a given copyright could only be held by one party at a time also helped prevent the proliferation of divergent variations, a problem that had vexed authors perhaps even more than plagiarism, as there was no easy method by which they could endorse or disclaim particular variations.

But the overall historical record is clear: copyright was designed by distributors, to subsidize distributors not creators. This is the secret that today’s copyright lobby never dares say aloud, for once it is admitted, the true purpose of subsequent copyright legislation becomes embarrassingly clear. The Statute of Anne was just the beginning. Having granted the premise that copyrights should exist at all, the English government found themselves under pressure to extend copyright terms further and further. In the long legal saga that ensued, what’s important is not the particular sequence of laws and verdicts, but the identity of the plaintiffs: they were just

the sort of stable, settled business interests capable of sustaining litigation and lobbying over a period of decades—that is, they were publishers, not authors. They had proposed the author’s copyright out of economic interest, and only after the crutch of a censorship-based monopoly had been taken away from them. When it became clear that the tactic worked, they lobbied to strengthen copyright.

And this is still the pattern today. Whenever the US Congress extends copyright terms or powers, it is the result of pressure from the publishing industry. The lobbyists will sometimes trot out a superstar author or musician as an exhibit, a human face for what is essentially an industry effort, but it’s always quite clear what’s really going on. All you have to do is look at who’s paying the lawyer’s and lobbyists’ bills, and whose names appear in the court dockets: publishers’.

The industry’s centuries-long campaign for strong copyright law is not merely a reflexive land grab, however. It’s a natural economic response to technological circumstances. The effect of the printing press, and later of analog sound recording technology, was to make creative works inseparable from their means of distribution. Authors needed publishers the way electricity needs wires. The only economically viable method of reaching readers (or listeners) was the bulk print run: to manufacture thousands of identical copies at once, then physically ship them to various points of distribution. Before agreeing to such an investment, any publisher would naturally prefer to buy or lease the copyright from the author, and just as naturally would lobby the government for the strongest possible copyright powers, the better to protect their investment.

There is nothing inherently exploitative about this; it’s just straightforward economics. From a business point of view, a print run is a daunting and risky project. It involves the high up-front costs of a physical medium—be it dead tree pulp, magnetic tape, vinyl platters, or pitted optical discs—plus complicated, expensive machinery to imprint the content onto the medium. There’s also the unseen investment of vetting the master copy: because a flawed master can reduce the value of the entire run, publishers and authors go to considerable trouble to generate a polished, error-free version of the work before printing. There is little room for an incremental or evolutionary process here; the work must be brought to near-perfection before the public ever sees it. If any mistakes are overlooked, they will have to be tolerated in the finished product, at least until the process is started again for the next print run. The publisher must also negotiate prices and line up distribution paths, which is not only a matter of bookkeeping, but of physical expenses, of trucks and trains and shipping containers. Finally, as if all this weren’t enough, the publisher is compelled to spend even more money on marketing

and publicity, to have a better chance of at least recovering all these outlays.

When one realizes that all this must happen before the work has generated a penny of revenue, it is little wonder that publishers argue hard for copyright. The publisher's initial investment—that is, their risk—in any individual work is greater, in economic terms, than the author's. Authors by themselves might have no inherent desire to control copying, but publishers do. And in a world filled with publishers' royalty-supported marketing departments, authors, of course, need publishers all the more. The concentration of distribution revenues results, inevitably, in the familiar logic of an arms race.

The arrival of the Internet fundamentally changed this equation. It has become cliché to say that the Internet is as revolutionary a development as the printing press, and it is. But it is revolutionary in a different way. The printing press may have made it possible to turn one book into a thousand books, but those books still had to travel from the press into the hands of readers. Physical books were not only the medium in which the content was consumed, they were also the medium in which it was transported to the consumer. Thus, a publisher's total expense was proportional to the number of copies distributed. In such a situation, it is reasonable to ask that each user bear a portion of the costs of distribution. Each user is, after all, more or less responsible for her particular quantum of expense. If the book (or record) is in her hands, it must have gotten there somehow, which in turn means someone spent money to get it there. Divide those expenses by the number of copies, add in some amount for profit, and you arrive, roughly speaking, at the book's price.

But today, the medium over which content is distributed can be unrelated to the medium in which it is ultimately consumed. The data can be sent over a wire, at essentially no cost, and the user can print up a copy at her own expense, and at whatever quality she can afford, on the other end. Furthermore, it is no longer important to possess the master; in fact, the concept of the master copy itself is obsolete. To make a perfect copy of a printed work is actually quite hard, although making a corrupt or abridged copy is very easy. Meanwhile, to make a perfect copy of a digital work is trivially easy—it's making an imperfect copy that requires extra effort.

Thus the practice of charging the same fee for each copy, regardless of how many copies there are or who made them, is now unjustifiable. The cost of producing and distributing the work is now essentially fixed, no longer proportional to the number of copies. From society's point of view, every dollar spent beyond the amount needed (if any) to bring the work into existence in the first place is a waste, an impediment to the work's ability to spread on its own merits.

The Internet did something the Company of Stationers never anticipated: it made their argument a testable hypothesis. Would creators still create, without centralized publishers to distribute their works? Even minimal exposure to the Internet is enough to provide the answer: of course they will. They already are. Many short works of both fiction and non-fiction are already available online. Printing and binding entire books on demand is rarer, but only because the equipment to do it is still somewhat expensive and the desire for a physical book is dwindling.

Some might argue that authors are different, that they are more dependent on copyright than musicians. After all, a musician expects to perform, and can therefore gain indirectly by releasing recordings for free—greater exposure leads to more performances. But authors don't perform; they reach their audience only through their works, not in person. If they now had to come up with ways to fund themselves without imposing an artificial scarcity on their works, could they do it? Imagine the simplest scenario: you walk into the neighborhood print shop and tell the clerk the Web address of the book you want. A couple of minutes later, the clerk comes back with a freshly printed, hardbound book, straight off the Internet. He rings up the sale.

“That'll be eight dollars. Would you like to add the one dollar author's suggested donation?”

Do you say yes? Perhaps you do, perhaps not—but note that when museums charge a voluntary admission fee, people often pay it. The same sort of dynamic is at work in the copy shop. Most people are happy to pay a tiny extra bit on top of some larger amount, if they have their wallet out already and think it's for a good reason. When people fail to make small, voluntary donations to a cause they like, it's more often due to the inconvenience (writing a check, putting it in the mail, et cetera) than the money. But even if only half, or fewer, of all readers were to make such donations, authors would still earn more than they do under traditional royalty schemes, and furthermore would have the pleasure of finally being the readers' ally in distribution, instead of their enemy.

This is not the only possible system, and it can easily coexist with others. Those not convinced by voluntary donations should consider another method: the Fund and Release system (also called the Threshold Pledge system). Those who have used Kickstarter or similar sites will be familiar with the concept, if not the term. This system is designed to solve the classic problem of distributed funding, which is that each contributor wants reassurance that others are also contributing, before putting in her own

money. Under fund-and-release, the hopeful creator of a new work states up front how much money will be required to produce it—this is the “threshold.” An intermediary organization then collects pledges, in any amounts, from the general public. When the total amount pledged reaches the threshold (or exceeds it by some standard percentage, to account for bookkeeping and assumption of risk), the intermediary signs a contract with the creator, and the pledges are called in. Only at this stage, when there is enough money to achieve the desired result, is anyone asked to actually pay up. The intermediary holds the money in escrow, paying the creator according to whatever schedule they negotiated. The last of the money is paid when the work is completed and made publicly available, not just to the contributors, but to the entire world. If the creator doesn’t produce, the intermediary returns the money to the donors.

The fund-and-release system has some interesting properties not found in the monopolistic, copyright-based marketplace. The resultant work is available to everyone in the world, free of charge. Yet the author was also paid enough to produce the work; if she needed more, she could have asked for more and seen if the market would bear it. Those who did choose to pay paid only as much as they were comfortable with, no more. And finally, there was no risk for the contributors—if the threshold is never reached, then no one pays anything.

Not all methods will be so pleasantly high-minded, of course. The author Fay Weldon famously accepted money from Bulgari jewelry to write a novel that featured Bulgari products prominently. She did so, titling the book *The Bulgari Connection*. The book was originally intended as a limited edition to be given away at a corporate function, but having written it, Weldon took it to a publisher for general release. Does this mean that in the future we’ll have to scrutinize all creative works for signs of hidden corporate sponsorship? Perhaps, but this is nothing new—product placement was invented in the context of traditional copyright, and has flourished there, as it probably would anywhere. Copyright is neither the cause of corporate sponsorship nor its antidote. To look to the publishing industry as a force for decommercialization would be weirdly out of touch indeed.

These are just a few examples of ways to support creative work without copyright. There are many other methods; there were many even before the Internet made convenient, direct micro-payments possible. Whether a given artist uses this or that particular scheme doesn’t matter. The important thing is that with little or no friction to impede the payment of tiny amounts, authors will find ways to make such payments happen on the scale they need. Those economists who are enamoured of markets as a solution to everything should be in love with the possibilities here; but, predictably,

many are not, because they hate to see anything become ‘not property.’

To see a glimpse of the future, it may be most helpful to look not at net-savvy musicians, but at software. The flourishing Free Software movement is probably the best example we have today of a post-copyright world. Instead of prohibiting sharing, the software’s license explicitly permits and encourages it. Some predicted that this initial success would quickly level off as the software increased in size and complexity and required centralized, hierarchical organizations to maintain. But instead of foundering, the Free Software movement has grown so quickly that even its own participants are surprised, and it shows no signs of stopping. It now produces software whose functionality rivals that available in the proprietary market. Free software is widely used by banks, corporations, and governments, as well as individual computer users. More web sites run the free Apache web server than run all other web servers combined. Free operating systems are now the fastest-growing segment of the operating system market. Although some free software authors are paid for their work (after all, their services provide a benefit to those who use the software, and some of those users are willing to pay for it), others volunteer their time. Each software project has its own reasons for existing, and each programmer their own reasons for contributing. But the cumulative effect is a direct flaunting of copyright’s entire justification: a thriving community of intellectual production now exists without enforcing copyrights, yet achieves substantially the same results as its mainstream counterpart.

According to the traditional justification of copyright, this shouldn’t be happening. The software is essentially in the public domain; its copyright serves mainly to identify the original authors, and in some cases to prevent anyone else from imposing a stricter license. The authors have given up every exclusive right except the right to be identified as the authors. They have voluntarily returned to a world before copyright law: they enforce no royalties, and have no control over the distribution and modification of their works. The software’s license gives everyone automatic permission both to use and to redistribute it. You can simply start handing out copies, there’s no need to notify anyone or ask permission. If you want to modify it, you’re free to do that too. You can even sell it, though naturally it’s difficult to charge much, since you’d be competing with others handing out the same goods at no cost. A more common model is to encourage people to download the software for free, and instead sell services such as technical support, training, and customization. These models are not fantasies, they are the basis for profitable businesses that exist right now, paying real programmers competitive salaries to work on free software. But the point is not that people are paid to do it—some are, but many more are not, and yet write

it anyway. The real point is that a tremendous amount of free software is produced and maintained every year, at a rate that grows quickly even by the standards of the software industry.

If this phenomenon were isolated to software, it would be explainable as an aberration—software is different, programmers are overpaid, and so on. But it's not just software; if you look carefully, there are signs of it happening everywhere. Musicians release their tracks online for free downloading, and the quantity of freely available writing on the Internet—starting with reference and non-fiction works, but now including fiction and poetry—long ago passed the point of measurability. Software is not fundamentally different from these other forms of information. Like poems, songs, books, and movies, it can be transmitted digitally. It can be copied in whole or in part; it can be excerpted for use in other works; it can be modified and edited; it can even be satirized.

The abandonment of copyright is farthest along in software mainly because programmers were among the first groups to have Internet access, not because of anything special about the nature of software. Gradually, creators in other areas are realizing that they too can disseminate their works without publishers or centralized distribution chains, by simply allowing the freedom to copy. And increasingly, they are choosing to do so, because they have little to lose, and because it's the easiest way for their work to find its way to an appreciative audience. Far from being especially dependent on copyright law, creators gain the most by abandoning the copyright monopoly.

Even in their early stages, these trends raise an obvious question. If copyright is not really needed to stimulate original creation, then what purpose does it serve today? For it is quite clear that if copyright did not exist already, we wouldn't invent it now. We just finished building ourselves a gigantic copying machine (the Internet) that doubles as a communications device, and incidentally makes it convenient to transfer small amounts of money between people. Sharing is now the most natural thing in the world. The idea that artists are somehow harmed by it is demonstrated false every day, by the thousands of new works that appear online, credited and fully acknowledged by their authors, yet free for the taking. If someone were to argue that creativity would soon dry up unless we immediately institute a system of strict controls over who can copy what, we could reasonably look on them as insane. Yet, in slightly more diplomatic language, this is essentially the argument used by the copyright lobby to press for ever stronger laws.

Creativity is not what's at stake here, and in its more honest moments the publishing industry even tacitly admits this. Although for public relations purposes industry leaders make token declarations about the need for poor

artists to earn a living, their most detailed and compelling statements are usually about the business effects of copyright.

“You’re not buying music, you’re buying a key. That’s what digital rights management does: it enables business models.”

It’s hard to imagine a more succinct statement of the industry credo. He might as well have said ‘That’s what copyright does: it enables business models.’ Unfortunately, not all of the propaganda put out by the industry is as straightforward and honest.

In Ray Bradbury’s iconic dystopian novel *Fahrenheit 451*, a war rages in a future society over the existence of books. Those in power seek to destroy them, both because of the controversial ideas they disclose and because of their perceived limited utility in a society filled with video-enabled walls and mobile media devices. Those who rebel against these rules hide books to preserve them for historical, political, and philosophical reasons. Bradbury’s infamous firemen—shock troopers who kick down doors and incinerate homes where books are hidden—and their mechanical drone-like hounds that sniff out literary contraband are meant as provocations to incite our fears that the very book we hold in our hands might be taken away from us at a moment’s notice in the name of “public happiness.” By personifying this version of absolute control, Bradbury makes clear that notions of personal property or domestic privacy stand no chance in a society that values centralized authority over individual autonomy and cultural heritage.

As a commentary on the McCarthy Era, Bradbury’s work is a reaction to a specific threat to our engagement with ideas and the cultural artifacts containing them. And although the particular brand of control Bradbury had in mind has not manifested itself in contemporary US culture, there is a different sort of threat to our freedom to read, explore, and share ideas—one that is more subtle, but all the more dangerous for it. This threat doesn’t kick down your door in the dead of the night; it already lives in your home. It’s embedded into the media you buy and stored on the devices you carry in your pocket. It doesn’t rely on physical force or the power of the state to enforce its rules, just the often unseen operation of software code: Digital Rights Management (DRM).

“You don’t need to be a lawyer to be a musician, but you do need to know one legal term—copyright. To all creative artists—poets, painters, novelists, dancers, directors, actors, musicians, singers, and songwriters—the term matters dearly.

To all artists, copyright is more than a term of intellectual property law that prohibits the unauthorized duplication or

performance or distribution of a creative work. To them, ‘copyright’ means the chance to hone their craft, experiment, create, and thrive. It is a vital right, and over the centuries artists have fought to preserve that right; artists such as John Milton, William Hogarth, Mark Twain, and Charles Dickens. Twain traveled to England to protect his rights, and Dickens came to America to do the same.”

Recognize that? It’s a page straight out of the Stationers’ playbook—an undisguised retelling of the copyright myth, complete with references to individual authors, designed to arouse our support for struggling artists valiantly fighting for their artistic integrity. Apparently, all those artists throughout history who did just fine without copyright aren’t included in “all creative artists.”

“Copyright law all started with The Statute of Anne, the world’s first copyright law passed by the British Parliament in 1709. Yet the principle of protecting the rights of artists predates this. It may sound like dry history at first blush, but since there was precedent to establish and rights to protect, much time, effort, and money has been spent in legal battles over the centuries.”

This breathless summary is the copyright equivalent of ‘Christopher Columbus sailed to America to prove the Earth was round and make friends with the Indians.’ Yes, much money has indeed been spent in legal battles, but the industry is careful not to say who spent it, nor are any further details given about the “principle of protecting the rights of artists” that is alleged to predate these developments.

The rest of their page continues in a similar vein, with so many omissions, mischaracterizations, and outright lies that it’s hard to imagine how anyone doing even a modicum of research could have written it. It is, basically, low-grade supporting propaganda in their ongoing campaign to convince the public that copyright is as fundamental to civilization as the laws of thermodynamics.

The RIAA also indulges in one of the favorite tactics of the modern copyright lobby: equating illegal copying with the unrelated offense of plagiarism. For example, a former head of the RIAA, used to speak at schools and colleges, urging the students to adopt the industry’s views about information ownership. Here is her own description of how she presents the case:

“Analogies are what really work best. I ask them, ‘What have you done last week?’ They may say they wrote a paper on this or that. So I tell them, ‘Oh, you wrote a paper, and you got an A? Would it bother you if somebody could just take that paper and get an A too? Would that bug you?’ So this sense of personal investment does ring true with people.”

Since people who download music and movies do not usually replace the artist’s name with their own, let’s ask the question she should have asked: ‘Would it bother you if somebody could just show a copy of your paper around, so other people could benefit from what you wrote, and see that you got an A?’ Of course, the students would have answered ‘No, we aren’t bothered by that at all,’ which isn’t what the RIAA wanted to hear.

The RIAA is extreme only in the clumsiness of their propaganda. Their message is, in essence, the same one offered by the rest of the copyright industry, which maintains a constant drumbeat of warnings that online content swapping will deprive creators of their reputations and their ability to work, despite overwhelming evidence that copyright never provided them with much of a livelihood anyway, and that they would happily continue to create without it as long as they have a way to distribute their works. The campaign might sound harmless or silly when described as I have described it here, but because they are fighting for survival, with large budgets and skilled publicity departments, the publishers have succeeded in shaping public opinion to a surprising degree. Consider this poor woman in an article about the RIAA file-sharing lawsuits:

“One woman who has received a subpoena from the recording industry association said she had struggled to explain to her 13-year-old son why file-sharing was wrong.

‘I said, suppose you wrote a song and a famous rock group sang it and you didn’t get paid,’ said the mother, who declined to give her name because of her legal situation. ‘He said: I wouldn’t care. That would be awesome. They’re still just in that young age where money doesn’t matter.’

The mother said she had better results when she compared taking someone’s song to plagiarizing a school paper.”

One can only hope the sensible 13-year-old manages to keep his head, when so many around him are apparently losing theirs. The combination of a still-sympathetic public and deep pockets has unfortunately allowed the copyright industry to exercise dangerous influence at the legislative level. The result is a disturbing trend: mutually reinforcing physical and

legal barriers that, while ostensibly designed to combat illegal copying, have the inevitable effect of interfering with all copying. Digital copy-protection schemes are increasingly enforced by your computer's hardware itself, rather than by malleable and replaceable programs. With government cooperation, this combination becomes even more powerful. In the United States we have a law—the Digital Millennium Copyright Act—that makes it illegal to circumvent a digital protection scheme, or even to produce software that helps others circumvent a digital protection scheme. Unfortunately, since much hardware and software automatically imprints such schemes on any media it produces, the Act effectively stifles authorized copying and many other activities that would otherwise fall into the category of “fair use” under current copyright law.

It is vital to understand that these side effects are not accidents, not unexpected consequences of an otherwise well-intentioned effort to protect artists. Rather, they are an integral part of a strategy that, at bottom, has nothing to do with encouraging creativity. The purpose of this three-pronged industry effort—the publicity campaign, the legal campaign, and the hardware “protections”—is simply this: to prevent the Internet experiment from being carried out to completion. Any organization that is deeply invested in the concept of copy control cannot be pleased to see a system arise that makes copying as easy as clicking a mouse. To the extent possible, such organizations would like to see the same pay-per-copy model that we've been using for centuries continue, even though the fundamental physics of information have changed to make pay-per-copy obsolete.

Although the copyright lobby succeeds in getting new laws passed, and even in winning some court cases, these victories rest on a disintegrating foundation. How much longer will the public continue to believe in the copyright myth, the notion that copyright was invented to make creative work possible? The myth has been maintainable so far because it always had a tiny a grain of truth: although copyright was not inspired by authors, and was not enacted to protect them, it did enable the widespread distribution of many original works. Furthermore, there are still many publishers (generally the smaller or individually-owned ones) who behave with an admirable sense of cultural stewardship, subsidizing unprofitable but important works with money earned by stronger sellers, sometimes even losing money outright in order to print things they think worthwhile. But because they are all bound by the economics of large-scale printing, they are all ultimately dependent on copyright.

There won't be a dramatic battle between the publishing industry and the copying public, with a climax, a denouement, and a clear winner striding out of the dust. Instead, what we will see—are already seeing—is the

emergence of two parallel streams of creative work: the proprietary stream, and the free stream. Every day, more people join the free stream, of their own volition, for all sorts of reasons. Some enjoy the fact that there are no gatekeepers, no artificial barriers. A work can succeed by its merits and word of mouth alone: although there's nothing to stop traditional marketing techniques from being used in the free stream, there's less to subsidize them, so word of mouth and peer-review networks are taking on a greater importance there. Others enter the free stream as crossovers from the proprietary, releasing a portion of their work into the free domain as an advertisement or an experiment. Some simply realize that they have no chance of success in the proprietary world anyway, and figure they might as well release what they have to the public.

As the stream of freely available material gets bigger, its stigma will slowly vanish. It used to be that the difference between a published author and an unpublished one was that you could obtain the former's books, but not the latter's. Being published meant something. It had an aura of respectability; it implied that someone had judged your work and given it an institutional stamp of approval. But now the difference between published and unpublished is narrowing. Soon, being published will mean nothing more than that an editor somewhere found your work worthy of a large-scale print run, and possibly a marketing campaign. This may affect the popularity of the work, but it won't fundamentally affect its availability; and there will be so many "unpublished" but worthwhile works, that the lack of a publishing pedigree will no longer be considered an automatic strike against an author. Although the free stream does not use traditional copyright, it does observe, and unofficially enforce, a "credit right." Works are frequently copied and excerpted with attribution—but attempts to steal credit are usually detected speedily, and decried publicly. The same mechanisms that make copying easy make plagiarism very difficult. It's hard to secretly use someone else's work when a search can quickly locate the original.

The proprietary stream cannot survive forever, in the face of such competition. The abolition of copyright law is a must; but the real force here is creators freely choosing to release their works for unrestricted copying, because it's in their interests to do so. At some point, it will be obvious that all the interesting stuff is going on in the free stream, and people will simply cease dipping into the proprietary one.

Or, we can sit back and allow this process to be halted, by permitting manufacturers to build in hardware "protections" that interfere with our ability to copy legitimately; by allowing the copyright lobby to capture our legislatures, to the point where we are constantly looking over our shoulders for the copyright police; and by hesitating to use the free stream to its full

potential, because we've been taught a false story of what copyright is all about.

We can, if we choose, have a world where concepts like “out of print” or “rare book” are not only obsolete, but actually meaningless. We can live in a fertile and vibrant garden of constantly evolving works, created by people who wanted deeply to make them available, not mandated by a publisher's market research. Schools would never be forced to stay with out-of-date textbooks because of the per-copy prices set by publishers, and your computer would always let you share songs with your friends.

One way to get there is to question the copyright myth. Copying isn't theft, and it isn't piracy. It's what we did for millennia until the invention of copyright, and we can do it again, if we don't hobble ourselves with the antiquated remnants of a censorship system from the sixteenth century.

“Invention does not consist of creating out of void, but out of chaos.”

“All have derived benefits from their ancestors and therefore, all are bound, as by an oath, to transmit those benefits, even in an improved condition, to posterity. Only an isolated, solitary being, having no relations to a community around him, can subscribe to the arrogant doctrine of absolute ownership.”

Knowledge is too important to remain the eternal possession of any company or individual. We know that future achievements must build on past ones; that monopolies, over the long-run, drain the creativity from a society.

No concept is truly unique and all ideas are created in the context of the society and culture in which they are engendered. Therefore, there cannot be any true ownership, or indeed theft, of these artifacts as they are an integral part of the environment that learning is taking place within.

“Creative work is to be encouraged and rewarded, but private motivation must ultimately serve the cause of promoting broad public availability of literature, music, and the other arts.”

The rules governing private property are constantly being contested and adapted, sometimes in big ways (banning slavery) but often in small ways barely noticeable to anyone not directly involved. What looks like government regulation is sometimes better understood as the creation of a property right. For example, before 1978, airlines with overbooked flights simply bumped their excess passengers arbitrarily. After many complaints,

the Civil Aeronautics Board (which then regulated airlines) began requiring airlines to treat each seat as the property of the passenger who booked it. That way, airlines with overbooked flights would have to “buy” the excess seats back by offering whatever inducement was necessary to get the right number of passengers to give up their “property” voluntarily.

The underlying mechanisms that define property become even more complicated when property takes the form of strands of genetic material, or combinations of molecules, or gigabits of software code, or, more generally, information and ideas. This sort of property doesn’t exist in one unique place and time. It can’t be weighed or measured concretely. And most of the cost of producing it goes into discovering it or making the first copy. After that, the additional production cost is often zero. Once the discovery or invention has been made, the public will benefit most by having full access to it at no more than the cost of replicating it—which, again, is often near zero. Why should a company that creates a blockbuster drug that can be reproduced for pennies earn billions while many who would benefit from it cannot afford it?

Our thoughts and creations owe an unpayable debt to those who came before, what makes us think we have the right the demand payment?

While we happily borrow, copy, and benefit from the ideas of those who have gone before us, without a thought, many of us are reluctant to let others use “our” ideas unless they pay us for doing so. When Walt Disney produced films like *Snow White*, *Pinocchio*, and *Alice in Wonderland*, he borrowed the stories freely from the public domain, but when the copyright on his films ran out, he lobbied to have it extended. And as the late Steve Jobs said, “We [Apple] have always been shameless about stealing great ideas.” Yet Apple is famously quick to litigate against any companies who borrow or appear to borrow Apple’s ideas. Most have no problem with copying as long as they’re the ones doing it.

When the nation was founded, copyrights covered only “maps, charts, and books” and gave the author the exclusive right to publish for fourteen years, which could be renewed once, for a maximum term of twenty-eight years. In 1831, the maximum was increased to forty-two years. In 1909, Congress again extended the maximum, this time to fifty-six years, where it remained for the next half century. Then, beginning in 1962, Congress extended the maximum eleven more times. In 1976, Congress extended it to the life of the author plus an additional fifty years. The creator did not even have to seek renewal. If the creation emerged from a corporation, the copyright lasted seventy-five years. This change operated retroactively, so any work still under corporate copyright in 1978, when the new law took effect, was eligible for an additional nineteen years of protection. In 1998,

Congress added twenty years on top of all this—to ninety-five years from the first publication, in the case of corporate owners.

The Copyright Term Extension Act of 1998 was also known around Washington as the Mickey Mouse Protection Act because it was basically about Mickey. Walt Disney had created Mickey in 1928, so under the prevailing seventy-five-year corporate limit Mickey would move into the public domain in 2003. Pluto, Goofy, and the rest would become public shortly thereafter. That would mean big revenue losses for the Disney Corporation. Accordingly, Disney lobbied Congress intensively to extend copyright protection for another twenty years, as did Time Warner, which held copyrights on many twentieth-century films and musical scores, along with the heirs of dead songwriters George and Ira Gershwin. They got what they wanted. Most of those old copyrights are now scheduled to expire in 2023. It seems a safe bet that before that year, copyrights will be extended yet again.

Moreover, copyrights now cover almost all creative works, including computer programs, and give owners (now, usually large corporations) rights over all derivative work that might be generated by the original. As a result, much of the creative output of the last century—not just Mickey Mouse and other Disney characters but many of the icons of the twentieth century, including Superman and Dick Tracy; a treasure trove of movies, among them *Gone with the Wind* and *Casablanca*; the last century's great outpouring of music, including George Gershwin's "Rhapsody in Blue" and Bob Dylan's "Blowin' in the Wind"; and masterpieces of literature, such as the works of Faulkner and Hemingway—have been locked away for an additional two decades. Here again, the result is higher corporate profits, higher costs to consumers, and less access for everyone. The reason more printed books are available on Amazon.com from the 1880s than from the 1980s, for example, is that anyone is free to republish books from the earlier era.

Ironically, many of Disney's original creations drew heavily on characters and stories that had become classics, such as Aladdin, the Little Mermaid, and Snow White, because they had long been in the public domain. But the public domain is now far smaller.

By allowing license terms to redefine transactions and strip consumers of ownership, courts are taking power away from the public lawmaking process and vesting it in the hands of private IP rights holders. Licenses function as a form of privately made law that allows rights holders to modify, supplement, and contravene IP law at the expense of the customers who pay for their products.

For most consumer goods, the contract is formed at the time of initial purchase. Let's say you walk into your local hardware store to buy a shovel.

You see one that looks suitable for your needs. It bears a \$20 price tag. Even though it's not as formal as a loan document, contract law calls that an offer. You take the shovel to the checkout counter and tender the asking price. That's acceptance. A contract has been formed. But let's say that once you get home, the hardware store calls you and says:

“You know that shovel you bought? Well, there are some additional strings attached. You can use it for ditch digging, but you can't use it for gardening. Gardening requires you to pay an extra \$30 upgrade fee.”

After depleting your reserve of expletives and hanging up the phone, chances are you would feel no obligation to avoid planting some shrubbery with your new shovel. And no court in its right mind would disagree with you. It would recognize that phone call as an ineffective attempt to modify an existing contract. Now imagine a slightly different scenario. While waiting in the checkout line, you notice a sticker on the handle of your shovel. It reads:

“This shovel is subject to a license agreement. You will be notified of the full terms by phone after your purchase.”

Does this change things? Most of us would probably say no. Vague references to unknown terms cannot form the basis of a contract.

“The door refused to open. It said, ‘Five cents, please.’ He searched his pockets. No more coins; nothing. ‘I'll pay you tomorrow,’ he told the door. Again he tried the knob. Again it remained locked tight. ‘What I pay you,’ he informed it, ‘is in the nature of a gratuity; I don't have to pay you.’

‘I think otherwise,’ the door said. ‘Look in the purchase contract you signed when you bought this apartment.’ In his desk drawer he found the contract; since signing it he had found it necessary to refer to the document many times. Sure enough; payment to his door for opening and shutting constituted a mandatory fee. Not a tip.

‘You discover I'm right,’ the door said. It sounded smug. From the drawer beside the sink Joe Chip got a stainless steel knife; with it he began systematically to unscrew the bolt assembly of his apt's money-gulping door. ‘I'll sue you,’ the door said as the first screw fell out. Joe Chip said, ‘I've never been sued by a door. But I guess I can live through it.’”

Motion Picture Patents Co. v. Universal Film Manufacturing Co., involved Edison's patented film projectors. Edison was happy to use Westinghouse dynamos over the patent holder's objections, but when it came to his own patents, Edison had a very different view. His projectors were extremely popular, but Edison quickly realized that the real money was in selling film reels, which he had also patented. So he attached a large steel plate to each of his projectors that asserted that they could only be used with Edison reels. After his patent on the reel expired, the defendants decided to make their own compatible film reels for use with Edison's projector. Edison sued them and their customers, claiming that use of the new reels with the patented projector violated the restriction stamped on the side of the device.

For Edison—much like Lexmark and Keurig—tethering a device that customers are likely to buy only once to a consumable accessory product like ink, coffee, or reels of film looked like a savvy business model. By locking out competitors, Edison could keep the more lucrative film reel market to himself. However, the Supreme Court's *Motion Picture Patents Co.* decision ultimately rejected Edison's attempt to trump patent exhaustion. It explained that “the primary purpose of our patent laws is not the creation of private fortunes for the owners of patents, but is ‘to promote the progress of science and the useful arts.’” As a result, “the right to vend is exhausted by a single, unconditional sale, the article sold being thereby carried outside the monopoly of the patent law and rendered free of every restriction which the vendor may attempt to put upon it.”

In 2013, the Supreme Court again revisited the doctrine of patent exhaustion, this time in relation to genetically modified soybean seeds. Monsanto owned patents on these seeds, and sued farmers who saved seeds from prior seasons and replanted them, claiming this infringed the exclusive right to “make” their patented products. One of these farmers argued that patent rights in the seeds were exhausted when farmers bought the original batch, and any subsequent seeds that came from the harvested plants were subject to exhaustion as well. Seeds, he argued, are naturally “self-replicating”; they grew themselves. The Court rejected such arguments, including the so-called “blame-the-bean” defense, but it noted that its holding was limited to the facts of the case; other technologies might, in fact, self-replicate “outside of the purchaser's control” or that self-replication might be “a necessary but incidental step in using the item for another purpose.” In noting this, the Court cited to section 117 of the Copyright Act, which allows for the creation of essential step copies and modifications of software programs.

So far, limitations on use have for the most part treated everyone the same: ‘you cannot lend this ebook,’ or ‘your rental period is twenty-four hours.’ But as technology reduces the costs of monitoring and valuing individual

behavior, we are likely to see increasingly fine-grained, individualized use-based restrictions. Imagine your reasonably-hip crossover vehicle alerting you after your third after-school stop, ‘I’m sorry; you’ve reached your limit of daily passenger drop-offs. Would you like to upgrade your vehicle plan to CarPoolPro?’ As if that weren’t indignity enough, your carmaker’s pricing algorithm—relying on information it has gathered about property values in your neighborhood, your driving patterns, and your in-car search history—predicts exactly how much you are willing to pay for the privilege of dropping off that last cranky first grader. This is exactly the goal of price and geographic discrimination tactics—to divide our lives into individual transactions and charge as much as we are willing to pay for each one. Shifting away from ownership is an essential step toward that future.

US copyright law does not protect fashion design, only fabric prints and jewelry, and the law has always been firm on this point. The copyright office has always said very consistently that clothing is just functional and therefore can’t be copyrighted. In Europe, as well as in India, Singapore, and with certain limitations in Canada, fashion design is largely covered by copyright rules, although they are often loosely enforced. France, perhaps not surprisingly, has had copyright protection on their fashions for a century.

The reason America lags behind other nations on fashion copyright law is perhaps because historically it was a manufacturing hub rather than a design center. Europe had the designers; the United States had the factories that mass-manufactured the European designs. Garment makers benefit from relaxed copyright laws because it means they can either skip hiring designers or simply hire sketch artists to copy the latest looks. They can just go out and choose what’s hot—it used to be what’s hot from Paris, now it’s what’s hot from anywhere—and make the copy.

However, now that you’re more likely to find a fashion designer than a garment worker in the United States this may have shifted the balance of power toward designers, many of whom are demanding that we reexamine our laws.

Does the artist who invents something deserve a different level of credit from those who employ that invention later, even if they do so in a more interesting way? Is originality more or less important than we pretend?

Copyright and patent laws which are structured to ensure fame and profit for those that can afford the fees and are the quickest to file forms have created a society and a history filled with people celebrated for creations they did not originate and filled also with creative people who died in poverty and anonymity because they did not have the gift of self promotion.

“Sure, copyright is silly—when you’re not the creator.”

False. Unless the individual raised themselves in a cave cut off from all other humans, creating the idea and product solely in that cave before emerging into a world they have no knowledge or experience with but luckily made a product that an alien culture finds useful, then they have not created the item without assistance. It is not purely their amazing business acumen or engineering skills or creative intellect that created the idea, it was done with assistance. Copyright is silly regardless of who you are, provided you value the common good over yourself. Now of course, in the current system, copyright is a way for some small segment of the population to be supported well. However this is done at the expense of everyone else in many extremely harmful ways.

The human mind is unable to form an original thought. An idea is either one that has been had before, or one that is the logical result of something else.

Once upon a time, people were active collaborators in the creation of culture. That was the essence of folk traditions. People took songs, tweaked them, and remade them as their own; they retold stories, adding their own embellishments. Higher forms of culture worked this way, too. What was Mark Twain but a skilled refashioner of the African American tales he overheard as a youth? If critics were honest, they would concede that every artist operated like this—borrowing, quoting, building supposedly original creations on the works of others. Jazz, at its core, entails the constant reinterpretation of the old songbook; hip-hop unapologetically swipes its beats and hooks. The great poets did this, too. T. S. Eliot, who stitched elusive and allusive quotations into his verse, issued the dictum:

“Immature poets imitate; mature poets steal.”

Knowledge is a river for all humans to drink from. In that sense, is intellectual property theft?

When Jonas Salk, a scientist at the University of Pittsburgh, developed the first polio vaccine in 1952, he did not patent the lifesaving treatment.

“There is no patent. Could you patent the sun?”

As Thomas Jefferson explained it:

“He who receives an idea from me, receives instruction himself without lessening mine; as he who lights his taper at mine, receives light without darkening me.”

If you have an apple and I have an apple and we exchange these apples then you and I will still each have one apple. But if you have an idea and

I have an idea and we exchange these ideas, then each of us will have two ideas.

We all know about taxes, but the government can also turn to non-tax mechanisms for funding public purposes, which impose tax-like burdens in the future. Grants of patents and copyrights are an obvious example. These government-granted monopolies are mechanisms through which the government provides incentives to innovate and do creative work, and in this sense can be thought of as alternatives to direct government payments for these purposes. The government could pay people and corporations to research new drugs, software, or other items, and to do creative work. In fact, it already does, paying over \$30 billion a year to finance research at the National Institutes of Health and funding—modestly—creative work through the National Endowments for the Arts and Humanities and the Corporation for Public Broadcasting. This direct funding appears as an expenditure in the government's budget. However, if the government pays for this work with a patent or copyright monopoly, then the cost never appears on the government's books. In effect, the government is committing the public to paying a higher price for the protected item for the duration of the patent or copyright. This is a form of taxation that need never show up in the government's accounts. A push to limit government spending can lead to longer and stronger patent and copyright protections as alternatives to direct spending, even if these monopolies are less-efficient mechanisms for financing innovation and creative work.

Patents and copyrights give their holders monopolies on technology or creative work for their duration. If we are concerned that money is going from ordinary workers to people who hold patents and copyrights, then one policy we may want to consider is shortening and weakening these monopolies, if not removing them altogether. But policy has gone sharply in the opposite direction over the last four decades, as a wide variety of measures have been put into law that make these protections longer and stronger. Thus, the redistribution from people who work to people who own the technology should not be surprising—that was the purpose of the policy. If stronger rules on patents and copyrights produced economic dividends in the form of more innovation and more creative output, then this upward redistribution might be justified. But the evidence doesn't indicate there has been any noticeable growth dividend associated with this upward redistribution. In fact, stronger patent protection seems to be associated with slower growth.

A large number of R&D labs in the United States were surveyed to gain insights into the relative importance of patents as a mechanism to support research. The study found that patents were viewed as a relatively

unimportant mechanism in allowing firms to profit from their research. The respondents cited lead time advantages, secrecy, and the use of complementary manufacturing and marketing as more important than patents. The survey also found substantial differences in answers by firm size, with large firms most frequently citing patents as a major way to protect their investment in R&D.

The biggest technology companies are spending billions accumulating patent portfolios and then suing and countersuing one another. By purchasing Motorola Mobility for \$12.5 billion in 2012, for example, Google gained ownership of seventeen-thousand patents, many of which would serve as valuable ammunition in the smartphone patent wars that Google, Samsung, and Apple were waging against one another. Google and Apple have been spending more money acquiring and litigating over patents than on doing research and development.

Fuisz came upon the startup's website. The home page gave a cursory description of the microfluidic system Theranos was developing. Under the website's News tab, he also found a link to a radio interview Elizabeth Holmes had given to NPR's "BioTech Nation" segment a few months earlier, in May 2005. In the interview, she'd described her blood-testing system in more detail and explained the use she foresaw for it: at-home monitoring of adverse reactions to drugs. Fuisz listened to the NPR interview several times while gazing out the window at the koi pond in his yard and decided there was some merit to Elizabeth's vision. But as a trained physician, he also spotted a potential weakness he could exploit. If patients were going to test their blood at home with the Theranos device to monitor how they were tolerating the drugs they were taking, there needed to be a built-in mechanism that would alert their doctors when the results came back abnormal. He saw a chance to patent that missing element, figuring there was money to be made down the road, whether from Theranos or someone else. His thirty-five years of experience patenting medical inventions told him such a patent might eventually command up to \$4 million for an exclusive license.

At 19:30 on the evening of Friday, September 23, 2005, Fuisz sent an email to his longtime patent attorney, Alan Schiavelli of the law firm Antonelli, Terry, Stout & Kraus, with the subject line *Blood Analysis—deviation from norm (individualized)*:

“Al, Joe, and I would like to patent the following application. It is a known art to check various blood parameters like blood glucose, electrolytes, platelet activity, hematocrit et cetera. What we would like to cover as an improvement is the presence of

a memory chip or other such storage device which could be programmed by a computer or similar device and contain the 'normal parameters' for the individual patient. Thus if results would differ significantly from these norms—a notice would be given the user or health professional to repeat the sampling. If the significant difference persists on the retest, the device using existing technology well known in the art, to contact the physician, care center, pharma company or other or all. Please let me know next week if you could cover this.

Thx. Rcf"

Schiavelli was busy with other matters and didn't respond for several months. Fuisz finally got his attention on January 11, 2006, when he sent him another email saying he wanted to make a modification to his original idea: the alert mechanism would now be "a bar code or a radio tag label" on the package insert of the drug the patient was taking. A chip in the blood-testing device would scan the bar code and program the device to automatically send an alert to the patient's doctor if and when the patient's blood showed side effects from the drug. Fuisz and Schiavelli exchanged more emails refining the concept, culminating in a fourteen-page patent application they filed with the US Patent and Trademark Office on April 24, 2006. The proposed patent didn't purport to invent groundbreaking new technology. Rather, it combined existing ones—wireless data transmission, computer chips, and bar codes—into a physician alert mechanism that could be embedded in at-home blood-testing devices made by other companies. It made no secret of which particular company it was targeting: it mentioned Theranos by name in the fourth paragraph and quoted from its website.

These government-granted monopolies can impose substantial costs on the public. In the case of prescription drugs alone the cost is in the neighborhood of \$380 billion a year (equal to 2.0 percent of GDP). Washington is filled with politicians and organizations that hyperventilate about government debt and the burden it imposes on our children, but they ignore the burdens imposed by patent and copyright monopolies granted by the government.

"The Constitution's language nowhere suggests that [copyright] should include a right to divide markets or a concomitant right to charge different purchasers different prices for the same book, say to increase or to maximize gain. Neither, to our knowledge, did any Founder make any such suggestion. We have found

no precedent suggesting a legal preference for interpretations of copyright statutes that would provide for market divisions.”

Patents, like copyrights, do not entitle their holders to control all valuable uses of their products. Those rights have limits, and patent holders have to live with them. Yet just as John Wiley pointed to the positive impact price discrimination could have on students in developing countries who need cheap textbooks, patent holders have told their own, even more compelling story of the upside of market segmentation. Instead of cheap books, patent holders point to cheap pharmaceuticals. Citizens in developed countries like the United States can generally afford to pay much more for a product than those in poorer or less developed nations. By charging rich countries more, drug companies can charge poor countries less. And often that’s what happens. For example, one 2010 study examined the difference in international drug prices and found that in the top five countries, the prices were almost five times as high as they are in the bottom five countries. The result, patent holders claim, is a net increase in access to potentially life-saving medicine.

Putting aside the fact that the pharmaceutical industry doesn’t tell us much about the market for smartphones or ink cartridges, there are reasons to doubt the accuracy of this simple story. No doubt, some patients in developing economies benefit from price discrimination. But not all do. Drug companies are sometimes tempted to take advantage of the vast disparities of wealth within poor countries by selling their products at high prices to a lucrative minority. Many drugs are still unaffordable in developing countries despite strict bans on exporting them. And countries like the United States have their own problems with wealth inequality. When rich countries supply subsidies through high consumer prices, the poor in those countries don’t fare well. Ultimately, while pharmaceutical companies feel public pressure to keep drug prices low in the developing world, the goal of price discrimination is not to increase social welfare but to maximize profits. Just like textbook publishers, large drug companies enjoy extraordinary profits. In 2014, *Forbes* reported Pfizer’s profits at an astounding 42 percent. That’s not a company that sets prices on the basis of social welfare.

There is a basic principle that everyone should understand: drugs are cheap, but patents and other forms of protection make them expensive.

Generic drugs are almost always cheap—patent protection makes drugs expensive. The cancer and hepatitis drugs that sell for tens or hundreds of thousands of dollars a year would sell for a few hundred dollars in a free market.

Many lifesaving drugs continue to be made by only one company long after the original patent expires. In part, that's because the Patent Office often renews patents on the basis of small and insignificant changes to the original drugs that technically make them new and therefore patentable. The office is not required to weigh the financial burdens its decisions impose on customers. And pharmacies cannot substitute generic versions of a brand-name drug when it has changed in even the most minor of ways. For example, Forest Laboratories announced in February 2014 it would stop selling the existing tablet form of Namenda, its widely used drug to treat Alzheimer's, in favor of new, extended-release capsules called Namenda XR. The capsules were simply a reformulated version of the tablet, but even that minor change prevented pharmacists from substituting generic versions of the tablet, whose patent was about to run out. "Product hopping" like this keeps profits flowing to the pharmaceutical companies but costs consumers and health insurers a bundle.

In many other instances, new drugs are just changed old drugs with no expectation that they will be better. When creating drugs through organic synthesis, mirror-image molecules are created. If drug D is created, you wind up with a compound consisting of half D and half D' (the mirror image of D). The mirror image is usually inert and has no effect on the drug or the individual taking the drug, but it is left in because there is an expense to remove it. Years ago, the drug companies hit upon a brilliant idea. If they removed that non-working, mirror-image part of the pill, they could claim they devised a new drug!

Think this is rare? Ever heard of Nexium ("the purple pill")? Nexium is just Losec, with the mirror-image part removed. And Losec is an effective, and now generic, drug for heartburn. Losec is D + D'; Nexium is just D. There is no reason to believe that equivalent amounts of the two drugs are not the same—and research supports this. Four head-to-head studies compared 20 milligrams of Losec to 20 or 40 milligrams of Nexium. But you have to remember—half of Losec is D'(filler)! So these studies really compared 10 milligrams of D to 20 or 40 milligrams of P. Shouldn't more be better? One would think so, but it was barely so, and only in half the studies. And, of course, none of the advertising stated that you could get the same improvement just by taking more Losec. This isn't the only offender. In fact, since 1990, the proportion of these mirror-removed drugs among approved new drugs worldwide has become greater than half of those new approvals.

Many drugs that are available over the counter in other countries can be bought only by prescription in the United States, and the drug companies aggressively market these brands long after the patents have expired so that

patients ask doctors to prescribe them. America is one of the few advanced nations that allow direct advertising of prescription drugs to consumers.

It is illegal for Americans to shop at foreign pharmacies for cheaper versions of the same drugs sold in the United States, either branded or generic. In 2012, Congress authorized US Customs to destroy any such medications. The ostensible reason is to protect the public from dangerous counterfeit drugs. But for at least a decade before then, during which time tens of millions of prescriptions were filled over the Internet, no case was reported of Americans having been harmed by medications bought online from a foreign pharmacy. The real reason for the ban is to protect the profits of US pharmaceutical companies, which lobbied intensely for it. Yet the real threat to the public's health is drugs priced so high that an estimated fifty-million Americans—more than a quarter of them with chronic health conditions—did not fill their prescriptions in 2012, according to the National Consumers League.

Drug companies pay the makers of generic drugs to delay their cheaper versions. These so-called pay-for-delay agreements, perfectly legal, generate huge profits both for the original manufacturers and for the generics—profits that come from consumers, from health insurers, and from government agencies paying higher prices than would otherwise be the case. The tactic costs Americans an estimated \$3.5 billion a year. Europe doesn't allow these sorts of payoffs. The major American drugmakers and generics have fought off any attempts to stop them.

These companies are banking on an apocalyptic future of rampant disease, one in which governments are forced to buy, at top dollar, whatever lifesaving products the private sector has under patent.

The importance of patents in the pharmaceutical and medical equipment industry is reflected in the large gap between patent-protected prices and the cost of production. As noted earlier, patent-protected drugs can sell at prices a hundred times higher than their generic equivalents. Medical equipment follows a similar pattern. The cost of manufacturing even the most complex scanning devices or other cutting-edge equipment will rarely be more than a few thousand dollars, yet patent protection allows these products to sell for hundreds of thousands or even millions of dollars. This cost is recouped in high prices paid by patients (or their insurers) for procedures that may have a trivial marginal cost.

Another issue with patent monopolies is that they distort the research process by encouraging drug companies to pursue patent rents rather than find drugs that meet urgent health needs. If a pharmaceutical company produces a drug for a particular condition that earns large amounts of revenue, its competitors have a strong incentive to try to produce similar

drugs for the same condition, in order to capture a share of the rents.

Patent protection also is likely to slow and/or distort the research process by encouraging secrecy. Research advances most quickly when it is open. However, companies seeking profits through patent monopolies have incentive to disclose as little information as possible in order to avoid helping competitors. This pressure forces researchers to work around rather than build upon research findings. An analysis found that the patenting of DNA sequences in the Human Genome Project slowed future innovation and product development by between 20 and 30 percent.

Relying on patent incentives to support medical research encourages drug companies to direct research toward finding a patentable product. If, for example, evidence suggests that a condition can be most effectively treated through diet, exercise, environmental factors, or even old off-patent drugs, a pharmaceutical manufacturer would have no incentive to pursue this research. Ideally, the manufacturer would make this evidence publicly available so that researchers supported by the government, universities, or other nonprofit organizations could pursue it, but there is little incentive for them to go this route. In fact, if they are concerned that such research could lead to an alternative to a patentable product that they might develop or be in the process of developing, their incentive is to conceal the research.

A system of directly funded research, paid for by the government, would be considerably more efficient for the development of new drugs and medical equipment.

The basic logic of a system of publicly financed medical research would be that the government expand its current funding for biomedical research, which now goes primarily through the National Institutes of Health, by an amount roughly equal to the patent-supported research now conducted by the pharmaceutical industry. PhRMA, the industry trade group, puts this funding at roughly \$50 billion a year, or 0.3 percent of GDP, a figure that is also consistent with data from the National Science Foundation. That would be a reasonable target, with the idea that public funding would eventually replace patent-supported funding. Adding in research on medical equipment and tests would increase this figure by \$12–15 billion.

Suppose that we were spending another \$50 billion a year on medical research in order to replace patent-supported research, and all the findings were placed in the public domain so that all drugs were sold as generics. The annual budget would be \$50 billion higher due to the additional spending on research, but we would save \$380 billion a year on drugs due to generic pricing. In Washington policy circles, the high-drug-price scenario would be the path of fiscal prudence and caring about our children. It might pull far more money out of their pockets, but money going to drug companies

doesn't bother Washington-policy-types anywhere near as much as money going to the government.

Some would argue the necessity of having some system of international coordination so that the United States was not funding research for the whole world. This would presumably involve some payments scaled to GDP, with richer countries paying a larger share of their income. Or perhaps we could see such programs as reparations paid by the US to the world and worlds poor for climate change, regime change, and everything else they've fucked up with their toxic culture and foreign policy.

Artemisinin is a compound extracted from Chinese sweet wormwood plants. Artemisinin-based drugs are some of the best treatments we have against malaria, but as every Chinese sweet wormwood enthusiast knows, growing enough of the plant is expensive and time consuming. This is especially bad for malaria because most sufferers live in economically impoverished sub-Saharan Africa. The availability of Chinese sweet wormwood has varied dramatically over time, creating wild price fluctuations. For instance, the price was about \$135 per pound in 2003, \$495 in 2005, about \$90 in 2007, and about \$405 in 2011. When the prices drop, farmers stop growing the plants. This creates the shortage, which increases the price again. And you really don't ever want to have a shortage of antimalarial drugs.

We can't get off this cycle because we insist on doing public goods for a profit. This is a prime example of why markets are shit at supplying public goods. We could easily subsidize and encourage the production and make prices stable with no new technology required. Instead we insist on finding complex new ways that can be properly monetized and ignoring the potential for both foreseen and unforeseen consequences.

Some economists are just plain deluded ignorant fucks, drinking way too much of a the Kool-Aid and trying to force it on everyone else. There are others who do see some of the problems but then simply offer outdated views like some kind of copyright tax credit would be great to help finance creative works. They all ignore the fact that the world has changed.

There are already huge amounts of creative work available on the internet—for free—with no copyright tax credit in sight. Yet the dynamics and causes of this are largely ignored. Economists are locked into a worldview that makes life harder for every living thing. It is as if we were birds, gifted with the ability to fly, and yet we have these economists telling us—and successfully convincing most—that we are nothing but flightless penguins. It would be so easy if we could fly, but alas we cannot, so toil in the current system we must.

People will also create works if they're not worried they're going to die of starvation, or freeze to death because they have no home when winter comes,

or watch their child die from a preventable disease because they don't have the resources to provide healthcare. Most products can be created at cost or slightly more, if you're not concerned with the above.

Where the reintroduction of copyright—modern copyright—was justified by publishing being several orders of magnitude more expensive than authoring, the Internet has made publishing several orders of magnitude cheaper than authoring, completely reversing the original premise.

Of course, there will be no shortage of people who profit from an artificial limitation, once it is in place. You could easily argue today that X and Y must not change, because A and B profit from the status quo—and so, the copyright industry readily claims that so and so many thousand jobs are upheld (“created”) by this artificial and harmful limit. But really, what kind of an argument is that? Who has the right to prevent the passage of time because they benefit from a lack of change? This is effectively the copyright industry's single argument today.

The spread of digital cameras essentially destroyed the traditional film industry, causing the collapse of two major US corporations, Kodak and Polaroid, and leading to the loss of tens of thousands of jobs. While the collapse of these companies and the job losses were unfortunate, no one would have considered it a reasonable strategy to block the spread of digital cameras. On the other hand, when the development of digital technologies and the Internet threatened the business model of the entertainment industry, the response was to pass laws to contain these technologies to preserve the sector's mode of doing business. This is a great example of how it is not technology itself that is determining the distribution of income, but rather how various interest groups are able to write the laws governing the use of technology.

From a purely economic perspective, artificial friction may well alleviate the concerns of the media industries and even save libraries money if the pricing is fair. Yet copyright law in the US was never designed solely to benefit private market actors. Instead, as a constitutional matter, US copyright law was intended to use private market incentives in ways that ultimately benefited the public at large, not exclusively or even primarily copyright holders. Thus, as enamored as some of the founders might have been with the romantic ideal of authors and inventors, it was ultimately public access to knowledge and the resulting “progress of science and the useful arts” that was the true metric of IP's success.

Innovations that create value are useful, but copying what works well is more practical.

The lack of free knowledge is crippling progress. Because no one can build on ideas that work and all must start from a different point, we lose a great

deal of innovation and research speed. In the case of diseases, environmental health, and other urgent crises, we cannot afford the loss in time or the added expense and inaccessibility brought by idea ownership.

Copyright is a government-enacted, granted, and termed restriction of people's rights to ideas. You own the VHS plastic and storage that information is held on, but the data held in the storage is as "owned" by anyone as one owns the sound waves coming from a mouth, or anyone can own the light coming from the sun.

If movies couldn't be made without copyright, fine. I guess movies wouldn't be business model. There is no inherent right for government or society to protect a business model. When it *is* done, it's entirely up for debate how and why it's done. The default state is no idea ownership.

We're owed the content because ideas and data cannot inherently be owned at all. We decided to restrict ownership for entirely practical reasons, not reasons of inherent moral imperative. If the practicality of the reasons goes away or is reduced, it's entirely feasible to adjust the limitations. If the limitations begin to infringe on topics we consider *actual* moral imperatives—like life, property, free speech—to a degree that is unacceptable then it can enter the realm of a *detriment* to morality, but never can copyright itself enter the realm of *being* a moral imperative by itself, because it isn't that in any way.

One of the subjective measures of feasibility is precisely how willing people are to abide by it. If most people say it's dumb and don't abide by it, then it *is* dumb because there is no other moral imperative behind its inception. It is also possible that people who say it's dumb don't think it through, or will change their minds if all TV, movies, and music goes away, but maybe it won't. Who knows.

Throughout human history, culture has been made by people telling one another stories, building on what has come before, and making it their own. Every generation, every storyteller puts their own spin on old tales to reflect their own values and changing times.

This creative remixing happens today and it happens in spite of the legal cloud cast by copyright law. Many of our modern cultural icons are owned by a small number of content companies. We rework popular stories to critique them or assign new meanings to them, telling our own stories about well-known characters and settings. When copyright holders try to shut us down, fair use helps us fight back.

The publishing industry's campaign to preserve copyright is waged out of pure self-interest, but it forces on us a clear choice. We can watch as most of our cultural heritage is stuffed into a vending machine and sold back to

us dollar by dollar—or we can reexamine the copyright myth and find an alternative.

In an extreme case, ASCAP, the recording rights organization, once requested that the Girl Scouts pay fees for singing copyrighted songs at their campfires.

“You are morally obligated to reimburse someone who thought it was worth charging for.”

Maybe you are, I feel morally obligated to prevent any money I can from going to the copyright lobby, who continue to push for ridiculous copyright terms. I might not be able to afford my own lobbyist, but I sure as hell can stop funding theirs.

“You are not entitled to free shit just because the rest of us have character.”

I’m just undoing the damage to society you are doing. You’re not entitled to ruin society just because you are too lazy to be informed about copyright.

In my opinion, if you create something that has any real value to the larger world, then everyone is entitled to see it for free. I think everyone has earned that little bit of joy for themselves. I’m not saying you shouldn’t get paid, you certainly should get paid. And people will pay you. But a lot of people can’t, and they shouldn’t be treated like they’re evil for wanting to see that exciting new shade of red everyone has been talking about.

The core problem with copyright is that enforcement of it requires monitoring of communications, and you cannot be guaranteed free speech if someone is monitoring everything you say. This is important, most people fail to see or address this point when debating the issue of copyright, so let me make it clear: ***You cannot guarantee freedom of speech and enforce copyright law.*** It is for this reason that a system designed to *protect* Freedom of Speech, must *prevent* enforcement of copyright.

What if one does not wish to cite sources for ideas, whether within the text or in some sort of index at the end? Is writing art? What if the act of implementing citations changes the fundamental nature of the work? What if the message is unavoidably altered, thereby essentially censoring the author’s message? In what way is restricting the manner—words, images, sounds—in which one can express an idea not a gross violation of the concept of free speech?

Tomorrow’s civil liberties should never have to take a back seats to preserving yesterday’s business models.

And therein lies the rub. Monsanto's scientists are not engineering seeds that generate extra seeds so farmers can expand planting during the next season or even eat during times of famine. That would certainly help African farmers who lack seeds, and assist Indian farmers struggling to afford Monsanto's seed monopoly.

Instead, the company developed a "Terminator gene" that rendered offspring seeds infertile. Monsanto says it will never commercialize this "genetic use restriction technology," which is good news. The bad news is that Monsanto can afford to keep that ace in the hole so long as its patents are enforced and farmers keep buying its pricey, patented seeds and the herbicide those seeds are built upon.

What's more, Monsanto's "white hats" in the white coats are not working on open-source drought-resistant crops for cash-starved farmers in poor nations. They are not working on open-source technologies to increase yields for a growing global population. No, they get paid to produce proprietary products for a profit-making company that ruthlessly enforces its monopoly.

They can argue that this is "science" and "progress." And they might point out that science is expensive. Patents help pay for the innovations that will "feed the world." Sadly, their science isn't really about true sustainability. It's about sustaining an otherwise unsustainable agrochemical model that denudes soil, poisons water, and stokes counter-evolutionary responses from Mother Nature.

It's not "pure science." It's a business model. Frankly, Monsanto's "innovations" wouldn't be needed if its scientists weren't perfecting poison and playing poker with evolution. And now they're doubling down with a sci-fi-sounding surfactant that could literally change life with one simple spray.

Like patents, copyright terms are protected by international agreements. However, it is possible to develop a comparable system or alternative funding to work around the copyright system. It is important that the system respect individuals' choices in supporting music, books, movies, and other types of creative work rather than having a government agency decide which work should be supported. For this purpose, an individual tax credit might be appropriate. The model for a tax credit to support creative work could be the tax deduction for charitable giving. It allows individuals to make tax-deductible contributions to religious, educational, social assistance, and cultural organizations with minimum interference from the government. In effect, the government is subsidizing the contribution at the taxpayer's marginal tax rate, which is 39.6 percent for the highest-income taxpayers. Because the deduction is not capped, it is limited only by the size of the taxpayer's tax liability (it is not refundable).

To qualify for tax-deductible contributions, an organization need only file with the IRS and indicate the sort of tax-deductible activity in which it is engaged. The IRS does not attempt to determine whether an organization is 'good' as a religious organization or as a provider of food to the poor; that determination is left to the taxpayer. The only concern for the IRS is that the organization is in fact engaged in the activity that provides the basis for its tax-deductible status and that it is not engaged in prohibited activities such as political campaigning or profit making ventures.

Eligibility to receive funds through a creative work tax credit would work much the same way. Individuals or organizations would register to be eligible to receive funds by indicating the type of creative work in which they engaged as individuals or supported as organizations. This means that individuals would indicate that they are writers, musicians, video producers or engaged in some other type of creative work. The only issue from the standpoint of the IRS (or any other enforcement agency) would be whether the person is in fact engaged in the activity and whether the organization used its funding to support the type of creative work it claimed to support. In other words, if an organization claimed to support the writing of mystery novels or jazz music, then the concern would be whether they had actually used their funds for this purpose. Because this system is intended to be an alternative to the copyright system, the condition for getting funding for both individuals and organizations is that they not would be eligible for copyright protection.

In order to ensure that the tax-credit system did not become a copyright farm system, in which people established their reputations in the tax-credit system and then cashed in with the copyright system, there should be a substantial gap (e.g. five years) between the last time creative workers received funding through the tax-credit system and when they could first receive copyright protection.

Individual taxpayers would have the option to give the tax credit to a single individual or organization or divide it up among as many individuals as they choose. One major difference with the tax deduction for charitable contributions is that the tax credit would be refundable, meaning that every person would have the option to support creative work of their choosing, even if they had no tax liability.

There would be some risk of fraud, just as there is with the charitable deduction. However, the risks are likely to be considerably smaller with the tax credit than with the charitable deduction because the sums involved per person would be much smaller. If a high-income person contributes \$1 million to a bogus charity, he or she receives an effective tax subsidy of \$396,000 that the charity and the individual could, in principle, split

between them. A \$100 tax credit would require 40,000 people to scam the government by the same amount.

A credit of \$100 opted for by 90 percent of the adult population (a high percentage, but this is free money) would generate more than \$22 billion a year to support books, movies, music, and other creative work. This amount would vastly exceed the amount currently going to creative workers through the copyright system, although it would total far less than the current subsidy for charitable contributions, which was likely in the neighborhood of at least \$54 billion in 2016. The ultimate check on the boundaries of the system is what people are prepared to support with their tax credits. If few people opted to support journalism or video games, then these industries would remain largely dependent on copyright protection.

Public funding could produce a large number of textbooks free from copyright restrictions. The arithmetic here is striking. An appropriation of \$500 million a year (0.01 percent of federal spending) to finance textbook writing and production would cover 500 books a year, assuming an annual cost of \$1 million per textbook. After 10 years, 5,000 textbooks would be available in the public domain to be downloaded at zero cost, or printed out in hard copy for the cost of the paper.

Discovery is a story of many participants, not of lone heroes or “eureka” moments.

When taken to extremes the collectivist view can seem trite. Every time I drink a great cup of coffee, I could thank the farmers in Colombia who grew the beans, those in Brazil who provided the lush green fields of swaying sugar cane used to sweeten it, or the herdsman in Devon who milked the cows so my pick-me-up could be decorated with a little froth. I could also thank the nuclear power workers who provided the electricity to heat it, the person who had the bright idea of drinking a beverage based on roasted seeds in the first place, or who patented the first espresso machine. I could list all those hundreds of people who worked in supply lines straddling the planet to bring the energy, information, and ingredients together. Many might prefer to thank the barista, since our amazing ability to cooperate is a defining characteristic of human society, and it’s a given that many others were involved in almost everything we do.

But this seems to be a view resulting from being enmeshed within a highly individualistic culture. The notion of thanking such a diverse range of people—or even those we might not deem people at all—is not necessarily going to be viewed negatively by all cultures. The simplest example to trot out would of course be a hunter thanking an animal for its sacrifice—a common cultural practice, even for some red-blooded modern Americans.

There is no way to steal an idea, the tech does not exist. Though I’m

sure some alphabet soup agency or government contractor has tried. The only way for me to possess your idea is if you have offered it up to the world. Should it remain within your own mind, it can certainly be claimed as 'yours'—though of course how much of our ideas are truly, originally, completely, ours is debatable—but if I am able to have it also within my own mind, then it is only because you have chosen to share it. Once shared, there are no limitations on its use, that privilege only extends to ideas within the confines of your own brain. To claim anything else is to seek control over another's most basic of freedoms—that of thought and expression. One cannot have a just world when this is allowed, tolerated, promoted, admired. Such things are relics of a more barbarous era, let us throw off the shackles our ancestors have placed upon us, let us help our brothers and sisters shed their own shackles, let us begin to make up for the harms of the past, let us cease our own harms, let us unite as one people, under a banner of justice for all, let us never again allow such greed to go unchallenged, let us start today.

Part II

Institutionalized Injustice

Oh, a rifle took its aim and a man fell to the ground
He tried to stand again but everybody held him down
A time of terror when the bullet pierced the air
I know that couldn't happen here
Oh, it must have been another country
Yes, it must have been another land
That couldn't happen in the USA
We'd never treat a man that way

And a migrant worker sweats underneath the blazin' sun
He's fallen to his knees but his work is never done
He begs someone to listen but nobody seems to care
I know that couldn't happen here
Oh, it must have been another country
Yes, it must have been another land
That couldn't happen in the USA
We'd never treat a man that way

And a man is working steady, it's good money he receives
But he's thrown out of work for the wrong things he believes
He didn't have the thoughts most everybody shares
I know that couldn't happen here
So it must have been another country
Yes, it must have been another land
That couldn't happen in the USA
We'd never treat a man that way

And a man is sent to prison to wait until he dies
He fights to save his life, for years and years he tries
Even though he changed himself he dies upon the chair
I know that couldn't happen here
Oh, it must have been another country
Yes, it must have been another land
That couldn't happen in the USA
We'd never treat a man that way
Oh, I know we'd never treat a man that way

Chapter Twenty-four

Needless Suffering

They had not yet started out across a continent of grief that a lifetime of walking could not cover.

“My mother told me, ‘You never turn anybody away. Don’t turn anybody away at night because anything can happen to them. Wait till the daytime so they can see their way.’”

“I was once asked by a troubled young boy whether there was any compelling reason for him not to pull the legs off a spider. I said that there was. ‘Well, spiders don’t feel any pain,’ the boy retorted. ‘It’s not the spider I’m worried about,’ I replied”

Once a man moved into a new village. He wanted to find out what his neighbors were like, so in the middle of the night he pretended to beat his wife very severely, to see if the neighbors would come and reprimand him. But he did not really beat her; instead he beat a goatskin, while his wife screamed and cried out that he was killing her. Nobody came, and the very next day the man and his wife packed up and left that village and went to find some other place to live.

When the suffering of another creature causes you to feel pain, do not submit to the initial desire to flee from the suffering one, but on the contrary, come closer, as close as you can to him who suffers, and try to help.

There is a neoliberal myth that the rich can only be incentivized with additional money while the poor can only be incentivized with increasingly debased material conditions and increasingly harsh punishments.

If we throw kids in holes at age ten, those who get out would be quite capable of getting themselves out of holes they’ve been thrown in. But is this a good skill to select for? Why can’t we just not throw them in holes?

So much of our modern day struggles are artificial constructs. It is not us against nature—if it ever was—but us against the constructs of whatever society we find ourselves in. One could argue that we are ill prepared for these struggles given the relatively recent onset of these conditions.

How much energy is spent on such artificial constructs. What additional harms are caused by these struggles and failures to achieve? Do they serve any legitimate purpose or are they simply no better than frat house hazing?

“Let me give an example. Recently I was thinking maybe I’d foster a kid. So I looked into the package. It’s quite generous. You get a council flat, and on top of that you get £250 a week to look after the child. But then I realized: wait a minute. They’re talking about £13,000 a year and an apartment, for one child. Which the child’s parents in probably most cases didn’t have. If we’d just given the same thing to the parents so they didn’t get into so many problems they’d never have had to foster the child to begin with. And, of course, that’s not even counting the cost of the salaries of the civil servants who arrange and monitor fosterage, the building and upkeep of the offices in which they work, the various bodies that monitor and control those civil servants, the building and upkeep of the offices in which they work, and so forth.”

How many homeless huddle in the cold, close to clean, heated, empty hotel rooms?

Something to ponder: compared to a more just world—with free health-care, free life-long education, clean air & water, 100% renewable energy, free inter- & intra-city rail & bus, universal basic income, living retirement stipend, public banking, guaranteed housing, et cetera—is your situation now, relative to that just world, nearly as shitty as a third-world world slum-dweller’s life compared to your current situation?

The burden of finding water in dryland communities almost always falls to women, many of whom must make laborious journeys through remote and dangerous regions and then return with their heavy loads—even when sick or pregnant. Water fetching is a leading cause of miscarriage and stillbirth in desert villages, and women often give birth during the arduous journeys. Such babies are called Mwanzia in Kenya, meaning ‘born on the way.’

People living without sanitation can ingest as much as ten grams of fecal matter a day.

Within three weeks, their pump was operational. The skin rashes, diarrhea, and stomach pains the community suffered from using filthy water disappeared within two weeks. Malaria incidence has plummeted because nobody uses the open pond to gather water and wash any more.

Supplying a \$30 clean-cook stove to the 500 million households who cook with open fires could be done for just \$15 billion. Distributing clean-cook

stoves would not only reduce the pollution burden, but also free girls and women from gathering and carrying firewood, a task that endangers their health, puts them at risk of rape, and prevents them from going to school. A big win all round.

In the 1980s, the IMF and World Bank imposed conditions on development aid, preventing African governments from subsidizing fertilizers. However, after decades in which the population was continuously on the edge of famine, and following a disastrous harvest in 2005 when more than a third of the population needed emergency food aid, Malawi's President Bingu wa Mutharika rebelled, and reintroduced fertilizer subsidies—the first sub-Saharan country to do so. Agricultural production trebled, and by 2007, Malawi was exporting its surplus corn to Zimbabwe and Kenya. A dozen countries are now following suit and introducing subsidies.

Some 40% of food produced in the developing world is wasted before it gets to market because of refrigeration and transportation issues. The same proportion of food is thrown away in the rich world. Cutting waste would be the fastest and cheapest way of meeting future global food requirements. Food wastage is the third largest emitter of greenhouse gases after the US and China, and uses a third of agricultural land even though 870 million people go hungry every day.

The adult cormorants had all gone. And their chicks—the offspring they devoted so much effort to feeding—had been left behind to die. The sight tore at his heart; even decades later, he couldn't forget walking among “the horde of downy babies” as they starved.

“They would flap their unfledged wings, while they gave their hunger call, at the feet of this strange, uncormorant-like creature. There was not a thing one could do for them. Day by day there were fewer begging, more staggering about and listlessly drooping. And then more—hundreds of thousands more—of the pitiful, collapsed, downy clumps that were the dead. Somehow, ever since, it has been possible to understand more fully the famines of China and India.”

Capitalism is a formidable social system. Despite the best efforts of hundreds of millions of socialists over the last century and a half, it remains the hegemonic system governing production and politics around the world. That dominance at least partially explains the sense of shock palpable in the writings of media figures who have slowly awoken to the growing socialist revival in the United States. There's a very real sense in reading these pieces that the authors just can't believe anyone is still questioning capitalism.

Writers often attempt to pile as many bodies at the foot of socialism as possible, through a familiar tour of the death tolls attributed to regimes in countries like the USSR, China, and Cambodia. These deaths, they argue, are ignored by contemporary advocates of socialism. In fact, some claim, the present resurgence of socialism in the United States is mostly grounded in an ignorance of twentieth-century history every bit as myopic as far-right Holocaust deniers. It's more than a little ironic that they attempt to paint socialists as historically ignorant, when their own writing and statements reveals a near total lack of understanding of anything about these societies. They're only really interested in body counts.

For example, they will often bring up the Khmer Rouge regime in Cambodia, which ruled the country from 1975–1979 and presided over a genocidal level of violence against the country's population. For these people, Cambodia was ruled by the same economic system as Russia or China. Such an assertion betrays a near-total ignorance of the actual history of the Khmer Rouge, whose connection to socialism was roughly analogous to Donald Trump's connection to Christianity. From long before they took power in 1975, the Khmer Rouge were an ethno-supremacist movement dedicated to restoring the glory of the Cambodian nation and scapegoating ethnic Vietnamese and Chinese. Socialist phraseology served as mere window-dressing.

Upon taking power, the regime emptied the cities of their populations to boost rural agriculture, abolished money, and grandiosely blew up the country's central bank. Predictably, the economy collapsed, and the regime was short-lived. This fact in and of itself should serve as a clue that it was a rather different kind of society than either China or Russia after their revolutions. After all, whatever the many crimes of those regimes, and whatever their considerable economic problems, both countries achieved relatively high levels of economic growth that considerably raised their populations' standards of living over decades.

To top it all off, the Khmer Rouge would never have come to power in the first place without the savage American intervention in Cambodia, most centrally a bombing campaign that devastated the countryside. Only the brutality of the world's foremost capitalist power, acting in the name of combating communism, could create the conditions in which a regime like the Khmer Rouge could attain state power. Avoiding historical myopia apparently means ignoring this kind of historical context, so long as it allows one to pile more corpses at the feet of socialism.

But what of China? Here, it would seem they come closer to the mark. The Chinese famine of 1958–61 was one of the greatest peacetime catastrophes of the twentieth century, and there is no doubt that the

particular forms of state planning the Chinese state adopted contributed to it. But once again, with some more historical context, things begin to look rather different. For while China experienced three years of world historic catastrophe in the mid-twentieth century, around the world, countries which did not have the systems of food support that China built experienced decades of slow-motion starvation. Around the world, landlords' ability to exclude rural populations from their private property left the rural poor in utter destitution.

Compare India, where, for all talk of socialism, landlords still held sway, and China, where they did not:

“It is important to note that despite the gigantic size of excess mortality in the Chinese famine, the extra mortality in India from regular deprivation in normal times vastly overshadows the former. Comparing India's death rate of 12 per thousand with China's of 7 per thousand, and applying that difference to the Indian population of 781 million in 1986, we get an estimate of excess normal mortality in India of 3.9 million per year. This implies that every eight years or so more people die in India because of its higher regular death rate than died in China in the gigantic famine of 1958—61. India seems to manage to fill its cupboard with more skeletons every eight years than China put there in its years of shame.”

In other words, though India experienced no concentrated period of starvation which can be easily identified and hung around the neck of a particular ideology, its ordinary conditions for the latter half of the twentieth century, in which an extraordinarily unequal distribution of land obtained, created an excess mortality that, over the long-term, dwarfed that of the worst famine of the century. Most of the death and suffering resulting from capitalism remains stubbornly unspectacular.

When people with diabetes ration their insulin because of rising costs, and some of them die, that's a consequence of the distribution of property rights that exists in our society. When the poor suffer increased mortality from airborne pollution, that too, is a consequence of our current economic system. This exercise could be extended indefinitely. The people whose lives are devastated because our society prioritizes the property rights of the wealthy over the needs of the poor are victims of an injustice every bit as much as those who died in compressed catastrophes under states calling themselves socialist.

One could, of course, turn this logic around, and point to the human potential lost in quotidian inefficiencies of the state socialist regimes, and

the human dignity assaulted by their political corruption. But what would be the point? Few today would honestly say that, given the choice between life in an advanced capitalist democracy like the US and an authoritarian developmental state like China or the USSR, they would choose the latter. But this is not the choice on offer today in the United States. It's not the vision of socialism of many, which is grounded in the centrality of democracy to human liberation.

In fact, the socialist tradition is full of voices who have been stridently critical of those regimes on precisely these grounds. Some might contend that it's where socialists end up, even when they want to go somewhere else, but it's hardly credible to argue that an attempt to build socialism in the most advanced economy in history will necessarily end up in the same place as revolutions in developing countries against tottering agricultural elites.

What contemporary socialists, whose numbers are growing at an incredible rate, are arguing is that life for tens of millions of Americans can be decisively improved by a whole host of measures that would rein in the power of capital, from Medicare for All to subordinate the healthcare industry to human need to a renewed union movement that would curb the despotic power employers wield over their workers. Some socialists go further, arguing that we will only have a humane society when a small portion of humanity no longer wields exclusive control over our productive resources.

These arguments are gaining traction today not because Americans are unfamiliar with the legacy of state socialism, but because they are all too familiar with the state of American society today. Today's socialists have succeeded in linking the everyday tragedies they see around them to an economic system that has delivered ever more spectacular rewards to the wealthy, while most barely tread water. They have understood that though Americans may not be perishing en masse in a famine, they are needlessly suffering in innumerable ways because of the way our society distributes property.

The task today's socialists have ahead of them is a daunting one. Capitalism's resilience is not to be underestimated. But their often ineffectual and ignorant criticisms are a reminder that whatever the sources of that resilience, the quality of the system's apologists is certainly not among them.

The more needless suffering and struggle we alleviate here, now, on Earth, the weaker God gets. In that sense, our goal must be to kill God.

Chapter Twenty-five

You Didn't Earn It

“The masses are feminine. In the area of politics, the masses are feminine. OK? And the feminine masses look to what? They look to the masculine for protection. And who is the masculine? The government. So the feminine masses look to the masculine government for protection. OK? So when the feminine masses see a Klansman on TV, or a militiaman running around with a gun, or a patriot wearing camouflage, what is she going to feel? She’s going to feel that her safety is being what? She’s going to feel that her safety is being altered. And she doesn’t want her safety to be altered. So she’s going to turn to who? She’s going to turn to the masculine for protection.”

“I have a rescue fantasy—what social worker doesn’t? Somewhere inside, we love to believe that we could just hug our clients and make everything better. If we took them home and gave them a good meal and enough sympathy, we believe we could fix everything and earn their undying gratitude. But that is an inside thought. You do not tell your clients about that thought. The point is to help, not to feel helpful. If I needed groceries, would I really want to go someplace where I might get hugged by some misty-eyed young lady with a savior complex? No way.”

“The idea of human rights is that people have basic dignity and that it’s the role of the government—yes, the government—to ensure that no one falls below the decent level. Civilized society doesn’t say for people to go and make it on your own and if you can’t, bad luck.”

World poverty isn’t reducing. Earning \$2 per day doesn’t mean that you’re somehow suddenly free of extreme poverty. Not by a long shot. People have been calling for a more reasonable poverty line for many years. Most agree that people need a minimum of about \$7.40 per day to achieve

basic nutrition and normal human life expectancy. So what happens if we measure global poverty at the low end of this more realistic spectrum—\$7.40 per day, to be extra conservative? Well, we see that the number of people living under this line has increased dramatically since measurements began in 1981, reaching some 4.2 billion people today.

Most of “people are making more money” comes from ‘people were forced off their subsistence farms so that they had to use money to buy what they got from their own labor before.’ So, for example, when NAFTA went into place, millions of Mexican subsistence farmers were forced off their land. This led, directly, to the massive increases in immigration to the US that occurred in the 90s and early 2000s, by the way.

People miss the essential point: it’s not how much money you have. It’s whether or not you have enough food, shelter, clothes, and so on. It’s whether you have what you need and some of what you want. Only a moron—or someone as disconnected from the realities of life like Bill Gates—could think that being able to buy as much as \$1.90 a day, in the United States of 2011, would qualify as enough money. These people who say with certainty how poverty is massively decreasing make me sick. They are either ignorant, or very stupid and disconnected from reality, or they are very evil.

Essentially all of the poverty reduction of the past 30 years comes from one source, and one source only: China—which industrialized by classic protectionist policies which the IMF, World Bank and poverty ghouls do their best to make impossible. And as for China, what is also clear from their experience, and in the data, is that the Chinese who moved to the cities to get those great new jobs are less happy than the people who stayed in the villages. Further, great amounts of force have had to be used to move peasants off the land, because they know the new factory jobs suck even worse than being a peasant. As they did in Britain during the Industrial revolution.

What made some parts of the world better wasn’t capitalism, per se. It was steam power and oil power. Those parts of the world then used that power, along with gunpowder and whatnot, to conquer most of the world and take what they wanted. Today we do it different ways, but the bottom line is simple enough: measured by any semi-reasonable standard—would you want to try to live on \$7.40 a day, including paying your rent?—poverty is not getting better. It is getting worse.

If you say poverty is decreasing, what you are saying is ‘it is ok to keep doing what we’re doing.’ And you are wrong.

“I say that you ought to get rich, and it is your duty to get rich. The men who get rich may be the most honest men you

find in the community. Let me say here clearly: ninety-eight out of one-hundred of the rich men of America are honest. That is why they are rich. That is why they are trusted with money. I sympathize with the poor, but the number of poor who are to be sympathized with is very small. To sympathize with a man whom God has punished for his sins is to do wrong. let us remember there is not a poor person in the United States who was not made poor by his own shortcomings.”

“Society tells me I have to go to school, get a good job, and then I’ll get a salary, because I’m in America. And that’s what I did, and now I’m in debt. And now I’m suffocating.”

Such stories expose multiple malfunctions in the machinery of American progress. They implicate the country’s health care system and the problem of unaffordable drugs; its public transport system; its wage and labor laws; its food system and food deserts; its student debt crisis; its so-called great risk shift, through which corporate America has stabilized its own income statements over a generation by off-loading uncertainty onto workers; and the ways in which shareholders were running companies more and more for themselves, to the detriment of every other stakeholder.

By every international metric of health and living standards, the rural counties of southern West Virginia and eastern Kentucky qualify as third-world. So do large areas of Detroit, Cleveland, Camden, Gary, and many other American cities. At the same time, wealth beyond computation, almost beyond imagining, piles up in the money center of New York and the technology hub of Palo Alto. It piles up long enough to purchase a \$95,000 truffle, a \$38 million vintage Ferrari GTO, or a \$179 million Picasso before the balance finds its way to an offshore hiding place.

What thoughtful rich people call the problem of poverty, thoughtful poor people call with equal justice a problem of riches.

We need to understand a little of the real origins of the modern social welfare state, which we now largely think of—when we think of them at all—as having been created by benevolent democratic elites. Nothing could be further from the truth. In Europe, most of the key institutions of what later became the welfare state—everything from social insurance and pensions to public libraries and public health clinics—were not originally created by governments at all, but by trade unions, neighborhood associations, cooperatives, and working-class parties and organizations of one sort or another. Many of these were engaged in a self-conscious revolutionary project of “building a new society in the shell of the old,” of gradually creating

Socialist institutions from below. For some it was combined with the aim of eventually seizing control of the government through parliamentary means, for others, it was a project in itself.

One must remember that during the late nineteenth century, even the direct heirs of Marx's Communist Party had largely abandoned the idea of seizing control of the government by force, since this no longer seemed necessary; in a Europe at peace and witnessing rapid technological progress, they felt that it should be possible to create a social revolution through peaceful, electoral means. Germany was one of the places where such parties were most successful. Even though Chancellor Otto von Bismarck, the great mastermind behind the creation of the German state, allowed his parliament only limited powers, he was confounded by the rapid rise of workers' parties, and continually worried by the prospect of a Socialist majority, or a possible Paris Commune-style uprising in his new united Germany.

His reaction to Socialist electoral success from 1878 was twofold: on the one hand, to ban the Socialist party, trade unions, and leftist newspapers; on the other, when this proved ineffective—Socialist candidates continued to run, and win, as independents—was to create a top-down alternative to the free schools, workers' associations, friendly societies, libraries, theaters, and the larger process of building socialism from below. This took the form of a program of social insurance (for unemployment, health and disability, et cetera), free education, pensions, and so forth—much of it watered-down versions of policies that had been part of the Socialist platform, but in every case, carefully purged of any democratic, participatory elements.

In private, at least, he was utterly candid about describing these efforts as a “bribe,” an effort to buy out working-class loyalties to his conservative nationalist project. When left-wing regimes did later take power, the template had already been established, and almost invariably, they took the same top-down approach, incorporating locally organized clinics, libraries, mutual banking initiatives, workers' education centers, and the like into the administrative structure of the state.

“My idea was to bribe the working classes, or shall I say, to win them over, to regard the state as a social institution existing for their sake and interested in their welfare.”

The quote is useful to bear in mind since I find that the general point—that the welfare state was largely created to pay off the working class for fear of their becoming revolutionaries—tends to be met with skepticism, and demands for proof that this was the self-conscious intention of the ruling

class. But here we have the very first such effort described by its founder quite explicitly as such.

The welfare system was originally planned in the interest of the nation rather than of needy individuals. When Otto von Bismarck pioneered state pensions and social security in late nineteenth-century Germany, his chief aim was to ensure the loyalty of the citizens rather than to increase their well-being. You fought for your country when you were eighteen, and paid your taxes when you were forty, because you counted on the state to take care of you when you were seventy.

The social safety net in the US and what is called the welfare state in Britain and Europe are a means of buying social peace. The safety nets—decent and humane and civilized—promote peace. Peace is good for countries. Peace is good for business—unless you're an armaments manufacturer I guess. Peace is good for capitalism.

The neoliberals in government should consider the safety nets a cost of doing business instead of a pot of money to be looted.

All of society's problems which could be solved by money were caused by money. Poverty is also regarded as a moral failure, as society needs to blame the victim to avoid blaming themselves for the situation the poor find themselves in. In this way, courage, duty, industry, thrift, kindness, loyalty—all of the traditional virtues may be replaced simply by wealth, the ultimate virtue respected in society today.

We still have 43 million people in poverty as well as 15 million in deep poverty. And the limits of those categories are likely far too narrow.

All across America, there are thousands of struggling cities and towns. Many of these places, and the rural regions where they are located, are hidden from view in pockets of the country that other Americans have largely forgotten. In these communities, too, the formal economy has all but disintegrated, and the social safety net—both public and private—is threadbare. To visit these impoverished regions is to experience what Lyndon Johnson and Robert Kennedy did fifty years ago, when they were visibly shaken by the conditions there. With so many of their citizens cut off from any legitimate access to a cash income, these places may seem unrecognizable as part of "America." And yet they are America, as much as any other place in the country.

Two dollars is less than the cost of a gallon of gas, roughly equivalent to that of a half gallon of milk. Many Americans have spent more than that before they get to work or school in the morning. Yet in 2011, more than four percent of all households with children in the world's wealthiest nation were living in a poverty so deep that most Americans don't believe it even exists in this country.

What happens when a community starved for cash forges a shadow economy that threatens to overtake the formal one—and the two become commingled, almost indistinguishable from each other? Does it become that much harder for a community to right its collective course, to return to a formal system with rules by which people play?

The old poverty was linked to an economy based on exploitation of the worst sort. But there were still jobs to be had. Then, for a time, there was a cash floor that kept families with children above a certain threshold. Now there are neither jobs nor a cash safety net. And a place that has experienced entrenched poverty for decades has met a new poverty of the deepest sort.

A federal program in existence for sixty years, a system that had survived would-be reformers for decades—including a full frontal attack by Ronald Reagan—was terminated by Congress and the stroke of the president's pen in the summer of 1996 without much fuss at all. Welfare, as the country knew it, was dead, and very few people seemed to care.

In truth, what Bill Clinton accomplished were things that no Republican could have done. Thanks to our two-party system, Democratic politicians carry a brand identity that inhibits them in some ways but allows them remarkable latitude in others. They are forever seen as weaklings in the face of the country's enemies, for example; but on basic economic questions they are trusted to do the right thing for average people. That a Democrat might be the one to pick apart the safety net is a violation of this basic brand identity, but by the very structure of the system it is extremely difficult to hold the party accountable for such a deed. This, in turn, is why only a Democrat was able to do that job and get away with it. Only a Democrat was capable of getting bank deregulation passed; only a Democrat could have rammed NAFTA through Congress; and only a Democrat would be capable of privatizing Social Security, as George W. Bush found out in 2005.

In 1995, Senator Daniel Patrick Moynihan famously predicted that the proposed welfare reform would result in children "sleeping on grates." Most observers think history proved him wrong. But does the rise in the number of the \$2-a-day poor represent the great failure of welfare reform? Perhaps Moynihan was not so far off after all. Perhaps his only mistake was in assuming that this failure at the very bottom of the economic distribution would be visible and obvious, when in fact, throughout history, American poverty has generally been hidden far from most Americans' view.

In effect, the new work requirements have merely reduced the number of poor people who are jobless, while increasing the number of poor people who have jobs.

Plunging our society's weakest and most vulnerable into economic des-

peration triggered a domino effect of misery right down the line, with the slightly better-off now feeling the competition of the utterly hopeless. The effect was to make all of us a little more precarious. On its own, welfare reform was a mean-spirited thing to do—one of the most regressive social programs promulgated by a democratic government in the twentieth century. Considered as part of a grander economic architecture, however, it makes an awful kind of sense. Welfare reform confirmed and accelerated the gradual replacement of a semi-protective welfare state by a disciplinary state mating the stinging goad of workfare with the dull hammer of prisonfare, for which the close monitoring and the punitive containment of undesirables stand in for social policy toward the dispossessed. Toil hopelessly or go to prison: that is life at the bottom, thanks to Bill Clinton, with ample assistance from his wife Hillary. But yeah, it was obviously the Russians who made her lose, not the decades of public displays of utter contempt for the poor.

The very act of jailing an indigent person for a fine-only, low-level offense is unconstitutional, and many of these jailings occur in states that actually have laws explicitly banning debtors' prisons. In 1983 the Supreme Court heard the case of Danny Bearden, an illiterate ninth-grade dropout who was convicted of receiving stolen goods and placed on probation with a fine of \$500 and a \$250 order of restitution. His parents put up the first \$200. Danny Bearden was going to pay the rest himself but was laid off from his factory job. He tried very hard to find work, but finally had to tell the probation people he had lost his job and could not make the payment then due. His probation was revoked and he was sent to jail. The Supreme Court decided in *Bearden v. Georgia* that "punishing a person for his poverty" violates the equal protection clause and that an indigent defendant cannot be jailed for inability to pay a fine unless he has "willfully refused to pay the fine or restitution when he has the means to pay."

Yet, Bearden and state law are flouted every day. The people who hear the low-level cases are often municipal judges or justices of the peace who are not lawyers or are lawyers but serve part-time and practice in completely different areas of the law. Some judges do not know the law, but other judges know it well and apply it harshly nonetheless. The Supreme Court has not given clear guidance for what "willfully refused" means, and the literature abounds with instances where the judge said the defendant had expensive-looking shoes or the like and therefore must be able to pay. A judge in Illinois asked all defendants if they smoked, and when any said yes, the judge said they have the means to pay. A judge in Michigan found that because the defendant had cable television he was capable of paying.

And the Bearden ruling that a defendant's ability to pay must be taken into account does not apply when a person is arrested on a bench warrant for

defaulting on a payment plan, because now the debtor has committed a crime that does carry a jail sentence. Failure to pay constitutes criminal contempt, which allows incarceration as well as further fines and fees. Because the contempt is a crime that allows jailing, there is no protection for indigence and Bearden becomes irrelevant.

Even the right to an attorney comes with a price tag. The Supreme Court decided in *Fuller v. Oregon* that charging a fee for a public defender can be constitutional if people who would suffer a “manifest hardship” are relieved from paying it (a requirement ignored in some states). In fact, forty-three states charge for having a public defender. Florida does not waive its \$50 public defender application fee for the indigent, instead instructing its courts to include it as part of sentencing or as a condition of probation. In North Carolina, defendants have to pay not only the \$50 fee but also the full value of the defense services provided, and in Virginia a defendant must pay up to \$1,235 for a public defender on each count for certain felonies. South Dakota charges \$92 an hour; even a defendant found innocent nonetheless owes \$920 for ten hours of representation. If he cannot pay, it is a crime.

The legal issues were simple. The Benton County District Court was violating Bearden and Gideon as well as state law by systematically failing to ascertain the ability of defendants to pay fines, fees, and other levies and to provide effective counsel to the defendants. The case was settled in 2016 and the county stopped jailing people for their debts or ordering them to work crews for failure to pay, and also stopped issuing warrants over not making payments. This is all good but it's like whack-a-mole: you get one of the bad actors, but another one pops up.

Damian Stinnie is one of the nearly million people in Virginia who have had their driver's licenses suspended. Despite spending much of his childhood in foster care, Stinnie graduated from high school with a 3.9 grade point average—a great story so far. Entering the world of work, he found a job and lost it and then, seeking work, received four traffic violations and racked up \$1,000 in fines and costs. He was unable to pay the full amount within thirty days on his new \$300-a-week job, so his driver's license was automatically suspended, meaning that Stinnie was among the 75 percent of those suspended who were sanctioned for not paying, not for the infractions themselves. As is routine in Virginia, no one asked Stinnie if he could afford to pay. At that point he joined the millions who face the dilemma of choosing between getting to work and taking the risk of being penalized for driving without a license. With the expansions of the state's fines and fees in 1998, assessments ballooned from \$281.5 million to \$618.8 million in 2014, with collections going from \$192.2 million to \$258.6 million.

No one ever asked debtors if they were able to pay, and the so-called

probation officer placed a series of further financial hurdles before them if they wanted to ask the court for a ruling that they were truly indigent. The company charged \$25 if a defendant requested a hearing before the judge and often required another \$20 drug test as a prerequisite as well. The company routinely “lost” records of payments and thereby won any payment dispute with the debtor. And because PCC always paid itself first, debtors who paid enough to cover the original fine often still had a balance due; the money they paid had gone to the private company rather than the government. This in turn occasioned another year of probation and fees. And PCC often invented new rules or interpretations to add more debt and/or new grounds for accusing the debtor of having violated the terms of their probation.

Money bail is ruining the lives of literally millions of poor people and costing the country unnecessary billions of dollars in incarceration costs every year. Local jail populations grew by 19.8 percent just between 2000 and 2014, with pretrial detention accounting for 95 percent of that growth. Just as one example, but typical of big cities around the country, is Philadelphia, where the cost of running the jails is \$110 to \$120 per inmate per day. The single feature shared by almost every defendant in pretrial detention is that they are poor. Rich people make bail; poor people don’t. Regardless of actual guilt or innocence, poor people are criminalized for their inability to buy their way out of jail. The major shortage of judges, prosecutors, and public defenders, coupled with the number of people being held in jail awaiting trial, has led to a crisis in which it is not possible for every defendant who wants a day in court to get one. So the courts need a way to keep the trials from taking place.

“Veteran lawyers remember a time when only clients charged with serious felonies had to make bail unless they were held without bail, but now it’s pretrial incarceration en masse. Even clients charged with petty, non-jailable offenses can have bail set on them nowadays. The predictable result is that many of our clients take a plea in order to get out rather than fight the case while sitting in jail, even if they have a great defense or are totally innocent.”

By imprisoning poor people who cannot put up money for bail, the system uses the threat or reality of extended imprisonment to extract guilty pleas, even from people who are innocent or have other valid defenses. Not able to get a timely trial, they have one option—plead guilty. It is a Hobson’s choice, more so even than many of the defendants realize, because the guilty

pleas have serious collateral consequences they may not even be aware of and which stay with them for the rest of their lives. But pleading guilty is what they do by the thousands, every day, all over America. And, ironically, when they plead guilty, they receive a sentence of credit for time served and they go home. While they were presumed innocent, they were too dangerous or unreliable to be released, but once convicted they are sent home.

The long pretrial stays in Rikers and other big-city and big-county jails are obvious antipathies to the very idea of having speedy trials. How these statutes work—what counts toward mandated time limits within which a trial must take place, and what does not—is complicated, but the basic point is that delays related to backlogs in the courts are not counted against the clock. Even if the defendant had a lawyer and was prepared to go to trial, under the current system, the clock stops every time there is a delay due to unrelated backlogs at the court.

“I heard them lock the shower door, and they were mocking him. He was crying, please stop, please stop. And they just said, ‘Enjoy your shower,’ and left.”

He might not be dead now if, when we closed mental hospitals in the 1960s, we had made major investments in community-based mental health services. He might not be dead now if we hadn't started incarcerating people at astronomically high rates in the 1970s. He might not be dead now if we hadn't slashed addiction treatment funds in the 1980s. He might not be dead now if, in the 1990s, we hadn't hired private companies to run our jails and prisons or portions of them and paid them so little that they could recruit only correctional staff who were untrained, incompetent, and too often sadistic, and mental health professionals who were stretched too far, were too frequently underqualified, and often operate under horrifying conditions. But he is dead, because what we did do in the wake of the deinstitutionalization of mental hospitals over the past half century was the worst possible combination of choices we could have made.

Schizophrenic, African American, poor, fifty years old, and doing time for a drug conviction, Rainey was an inmate at the Dade Correctional Institution of the Florida Department of Corrections, and specifically at the Transitional Care Unit or mental health ward when he died on June 23, 2012. Correctional officers there had rigged a shower with water at the scalding temperature of 180 degrees to torture prisoners whom they deemed uncooperative. Darren Rainey had defecated on the floor of his cell and would not clean it up. As punishment, the officers put him in the

shower for almost two hours, taunting him as he screamed in panic and pain. Ultimately, Rainey was scalded to death.

Mental illness and addiction are pathways to poverty, and poverty is a pathway to mental illness and addiction. The toxic stress that is emblematic of people coping with poverty culminates all too regularly in mental illness and addiction.

The most a person can receive under SSI is \$735 a month, but a recipient can be docked or terminated if, for example, she pays less for room and board than what the government deems a fair amount; according to the rules, this “discount” counts as extra income. The government also calls it extra income if a friend or relative gives the person some money to help get by. And a stint in a hospital for more than thirty days that is paid for by Medicaid can be counted as an SSI overpayment and place the beneficiary in jeopardy of being penalized.

There is evidence that welfare reform coincided with a fundamental shift in the way low-income single mothers thought about parenting. In the years prior to welfare reform, in-depth conversations with hundreds of single mothers on welfare illuminated their belief that taking a full-time job would greatly detract from their ability to be a good parent, especially if they had young children. Then came the roaring 1990s, when an unprecedented number of these single mothers found themselves going to work, “pushed” by the changes in the welfare rules and “pulled” by the EITC expansions, minimum-wage increase, and unprecedented strength of the economy.

Years after welfare reform, when researchers engaged in a further series of in-depth conversations with former welfare recipients, the typical single mom talked about work in a very different way from those interviewed just a few years before. Now she was telling researchers that to be a good parent, she had to model the value of education by getting a job. For these single mothers, the idea of returning to welfare violated their views of what being a good parent required, adding a self-imposed stigma to the potent societal stigma that came with claiming benefits from the program.

The beggarly question of parentage—what is it, after all? What does it matter, when you come to think about it, whether a child is yours by blood or not? All the little ones of our time are collectively the children of us adults of the time, and entitled to our general care.

Researchers estimate that American workers lose billions of dollars each year to what is referred to as “wage theft”—clear violations of labor standards that include paying less than the minimum wage, forcing employees to work off the clock, and failing to pay mandated overtime rates. If one tallied all of the losses suffered by victims of robberies, burglaries, larcenies, and motor vehicle thefts combined, the figure wouldn’t even approach what is taken

from hardworking Americans' pockets by employers who violate the nation's labor laws. And the victims are generally the most vulnerable among us.

Fifty years ago, Rev. Dr. Martin Luther King, Jr. proposed that America launch a broad-based, gigantic Bill of Rights for the disadvantaged and a Marshall Plan for the poor and the hurting. He said if we were willing to rebuild Europe after World War II, then America should be willing to rebuild Appalachia where poor whites were; the inner cities of Detroit and Chicago; and the Deltas of Mississippi and Alabama.

“While Negroes form the vast majority of America's disadvantaged there are millions of poor whites who would also benefit from this kind of bill. The moral justification for the special measures for the negro is rooted in the robberies of the institution of slavery. Many poor whites, however, were the derivatives of the victims of slavery. As long as labor was cheapened by involuntary servitude of the black man, the freedom of white labor, especially in the South was little more than a myth.”

King understood that saving communities should be first over saving corporations, that we should not treat corporations like people and people like things. He understood that if you ignore the poor, eventually there will be an implosion. What we're really beginning to experience is a process of slow decay, punctuated by a recurring economic crisis, one in which reforms achieve sporadic gains. But the long-term trends of growing inequality, economic dislocation, failing democratic accountability, deepening poverty, ecological degradation, greater invasions of liberty and growing imprisonment especially of minorities, continues to slowly and quietly challenge the belief in the capacities and moral integrity of the overall system and its governing elite.

There is a blind spot in American economic theory. It's called consciousness. Our refusal to have an economic theory that looks and sees that we are all integrated and we all really need each other. The question we face, is how can the nation's wealth ultimately be shifted institutionally to benefit the vast majority of people? Because we cannot live in isolation. For years we were taught that what was good for Wall Street was good for your street and our street, but that no longer holds true. As King warned 50 years ago, when you ignore the poor, the whole system will collapse. The first thing we must recognize, is that economic justice is a moral issue. And economics can't be separated from moral questions. It was never intended that way.

As far back as the Torah, Deuteronomy says caring for the stranger and being just to the poor must be the hallmark of a nation. The Psalmist said

relieving the poor and the oppressed is a moral value we need in the public square. Every prophet of the Old Testament: Jeremiah, Malachi, Ezekiel always began their criticism of Israel, their criticism of the nation, with a critique of systems of poverty. Jeremiah says taking care of children and the vulnerable and the innocent must be the call of leaders and their society, and in fact, Jeremiah 22 says go to the palace and tell the king:

“Do not hurt the poor and the widows; otherwise, this palace will become rubble.”

Isaiah 10 says this:

“Woe unto those who legislate evil and rob the poor of their rights, and make women their prey.”

Isaiah 58 says “Secure the rights of the poor”; in fact, in Isaiah 58, we’re supposed to call for the “loosing of the bands of wickedness.” Do you know what “loose the bands of wickedness” means? In Hebrew, it means pay people what they deserve. Pay a living wage, because if you don’t, it’s not merely considered conservative ideology. In the Bible, if you do not pay people a living wage, it is called wickedness. Ezekiel says to refuse dishonest gain, and refuse to be—or to give status to—economic predators. In fact, in Ezekiel 22, Ezekiel says whenever the preachers and the politicians stand on the side of greed and hurt toward the least of these in the poor, whenever the morality preachers and the policy people come together to engage in bad policy that hurts the poor, Ezekiel describes them as acting like rabies-infested wolves.

And Jesus—you know, that brown-skinned, Palestinian Jew who never charged the leper or sick person a co-pay, always gave free healthcare, and who was eventually killed by the state? In his first sermon, he said:

“The spirit of the Lord is upon me for he hath anointed me to preach good news to the poor.”

And the word ‘poor’ in Greek is *patokos*. There are three other words for poor: One has to do with somebody being lazy; the other one has to be with somebody suddenly becoming poor because they are suddenly sick. But the word *patokos* means people who have been made poor by economic systems of exploitation, by stratification that existed in the Roman Empire, where the one percent demanded that all the rules operate in their favor, while the 99 percent suffered. And it was those people that Jesus said were at the center of the attention of God, and better be the center of the attention

of your community and your nation if you plan that nation to survive the judgment of God.

The millennial embrace of socialism, then, does not mean that millennials are trying to implement some complicated new economic system that they do not understand. It means that they measure any economic system by the degree to which it is humane and democratic, and they are angered by the degree to which our current one fails people. It means that they reject selfishness and believe in solidarity. And it means that they are determined to help each other build something better, whatever that may be.

Would you allow yourself to be exploited so ruthlessly in a stable, local market? I wouldn't. This is how revolutions are born and the local industries are taken over by angry citizens.

Mass poverty can only be maintained by a corrupt elite running the society. To think this could be the natural state of affairs is the root of the neoliberal problem. I think the wealthy have deluded themselves with their own propaganda into thinking that this social condition is possible to maintain. It is not. It is more wasteful of resources and effort than anything else but—because of human timidity, nature's abundance, and cheap energy—can be ignored.

When it is finally realized how badly the citizenry has been treated, there will be much to account for. Poverty is another phenomena distorted by the elite. Poverty could be ended today if there was the will.

I find it revealing when people are forced to express their visions in simple, unmasked terms. Anyone who believes, or tolerates a society where its citizens are forced to live in abject poverty is a sociopath. This is what the capitalist world has wrought.

A world moving beyond the capitalist mindset is what I am counting on.

“Its not fair if everyone gets the same, if I worked harder I should get more.”

Why did you work harder?

“Because I wanted more.”

Is that fair, in a reality where resources are finite?

The misanthropic refrain of conservatives is that “it's wrong to give something to people who have done nothing to earn it.” But other answers are possible. One might point out that people born into the middle or upper class have done nothing to “earn” their privileged position. The wealthy haven't earned the inheritance they receive from their parents.

White Americans didn't earn their skin-color or the fact that they weren't born in, say, a Haitian slum. People who benefit from charisma or physical beauty or intelligence did nothing to earn that; they were born with it. They deserve no credit for it. Somebody who happens to meet the right person at the right time and is launched on a successful career is the beneficiary of luck—as, in short, every “successful” person is, in innumerable ways.

Nor does any of this begin to address all the ways that the wealthy or corporations or Silicon Valley entrepreneurs benefit from state policy designed to give them what they want and to strip the poor of the right to live. Through the agency of the state—its corporate welfare programs, defense budget, patent and copyright protections, and, to some extent, interest payments on bonds—the population subsidizes the power and wealth of people whose ideology is to shame those who benefit from state programs. According to their own ideology then, these “libertarians” in the business class ought to have their property confiscated, since, strictly speaking, they have “earned” none or little of it.

The more one gains economically from living in civilized society, the greater one's duty to maintain that society by paying taxes.

“Our hard earned tax payments shouldn't go toward supporting the lazy”

Because, of course, poverty can only be a result of laziness. This is a comforting thought, that somehow poverty and misfortune can be avoided if you simply work hard enough.

Of course since in many cases such an individual is referring to federal taxes, it is incorrect that their tax payments support the lazy. Federal taxes do not fund federal spending.

How many catastrophes would it take to undo the security in your life? That is a question I think every person should ask themselves, and consider in judgment of others. I think the truth is it's usually a lot less than you'd think.

The simultaneous rise of both the working poor and non-working rich offers further evidence that earnings do not correlate with effort.

Don't tell me that raising the minimum wage to \$15 an hour solves the problem. No one can doubt the moral significance of the movement. But at this rate of pay, even at forty hours a week—an unlikely amount in fast-food franchises—you're still at that official poverty line. What, exactly, is the point of a earning a paycheck that isn't a living wage, except to prove that you have a work ethic?

When we place our faith in hard work, we're wishing for the creation of character; but we're also hoping, or expecting, that the labor market will allocate incomes fairly and rationally. And there's the rub: they do go together. Character can be created on the job only when we can see that there's an intelligible, justifiable relation between past effort, learned skills, and present reward. When I see that your income is completely out of proportion to your production of real value, of durable goods—and by 'durable' I don't mean just material things—the rest of us can use and appreciate, I begin to doubt that character is a consequence of hard work. When I see, for example, that you're making millions by laundering drug cartel money (HSBC), or pushing bad paper on mutual fund managers (AIG, Bear Stearns, Morgan Stanley, Citibank), or preying on low-income borrowers (Bank of America), or buying votes in Congress (all of the above)—just business as usual on Wall Street—while I'm barely making ends meet from the earnings of my full-time job, I realize that my participation in the labor market is irrational. I know that building my character through work is stupid because crime pays. I might as well become a gangster like you. And when you make good people into criminals, don't be surprised when one of them eventually shows up to slit your throat—for the people.

Why is it so much easier for some to believe 150,000,000 people are lazy/stupid as opposed to 400 people being greedy?

The 1% in the US keep on arguing how they only collect 20% of income but pay 40% of taxes. They don't seem to realize that if their income had stayed at 30x the lowest paid instead of 300x, the lower paid would actually be paying more taxes.

It also displays an ignorance of history, since the income tax, which began as a tax only on the 0.1 percent was never designed to target the poor.

The best thing about this program of reverse taxation, as far as the 9.9 percent are concerned, is that the bottom 90 percent haven't got a clue. The working classes get riled up when they see someone at the grocery store flipping out their food stamps to buy a T-bone. They have no idea that a nice family on the other side of town is walking away with \$100,000 for flipping their house.

Laying the blame on a lack of personal responsibility obscures the fact that there are powerful and ever-changing structural forces at play here. Service sector employers often engage in practices that middle-class professionals would never accept. They adopt policies that, purposely or not, ensure regular turnover among their low-wage workers, thus cutting the costs that come with a more stable workforce, including guaranteed hours, benefits, raises, promotions, and the like. Whatever can be said about the

characteristics of the people who work low-wage jobs, it is also true that the jobs themselves too often set workers up for failure.

Poverty is structural, it is a construct, it is a basic underpinning of capitalism. The suffering all around us is the result of capitalism run amok. And our current crony-capitalism on steroids is the result of our collective failure to regulate. Because capitalism, and the inherent greed that comes with it, is seductive.

How do we get the hoarders to realize it's a zero sum game? They've been hoarding for so long and can be so indignant and entitled about their silly stash, it's as if they'd rather die than change.

Part of the reason TANF isn't doing its job is that it is a block grant given to the states, which have broad flexibility as to how they spend the money. This means that they have plenty of reasons to keep families off the rolls, because if they do, they get to use the money for other, related purposes. Of the \$16.5 billion the federal government transfers to states for TANF, more than \$11 billion is siphoned off for other uses, sometimes to fund a state's child welfare system. Strained state budgets are thus eased. TANF has become welfare for the states rather than aid for families in need. Beyond eligibility rules and other formal restrictions on who qualifies, there's evidence that some prospective applicants may be diverted from applying for aid in unauthorized ways.

Barely three-million people receive TANF now, less than one percent of the population. Almost half of those are in California and New York, so the remaining 1.7 million are divided among forty-eight states and the District of Columbia. And the numbers are still going down, 600,000 fewer in 2013 and 2014 alone.

As former congresswoman Michele Bachmann once put it, if the minimum wage were repealed "we could potentially virtually wipe out unemployment completely because we would be able to offer jobs at whatever level." Theoretically, Bachmann is correct. But her point is irrelevant. It is no great feat for an economy to create a large number of very-low-wage jobs. Slavery, after all, was a full-employment system.

Whatever wage gains these workers receive are rarely passed on to consumers in the form of higher prices. That is because big-box retailers and fast-food chains compete intensely for customers and have no choice but to keep their prices low. It is notable, for example, that in Denmark, where McDonald's workers over the age of eighteen earn the equivalent of twenty dollars an hour, Big Macs cost only thirty-five cents more than they do in the United States. Any wage gains low-paid workers receive will more than likely come out of profits—which, in turn, will slightly reduce returns to shareholders and the compensation packages of top executives.

The reason for the sharp divergence in labor market experiences between Germany and the US is that Germany encouraged its employers to reduce work time rather than lay off workers in response to a reduction in demand. While there were differences across firms, the basic story was that if a company cut back workers' hours by 20 percent, the government would make up 40 percent of the loss in pay (eight percent of total pay), the company would make up 40 percent (eight percent of total pay), and the worker would accept a four percent pay cut. The basic logic behind this system was that, if the government is willing make up lost pay of workers when they are completely unemployed, why not pay workers when they are partially unemployed as a result of a reduction in work hours?

Twenty-six states now have work-sharing programs as part of their unemployment insurance systems, including several large states like California and New York. However, the take-up rate on these programs has been low. Most employers are not even aware that support for work sharing exists as an alternative to layoffs. It doesn't help that the programs tend to be overly bureaucratic and in many cases have not been modernized since they were first put in place at the end of the 1970s or early 1980s.

In addition to having an unemployment insurance system that is both ungenerous and encourages layoffs, as a longer run matter we have an institutional structure in place that tends to encourage longer hours for workers. As a result, insofar as workers get benefits from productivity growth, they take them in the form of higher pay rather than more leisure. Specifically, because health care insurance is mostly an employment-based benefit, rather than universally provided through the government, employers typically see it as a fixed cost per worker. So rather than hiring additional workers and paying for their health insurance, employers would generally prefer their existing workforce to work more hours. The preference for longer hours is even greater in cases where employers provide defined benefit pensions in addition to health insurance.

Consider this basic arithmetic: if we produced the same number of cars but the average work year in the auto industry had 20 percent fewer hours, we would have 25 percent more people working in the auto industry. The reality will always be more complicated, but the basic point is straightforward: for the same levels of output, shorter hours mean more workers. In other wealthy countries, the average number of work hours in a year has fallen sharply over the last four decades. Most countries in Western Europe mandate five to six weeks a year of paid vacation. Between six months and one year of paid parental leave is standard, as is some amount of paid leave for other family reasons. In some countries, the standard work week is less than 40 hours.

By contrast, in the United States the number of hours in the average work year has changed little over the last four decades, due almost certainly in large part to the benefit structure that creates substantial per-worker overhead costs. As a result of our different histories, workers in the United States average considerably more hours each year than workers in Europe. According to data from the OECD, the average work year in the United States is 1,790 hours, compared to 1,419 hours in the Netherlands, 1,482 in France, and 1,371 in Germany. If the average work year in the United States were comparable to those in Western Europe, more workers would be employed at relatively well-paying jobs in sectors like manufacturing, construction, and communications instead of being forced to accept lower-paying jobs in sectors like retail and restaurants. By reducing the supply of workers in the lower-paying sectors, the reduction in average hours would lead to higher wages in low-paying sectors for the workers who were left behind. In short, it is reasonable to believe that the longer average work year in the United States has been a factor contributing to inequality.

What are called “public schools” in many of America’s wealthy communities aren’t really public at all. In effect, they’re private schools, whose tuition is hidden away in the purchase price of upscale homes there, and in the corresponding property taxes. Even where courts have required richer school districts to subsidize poorer ones, large inequalities remain. Rather than pay extra taxes that would go to poorer districts, many parents in upscale communities have quietly shifted their financial support to tax-deductible parents’ foundations designed to enhance their own schools. About 12 percent of the more than fourteen-thousand school districts across America are funded in part by such foundations. They’re paying for everything from a new school auditorium (Bowie, Maryland) to a high-tech weather station and language arts program (Newton, Massachusetts). Parents’ foundations are visible evidence of parents’ efforts to reconnect their money to their kids—and not to kids in another community, who are likely to be poorer.

How many people does it take to make an urban farm? Twenty-five film makers and journalists to do pieces on urban farming, sixty-three grad students to study the farm, a few people from the not-for-profit complex to hold meetings about farming, a few elected officials to have their pictures taken at the farm, and about five people to do the actual farming.

Although civil society groups are assumed to be motivated by altruism they are nonetheless embedded in a global capitalist economy and have quite specific material requirements that must be fulfilled in order to operate successfully. To be successful, an organization must survive and, in a market-based environment, this means finding ways to generate the funds necessary to sustain operations. Yet, it is more than this. Those at the helm share the

same ideologies and Western mindsets as the capitalists and corporations whose interests they serve.

“What’s infuriating about manipulations by Non-Profit Industrial Complex is that they harvest good will of the people, especially young people. They target those who were not given skills and knowledge to truly think for themselves by institutions which are designed to serve the ruling class. Capitalism operates systematically and structurally like a cage to raise domesticated animals. Those organizations and their projects which operate under false slogans of humanity in order to prop up the hierarchy of money and violence are fast becoming some of the most crucial elements of the invisible cage of corporatism, colonialism, and militarism.”

There is an old joke that conservatives told about left-wing agitators at the start of the twentieth century. The story goes that the speaker jumps up on the soap box and yells out: “If I had two-million dollars, I would give you one.” He then says, “And if I had two houses I would give you one.” He continues, “If I had two pigs,” the radical then pauses and says quietly, “wait, I have two pigs.” This perspective seems to describe many of those working against inequality at our leading nonprofit foundations. While many foundations now list combating inequality as major part of their agenda, their top executives often draw paychecks in the high hundreds of thousands of dollars. For example, the average pay package for the highest paid non-financial position at the country’s ten largest foundations in 2014 was \$820,000.

Revolutionaries must always go forth to answer the momentary desires and needs of the people, the poor and the oppressed people, while waging the revolutionary struggle. It’s very important because it strengthens the people’s revolutionary camp while it weakens the camp of the capitalist power structure.

During a time when a person’s worldview is under attack, friends and community remind him that everything is OK. This is true at the individual level and the societal level: citizens need to know that they are being taken care of and supported during times of crisis, meaning communities need respected and trusted police forces, governments, fire departments, and religious leaders. When that safety net is gone, crisis, trauma, stress, and violence all become a lot more difficult to deal with. This may be one reason that countries with long histories of upheaval have a hard time bouncing back.

“But poverty doesn’t bind the poor together as much as wealth and the need to protect it bind the rich. If it did, we would hear the rattle of tumbrels in the streets. One hears mutterings, but the chains have not yet been shed.”

There is no demographic that has a sharper instinct for empathy than the downtrodden.

Poor folks rely on people the way rich folks rely on money. Since money is never a solution, the only thing to rely on is social connections, preferably local ones. For example, poor mom’s car breaks down. Calling the tow truck is a no go. Paying for something like AAA is a rich people solution, so no go. Instead she calls Uncle Jim, who can at least come get her and the baby from the side of the road, if nothing else.

Likewise if she’s about to get evicted, and has no money in the bank, she calls Aunt Judy, or Mom, or somebody, hoping for a place to stay, at least for a little while, just to stay off the street.

Nobody likes to be called up only when you want something from them. So these social ties have to be constantly tended and strengthened, indefinitely, just in case of a someday problem. You never know when you need to beg \$100 off someone, so you need to be on good terms long before that ever happens. Most poor people will not be doing this in some scheming way, they only know that you need to stay tight with your friends and family. That’s just how life is lived.

These social networks are the number one survival method the poor rely on, since money is forever a problem. So they put a lot of time into maintaining them.

Wealthier folks can rely on their financial resources to get them out of binds, and can afford to be less attached to a local social circle. This is why the poor resent it so much when one of their own does well but then moves away. You’ve become somebody they can rely on, except then you took that from them, leaving them no better off. Whatever of their own resources went into helping you in childhood have been a waste. At the least your success reflected well on them, but then you made sure to keep your distance from “those people.” They don’t even gain a bit of social status from you. You used them and threw them away.

The often unspoken attitude is that the ‘poors be yappin,’ like it’s some ignorant, self-defeating behavior that wastes time, and accomplishes nothing. Great minds discuss ideas, the stupid poors discuss people. As if the poor were just trying to create some fruitless Kardashian-esque existence for themselves. They are not. They are building, maintaining, and tapping into the one reliable resource they have, essentially crowdsourcing their survival

prospects. They are resource pooling. This is also the fundamental utility of the church, and explains its true meaning in the lives of the poor.

So the divide between rich teens and poor teens. Constant chatting is how you maintain social bonds. A 16-year-old may not grasp this. But then again, she may grasp it quite well. If you've got no people, you've got nothing. She was the toddler in that car when mom called Uncle Jim, after all. It's not rocket science. The poor are using the internet for the main thing it appears to be good for, which is strengthening the social networks that allow them to get by. There's a lot more to it than games.

Rural poverty happens because people aren't being paid to take adequate care of their places. There's lots of work to do here. And you can't afford to pay anybody to do it! If you depress the price of the products of the place below a certain level, people can't afford to maintain it. And that's the rural dilemma.

Even for those who did make foolish mistakes, they were kids. At some point, continuing to fuck up their lives over a debt that they'll never reasonably be able to pay makes no sense at all. If we continue down this path, we're no longer allowed to wonder why younger people aren't buying cars, aren't buying houses, aren't investing, and generally aren't engaged with society. You can't have it both ways, and we're ruining an entire generation of Americans because they bought into a flawed system that was aggressively sold to them by figures of authority when they were kids. On a societal level, it's so stupid that we almost deserve the inevitable consequences that it's having on a consumer spending-driven economy.

The mythology aims to convince people that if they're the beneficiaries of Social Security, they should be responsible for saving up to pre-fund it. That's like saying that you're the beneficiary of public education, so you have to pay for the schooling. You're the beneficiary of healthcare, you have to save up to pay for that. You're the beneficiary of America's military spending that supposedly keeps us from being invaded next week by Russia (or maybe it's China now), you have to spend for all that—in advance, and lend the money to the government for when it's needed.

Where do you draw the line? Nobody anticipated in the nineteenth century that people would have to pay for their own retirement. That was viewed as an obligation of society. You had the first public pension (social security) program in Germany under Bismarck. The whole idea is that this is a public obligation. There are certain rights of citizens, and among these rights is that after your working life you deserve to live in retirement. That means that you have to be able to afford this retirement, and not have to beg in the street for money. The wool that's been pulled over people's eyes is to imagine that because they're the beneficiaries of Social Security, they

have to actually pay for it.

The US federal government is a monetary sovereign, it alone controls the value and quantity of its currency in existence. The US government cannot involuntarily run out of money, it is impossible. Your taxes do not fund any federal government spending. It does not need your taxes for any of its expenses, this includes Social Security. The government—federal only—creates money as needed when it pays its bills, whether that's for drones to attack wedding parties or grandma's Social Security check.

The myth of money as a finite resource is used to keep the gap between the rich and the poor as wide as possible.

Yes, a dollar is simply paper with pictures of dead dudes on it—though really this is outdated since most is just digital at this point—which the federal government has complete control over. It's not a real resource; ecosystems, metals, labor, time—those are the resources that matter and constrain our actions. Bombs, drones, fighter jets are bad uses of real resources, the dollar cost doesn't really matter.

How many dollars are created out of thin air, how many exist in total, only matters from an inequality standpoint, since dollars can become power, influence, control. The solution to this is simply the destruction of dollars via federal taxation. No one should be allowed to hoard wealth, power, influence.

As long as we collectively desire to feed, clothe, house, educate, care for every individual then we can. Of course there are ultimately limits: real resource, famine, et cetera, but a lack of dollars is not one of them. What value the paper we call dollars has is irrelevant especially in a country as large and resource-rich as the United States. The problem is, those that wish to deny these basic rights to people control the power structures necessary to ensure that these needs are met. This problem is not just one that exists in the US, it is one that plagues most of us.

The use of the market to provision fundamental public goods is unjust, immoral, insane. Energy production, transportation infrastructure, education, essential food production, healthcare, pharma, electricity generation & distribution must all be under collective control. No profits should be made from such public goods.

Anything less is theft, assault, makes the existing governments illegitimate, makes it one's moral obligation to overthrow such institutions and replace them with ones which will work for the collective good.

It's self-evident that goods on which everybody is dependent should belong to the public.

Two Treatises of Government is a strange medley of logic pieced together on selective authority from the Christian Bible, a very flawed understanding

of zoology, and a state of nature which has never existed for homo sapiens. Unfortunately for Locke's libertarian arguments, man has never been "a lion or a tyger" and may better look to bees and ants as models for behaviour. Locke's state of nature with unbridled free will has never existed except in isolated instances as humans are social and do not act independently. He confused autonomy for all with an excess of free will, creating a survival of the fittest structure which allows autonomy only for a very few of the most ruthless.

To say that what has always been is what always must be denies all of civilization. Locke's writings are the foundation for the system of dissociation we live in today. Societal pressure to respect and assist the needs of others was replaced by blame for the weak. Charitable obligation was replaced by entitlement. Patriarchy was replaced by corporate power. Governance passed from families to cities to states to its first fully dehumanized form in corporations. The libertarian ideals assisted the powerful who considered it their free will to violate the rights of others in their quest for ever more power, the ultimate virtue in Locke's ideal state of nature.

The opposite of poverty is not wealth. It is justice. And Deuteronomy gives us our charge:

"Justice, justice shall you pursue."

The Rule of Law

Measuring Civilization

“Most of what ails our criminal justice system lies in unwarranted certitude on the part of police officers and prosecutors and defense lawyers and judges and jurors that they are getting it right, that they simply are right. Just a tragic lack of humility by everyone who participates in our criminal justice system.”

Illicit behavior defines the difference between right and wrong for a culture, and acts as a safety valve to drain off excess energy generated by the pressures of institutional routines. It also helps instigate social change. Where crime exists, collective sentiments are sufficiently flexible to take on a new form, and crime sometimes helps to determine the form they will take. How many times, indeed, it is only an anticipation of future morality—a step toward what will be.

When the injustice of harm is overpowering, we react by denying its injustice and seeing harm as justified and deserved.

“Sometimes I think this whole world is one big prison yard. Some of us are prisoners, some of us are guards.”

“The degree of civilization in a society can be judged by entering its prisons.”

—Fyodor Dostoyevsky

The more a crime sounds like the plot from a movie, the less likely it is to happen in real life.

More than five-hundred citizens of Falaise had come to the execution. They assembled around the town scaffold, where the Vicomte de Falaise himself presided over the proceedings. Earlier, the accused had been tried and convicted of a vicious crime: savagely biting a child in the face and arms. And though the child had subsequently died, there was no expression

of remorse at trial, no apology to the family. Indeed, the guilty party had not spoken a word since being taken into custody, and she said nothing when a harsh sentence was handed down: she was to be given injuries that matched the child's—wounds in the head and arms—before being garroted and hanged.

The crowd watched with eager eyes as she was brought up the scaffold for all to see. She had been dressed in men's clothes, and a special executioner had been brought in from Paris. It was 1386, and the population of northern France expected a show. But still, the condemned refused to speak. As the last preparations were made, the assembled men and women waited for the final act. It was, the Vicomte must surely have thought, a righteous punishment for an atrocious act, and after the executioner had done his work and the body of the felon hung limp, he ordered a fresco of the scene painted in the Church of Holy Trinity in the town.

When, some three decades later, Henry V and his British compatriots destroyed much of the church, the people of Falaise came together to have the fresco repainted, where it remained for more than four-hundred years. Though the fresco has not survived—it was whitewashed by the church in 1820 during a renovation—today we know for certain why the condemned never spoke. She was a pig.

The events at Falaise were far from an anomaly. Trials and punishments of animals were common for centuries. Judicial proceedings were brought against rats and locusts that infested villages and destroyed crops. Mastiffs were guillotined for assaults. Murderous bulls were seized, tried, and convicted. Horses were burned by court order for their transgressions. The prosecution of animal crimes was not just a matter of backwoods folk practice; it was written into legal codes and religious sources. It was official and sanctified. There were processes and procedures to be followed. In some cases, lawyers were even appointed to represent the accused.

In 1918, Kentucky had passed a law abolishing murder trials for dogs accused of killing sheep. But the courts were slow to learn new tricks, and over the next decade a number of dogs were prosecuted.

When Bill, a collie, was “charged with being a dog of vicious character,” in the winter of 1926, the Associated Press was there to report the story:

“We, the jury, find the defendant guilty as charged,” was the instructed verdict returned by a jury here yesterday in the case of the State of Kentucky versus Bill. The death sentence was imposed by County Judge J.W. Pruitt, and Bill was legally executed. The dog was brought into court by the husband of his owner, Mrs. Sophia Stone. Witnesses testified as to Bill's charac-

ter prior to his attack on a neighbor's daughter, the cause of the trial. Within a few minutes after the passing of sentence, Bill was electrocuted. His head was sent to a Lexington laboratory for examination."

We would like to believe that we have finally achieved a modern, enlightened approach to justice—punishing only those with “guilty minds,” and not because we like it, but because we must protect society. But even today our basic instincts bubble to the surface. We, too, seem to feel vengeful toward animals from time to time. A surfer is dragged underwater off the coast of Australia, and we demand that the protected legal status of great white sharks be lifted so that they may be killed. A grizzly bear attacks a hiker in Yellowstone National Park, and we conduct a full investigation, reconstruct the crime scene, match the DNA, and execute the animal. Occasionally we even feel the urge to punish inanimate objects. Be honest: Have you ever wanted to get back at your computer for losing a file or freezing up at a key moment? Have you kicked the chair that stubbed your toe? And we sometimes take pleasure in the pain and suffering of those who have harmed us—bullies, pickpockets, terrorists—even when that misery does nothing to make us safer in the future.

The best available evidence suggests that although many of our decisions reflect deliberation and reasoning, our moral compass often directs our behavior beyond our conscious awareness. In one famous experiment, people read descriptions of behaviors that are generally viewed as immoral, like two siblings having sex, and then told researchers what they thought. The trick was that the researchers carefully tailored the details of the scenarios to eliminate obvious reasons to object to the conduct. In the incest scenario, for example, the brother and sister were adults, used contraception, freely consented to the act, and experienced no resulting negative feelings. In addition, the incest never occurred again and was never disclosed. Study participants were quick to conclude that the sex was wrong, but they struggled to explain why when the experimenter pointed out that their grounds for objection (for example, that a baby with a genetic defect might be conceived) were nullified by the provided description (effective birth control was used). Even when they ran out of explanations, the participants did not change their opinions: around 80 percent clung to the idea that a wrong had been committed.

There is often a disjunction between the punitive rationales that people give and their actual motives. Indeed, there is a growing scientific consensus that it is a desire for retribution—not deterrence or incapacitation—that has the strongest influence on why we punish.

Eliminating the possibility that our drive to punish comes down simply to a desire to incapacitate dangerous agents is straightforward: we need only ensure that the perpetrator will be fully incapacitated regardless of what we choose to do. Imagine two scenarios. In one, a shark attacks a young girl playing in the waves; in the other, a shark attacks a forty-eight-year-old pedophile. The shark has been hunted down and condemned to death by the authorities, and the only question is the method used to kill it. How much of a numbing agent should authorities give to the shark so that it does not feel any pain as the fatal poison does its work?

If your motivation is ensuring the future safety of the beach, the identity of the victim should not affect your answer, since the shark is going to be killed—that is, rendered unable to harm anyone in the future—no matter what. But your answer should change if you are motivated by retribution, because killing an innocent little girl is seen as a worse harm than killing an adult sex offender and thus would require a harsher response. Sure enough, that’s what researchers found: people provided more of the painkiller to the shark that killed the pedophile than to the shark that killed the girl. We can alter the types of animal perpetrators and we can change the circumstances, but the effect holds. People are driven by retribution to punish attacking sharks, oxen, and dogs in ways that are not significantly different from how they are driven to punish human offenders guilty of comparable misdeeds.

The implications of the research are troubling, suggesting that when a harm has been committed, our desire to find a culprit and reset the moral scales by inflicting punishment may sometimes override our commitment to fair treatment. In the back of our minds, we may already know this about ourselves—though we are loath to acknowledge it. The bloody unfairness stains our history books and our newspaper stories: a mob lynching of an innocent black man after police describe a rape suspect as black; the gangs that live by the motto “You take one of ours and we take one of yours”; the waterboarding of purported “enemy combatants” following the attack of September 11th. When you look closely, these retaliatory acts look far less like accidents, anomalies, and collateral damage. They look like reflections of our culture and its toxic tendencies.

People with an ardent belief in pure evil are active participants in determining sentences, reviewing punishments, and setting policy. It matters when a governor or president evaluating petitions for clemency from death-row inmates thinks—as George W. Bush did—that “good and evil are present in this world, and between the two there can be no compromise.” And it matters when a sitting Supreme Court justice wholeheartedly believes that the Devil is a real person, as former Supreme Court Justice Antonin Scalia did—though maybe he had some insider information. Such individuals are

at a distinct disadvantage when it comes to appreciating the various forces outside of an offender's control that may have led him to commit a terrible act. And this creates a tragic paradox in which those who are more likely to see evil in others are more likely to commit evil acts themselves—supporting or perpetrating cruel acts against people whose crimes ultimately reflect not their corrupted dispositions but their genetic and environmental bad luck.

Are our beliefs and motivations really that different from those of our medieval French counterparts who tried and executed a pig? The ever-optimistic Steven Pinker has offered an argument that, viewed against the backdrop of human history, the modern world is relatively peaceful. One of the driving forces behind the decrease in violence, he argues, is the transfer of punishment responsibilities to a disinterested third party. And it seems obvious that the modern judicial system, with its judges, jurors, police, lawyers, and correctional officers, has indeed preempted much of the bloody individual and group retaliation that characterized our past. But have we simply hidden the wounds?

We would very much like to believe that superstition has no place in our courthouses and that we are never driven by blood revenge. We would like to think that we take no pleasure in punishment. We want to believe that feelings of warmth toward our fellow man always outweigh feelings of disgust and hatred. It is true that, in the West, we no longer have public executions—for pigs or humans. It is true that we no longer break people on the rack or draw and quarter. But are we “better angels” on the inside, or have we merely constructed elaborate structures that camouflage the retributive drives within us?

The decline of the trial by ordeal was not brought about because people suddenly realized that dipping men and women into water to see if they float was a poor way to assess innocence. It disappeared because the Catholic Church hierarchy decided that commanding God to work miracles in the service of a human judicial system violated biblical principles. And what replaced the ordeal was not a system of evidence and reason but something arguably less accurate and humane than what had come before: judicial torture. For roughly the next half millennium, when a person was strongly suspected of a serious crime, but there were no witnesses, he would be broken on the rack or subjected to the thumbscrew to elicit a confession. Like those who had administered the ordeal, the officials in charge did not see themselves as cruel or unjust. Like us, they constructed an elaborate structure of seemingly objective rules and procedures that affirmed their righteousness and impartiality.

With no dominant governmental authority to manage the conflicts of the scattered small communities of Europe through much of the Middle Ages,

the legitimacy of human action in matters of law was always contestable. But godly action was not.

But how will someone nine-hundred years from now view our current system of justice? The truth is that our descendants will be no less surprised by the routine and systematic unfairness we tolerate today than we are by our ancestors' trials by ordeal. They will look back at our judges and juries and see biases that are just as obvious as the ones we now perceive in the bishops and abbots who presided centuries ago. They will look back at our criminal code and see laws as wrongheaded and illegitimate as the prohibition on heresy. They will examine our processes and procedures—how strictly we followed them, how heartily we trumpeted them as bastions of integrity and accuracy—and laugh at our naïveté just as we laugh today at the mumbo-jumbo justice of Sir Bedevere the Wise. If there is a Monty Python of the thirtieth century, its members will write skits that look an awful lot like episodes of *Law & Order*.

America accounts for less than five percent of the world's population, but almost a quarter of all prisoners. Some 2.3 million individuals are behind bars across the country, and in excess of 6 million are under "correctional supervision"—more, by far, than in any other nation. Even at their height, the Gulag labor camps never came close to the number of our citizens currently on probation, in jail or prison, or on parole.

Take one-hundred-thousand Americans, and 707 of them are languishing in a cell. By contrast, 284 out of every hundred-thousand Iranians are locked up, 118 out of every hundred-thousand Canadians, and only 78 out of every hundred-thousand Germans. A country that abolished slavery 150 years ago now has a greater number of black men in the correctional system than there were slaves in 1850 and a greater percentage of its black population in jail than was imprisoned in apartheid South Africa.

These places are also what sociologists call "total institutions," places that isolate people, usually without their consent. There are several types of total institutions: places that care for those who can't care for themselves or are a danger to themselves and others, like nursing homes and psychiatric hospitals; places that confine criminals, like jails and penitentiaries; and voluntary total institutions, like schools, abbeys, and monasteries. Though they are not inherently 'evil,' these places are the sites of many of history's most tragic and horrendous crimes against humanity. The monsters inside total institutions are not necessarily the ones behind bars.

Research shows any form of long-term association with an involuntary total institution can leave you feeling less than human, which is, for many, a fate worse than death. To paraphrase Michel Foucault: the executioner has power only over your death; an institution has power over everything

else. People realized such isolation was not a good idea, and a number of activists began to denounce it, among them Charles Dickens:

“In its intention I am well convinced that it is kind, humane, and meant for reformation; but I am persuaded that those who designed this system of Prison Discipline, and those benevolent gentlemen who carry it into execution, do not know what it is that they are doing. I hold this slow and daily tampering with the mysteries of the brain to be immeasurably worse than any torture of the body; and because its ghastly signs and tokens are not so palpable to the eye, and it extorts few cries that human ears can hear; therefore I the more denounce it, as a secret punishment in which slumbering humanity is not roused up to stay.”

Eventually courts ruled that forced institutionalization of those with disabilities is unconstitutional. But total institutions for other marginalized groups continues today. Prisons are the new asylums, once again putting our “monsters” into cages.

In the United States, there are more than three times as many people suffering from significant mental illness locked in our prisons and jails as there are in our mental health facilities. And only about a third of those individuals have received treatment since their incarceration began.

The fact that it was not until 2014 that Pennsylvania agreed not to put inmates with serious disabilities or mental illness in solitary confinement is further testament to how far we still have to go in building institutions that respect human rights.

Convicts had no meaningful legal rights at one point and no effective redress. They were understood, quite literally, to be slaves of the state. The Thirteenth Amendment to the US Constitution had abolished slavery but allowed one major exception: slavery remained appropriate as punishment for a crime. In a landmark decision by the Virginia Supreme Court, *Ruffin v. Commonwealth*, issued at the height of Southern Redemption, the court put to rest any notion that convicts were legally distinguishable from slaves:

“For a time, during his service in the penitentiary, he is in a state of penal servitude to the State. He has, as a consequence of his crime, not only forfeited his liberty, but all his personal rights except those which the law in its humanity accords to him. He is for the time being a slave of the State. He is *civilter mortuus*; and his estate, if he has any, is administered like that of a dead man.”

About 70 percent of offenders and ex-offenders are high school dropouts, and according to at least one study, about half are functionally illiterate. Many offenders are tracked for prison at early ages, labeled as criminals in their teen years, and then shuttled from their decrepit, underfunded inner city schools to brand-new, high-tech prisons.

Those sent to prison are institutionally branded as a particular class of individuals with major implications for their place and status in society. The negative credential associated with a criminal record represents a unique mechanism of state-sponsored stratification. It is the state that certifies particular individuals in ways that qualify them for discrimination or social exclusion. The official status of this negative credential differentiates it from other sources of social stigma, offering legitimacy to its use as a basis for discrimination. Four decades ago, employers were free to discriminate explicitly on the basis of race; today employers feel free to discriminate against those who bear the prison label—those labeled criminals by the state. The result is a system of stratification based on the official certification of individual character and competence—a form of branding by the government.

Felony is the new nigger. They don't have to call you a nigger anymore. They just say you're a felon. In every ghetto you see alarming numbers of young men with felony convictions. Once you have that felony stamp, your hope for employment, for any kind of integration into society, it begins to fade out. Today's lynching is a felony charge. Today's lynching is incarceration. Today's lynch mobs are professionals. They have a badge; they have a law degree. A felony is a modern way of saying, 'I'm going to hang you up and burn you.' Once you get that 'F,' you're on fire.

In "colorblind" America, criminals are the new whipping boys. They are entitled to no respect and little moral concern. Like the "coloreds" in the years following emancipation, criminals today are deemed a characterless and purposeless people, deserving of our collective scorn and contempt. When we say someone was "treated like a criminal," what we mean to say is that he or she was treated as less than human, like a shameful creature. Hundreds of years ago, our nation put those considered less than human in shackles; less than one-hundred years ago, we relegated them to the other side of town; today we put them in cages. Once released, they find that a heavy and cruel hand has been laid upon them. In this brave new world, punishment for the original offense is no longer enough; one's debt to society is never paid.

Collectively, these sanctions send the strong message that, now that you have been labeled, you are no longer wanted. You are no longer part of 'us,' the deserving. Unable to drive, get a job, find housing, or even qualify for public benefits, many ex-offenders lose their children, their dignity, and

eventually their freedom—landing back in jail after failing to play by rules that seem hopelessly stacked against them.

The consequences for real families can be devastating. Consider housing, without it people can lose their children. Take for example, the forty-two-year-old African American man who applied for public housing for himself and his three children who were living with him at the time. He was denied because of an earlier drug possession charge for which he had pleaded guilty and served thirty days in jail. Of course, the odds that he would have been convicted of drug possession would have been extremely low if he were white. But as an African American, he was not only targeted by the drug war but then denied access to housing because of his conviction. Since being denied housing, he has lost custody of his children and is homeless. Many nights he sleeps outside on the streets. Stiff punishment, indeed, for a minor drug offense—especially for his children, who are innocent of any crime.

Remarkably, under current law, an actual conviction or finding of a formal violation is not necessary to trigger exclusion. Public housing officials are free to reject applicants simply on the basis of arrests, regardless of whether they result in convictions or fines. Because African Americans and Latinos are targeted by police in the War on Drugs, it is far more likely that they will be arrested for minor, nonviolent crimes. Accordingly, HUD policies excluding people from housing assistance based on arrests as well as convictions guarantee highly discriminatory results.

Perhaps no aspect of the HUD regulatory regime has been as controversial, however, as the “no-fault” clause contained in every public housing lease. Public housing tenants are required to do far more than simply pay their rent on time, keep the noise down, and make sure their homes are kept in good condition. The “One Strike and You’re Out” policy requires every public housing lease to stipulate that if the tenant, or any member of the tenant’s household, or any guest of the tenant, engages in any drug-related or other criminal activity on or off the premises, the tenancy will be terminated. Prior to the adoption of this policy, it was generally understood that a tenant could not be evicted unless he or she had some knowledge of or participation in alleged criminal activity. Accordingly, in *Rucker v. Davis*, the Ninth Circuit Court of Appeals struck down the “no-fault” clause, on the ground that the eviction of innocent tenants—who were not accused or even aware of the alleged criminal activity—was inconsistent with the legislative scheme.

The US Supreme Court reversed. The Court ruled in 2002 that, under federal law, public housing tenants can be evicted regardless of whether they had knowledge of or participated in alleged criminal activity. According to the Court, William Lee and Barbara Hill were rightfully evicted after their

grandsons were charged with smoking marijuana in a parking lot near their apartments. Herman Walker was properly evicted as well, after police found cocaine on his caregiver. And Perlie Rucker was rightly evicted following the arrest of her daughter for possession of cocaine a few blocks from home. The Court ruled these tenants could be held civilly liable for the nonviolent behavior of their children and caregivers. They could be tossed out of public housing due to no fault of their own.

Throughout the United States, newly released prisoners are required to make payments to a host of agencies, including probation departments, courts, and child-support enforcement offices. In some jurisdictions, ex-offenders are billed for drug testing and even for the drug treatment they are supposed to receive as a condition of parole. These fees, costs, and fines are generally quite new—created by law within the past twenty years—and are associated with a wide range of offenses. Every state has its own rules and regulations governing their imposition.

Examples of preconviction service fees imposed throughout the US today include jail book-in fees levied at the time of arrest, jail per diems assessed to cover the cost of pretrial detention, public defender application fees charged when someone applies for court-appointed counsel, and the bail investigation fee imposed when the court determines the likelihood of the accused appearing at trial. Post-conviction fees include pre-sentence report fees, public defender recoupment fees, and fees levied on convicted persons placed in a residential or work-release program. Upon release, even more fees may attach, including parole or probation service fees. Such fees are typically charged on a monthly basis during the period of supervision. In Ohio, for example, a court can order probationers to pay a \$50 monthly supervision fee as a condition of probation. Failure to pay may warrant additional community control sanctions or a modification in the offender's sentence.

Some offenders, like Ora Lee Hurley, find themselves trapped by fees and fines in prison and find it nearly impossible to get out. Hurley was a prisoner held at the Gateway Diversion Center in Atlanta in 2006. She was imprisoned because she owed a \$705 fine. As part of the diversion program, Hurley was permitted to work during the day and return to the center at night. Five days a week she worked full-time at a restaurant earning \$6.50 an hour and, after taxes, net about \$700 a month. Room and board at the diversion center was about \$600, and her monthly transportation cost \$52. Miscellaneous other expenses, including clothes, shoes, and personal items such as toothpaste, quickly exhausted what was left. Hurley's attorney decried the trap she was in:

“This is a situation where if this woman was able to write a check for the amount of the fine, she would be out of there. And because she can’t, she’s still in custody. It’s as simple as that.”

Although she worked a full-time job while in custody, most of her income went to repay the diversion program, not the underlying fine that put her in custody in the first place. This harsh reality harks back to the days after the Civil War, when former slaves and their descendants were arrested for minor violations, slapped with heavy fines, and then imprisoned until they could pay their debts. The only means to pay off their debts was through labor on plantations and farms—known as convict leasing—or in prisons that had been converted to work farms. Paid next to nothing, convicts were effectively enslaved in perpetuity, as they were unable to earn enough to pay off their debts.

Post-conviction penalties have a long history. The American colonies passed laws barring criminal offenders from a wide variety of jobs and benefits, automatically dissolving their marriages and denying them the right to enter contracts. These legislatures were following a long tradition, dating back to ancient Greece, of treating criminals as less than full citizens. Although many collateral sanctions were repealed by the late 1970s, arguably the drug war simply revived and expanded a tradition that has ancient roots, a tradition independent of the legacy of American slavery.

Remarkably, even in communities devastated by mass incarceration, many people struggling to cope with the stigma of imprisonment have no idea that their neighbors are struggling with the same grief, shame, and isolation. This type of phenomenon has been described in the psychological literature as pluralistic ignorance, in which people misjudge the norm. One example is found in studies of college freshman who overestimate the drinking among other freshman. When it comes to families of prisoners, however, their underestimation of the extent of incarceration in their communities exacerbates their sense of isolation by making the imprisonment of their family members seem more abnormal than it is.

The silence this stigma engenders among family members, neighbors, friends, relatives, co-workers, and strangers is perhaps the most painful—yet least acknowledged—aspect of the new system of control. We can have no significant understanding of any culture unless we also know the silences that were institutionally created and guaranteed along with it.

Ultimately, the fatal flaw of Broken Windows was its ignorance of history. Even if you put the best possible spin on it and stipulated that it was conceived by well-meaning people as a race-neutral tool for an ostensibly race-neutral problem, in its implementation it drifted inexorably in another

direction. To the black people who were its most frequent targets, the real-life, non-theoretical version of the program instantly evoked overtly racist policing programs from the past. For them, Broken Windows and Stop-and-Frisk never had a chance of being taken seriously as anything but the latest excuse to harass minorities. George Kelling had the foresight to understand that the optics of blasting homeless people with fire hoses in the Commando subway cleanup program would be bad. But somehow nobody worried that ticketing hundreds of thousands of people a year for obstructing pedestrian traffic or loitering might strike a particular chord with a population of people once targeted en masse for crimes like vagrancy and “impudence” for nearly a century after the Civil War.

According to a report released by the US Department of Justice’s Bureau of Statistics in 2006, the US spent a record \$185 billion for police protection, detention, judicial, and legal activities in 2003. Adjusting for inflation, these figures reflect a tripling of justice expenditures since 1982. The justice system employed almost 2.4 million people in 2003—58 percent of them at the local level and 31 percent at the state level. If four out of five people were released from prisons, far more than a million people could lose their jobs.

Unlike in the majority of democracies, in the United States, prisoners cannot vote; they are barred from political participation. The United States is unique among Western democracies in barring some prisoners from voting even after they have been released. As a consequence, there is no one recognized by the polity who can speak from the perspective of prisoners. Prisoners have become dehumanized as a consequence. They now serve as a strategic instrument in politics. A politician summons up crime to elicit fear, and then offers himself as the instrument to satisfy the desire for retribution (though the desire is for retribution of the fear caused by that very politician). The disappearance from public political life of the perspective of the prisoner has resulted in an ethical crisis for the United States. Recent decades have borne witness to ever more draconian prison torture practices, including the extensive use of solitary confinement and inhumane prison-sentencing practices.

What is less often remarked upon is that the disappearance of the prisoners’ perspective from public political discourse has resulted in another kind of crisis, a political crisis. The dehumanizing of prisoners has undermined our democracy. One example is the widespread practice in the United States of prison gerrymandering. In the many states that practice it, prisoners confined there also count as residents of the area where the prisons are. Many prisons are located in rural areas, and many of those areas have too few nonincarcerated residents to allow a representative to the state legis-

lature. In the state of Pennsylvania alone, there are eight state legislative districts that have too few nonincarcerated residents to be state legislative districts without counting the nonvoting (and mostly urban) prisoners in their prisons. Prisons thus give the rural voters in the areas in which prisons are located vastly enhanced political power and money from the state. This, in turn, gives such voters extra incentive to promote brutal prison-sentencing practices to keep the prisoners incarcerated and bring more to their districts.

Although there are many factors behind America's high incarceration rates, the ever-expanding list of criminal violations and the harshness of our sentencing are front and center. When Illinois's criminal code was updated in 1961, it was 72 pages, but by 2000 it had grown to 1,200 pages. Illinois is no anomaly: in every state, we imprison people for relatively minor, nonviolent crimes—like using drugs or passing a bad check—that would receive a slap on the wrist in other countries. While no more than 10 percent of those convicted of crimes in Germany and the Netherlands are sentenced to prison, in the United States it's 70 percent.

We also hand out much longer prison sentences than in other parts of the world. Burglarize a house in Vancouver, and on average you can expect five months in a Canadian facility. But drive an hour south to Bellingham, Washington, and commit the same offense, and you'll spend more than three times as long in prison. The same pattern is true for serious crimes. In Norway, for example, no one can be given a sentence of more than twenty-one years, while in the United States we regularly lock people up and throw away the key. Unlike many of our European counterparts, we also have all sorts of penalty enhancements and mandatory rules that can turn a seemingly small infraction into decades in prison.

The end of the law is to reconcile different interests and let them live together without undue fanaticism—and everyone should have a fanatic attachment to that end.

“If I take a broom handle and penetrate your stomach with it, that's not rape. If I take that same broom handle and penetrate your vagina or anus, that's rape. Now, I'm not trying to be offensive here, but if I'm choosing, it's the handle in the hole that already exists, not a new one made by it, that is going to be the less worse outcome. But simply, they're both assaults, not one sexual, one not, perhaps both violent assaults, but still simply assaults. Sexualizing a crime does nothing but bring cultural biases and emotions into the law.”

Of course, cultivating a flat affect does little or nothing to eliminate the biases that a person might bring to the issue. And approaching something like assault without emotion is neither objective nor fair and balanced. It only feels that way.

The carceral system has always used sensationalized cases and the specter of unthinkable harm to create new mechanisms of disposability. Those mechanisms are what feed bodies to hungry dungeon economies while we are distracted by our own fears of “bad people” and what they might do if they aren’t contained. Of course, a system that never addresses the ‘why’ behind a harm never actually contains the harm itself. Cages confine people, not the conditions that facilitated their harms or the mentalities that perpetuate violence. Yet, for some reason, even people who are well versed in the dynamics of the system often believe Law and Order moments are possible, when, just for a moment, an instrument of state violence can be made good.

Do you think we should rape people who rape? We don’t rape rapists, because we think about the person who would have to commit the rape. Should we assault people who have committed assault? We can’t imagine replicating a rape or an assault and holding on to our dignity, integrity, and civility. But because we think we have found a way to kill people that is civilized and decent, we are comfortable.

I hate it when people say, ‘Well, what if it was your kid that was kidnapped? Would you still care so much about human rights?’ Nope. I’d go full genocide to get my kid back, cheerfully murdering hundreds of millions of innocent people along the way. I’d make Hitler look lazy and uncommitted. This is why we mustn’t factor in the personal perspective of the victims. It torpedoed our ability to act justly, and just creates a cycle of ever-escalating vengeance.

Not contained in the judge’s sentence of death was that his last vision on earth would be looking up into the faces of those who hated him. They would hate him because they believed him to be a murderer—yes, like them. They would hate him because he is black. And those who hated him would be the ones to whom he would say good-bye.

Long in advance the condemned man knows that he is going to be killed and that the only thing that can save him is a reprieve. In any case, he cannot intervene, make a plea outside himself, or convince. Everything goes on outside him. He is no longer a man but a thing waiting to be handled by the executioners. This explains the odd submissiveness that is customary in the condemned at the moment of their execution.

Preacher was executed at Stateville Correctional Center at Joliet, Illinois. Some mammal, claiming to be a member of the human species, stuck a needle in Preacher’s arm, and another unidentified bipedal turned on the

poison, and Preacher Man died with love, along with those deadly chemicals, in his heart.

The innocent die a slower, more torturous death. To know that one is innocent, but day after day, year after year, decade after decade one is penned up like an animal in the zoo—such is the ultimate torture. There the innocent will live out their remaining years in a cramped, concrete closet as the hated, and in the company of the hated. There they will die at the hands of other inmates, or by the clubs of sadistic guards, or from inadequate medical care, or, at last, from the accursed needle itself.

Other familiar problems include mental illness, ineffective assistance of counsel, defendants who have insisted on representing themselves, and a lack of consideration for the trauma and abuse predating their crimes. Among the few people ever executed at the federal level since 1988 was Louis Jones, a black Gulf War veteran convicted for a rape and murder on a military base; Jones had no criminal history and had been diagnosed with PTSD. He died by lethal injection in 2003.

So many people snort and roll their eyes at mitigators such as extremely abusive childhoods, mental illness, or veterans with PTSD. The common refrain is:

“Lots of people with the same horrific experience don’t go around killing innocent people.”

This is trivially true, but fundamentally stupid and the reasoning immoral. Human beings’ behavior results from an established—but still poorly understood and complex—interaction of nature with nurture. Some individuals lack the genetic capacity to withstand extremely horrific conditions and retain their stability and judgment. In the birth and family lotteries—or a war experience imposed by the state—they are far more vulnerable to losing their shit.

Their victims, moreover, are not at all uniformly supportive of execution. But even if it were otherwise, the state kills people in the name of all of us, and the justice of this must be assessed in terms of whether all of us are moral when telling the government to kill in our names. It is very clear to me that to empower the state to kill a helpless human being in our name is immoral.

“I put my life on the line for this country. To me, not voting is not right; it lead to a lot of frustration, a lot of anger. My son’s in Iraq. In the army just like I was. My oldest son, he fought in the first Persian Gulf conflict. He was in the Marines. This is my baby son over there right now.

But I'm not able to vote. They say I owe \$900 in fines. To me, that's a poll tax. You've got to pay to vote. It's 'restitution,' they say. I came off parole on October 13, 1999, but I'm still not allowed to vote. Last time I voted was in '88. Bush versus Dukakis. Bush won. I voted for Dukakis. If it was up to me, I'd vote his son out this time too.

I know a lot of friends got the same cases like I got, not able to vote. A lot of guys doing the same things like I was doing. Just marijuana. They treat marijuana in Alabama like you committed treason or something.

I was on the 1965 voting rights march from Selma. I was fifteen years old. At eighteen, I was in Vietnam fighting for my country. And now? Unemployed and they won't allow me to vote."

His vote, along with the votes of millions of other people labeled felons, might have made a real difference in 2004 and beyond. There is no doubt their votes would have changed things in 2000. Following the election, it was widely reported that, had the 600,000 former felons who had completed their sentence in Florida been allowed to vote, Al Gore would have been elected president of the United States rather than George W. Bush.

Research indicates that a large number of close elections would have come out differently if felons had been allowed to vote, including at least seven senatorial races between 1980 and 2000. The impact on those major elections undoubtedly would be greater if all those deterred or prevented from voting were taken into account. But as ex-offenders will hasten to emphasize, it is not just the big elections that matter. One ex-offender put it this way:

"I have no right to vote on the school referendums that will affect my children. I have no right to vote on how my taxes is going to be spent or used, which I have to pay whether I'm a felon or not, you know? So basically I've lost all voice or control over my government. I get mad because I can't say anything because I don't have a voice."

First, the sentiment in favor of letting prisoners vote is quite simple: Universal suffrage means universal suffrage. You get to vote because you're a person, and you are still a person even if you commit a crime. A universal right is neither means-tested nor morals-tested, it's something you're entitled to no matter what. The criminal sphere is separate: You may do things that warrant punishment, you may be dangerous to others and have to be

confined, but nothing you could do warrants stripping you of your citizenship. There are also strong pragmatic arguments for letting prisoners vote, such as the fact that the criminal justice system has historically been used as a means of keeping disfavored populations from participating in democracy. Giving the state the ability to selectively revoke people's right to determine who runs the state creates strong perverse incentives to criminalize the existence of those people who would vote for the political opposition.

How, then, can we respond to the Dylann Roof Problem? If you murder nine people, you still get to participate in democracy? Why shouldn't we just adopt the Mehdi Hasan Compromise, and create categories of especially heinous crimes that make you ineligible to vote? Just exclude Roof and the really bad people.

This position is very tempting, but I think it fails to appreciate what is so powerful and important about truly universal rights. It may seem simple to distinguish the 'really bad' people from the 'merely bad' people, but once you've committed yourself to instituting a moral test for voting the line-drawing questions will become very difficult. For example, robbery is considered a violent crime. Should purse-snatchers be denied the right to vote, but embezzlers and fraudsters be granted it? In fact, in attempting to reinforce the badness of bad crimes, this approach actually ends up diminishing the badness of some crimes. Why? Because if we say that 'Your rights depend on whether you pass a moral test,' then anyone who passes the moral test will have, well, passed a moral test. But we might not want to signal any kind of approval of imprisoned people's conduct or create tiers of citizenship and have them fall into the Good Tier.

One reason that keeping universal programs absolutely universal is useful is because it means that granting people their rights isn't a judgment of their merit. To many people, if we start asking 'But what about Dylann Roof?' then any basic human entitlement will seem gross. Why should Dylann Roof get to stay in a soft bed? Why should he get state-funded medical care? Why should he even be allowed to live? If personal moral character is a factor in these questions, then to many, obviously someone like Roof deserves nothing at all, because he's so reprehensible. But if we look at basic rights questions that way, then we will end up doing terrible things: letting prisoners die because we refuse to give them adequate medical treatment, for instance. If you think the crimes of people like Dylann Roof are so horrible then if we start using the seriousness of the crime as the measurement of how much humane treatment Roof deserves, he won't be treated humanely. Some people are completely fine with that, and do think that when someone commits an atrocity it grants the rest of society license to brutalize and even murder that person. Others of us, however, think

nobody deserves that.

People often fail to appreciate why a kind of absolutism can be very valuable in protecting liberties. The same thing goes for the free speech principle: Instead of having to empower someone to determine who the acceptable speakers and the unacceptable speakers are, even if we agree that there are some unacceptable speakers, allowing all speakers divorces the question of how bad the content is from the question of whether the person can speak. This is useful, because once permission is conditional on content, you get into tricky questions like ‘Well, if a fascist can’t speak, why can George W. Bush, who is responsible for the deaths of 500,000 people?’ Of course, it’s usually impossible to fully decouple these questions, and nobody who has an easy answer to free speech issues has thought about them enough, but there is a reason why leaning toward ‘absolutes’ and ‘universals’ is valuable. If line-drawing is tricky and likely to lead to abuse, then it’s better to simply avoid having to draw any line at all.

Most people don’t think that all prisoners should vote. I see why they think that: Some people in prison have done truly horrible things, and it might seem like an insult to victims to let them help choose their country’s leaders. But there’s a different way to think about it: The question of whether they should vote says nothing whatsoever about what they did to victims. It’s like the question of whether they deserve to see a doctor when they’re sick. It is not a diminishment of their crimes, but a recognition that their crimes are not the issue when it comes to the basic rights of life, health, and democratic participation. Everyone gets to vote, not because they are morally good enough, but because they are people.

Once rights become privileges for any segment of a population they can be revoked for the rest of the population.

The truth is that we’re not going to make much more progress until we realize that we are just as ignorant of the effects of our punishments as we are of what actually drives us to punish. Our favored tools of mass incarceration and solitary confinement do not do what we think they do. And we remain wedded to the same mistaken theories espoused some two-hundred years ago by the Society for Alleviating the Miseries of Public Prisons.

Now, as then, the prisoner and potential prisoner are viewed as rational beings who make decisions to offend based on a cost-benefit analysis. To decrease crime, the thinking goes, you just need to increase the magnitude of the punishment until violating the law no longer seems to pay. The more distasteful the punishment—that is, the more we deprive criminals of the things that they normally enjoy—the less likely a person will be to choose to offend in the future.

Harsh treatment is acceptable because it’s directed only at people who

deserve it in proportion to their wrongdoing. However, as moral individuals, we understand that we shouldn't cause a prisoner physical pain, which rules out various forms of abuse at the hands of the state. Tough prison sentences, then, are the optimal approach to punishment because they act as a strong deterrent without forcing us to "mistreat" the prisoner.

They also provide a ready means for incapacitating people who just don't respond to the threat of being locked up. Prisoners who are uncontrollable are never let out; the rest, we can feel confident, will now steer clear of crime, knowing how unpleasant it is behind bars. Put simply: our prisons are humane; our punishments are deserved; and our system makes us safer. That's what Eastern State's progenitors proclaimed, and that's what we believe. And we are dead wrong.

It can be no surprise that members of the public fail to raise an eyebrow when a new, harsh mandatory sentence is handed down, or when a study suggesting endemic prison rape or deplorable living conditions is released, or when legislation is enacted that prevents parolees from living within the confines of a city, deprives them of their ability to vote, or stamps them with a permanent badge of ignominy. But these are terrible things. And if we stopped to think about our common humanity and shared destiny, we'd realize that they are directly at odds with our values and we would not stand for them.

Hopelessness, the Department of Corrections is well aware, breeds desperation, so incentives are built into the system to encourage even men with nothing to lose to obey the rules. If you obey the rules, you get privileges. If you break the rules, you lose them. If you break enough rules, you wind up in solitary confinement with only an hour of exercise a day. Man is a social animal, and the threat of solitary is usually enough to keep all but the most troubled inmates in line.

What is solitary confinement actually like? To get a sense, walk into your bathroom, shut the door, lie down in your bathtub, and close your eyes. When you reopen them, imagine that this is where you will spend the next five years of your life. Take a look at your new kingdom. Wake up in the morning and the fluorescent lights are already on, just as they have been all night. Roll from your bed and you can touch the walls—off-white or white. It may be thirteen by eight, or eight by ten, or fourteen by seven, but take a step and you touch the walls. There are no windows, but maybe you get a slit. There is a toilet and a sink. This is where you sit for twenty-three hours each day for weeks and months and years on end. You get taken out only to shower and, on certain days, for a bit of movement in a slightly bigger cage—a narrow dog run.

In Maine, no radios or televisions were permitted. At California's Pelican

Bay, those in solitary get a personal phone call only in the case of emergency. It is a bit softer in the Departmental Disciplinary Unit of the Walpole prison in Massachusetts: a radio after thirty days, a thirteen-inch black-and-white television after sixty, and up to four calls a month, if merited by good behavior. Human contact is virtually nonexistent. The doors are often solid metal, preventing you from talking with other inmates. For many, the opening of the door slot for the guard to push through a food tray is it for the entire day. If you want to feel a human touch, your only real chance is to break the rules—block out the lights to sleep or cover the opening in the door, and you can expect an “extraction.” Officers with shields and helmets will rush into your cell, pin you to the ground, and shackle your arms and legs. Your clothes may be cut off your body as they kneel on your legs and back. You may then be strapped naked to a restraint chair.

Our attention may be drawn to the fight against capital punishment, but only a few dozen people are executed each year in the United States. Meanwhile, thousands of our citizens are locked in boxes for months and years, and thousands more imprisoned for decades without the possibility of parole. Few of us stop to consider whether burying people alive is really such an enlightened alternative to lethal injection.

And it is hard to maintain that narrative of “deserved” suffering when the inmates who are raped in prison are not the worst criminals. They are disproportionately nonviolent first-time offenders. They are disproportionately young and physically small. They are disproportionately mentally disabled. They tend to have histories of being sexually abused as children. And in a horrible twist, those who would seem most deserving of brutal treatment not only avoid the worst abuse in prison but are given *carte blanche* to act as perpetrators. There is something unquestionably perverse about a system of justice that tacitly sanctions as part of punishment the very abuses that it condemns as mandating punishment.

To succeed in the long-run, rules must have a moral or practical basis and the support of the people. If society says that you may do one thing and not another, there must be some rationale or the rule will be flouted. There is no legitimacy in officials writing rules as they choose simply because they have the power to do so. Such is tyranny.

So we’ve got “inclosed” trucks—potentially used for business or sleeping—as well as housetrailer, watercraft, secondary schools, elementary schools, and more. California law actually adds to this list. In California, burglary can be charged of anyone “who enters any house, room, apartment, tenement, shop, warehouse, store, mill, barn, outhouse or other building, tent, vessel, floating home, sealed cargo container, or mine or any underground portion thereof, with intent to commit grand or petit larceny or any felony.” Think

about this: if you step into an abandoned mine “or any underground portion thereof” with no plans to steal anything, but instead simply intending to shoot an unlicensed handgun (a felony), you are legally guilty of burglary. Why? Because it took place inside a legally recognized artificial structure (the mine).

Even a hole in the ground could be considered a building for the purposes of burglary law. In *People v. Buyle*, a 1937 court case in California, a company stores property in a cave dug out of a hillside, an employee tries to make off with some of the goods. A burglary has been committed. The court’s instructions for the case specifically stated that a small bubble of negative space dug into the landscape, even if lacking a complete front wall, “is nonetheless a house merely by virtue of the fact its walls and roof may be produced by an excavation in the hillside.” Nonetheless a house. Because of burglary law, architecture is suddenly everywhere. We are surrounded by invisible buildings.

Legally speaking, architecture is a form of magic, one that has no place in an otherwise rational system. Architecture is the magic of four walls with the power to fundamentally transform how certain crimes are judged and how their perpetrators can be sentenced. True, other crimes may still have been committed, but that is exactly the point. Why not simply indict on the strength of these other crimes alone and be done with accusations of burglary? Why is burglary so beloved by lawyers and police? It is often easier to convict someone of burglary than it is of other crimes, including rape. What’s more, a burglary charge also frequently increases—sometimes quite drastically—the possible sentencing. Think of burglary perhaps as something like an augmentation spell, always ready to be cast upon the crimes at hand: a little special something a prosecutor can tack on to any felony charge as long as it occurred inside a legally recognized architectural space. Conclusively determining a crime’s precise architectural circumstances—demonstrating unimpeachably that the accused was inside a built structure at the time of commission—thus takes on great forensic and punitive importance.

A recent indication of how flexible the spatial circumstances can be for determining whether someone has committed burglary came after an escapade in New York City. Early in the morning of July 22, 2014, two American flags mounted atop the city’s iconic Brooklyn Bridge were mysteriously replaced with white flags. After two German artists claimed responsibility for the act a few weeks later, NYPD deputy commissioner Stephen P. Davis remarked to the *New York Times*:

“At a minimum, it’s trespass, but there is a possibility you

could charge burglary. If you go into a fenced-in area for the purpose of committing a crime, that legally constitutes a burglary.”

In this case, the artists climbed into a fenced-in portion of the bridge at the base of each tower. Neither of these spaces has a roof, as they are little more than chain-link cages open to the wind—yet this is considered an architectural interior in the eyes of the law, transforming mere trespass into burglary with one enchanted close.

It does not take much imagination to suspect that, someday, an altogether-too-clever team of lawyers, police officers, and architects will combine forces to devise any number of speculative wall-like barriers peppered around the city so that other people can, rightly or not, be charged with burglary after stepping “inside” these imaginary spaces. Burglary, then, would fully and absurdly have become a pointless mathematical exercise in which unreal architectural forms are brought forth into the world in a form of legal sorcery.

Experiencing a trial sometimes feels like finding oneself dropped into a room filled with noisy, gibbering psychos—lawyers and even the judges—all of whom are trying to act as if they are sane. And what sane result, if any, finally emerges years later is anyone’s guess. Moreover, a delay of years is meaningless to the justice system since the system enjoys a perpetual life, while the accused, guilty or not, can die without having tasted the first morsel of justice.

One of the virtues of tribal law is that it presupposes that people are just the way we know they are: generally wise, kind, generous, and well-intentioned, but perfectly capable of being foolish, unruly, moody, cantankerous, selfish, greedy, violent, stupid, bad-tempered, sneaky, lustful, treacherous, careless, vindictive, neglectful, petty, and all sorts of other unpleasant things. Tribal law doesn’t punish people for their shortcomings, as our law does. Rather, it makes the management of their shortcomings an easy and ordinary part of life.

There is no crueller tyranny than that which is perpetuated under the shield of law and in the name of justice.

We may think we know how the criminal justice system works. Television is overloaded with fictional dramas about police, crime, and prosecutors—shows such as *Law & Order*. These fictional dramas, like the evening news, tend to focus on individual stories of crime, victimization, and punishment, and the stories are typically told from the point of view of law enforcement. A charismatic police officer, investigator, or prosecutor struggles with his own demons while heroically trying to solve a horrible crime. He ultimately achieves a personal and moral victory by finding the bad guy and throwing him in jail. That is the made-for-TV version of the criminal justice system.

It perpetuates the myth that the primary function of the system is to keep our streets safe and our homes secure by rooting out dangerous criminals and punishing them. These television shows, especially those that romanticize drug-law enforcement, are the modern-day equivalent of the old movies portraying happy slaves, the fictional gloss placed on a brutal system of racialized oppression and control.

Those who have been swept within the criminal justice system know that the way the system actually works bears little resemblance to what happens on television or in movies. Full-blown trials of guilt or innocence rarely occur; many people never even meet with an attorney; witnesses are routinely paid and coerced by the government; police regularly stop and search people for no reason whatsoever; penalties for many crimes are so severe that innocent people plead guilty, accepting plea bargains to avoid harsh mandatory sentences; and children, even as young as fourteen, are sent to adult prisons. Rules of law and procedure, such as ‘guilt beyond a reasonable doubt’ or ‘probable cause’ or ‘reasonable suspicion,’ can easily be found in court cases and law-school textbooks but are much harder to find in real life.

There is a difference between the letter of the law and justice, and that usually depends on the person wielding the power in a given situation.

The law is always up for grabs. The law is not an inflexible instrument like a cannon that can be lined up and fired. It’s a flexible human instrument that responds to political power. When you have the power of the presidency, you have the capacity to put people in place who will be sensitive to upholding these laws. When you lose that authority, you’re left with futile rear-guard actions.

The US has more people in jail than any other country in the world, yet executives who cause enormous economic devastation not only go unpunished, but are incentivized to do it again. Isn’t this a huge inequality?

When we talk about inequality in this country, often we’re talking about jobs and wealth and economic opportunity. But I would say that the greatest perquisite of the power class in America is the ability to commit crimes with impunity. I think this profoundly undermines the sense that we live in a just and fair society when we see top corporate executives getting the kinds of protections from our legal system that are not available to people of lower means.

In one case, corporate executives are found guilty, but their criminal charges are overturned because the prosecutors put up the wrong stock chart. They put up a stock chart that prejudiced the jury because the chart went down, when maybe it didn’t go down as much as they thought. For that, these guys get their charges thrown out. The courts have been very

interested in reversing white collar convictions.

In a 2012 speech, the head of Obama's Criminal Division, Lanny Breuer, announced that he was sometimes persuaded when banks and corporations asked him not to prosecute on the grounds that it might cause the company in question to fail and thus hurt the economy. "We must take into account the effect of an indictment on innocent employees and shareholders," Breuer said, describing a courtesy that American prosecutors extend to no other group and that, by its nature, makes a joke of the idea of equality before the law.

One thing soon becomes clear: The quantum of justice available to most Americans is in direct proportion to that individual's social and economic status, which is to announce the controlling rule of law in America: Little money, little status—little justice.

What the poor get is discipline; what the professionals get is endless indulgence.

The thread by which good governance hangs is this equality before the law, for the only fear of the man who turns the gears is that he may find himself upon them.

There can be no equal justice where the kind of trial a man gets depends on the amount of money he has. And the gap between the haves and have-nots is only going to widen. For those at the top, crime really does pay—and the more you make, the more access you have to those who can help you game the system. And the more you have that power, the less likely the government is to investigate you, prosecute you, or take a hard line in plea bargaining, because they know that they aren't going to win at trial.

For those at the bottom, by contrast, the lack of access initiates a devastating downward cycle. You can't stop losing, because every time you return from prison, you are in a worse position to gain the help you need. Each new sentence keeps you away longer from gainful employment, education, and personal connections. You never have the chance to build up the necessary capital to buy in to the secret world that hedge-fund fraudsters take for granted. And you pass on the curse to your children: when you're incarcerated, they, too, are less likely to go to college or rise out of poverty. Entire inner-city communities become locked into this self-reinforcing inequity, while gated ones across the river are able to secure wealth and success for generations to come.

One can suffer all nature of physical injury and survive; one can never bear the supreme injury of being deprived of justice. The pain is too deep and too real, too disabling and too lasting. As time passed, the need for

retribution will become an irresistible compulsion. Such is the resulting disease of injustice.

Deprive a human being of justice and the human will die for it. Ask the martyrs of history. The refusal of justice plants a cancer in the soul.

One of the strangest side effects of our ineffective and unfair incarceration system is that it may also make people less likely to follow the law in the first place. To many policymakers, severe mandatory sentences seem to offer a powerful incentive to follow the rules. But the extreme harshness of our punishments may actually increase the likelihood of malfeasance because they suggest that the law is not worthy of respect. If a couple of garage break-ins over the summer and a stolen car can land a nineteen-year-old in prison for life, then it is hard to trust the system, believe in its rules, and rely on its processes and officers.

Research has shown that citizens are more willing to defer to the decisions of legal authorities and more willing to follow the law when they see those authorities and legal rules as legitimate. In one study, a group of participants read about a proposed law that seemed unjust because it raised civil liberties concerns or hurt certain citizens, while another cohort read about a seemingly just law. Those who had read about an unjust provision were more likely to report that they planned to disregard other completely unrelated criminal laws in their day-to-day lives.

An 1867 editorial:

“If it had previously existed in the convicted person’s bosom a spark of self-respect this exposure to public shame utterly extinguishes it. Without the hope that springs eternal in the human breast, without some desire to reform and become a good citizen, and the feeling that such a thing is possible, no criminal can ever return to honorable courses. The boy of eighteen who is whipped at New Castle for larceny is in nine cases out of ten ruined. With his self-respect destroyed and the taunt and sneer of public disgrace branded upon his forehead, he feels himself lost and abandoned by his fellows.”

We are so obsessed with the idea that the experience inside prison must not be like the experience outside that we overlook how much harder that makes it for inmates to rejoin society once they are released. Depriving people of normal human contact does not eliminate criminal behavior; it eliminates the capacity to engage in normal human contact. Losing the stimulation of work, entertainment, or socialization does not prompt people to make better choices in the future; it leaves them unprepared to get a job or interact with the outside world when they are released.

Our current system does everything wrong in terms of optimal deterrence. Deterrence works when potential offenders think that they are almost certain to be caught and given a clear, immediate punishment. Our system, by contrast, offers a low probability of getting caught and a hazy potential punishment far in the distant future.

Despite our admission that “justice delayed is justice denied,” our judicial process is often dragged out over a series of months. In Brooklyn, the average wait time for a trial is 243 days; in the Bronx it is 408 days. Some cases take three, four, or five years. Even when punishment is certain, the greater the delay between the violation and the punishment, the less the penalty will act as a deterrent.

Harsher punishments or minimum sentencing do not equal automatic deterrence, nor help those already in the system. Put simply, harsh punishments deter people who will never enter the criminal justice system; harsh punishment and minimum sentencing ignore particularities to criminal activity, instead painting every offender under the same light of guilt, a practice which ignores societal variables relating to current socioeconomic standing, law enforcement bias, past detainment, and even upbringing. Such policy is in direct conflict with the theory of deterrence, a theory of which is the foundation to much modern penology following the sovereign era.

Deterrence theory states that criminal behavior can only be deterred with policy that is speedy, consistent, and relative. Meaning, a lack of the aforementioned variables such as in a system—very much like the current one in the US which has many accounts of pretrial detainment or light bail for some but not all (especially in relation to socioeconomic status)—results in little deterrence as those who will enter the system do not know what to expect to get out of it.

Further, harsh punishments ignore the social contributions to a fostering of eventual deviance; for example, a large contributor to deviance is the idea of the ‘American Dream.’ The American Dream represents a goal all in America are taught to want, yet only a select few can actually attain. Put simply, those who cannot attain such a goal resort to crime to attain the same goals as those not limited by social factors. Harsh punishments typically end up targeting certain groups over others due to natural bias within law enforcement—based on historical and cultural factors—and thus violate the consistency principle for the effect of general deterrence to the overall populace. Harsh punishments ultimately separate communities and illuminate some as deviant and some as not, simply reinforcing political bias to encourage a lack of support for certain social programs and areas.

The fact that our punishments are often vastly out of proportion with the crime, say for example mandatory minimums and the prevalence and

expectation of prison rape, is direct evidence of the unfairness of the system, which any adult will pick up on, and correctly take as evidence that the system is out to get them.

Our policy of punishing people—hurting them, making them feel helpless—for bad behavior seems to be built on the idea that we'll change their minds and subsequent behavior by force. However, successfully changing someone's mind without their consent or cooperation is the definition of brainwashing, which requires far more extreme tactics than imprisonment—tactics which we don't—and shouldn't—have the stomach for as a society. I suspect that, to the extent that spanking children—hurting them and making them feel helpless—works at all, it's only because children haven't yet built up the psychological defenses to physical coercion that adults have.

Most crimes, like robbery, assault, and rape, are committed by habitual offenders who have serious difficulty functioning peacefully in society. There are of course a number of reasons for this, many not within the control of the habitual offenders. If they are released, around 50 percent of them go right back to committing their crimes. Murderers are different. If you exclude professional hit men and the insane, most murderers are in prison for a onetime eruption of violence that they themselves are often shocked to have committed. Once released, they have a recidivism rate of two percent. In a strictly statistical sense, murderers are much better candidates for judicial mercy than men who have committed far lesser crimes.

For any severe crime, punishment for first time offenders is quite stupid. Society, the community, has already paid a price for such individuals to learn, to be wiser in the future in many cases. What good does it do to imprison them for decades or more when many will now be—especially with the aid of rehabilitation and other assistance programs—much less likely to cause future harm than the general population which has not made such mistakes.

Everyone is capable of committing any horrific act given the right circumstances. To act otherwise is to enshrine ignorance and increase the risk of harms.

The lack of correlation between crime and punishment is nothing new. Sociologists have frequently observed that governments use punishment primarily as a tool of social control, and thus the extent or severity of punishment is often unrelated to actual crime patterns. Governments decide how much punishment they want, and these decisions are in no simple way related to crime rates. This fact can be seen most clearly by putting crime and punishment in comparative perspective. Although crime rates in the United States have not been markedly higher than those of other Western countries, the rate of incarceration has soared in the United States while

it has remained stable or declined in other countries. Between 1960 and 1990, for example, official crime rates in Finland, Germany, and the United States were close to identical. Yet the US incarceration rate quadrupled, the Finnish rate fell by 60 percent, and the German rate was stable in that period. Despite similar crime rates, each government chose to impose different levels of punishment. Today, due to recent declines, US crime rates have dipped below the international norm. Nevertheless, the United States now boasts an incarceration rate that is six to ten times greater than that of other industrialized nations—a development directly traceable to the drug war.

I can tell you that there is a huge disconnect between perception of punishment and effectiveness of our systems.

The problem, is that punishing people too much actually makes them more likely to recommit a crime. People feel that leniency is a bad thing, but what if I told you that all research points to incarceration as often exacerbating risk and recidivism? Then what do you do?

The end goal of the correctional system is to stop recidivism, and crimes like manslaughter have some of the lowest rates of recidivism. Manslaughter is the taking of someone's life without intending to do so, which is not something that happens very often, since it's not intentional. Research also shows that murder, for the most part, is a one time deal; usually out of a shitty situation—caught your wife cheating on you, for instance.

So, that guy who got uber-wasted one night, and ended up killing two people behind the wheel of his car. He goes to prison, and after three years has done a bunch of programs, half his family disowns him, he lost all his friends, and he's bankrupt. There are two options:

1. Keep him incarcerated, at the cost of \$80K+ per year, where his risk to become a violent criminal increases exponentially for each year he is incarcerated, because he is removed from society, his support system is shattered and he becomes bitter. And unless you plan to keep him in for life, or he gets killed, he will be released with those emotions into society eventually.
2. You reintegrate him within society with a number of conditions, at two-thirds of his sentence, and research shows he has a very little chance of recommitting any offense, let alone another DUI. He gets to have a job and pay taxes, and give back to society.

What is the best course of action? How do you justify keeping him incarcerated?

Of course you can also find that rare example where one guy did it three, four, five times—but he should be dealt with accordingly as well. I'm talking about the majority of offenders. Most Canadians would be shocked at how many people were incarcerated and now live productive lives around them, but you don't hear about those in the media, only the sensationalist shitstorms that occur occasionally.

The problem is that the public only sees the 'HE KILLED 2 PEOPLE AND WAS ONLY IN JAIL FOR 3 YEARS!' reaction to the decisions, and their response is 'FUCK THAT, HE SHOULD GET LIFE!'

I understand that people feel a need for vengeance, but if there is anything that I've learned through the years, it's that the end goal of corrections is not vengeance, or punishment, nor should it be—the end goal is to reduce crime. That is how you get a safer community, and that is how you reduce the number of victims.

Sure, it may seem unfair for that family who lost the two people and feel that he should be in for life, but what about the other thousand families that aren't victimized in the future, because the offenders were reintegrated properly?

It's a hard concept to grasp, because it asks us to override our emotional response for vengeance, with rational thinking, something that isn't very easy—it's the hardest thing you can ask a victim to do. It's even harder in the hivemind of the world, especially those commentators who talk the loudest—looking at you Nancy Grace or "Judge" Jeannine Pirro.

Don't feel that lenient sentences in your nation are a downside, please, please don't—be grateful that your society is progressive with human rights and an evidence-based understanding of the greater good of society. The stark contrast is what we see in Saudi Arabia, and Malaysia, where even the smallest crime can end in a death sentence. They are far from progressive, and care little for evidence.

Please don't take this as a preaching for the system, it's far from perfect, however we have come a very long way from the barbaric, and most importantly—ineffective—types of punishment that aim only to quench our thirst for vengeance; especially since this aim only made our society less safe.

“If a man is returned to society more embittered, vengeful, demoralized, and incapable of social and economic survival than when he first came to prison, then we certainly have failed to protect society.”

‘Punishing’ is too narrow and ill-defined. In theory, prison has three good purposes:

1. An incentive to not commit crimes.
2. A way to keep the most dangerous criminals off the street.
3. A place to rehabilitate criminals so that they do not continue committing crimes after leaving.

All three of these provide a benefit to society, though the exact amount of value is up for debate. Many people believe also there is a fourth purpose: Retribution or vengeance for victims of crimes. However, this does not benefit society. This type of punishment screws people up and makes recidivism even more likely while also making society more likely to turn a blind eye to prison health and safety issues. Both of these benefit the for-profit prison system which is itself partly responsible for one of the highest incarceration rates in the world.

If that’s not enough, we have an abnormally high incarceration rate for people who are actually innocent because the District Attorney is an elected position and Americans are, as mentioned before, a very angry and vengeful bunch. They’re elected on promises that they will successfully prosecute more people. So when the prison system reflects a desire for revenge against criminals, every innocent person gets caught in this web.

What if you were falsely accused of rape? Or molesting a child? Maybe a crooked police officer plants something on you or claims you assaulted him while his dash cam was “broken?” A prison system that reflects those first three goals would take away your freedom, but not abuse you. The one we often have—though it varies from place to place—would have you bruised, raped, or even killed by other inmates depending on the crime you were accused of, working for pennies an hour to put a tiny dent in the debt you are accumulating, or possibly putting your family into debt to pay outrageous prices for your basic needs.

Criminal punishment is so extreme that it should be used only when every other possible means of solving a social problem has been exhausted. The criminal punishment system is so blunt and harmful in its effects that it should be reserved only for the most serious offenses, and anything that can be resolved outside it should be. If you are a prison abolitionist, as I am, you think we should take prosecution off the table most of the time as a response to a given social problem. To see why, imagine that you and I are discussing how we can persuade our friend Dennis to stop showing up late to union meetings. You suggest that we offer to give Dennis a ride, so

that he won't be able to blame the bus system. I suggest that we sit down and ask Dennis to level with us about why he's late, and tell him why his presence matters. We can debate how to approach this. But imagine if a third person piped up and said:

“I suggest that we give him a warning, and if Dennis is late to one more meeting, we show up to his house, armed, drag him away in front of his children, and lock him in a cage for a week.”

Person 3 would appear to lack basic humanity, and their suggestion would (hopefully) be dismissed out of hand. That's true even if we believe this would objectively be an effective way of convincing Dennis to show up on time. Prosecution may work, then, but it's an extreme option. We might need it in the case of murder or physical abuse, but on the whole we need to think more creatively.

As recently as the mid-1970s, the most well-respected criminologists were predicting that the prison system would soon fade away. Prison did not deter crime significantly, many experts concluded. Those who had meaningful economic and social opportunities were unlikely to commit crimes regardless of the penalty, while those who went to prison were far more likely to commit crimes again in the future. The growing consensus among experts was perhaps best reflected by the National Advisory Commission on Criminal Justice Standards and Goals, which issued a recommendation in 1973:

“No new institutions for adults should be built and existing institutions for juveniles should be closed.”

This recommendation was based on their finding that:

“The prison, the reformatory, and the jail have achieved only a shocking record of failure. There is overwhelming evidence that these institutions create crime rather than prevent it.”

Every minute under the carceral, colonial project is inconceivable violence. We too often place abolition as something only possible in a far-off future, which means we're allowing the right-now to be stolen. The only logical time for abolition and decolonization is now.

While no one organization can do everything, a successful anti-prison movement will need to synthesize direct action, popular relevancy, and radical critique. To separate these approaches is to grant victory to the prison state.

Too much twenty-first century US-based anti-prison advocacy huddles within a safe limit. The goal has become to find people who are relatively

or absolutely innocent under the law, and agitate for their release. Make no mistake: getting people out is a good thing. But the persuasive means used to attract attention and gain sympathy often reinforces the deadly belief that, aside from some errors, confinement reduces more harm than it generates. This kind of thinking detours anti-prison work into a charitable enterprise—to help the so-called deserving—rather than what it should be: a cornerstone of large-scale fights for social, economic, and environmental justice.

The purpose of abolition is to expose and defeat all the relationships and policies that make the United States the world's top cop, warmonger, and jailer. Practicalities rather than metaphors determine the focus and drive the analysis, because the scope of prison touches every aspect of ordinary life. Thus, it is possible and necessary to identify all those points of contact and work from the ground up to change them. This ambition makes some people impatient, as well it should. Abolition is a movement to end systemic violence, including the interpersonal vulnerabilities and displacements that keep the system going. In other words, the goal is to change how we interact with each other and the planet by putting people before profits, welfare before warfare, and life over death.

By imagining most criminals as autonomous, rational actors deciding to pursue greedy, lustful, or hateful ends, we underestimate the significance of forces in the world around us and dynamics in our brains over which we have little control. Once again, we are paying attention to all the wrong things.

We are always seeking to address problems that are not the root cause. Address why the innately social animal is perpetrating violence against its kin and fix that. This will have a much more widespread positive effect than doing anything to specifically address guns. Mental illness, greed, ignorance, lack of empathy, irrational passion, manipulation, lack of options. How many issues can we solve if we recognized that these were our true problems? Focusing on individual issues like gun control, or gay or transgender rights simply divides your power as a people striving for justice.

“Though anthropologists have long focused on the distinctions between people, it is recognizing the sameness that allows us to most accurately predict violence. Of course, accepting someone's humanness does not mean excusing his behavior. This lesson is probably starkest when you spend time with the world's most violent and dangerous people, the ones you might call monsters, the ones who committed acts you might think you couldn't have imagined. Many of them are locked up at Atascadero State

Hospital in California. I founded and fund a program there called Patient Pets, which allows patients to care for small animals. Many of these men will be locked up for life without visitors, and a mouse or bird might be all they have.

I recall the way the patients reacted to the death of a particular guinea pig who had been one of the first pets in the program. When they noticed the old animal was sick, they wanted to find a way to keep her from dying, though most knew that wasn't possible. The program's coordinator sent me this report: One patient, Oliver, made it his job to be sure the ailing animal had everything she needed. Oliver asked to keep her in his room, 'so she won't be alone at night, just in case she decides to die then.' Eventually, the old guinea pig was unable to move and her breathing was labored. Oliver gathered several patients in my office, and the guinea pig died in his arms, surrounded by an unlikely group of mourners. There was not a dry eye in the ward as the patients said their good-byes and silently left the office. I have often shared with you the effects these events have on the patients, some of whom, moved by the death of one of the animals, cried for the first time about the harms they had committed on others.

As I sat in my office watching the patients, all felons, many guilty of brutal crimes, most lost in a variety of addictions (you choose), mental illness (pick one), and regarded as the bottom of the barrel, I saw a glimmer of compassion, a bit of emotion, and the glimpse of humanity that society believes these men lack (and in most situations, they do). It is true that the majority of these men are exactly where they belong; to unleash them on society would be unthinkable, but we cannot disregard their humanness, because if we do, I believe, we become less human in the process. So, even in a gathering of aberrant murderers there is something of you and me.

Scientists, after all, do not observe a bird that destroys its own eggs and say, 'Well, that never happens; this is just a monster.' Rather, they correctly conclude that if this bird did it, others might, and that there must be some purpose in nature, some cause, some predictability."

Universal among the violent criminals was the fact that they were keeping a secret, a central secret. And that secret was that they felt ashamed—deeply ashamed, chronically ashamed, acutely ashamed. It was shame, every

time. I have yet to see a serious act of violence that was not provoked by the experience of feeling shamed or humiliated or disrespected or ridiculed. As children these men were shot, axed, scalded, beaten, strangled, tortured, drugged, starved, suffocated, set on fire, thrown out of the window, raped, or prostituted by mothers who were their pimps. For others, words alone shamed and rejected, insulted and humiliated, dishonoured and disgraced, tore down their self-esteem, and murdered their soul. For each of them the shaming occurred on a scale so extreme, so bizarre, and so frequent that one cannot fail to see that so many of the men who occupy the extreme end of the continuum of violent behaviour in adulthood occupied an equally extreme end of the continuum of violent child abuse earlier in life.

The rule in crisis management is: Don't make it your goal to control effects, make it your goal to control causes. If you control causes, then you don't have to control effects.

The biggest driver of violence is treating money as a finite resource.

A year in a New Jersey prison costs more than a year at Princeton University. State spending on prisons has outpaced spending on higher education in the last twenty years, increasing at six times the rate.

A single death-penalty case, from arrest to execution, costs a state government between \$1 million and \$3 million. The average cost of housing an inmate in a supermax prison is approximately \$75,000 a year. Justice is a finite resource: we have only so much time, and so much empathy. Should we spend such a large portion of what we have on trials and punishments?

Law & Order

Over the decades, the FBI has best served the cause of national security by bending and breaking the law. A secret police is anathema in a democracy. But the FBI's powers make it America's closest counterpart.

Hoover was not a monster. He was an American Machiavelli. He was astute, he was cunning, and he never stopped watching his enemies. He was a founding father of American intelligence and the architect of the modern surveillance state. Every fingerprint on file, every byte of biographic and biometric data in the computer banks of the government, owes its origins to him.

People usually focus on what burglars take, but it's how they move that's so consistently interesting. Burglars explore. They might not live in a city full of secret passages and trapdoors—but they make it look as if they do. As burglars have chipped and slithered away at their self-chosen jobs throughout the cities of the world, the FBI have become twenty-first-century break-in artists extraordinaire, controlling the scenography of intrusion to a degree that would stun even Hollywood concept artists.

The FBI's present-day program tasked with making sure that state-sanctioned break-ins go off without a hitch is code-named, appropriately enough, Stagehand. Picture G-men dressed as traffic cops, (mis)directing cars away from certain streets and intersections; parking buses in front of mob-operated shops to disguise the lock-picking operation going down on the other side; even carrying their own collections of dust around with them in envelopes and vials, in case they disturb any dust-covered objects (or floors or tables or any other flat surface) in a target's apartment. They sprinkle replacement dust as they walk backward out the door, and as if it were fairy tale, no one will ever know they were there.

Easily one of the more outlandish stories of surreptitious entry by America's Secret Police: While breaking into what is described only as a Soviet-bloc embassy, one of the participating agents promptly died of a heart attack. Right there, he collapsed onto the carpet, his heart giving out. Not only did the other agents on the case have to carry him out, but his body relaxed in its sudden death to the grotesque extent that "his bowels emptied on an oriental rug in the office." Not only did the team have to remove the entire rug from the embassy in the middle of the night, but they had to find a twenty-four-hour dry cleaner to fix the stain. Then, because the carpet would still be partially wet the next morning, they decided to paint the ceiling above it to make it look as if a water pipe had ruptured in one of the rooms above. Then and only then—improvised narratives piling on top of

outright lies, newly cleaned rugs drying below freshly painted ceilings—could the FBI effectively rid the target building of their traces.

We should not seek to stop acts of terror—or any other crime—through surveillance, that is not a free society. In a free society, the way you prevent crimes from occurring is that you remove the conditions, the catalysts for those crimes. You preempt terrorism not by catching them before they can act but by removing the reasons, the justifications for engaging in such acts. To do anything else is to surrender freedom, justice, for the illusion of security.

Afghan detainee Gul Rahman was tortured to death. He was dragged outside of his cell, stripped naked, beaten, and repeatedly immersed in cold water. After being put in an isolation cell overnight, he died of hypothermia. An internal CIA investigation admits that Rahman froze to death, but blames it on Rahman for rejecting his last meal, saying:

“He denied his body a source of fuel to keep him warm.”

“Policing is broken. It has evolved as a paramilitary, bureaucratic, organizational arrangement that distances police officers from the communities they’ve been sworn to protect and serve. When we have shooting after shooting after shooting that most people would define as at least questionable, it’s time to look, not just at a few bad apples, but the barrel. And I’m convinced that it is the barrel that is rotted.”

“The NSA, CIA, and FBI aren’t intended to be criminal organizations. They were built to help the people of the US. The hope of the public at large is that this draws honorable people to those organizations, and that at worst, only a few bad apples will exist.”

I really wish people would stop using this expression.

Have you ever left a bad apple in a bunch of apples? If you had, you’d know exactly what happens: the whole bunch turns bad very quickly. That’s where the expression came from, and that’s why it’s invalid to say “only a few bad apples”—there is no such thing as a few bad apples! When you have a ‘bad apple’—whether it’s an apple or a cop in a police department—unless it’s removed quickly, pretty soon they’re all bad. Which is why the expression is apt for police, except that everyone keeps forgetting about what really happens with bad apples. Does no one keep bunches of apples any more?

Repeat after me: if the bad apples remain after being found, it is not just a few bad apples, everyone is complicit.

You do realize the saying is not: ‘Feel free to leave the bad apples there, so long as only a few of them are moldy and oozing juices all over the others it doesn’t matter because the rest remain good.’ You’re only allowed to call them “a few bad apples” without looking like a moron, if they are treated like bad apples are treated.

One murder might be the fault of a single bad cop. But many murders are almost always the fault of supervisors and politicians, through the systems they construct to make those murders disappear.

We must not pretend that the countless people who are routinely targeted by police are ‘isolated.’ They are the canaries in the coal mine whose deaths, civil and literal, warn us that no one can breathe in this atmosphere.

“You only have a few seconds to decide how to react. You want only to survive this call and ensure your fellow officers also survive.”

Then the solution is easy. Don’t show up! If that’s really the only or main, or even top-three goal of the police officers, then they can stay back at the station. Maybe hide under a desk. Honestly if that’s all they want then, as soon as they get the call about the situation, they should all hop in their cars, turn on the sirens, and drive out of town until the whole thing blows over.

“Officers’ safety comes first, and not infringing on people’s rights comes second.”

—Fran Healy, Philadelphia Police Department Spokesperson

American police are particularly violent. In 2015, an article in the Guardian stunned many with its side-by-side comparisons of police violence in America relative to other countries. Iceland had one fatal police shooting in seventy-one years; Stockton, California had three in six months. Australia had ninety-four fatal police shootings between 1992 and 2011; the US had ninety-seven in March 2015.

And the numbers have not improved since then. When adjusted for population, American police killed over two-hundred times more people than UK police did in 2018. In Germany, where police are far more violent than in the UK, police killed twenty-seven times fewer people than their American counterparts.

In this lethal landscape, a number of programs have emerged in the US to teach young people about how to live in the world police create.

“I’m hoping the law enforcement officer will walk up, see this child doing exactly what the curriculum told them to do and think, ‘I can relax. This child knows exactly what he or she is supposed to be doing.’ And perhaps, it will not escalate.”

“Our number one goal is to teach children what they need to know to be able to live through the police stop and make it home safely. There is no silver bullet. There is no way you’ll be able to determine whether or not the police will actually harm you, but if you can be respectful and humble you stand a better chance showing the officer you’re not a threat.”

Five states—Texas, North Carolina, Virginia, New Jersey, and Illinois—now mandate some form of instruction on how to interact with police, either as part of the civics curriculum or drivers education. Other states are considering similar measures. Many school districts also now use informal instructional programs organized and run by police, public defenders, church groups, the ACLU, or other community organizations. These programs are often pitched as a stopgap—a concrete way to equip young people with life-saving tools in a country where racism is intractable and structural reforms are elusive.

Yet there is a deep cynicism at work when police violence is treated as a fact of contemporary life that can only be mitigated through a series of subservient rituals. In fact, rather than fostering a less violent present and future, the programs end up shifting the onus for avoiding deadly interactions from police onto the very civilians they brutalize.

The realities of modern policing are nowhere to be found in the various policing curricula used by states and localities. In an instructional video that high school students in Texas are now mandated to watch, police officers are portrayed as a strikingly diverse group of men and women—a stark contrast to the state’s overwhelmingly white and male police force.

An online course that Virginia now requires all Drivers Ed students to take notes that teens might have a bad attitude “because they think police are singling them out based on their age or other visible characteristics for unfair treatment.” The elephant in the room, racial discrimination in traffic stops, goes unmentioned. Later, the lesson provides four strategies “that will ensure a safe and appropriate interaction with law enforcement officers,” including “staying calm and being respectful.” Again it is silent on an obvious question: “What do I do when the police choose to attack me?”

“What we tell teens very strongly is that you want to be able to go home. If you act crazy, you don’t get that chance. Let the

officer give you a ticket and you can go fight it in court. That's a lot better than being carted off to jail or worse."

"You should tell police that you would like to remain silent. You should not just remain silent—that can be seen as a form of aggression."

The constant threat of violence, though unmentioned, hangs in the air. Police are understood as forces of nature, figures whose behavior can be slightly modified at best. Among the "Don'ts" listed by Strategies for Youth in their presentation "Be SMART with Police" are items like:

- "Don't keep your hands in your pocket—take them out slowly."
- "Don't make quick movements."
- "Don't question or mock an officer's authority."

A presentation used in the Midwest called "Get Home Safely: 10 Rules of Survival" instructs:

"Avoid physical contact with the police. No sudden movements, and keep hands out of pockets."

"Don't, under any circumstance, get into an argument with police."

Do not run, even if you are afraid and do not resist, even if you are innocent. Finally, they counsel:

"Stay calm and remain in control. Watch your words, body language, and emotions."

There's a startling transference of responsibility here from the adult who is ostensibly trained for the encounter—the police officer—to the teenager. The burden of restraint is not on the officer, the one with lethal force—that is the business of the child. It is the very definition of blaming the victim.

Many of these programs imply that their *raison d'être* is as much about officer safety as about the well-being of the kids receiving the lesson. Texas's recently approved curriculum guide asks:

"Why should you place your hands on the steering wheel while the officer is approaching?"

A: For the officer's safety; it signals that you are not armed."

Under the “Driver Dos” it warns that “certain movements, such as reaching for required documents, could be interpreted as a threat to the officer’s safety.”

This inverts the actual danger present in any encounter with police. In 2017, police killed 987 people; police deaths caused by another person stood at forty-six. Police are twenty-one times more likely to kill civilians than the other way around.

Civilians like Sandra Bland. In 2015, Bland was beaten by a Texas police officer during a traffic stop and later died in police custody. What do these programs have to say about her death?

“While the officer went up to 10, if Bland had given him her license and insurance, she might be here with us today.”

Some students know a self-serving lesson when they see one. At a 2017 presentation for teens in Baltimore put on by the National Organization of Black Law Enforcement Executives (NOBLE) and sponsored by the Urban League, a sixteen-year-old asked the police officer:

“Since this kind of stems from police misconduct, are police officers being told how to interact with us?”

The officer volleyed that police are trained how to interact with the community in the police academy, adding that if students “show respect,” it will go “a long way in setting the tone for how the encounter will go.” But throughout the morning session the students sought to relate their real-life experiences and stories of Baltimore police corruption or misconduct to challenge the lessons of obedience to police being put forward.

NOBLE runs a similar program in Chicago, where the history of police violence creates a particularly fraught environment for pro-police lecturing. Students here do not need to point to the ACLU reports documenting racism in police stops, or the fact that the vast majority of police stops in the city do not lead to arrest, or that in half the stops the ACLU reviewed police either gave an unlawful justification or no reason at all. They can simply draw on their own experience.

“We were walking and they just pulled us over. They asked what we were doing. They put our name in the system. I don’t need to have my name in the system with jailed people. It just wasn’t fair.”

Presenters for NOBLE acknowledged that their department has “bad apples” and gave students the canned response for what to do when faced with an abusive police officer:

“Cooperate at the time and file a misconduct report later.”

They declined to mention that somewhere between 89 percent and 96 percent of police misconduct reports in Chicago are dismissed.

At Oakland schools, where the Alameda County public defender’s office puts on its own presentation instructing teens how to interact with police, students are told to always remember the magic words: “I have the right to remain silent” and “I want a lawyer.” They also warn students that oversharing with police “can quickly and needlessly escalate a situation.”

This is sound legal advice, but in places like Chicago—where NOBLE advises students, “Most of the time, you should answer the questions. Because if you don’t, you’re making something that could have been two questions worse”—the hard realities of American policing inevitably intrude. This, after all, is the city where police commander John Burge ran a torture program on Chicago’s predominately black South Side from 1972 to 1991. His program did not simply mete out beatings, but also designed torture instruments—most notably a device that sent out electroshocks when applied to the testicles—for the police to extract (often false) confessions. In 2015, the Guardian revealed that Chicago police operated a black site where seven-thousand people were disappeared for off-the-books interrogations.

And herein lies the core problem with these classes. None of them deal with the inherent power imbalance between a teenager and an agent of the state, who holds a monopoly on legitimized violence. Some who run these programs have a genuine desire to curb police violence. But because they assume that radical changes to policing are impossible, we are left with a series of hacks and tips that they hope might, just might, prevent the police from killing more people. Suffused with the illusion, the comfort, of “doing something,” they forget the fundamental problem: as a student in Chicago summed it up at a recent event:

“We don’t know what a police officer is going to do. They always have the upper hand.”

You know what you’ll get if you walk into a Walmart or McDonald’s anywhere in the country and act like a schmuck? Sweetness and light. It may be forced. It may be covering some real hostility. But there’s not a three-ring binder in the world that says:

“If the customer is an asshole, be an asshole right back at them.”

So when a cop or another individual tells you ‘be nice to a cop and they’ll be nice in return,’ they think they’re describing paragons of virtue. What they are actually saying is ‘police are less capable of keeping their egos and tempers in check, less capable of displaying professionalism in public, and more prone to violent, childish petulance than the lowest paid, least trained workers around.’

Somehow it escapes them that their advice for dealing with cops overlaps significantly with advice for dealing with, say, wild animals.

This notion that police officers have to control every situation, to control all the variables—that’s an awesome responsibility, and if you take it on, you’re caving to delusion. You no longer exercise discrimination or discretion. You have to control, and the way you control is with authority, power, and force. With a dog, the easiest way to take control is to simply kill it. I mean, especially if there are no consequences for doing so.

When the law guns down 12-year-old children, or beats down old women on traffic islands, or chokes people to death over cigarettes; when the law shoots people over compact discs, traffic stops, drivers’ licenses, loud conversation, or car trouble; when the law auctions off its monopoly on lethal violence to bemused civilians, when these civilians then kill, and when their victims are mocked in their death throes; when people stand up to defend police as officers of the state, and when these defenders are killed by these very same officers; when much of this is recorded, uploaded, live-streamed, tweeted, and broadcast; and when government seems powerless, or unwilling, to stop any of it, then it ceases, in the eyes of citizens, to be any sort of respectable law at all. It simply becomes force.

In the black community, it’s the force they deploy, and not any higher American ideal, that gives police their power. This is obviously dangerous for those who are policed. Less appreciated is the danger illegitimacy ultimately poses to those who must do the policing. For if the law represents nothing but the greatest force, then it really is indistinguishable from any other street gang. And if the law is nothing but a gang, then it is certain that someone will eventually resort to the kind of justice typically meted out to all other powers in the street.

In one experiment, a group of elementary school students at a Halloween party played games—first wearing their normal clothes, then their costumes, then their normal clothes again. In the “anonymous” second set of games, students were significantly more aggressive, but that aggression disappeared when they removed their masks for the final games. It seemed to be the

costumes and not the children's inherent character that mattered—a finding that some have connected to anthropological research showing that societies in which warriors mask or change their appearance during battle are far more likely to also kill and torture their victims.

An almost unquestioned but utterly pernicious fact is that when they empowered cops to lie to people in order to trick them they knocked a critical block out from under the citizen-government edifice. No government official should ever be allowed to lie to a citizen. This is pure ends justify the means immorality. And the only way I can trust the police is by willfully ignoring the basic fact that everything they say could be a lie. This leads to the kind of mental gymnastics that excuses the worst kinds of behavior in the name of efficiency and safety. The government is not, first and foremost, in existence to be efficient or make me safe. It is there to protect my rights and be a conduit for collective democratic action. That's why governments were instituted among men.

The truth-seeking objective is most likely to be overridden in high-profile cases, where the pressures to solve the crimes are the strongest. In some instances, the adversarial pull results in deliberate police malfeasance, and even entails lying outright in court, a practice known as testilying.

One study found that testilying began soon after cases were dismissed under the 1961 Supreme Court holding in *Mapp v. Ohio*, which created the exclusionary rule. To police, there is a deep-seated disregard for what they consider to be silly little laws made by a silly little Supreme Court in a backroom far removed from the dangerous streets they are trying to bring order to.

The logic of this rule is that it is sometimes necessary to let the guilty go free in order to protect the innocent from overzealous law enforcement.

“Only occasional and more flagrant abuses come to the attention of the courts, and then only those where the search and seizure yields incriminating evidence and the defendant is at least sufficiently compromised to be indicted.”

If police raid an innocent man's or woman's home and uncover no evidence, then there will be no arrest, and no subsequent criminal trial permitting a judge to determine if the raid was unconstitutional. More importantly, there will often be no way to sanction the police officers who authorized this raid, and, thus, nothing deterring them from conducting more illegal raids in the future. *Mapp* held that the only way to “compel respect” for the Constitution's ban on unlawful searches and seizures is “by removing the incentive to disregard it.” Police conduct illegal searches

because they hope to find evidence of criminal activity, so the way to deter such activity is to render the fruit of these searches useless to the prosecution.

In many cases, it may be the impulse to do right—to act altruistically—that causes us to cut corners. In a startling finding, scientists have shown that people may actually cheat more when their cheating benefits others but not themselves. If we are acting solely for others, it is hard to see ourselves in a negative light and much easier to rationalize unethical acts. People who work for nonprofit foundations, schools, or other public benefit organizations may be relatively more inclined to bend the rules because the charge of enhancing social welfare seems to justify the dishonest behavior. If this theory is correct, both prosecutors and police might well be particularly vulnerable to rationalizations of this kind.

Ironically, then, it is caring deeply about other people, not a callous lack of empathy, that can set in motion some acts of dishonesty—or violence.

Police officers are no more or no less honest than the vast majority of witnesses that testify in court, but there's this unofficial presumption that they are more honest and that their testimony should be believed more. Part of it is because they are the police, the good guys, and part of it is that they are trained on how to testify.

In early America, citizens were considered equals with law enforcement officials. Authorities were rarely permitted to enter one's home without permission or in a deceitful manner. And it was not uncommon for police officers to be held personally liable for trespass when they wrongfully invaded a citizen's home. Unlike today, early Americans could resist arrest when a police officer tried to restrain them without proper justification or a warrant—which, of course, the police had to allow citizens to read before arresting them. Some would argue that daring to dispute a warrant with a police official today who is armed with high-tech military weapons and tasers would be nothing short of suicidal.

The reason for this boils down to propaganda and indoctrination from a very young age. Our entire school system spends an inordinate amount of time to reinforce the idea of American exceptionalism, prepping kids to be receptive to propaganda channels and to follow orders from authority figures—especially those in the military and police. Children are exposed to what is essentially police advertising/propaganda from a very young age through field trips, rallies, and school visits where police show off their cool tech and gear while reinforcing the cops and robbers binary way of thought. It's not something that's widely talked about here—and many Americans would essentially consider it blasphemy—but, the propaganda machine in this country is as large or larger than China or North Korea—it's just much more gentle, subtle, and I'd argue much more effective as a result. Americans

are primed from the beginning to believe there are either good guys or bad guys, democrats or republicans, cops or robbers, soldiers or enemies, for many the idea of corrupt cops goes against their whole worldview so they marginalize, rationalize, and excuse it because the alternative is realizing the world is complex and full of color, not simply black and white.

Laws do not tie the hands of the state nearly so much as public opposition can; given the choice between legal rights and popular support, we are much better off with the latter.

We shouldn't harbor any illusions that a return to the 'rule of law' will save us. The thing about the rule of the bourgeoisie is that it is just that—the way the bourgeoisie rule. As an instrument of capital and empire, the law could be read or stretched to allow all sorts of thuggery and mischief. And as the crises of US hegemony grow and magnify, it perpetuates the urge toward more expansive power and brutality. The rule of law was and is nurturing the seeds of its own abuse.

“Without knowing it, they had intuitively grasped the reason for William Blackstone's famous observation that it is better that some who are guilty go free than even one person who is innocent be wrongly imprisoned—so that people have reason to obey the law because it is just.”

Does of a “country of laws” simply condition its citizens to not resist government overreach or violence and instead utilize methods that are ineffective or will come too late? Why is one obligated to “not resist” what one knows to be an indefensible or immoral act?

The people who hid Anne Frank were breaking the law, while the people who killed her were following it.

Can a law be accepted as just in one era and be considered fundamentally unjust at a later time? Are there, in other words, laws that are simply unjust at their core? Or is it possible for a law to be just at the time and later experienced as unjust because of changes in historical circumstances? There is no easy answer to this question, but I would suggest a general rule: laws that privilege one group's survival and flourishing, while depriving another group, can never be deemed to be just. A law that is deemed to be just at the time it is enacted, but then later found to be unjust, often means that it was unjust at the start. At the dawn of the US, laws privileging white men of property, despite being considered just at the time, were fundamentally unjust because they impeded women, unpropertied white men, people of color, and slaves from flourishing. It took time for

enough people to experience and lament the injustices before these laws were changed or eradicated.

The worse kind of unjust laws are those that are hidden from view, ensconced in language of Nature, God, or simply the way it is and always has been. The meta-message in these language games is that the law is just and unquestionable. There is no alternative. We have no choice but to accept and submit to the law and accept our lot in life. At the same time, unjust laws may have been enforced for so long that they have become part of the ethos and common practice of the people; this feels as if it is natural despite obvious injustices. An unjust law operates such that those who suffer the effects of the law do not or are unable to question it or accurately attribute the real source of their suffering. In fact, they may find some other source to blame for their suffering.

An unjust law is no law at all. One is not bound to enforce or obey an unjust law, for to do so would mean participating in an injustice. Naturally, unjust laws are accompanied by institutions charged with enforcing them, making disobedience precarious. If we shift here to those who make the laws, three observations can be made. First, it is usually the case that legislators do not believe that the laws they make are unjust. They typically offer “good” reasons for a law and these reasons may go unquestioned by most of the populace, especially those who may benefit from the law. Second, it is rare that persons who possess the power to make and enforce laws do so at the expense of themselves, which leads to a question regarding the making of any law, *cui bono*, who benefits. Third, an unjust law either enacts or simply codifies existing unjust practices. Laws enacted regarding slavery, for instance, reinforced the already existing injustices associated with trafficking and exploiting human beings.

Unjust laws exist, shall we be content to obey them or shall we endeavor to amend them, and obey them until we have succeeded, or shall we transgress them at once? Many generally, under such a government as this, think that they ought to wait until they have persuaded the majority to alter them. They think that, if they should resist, the remedy would be worse than the evil. But it is the fault of the government itself that the remedy is worse than the evil. It makes it worse. Why is it not more apt to anticipate and provide for reform? Why does it not cherish its wise minority? Why does it cry and resist before it is hurt? Why does it not encourage its citizens to be on the alert to point out its faults, and do better. Why does it always crucify Christ and excommunicate Copernicus and Luther and pronounce Washington and Franklin rebels?

If the injustice is part of the necessary friction of the machine of government, let it go, let it go: perchance it will wear smooth—certainly the

machine will wear out. If the injustice has a spring or a pulley, or a rope, or a crank, exclusively for itself, then perhaps you may consider whether the remedy will not be worse than the evil; but if it is of such a nature that it requires you to be the agent of injustice to another, then I say, break the law. Let your life be a counter-friction to stop the machine. What I have to do is to see, at any rate, that I do not lend myself to the wrong which I condemn.

There are two ways to change an unjust law. You can ask lawmakers to amend it, or you can break it together in a way that makes it unenforceable. Which approach is more empowering? The former concentrates power in the hands of a few; the latter disperses it to everyone. The former frames leaders as the only agents of change; the latter enables all of us to determine the shape of our lives and our communities.

We can apply this logic of direct action to all the problems we face.

“I submit that an individual who breaks a law that conscience tells him is unjust, and who willingly accepts the penalty of imprisonment in order to arouse the conscience of the community over its injustice, is in reality expressing the highest respect for the law.”

One has not only a legal but a moral responsibility to obey just laws. Conversely, one has a moral responsibility to disobey unjust laws. I would agree with St. Augustine that ‘an unjust law is no law at all.’”

When the thick mesh of interactions between people and the state has been reduced to nothing but authority and obedience, the only remaining force that binds us is state power. The totalitarianism Hayek feared is more likely to emerge when governments, having lost the moral authority that arises from the delivery of public services, are reduced to cajoling, threatening, and ultimately coercing people to obey them.

Since when have we Americans been expected to bow submissively to authority and speak with awe and reverence to those who represent us? The constitutional theory is that we the people are the sovereigns, the state and federal officials only our agents. We who have the final word can speak softly or angrily. We can seek to challenge and annoy, as we need not stay docile and quiet.

Lying to authorities, misleading them, frustrating their effort through verbal actions, is a fundamental right to free speech.

But what if, despite the skewed playing field, someone manages to say something that threatens to destabilize the power structure? If history

is any indication, it swiftly turns out that freedom of expression is not such a sacrosanct right after all. In practice, we are permitted free speech only insofar as expressing our views changes nothing. The premise that speech alone cannot be harmful implies that speech is precisely that which is ineffectual: therefore anything effectual is not included among one's rights.

During World War I, the Espionage Act criminalized any attempt to "cause insubordination, disloyalty, mutiny, [or] refusal of duty" or to obstruct recruiting for the armed forces. President Woodrow Wilson urged the bill's passage because he believed antiwar activity could undermine the US war effort. Alexander Berkman and Emma Goldman were arrested under this law for printing anarchist literature that opposed the war. Likewise, the Anarchist Exclusion Act and the subsequent Immigration Act were used to deport or deny entry to any immigrant "who disbelieves in or who is opposed to all organized government." Berkman, Goldman, and hundreds of other anarchists were deported under these acts. There are countless other examples showing that when speech can threaten the foundation of state power, even the most democratic government doesn't hesitate to suppress it.

Thus, when the state presents itself as the defender of free speech, we can be sure that this is because our rulers believe that allowing criticism will strengthen their position more than suppressing it could. Freedom of speech can act as a kind of 'safety valve' to let off steam when people might otherwise be bent on revolution. Therein lies the true purpose of the right to free speech in the US.

Anyone who thinks the forces of law and order are going to defend their right to free speech is either on the same side as those forces or has not been paying attention. There is no free speech in the United States if one's politics oppose the essential racism and economics of this nation.

Civil disobedience is not something we should shy away from. Civil obedience should horrify us—there is an epidemic. The problem we have to solve is not too much civil disobedience, but too much civil obedience.

Under a government which imprisons any unjustly, the true place for a just man is also a prison. If any think that their influence would be lost there, and their voices no longer afflict the ear of the State, that they would not know by how much truth is stronger than error, nor how much more eloquently and effectively he can combat injustice who has experienced a little in his own person. Cast your whole vote, not a strip of paper merely, but your whole influence. A minority is powerless while it conforms to the majority; it is not even a minority then; but it is irresistible when it clogs by its whole weight. If the alternative is to keep all just men in prison, or give up war and exploitation, the State will not hesitate which to choose. When the subject has refused allegiance, and the officer has resigned his

office, then the revolution is accomplished. But even suppose, blood should flow. Is there not a sort of blood shed when the conscience is wounded? Through this wound a man's real manhood and immortality flow out, and he bleeds to an everlasting death. I see this blood flowing now.

If you're neutral in situations of injustice, you've chosen the side of the oppressor. Washing one's hands of the conflict between the powerful and the powerless means to side with the powerful, not to be neutral.

The state protects one's rights—or should—it does not grant one anything, it cannot, because those rights are not its to give.

Focusing on the right to free speech, we see only two protagonists, the individual and the state. Rather than letting ourselves be drawn into the debate about what the state should allow, we should focus on a third protagonist—the general public. We win or lose our struggle according to how much sovereignty the populace at large is willing to take back from the state, how much intrusion it is willing to put up with. If we must speak of rights at all, rather than argue that we have the right to free speech let us simply assert that the state has no right to suppress us. Better yet, let's develop another language entirely.

One dictionary defines civil liberty as “the state of being subject only to laws established for the good of the community.” This sounds ideal to those who believe that laws enforced by hierarchical power can serve the “good of the community”—but who defines ‘the community’ and what is good for it, if not those in power? In practice, the discourse of civil liberties enables the state to marginalize its foes: if there is a legitimate channel for every kind of expression, then those who refuse to play by the rules are clearly illegitimate. Thus we may read this definition the other way around: under ‘civil liberty,’ all laws are for the good of the community, and any who challenge them must be against it.

The first prong is making exceptions to universal liberty when certain keywords are present. There's no shortage of “terrorist laws” in the world. Basically none of them make terrorism a worse crime—preparing to cause widespread devastation is already a serious crime in most or all countries—instead they remove rights to due process for people suspected of such crimes, and frankly, for people in general.

Many crimes involve hate, assigning special significance to some is dangerous and unjust.

We have always held that you should own the thoughts in your head. This is why people can plead the fifth in the US. The only problem is now the barrier between your head and your computer is pretty thin. For people who spend the better part of their day interacting with the machine and store their whole lives on it, the difference between thoughts in your head

and thoughts on your laptop is not much, especially now that we sort of use it as a way of outsourcing our memory.

There's a reason you separate military and the police. One fights the enemies of the state, the other serves and protects the people. When the military becomes both—even something as simple as encouraging former members of the military to become police qualifies—then the enemies of the state tend to become the people.

Excessively complex laws applied on a large scale end up eroding the effective rule of law, one way or another. Laws and government are hugely important, but having a massive, complex body of law undermines the purpose of that body of law.

The more fundamental and widespread the laws, the more strict they must be. Likewise, as you get more and more local in the jurisdiction and impact of the law, you can afford to be looser with text versus intent because the impact is far less dire, and people physically amongst themselves can operate like that efficiently. A few rulers may work, but hundreds or thousands cannot.

This extends to make the case that, because textualism would require sufficiently prescriptive laws, and sufficiently proscribing the possibilities involved over hundreds of millions of people is impossible, the federal government should limit itself to the simplest, universally fair and applicable laws, and leave smaller groups of people to manage themselves and write the more specific, tailored laws on their own.

No law is going to be perfectly drafted for every contingency, and simply from a pragmatic standpoint, you need to enforce the obvious intent of the law, even if sometimes it isn't spelled out. Seems reasonable to most people. So what's the problem with the statement? If you take it too far, you're letting the courts literally rewrite binding laws based on their whim. If you don't have rules, you have rulers. Whenever you leave things up to interpretation and judicial precedent, you run the risk of people with the designated power of interpretation manipulating things for their own ends. Even if not maliciously, they're still exercising their version of what's right over the properly voted and passed laws the people consented to.

It's not exactly a question of textualism, but the same concept applies in the example of the Federal ban on marijuana. Currently it is on the books, and largely not being enforced. Is this good, or bad? The same people that argue for textualism would say that this is bad (even if they're pro-weed) because if no prohibition on weed is truly what the populace wants, then a new President can get elected and come right back and enforce it, turning a number of distributors and consumers into criminals overnight. Meanwhile, if the general populace does want the ban, they are having their will directly

contradicted because someone is exercising discretion with interpreting the law.

What a textualist would say, more or less, is that laws should be enforced exactly as they are written. If the law is good, then all the better that it is properly upheld. If the law has bad parts to it, it's better to enforce those parts too, make it painful, and drive people to properly amend the law. If you just use discretion to soften the bad parts of a law, then people and representatives will never be motivated to fix it properly. Then you get this weird, unwritten law that society goes by, sitting on top of what you can actually point to on the books. Basically when you don't adhere enough to the text of the law, you start to undermine the rule of law itself. Again, in place of rules, you end up with rulers. Which is quite a step back on the path of political evolution.

“Judges are like umpires. Umpires don't make the rules; they apply them.”

Chief Justice John Roberts certainly wasn't the first person to use the metaphor, but in the fall of 2005, it seemed a particularly compelling notion to many denizens of Capitol Hill and their constituents back home. Good judges call balls and strikes. They don't pitch or bat. They put their backgrounds, experiences, and allegiances to the side and apply the clear law to the clear facts. Bad judges, by contrast, let their personal opinions about policy infect their rulings. They are unelected activists, advancing their own ends by interpreting things where there is no room for interpretation and by legislating from the bench.

This was Roberts's master stroke. During his confirmation hearings, he wasn't just playing defense to survive the confirmation battle; he was also establishing an offensive position to reshape the nature of adjudication in the long-term. There was a war over what judges could and should do. Establishing the umpire as an ideal would constrain judges who thought that their backgrounds ought to play a role in their decisions, as well as presidents who sought to appoint more women, blacks, Hispanics, Asians, Muslims, and gays to the judiciary. There was no need for diversity on a court of referees. And it would limit others who thought that the law was not neutral, clear, and set in stone, but rather frequently ambiguous and subject to changing meaning with changing times. The umpire judge was necessarily a textualist—a strict constructionist—with no right to look outside his little black book of rules to decide a case.

They may say—and often do—that it is not they who make the decisions, lay down the rules, give orders to every other governing official in the

land; they may say they do nothing but interpret the laws, including the Constitution; they may talk at times as though they neither had nor need human minds, as though they might almost as well be a nine-headed calculating machine, intricately adjusted to the words of the Constitution and of lesser laws, and ready to give automatic answers to any attorneys who drop their briefs in the proper slot and push the button. But even non-lawyers have come to find a trifle naïve and unconvincing the old fantasy that our government, especially its judicial branch, is mechanically controlled by laws, not by men.

Our system is rooted in the principle of *stare decisis*—the notion that courts should generally adhere to the law as established by earlier cases—and many criminal statutes also reflect what judges decided many decades ago. What qualifies as rape? What are the elements of a valid self-defense claim? Should victims have to face their accusers in court? The psychological evidence suggests that we should expect very different responses depending on the gender, religion, sexual orientation, and political orientation—among many other things—of the judge or legislator making the call. Yet the answers we have are largely the creation of a very narrow band of Ivy League-educated Christian men of northern and western European ancestry.

The Supreme Court was pumping out precedent for almost 180 years before the first African American had a chance to share his perspective, more than 190 before the first woman left her mark, and 220 before the first Hispanic authored an opinion. So, even if you happen to come before a Latina judge whose background and perspective actually benefit you, she will be operating under an elaborate legal structure built over centuries by individuals whose experiences may be quite foreign to your own.

This very significant branch of government has in effect the final word over some of the most consequential issues—the ones that are closest to our feelings and identities—and it is not only produced by a two-layer undemocratic process but is also staffed by people who graduated almost exclusively from two or three graduate schools. The Supreme Court is like a House of Lords for our meritocrats from Harvard, Yale, and sometimes Stanford law schools.

Certainly, precedent and statutory laws can act as powerful constraints on judges—and may even help eliminate or reduce certain biases—but professors engage in a damaging charade when they pantomime a legal world in which clear instructions are implemented by dutiful technicians. That world does not exist, but it's what all judges have been trained to expect.

The truth is that a text is rarely confined to just one interpretation, and figuring out the proper historical meaning of a legal source is inherently subjective and conjectural. The Fourth Amendment begins:

“The right of the people to be secure in their persons, houses, papers, and effects, against unreasonable searches and seizures, shall not be violated. . . .”

So what is a ‘search’? Is using a thermal-imaging device from across the street to see if someone is using high-intensity lamps producing a lot of heat to grow marijuana in his home a search? Is placing a GPS tracking device on a car a search? Textual originalism does not dictate a clear answer; it just provides a cover of legitimacy to an inherently biased task.

When judges do research, they already have an idea of what they are looking for and—surprise!—they tend to find it. The underlying drive is to bolster an argument, not discover the truth. We tend to assume that the more data a person has at her fingertips, the more accurate she’ll be. But, in fact, having more information may make it easier to find the necessary support for an erroneous proposition.

Amicus curiae briefs—“friend-of-the-court” filings, widely believed to aid the justices by helping to fill informational gaps—are a dead end as well. Although they often purport to offer impartial counsel, they are advocacy documents with facts chosen to persuade. And members of the Court draw from them—more than a hundred times between 2008 and 2013—with a startling lack of scrutiny, citing amicus facts backed up by e-mails, research funded by the amicus itself, unpublished studies “on file with the authors,” and, sometimes, nothing at all. With dozens of amici in certain cases and more each year, it seems as if justices are being given a deep reservoir of knowledge, but all that the system really does is supply an easier way to support preexisting conclusions.

Much of the bias that infects a judge’s decision-making is subtle and automatic. And in many cases it is small enough or disguised enough to go unnoticed by others. It is like having a single step that’s ever so slightly higher than the others. Until recently, at the 36th Street subway stop in Brooklyn, there was just such a step. Every day it caused numerous people to trip as they ascended to street level. But no one did anything, even those who were most severely affected. The guy who nearly dropped his baby? The woman who fell to her knees? They caught their balance or brushed themselves off and walked on, thinking that it was just bad luck or that they had been clumsy or distracted. Few, if any, blamed the step, and so there it remained, a fraction of an inch off, until someone decided to film the entrance. Suddenly, with a pool of data, the problem was so clear it was comical. In under an hour, the videographer captured seventeen people stumbling on the step. And within a day of the evidence being posted online, New York’s MTA had begun replacing the staircase.

Take the matter of introspection. There's a wealth of research suggesting that many biases can't be detected through soulsearching. And while it's one thing for us all to walk around believing that it's possible to self-reflect and identify all of our hidden proclivities, it's quite another thing to have the legal establishment confirm that intuition. Unfortunately, that is exactly what many of our rules and procedures do.

The same thing happens when our legal system bolsters the myth that being impartial is simply a choice. Over and over, during the trial process, jurors are instructed to switch off their irrelevant thoughts, emotions, and beliefs. "Do not allow sympathy, prejudice, fear, or public opinion to influence you," Third Circuit jurors are told. "You should also not be influenced by any person's race, color, religion, national ancestry, or gender." Likewise, whenever the judge sustains an objection, "you must disregard the question or the exhibit entirely. Do not think about or guess what the witness might have said in answer to the question; do not think about or guess what the exhibit might have shown." And if the judge orders evidence to be stricken or removed from the record, "you must not consider it or be influenced by it in any way."

Knowing how little control we have over the many automatic processes in our brains, such directives seem almost laughable. But this is no farce: these are the instructions that guide those participating in our legal system every single day. Out of thin air, the Third Circuit has conjured up a magical remote control for the brain, allowing jurors to erase, pause, and mute on command.

Doubt is the friend of fairness. Without it, you cannot convince anyone that they really do have it wrong or that change is urgently needed.

That's equally true for police officers, lawyers, jurors, and witnesses: we need to get all of our key legal actors in the business of second-guessing themselves. Doubt isn't the enemy of justice—blind certainty is. And, in most cases, healthy skepticism isn't going to develop on its own because there are so many forces pulling the other way.

The only way forward is to be fearless about looking back. The legal system should become very sensitive to the question of have we done justice? Have we made a mistake?

Sophistry over time—it goes something like this: first, a court decision (Abood) says that while forcing workers to subsidize political speech is coercive, they can indeed be forced to pay for nonpolitical speech. Then another decision (Janus) says that this distinction doesn't make sense, that the supposedly nonpolitical speech is still pretty political, that Abood's justifications for requiring it fail, and that coercion is coercion. If we get caught up in 'law logic,' we can end up having a fight over whether the

government's interests in drawing the political/nonpolitical distinction are 'compelling.' And we can forget how many premises we've already tacitly accepted, namely that having a buck deducted from your paycheck is the same as being forced to say words on penalty of imprisonment. Law often evolves through a series of syllogisms that occur gradually, and look insane when they're put together, but because they come in separate cases, can seem reasonable one by one. Consider this logic:

1. There should be no difference between the way laws are applied to individuals versus organizations of multiple individuals.
2. The government cannot prevent individuals from exercising their right to free speech.
3. Preventing people from spending money to speak is preventing them from exercising their right to free speech. If the government prohibited someone from buying flyers to speak, it would be the same as if it prohibited them from speaking.
4. Corporations are organizations of multiple individuals.
5. Any restriction on how corporations spend money to influence the political process is a freedom-destroying tyrannical violation of the First Amendment.

From voting rights to prosecutorial accountability to class actions, there are numerous examples of how premises that sound plausible in isolation can lead to disastrous and absurd results when taken as a whole.

A judge will let you off of your shoplifting charge if the police stepped into your home and seized evidence without a warrant, but a court will rarely intervene in the obviously unjust situation of a man being sent to prison for the rest of his life for stealing a few DVDs. And a court will almost never overturn a sentence on the grounds that it is inherently wrong for someone to face the threat of gang rape while under the sole control of the state.

How did we get to this point? What are judges actually for? Historically, judges were basically people who were good at dispute resolution at a time when state enforcement wasn't really a thing. They needed to be able to come up with judgments that parties would actually follow, instead of just, say, murdering each other. This judicial role makes some kind of abstract sense. In less regulated times, judges were probably pretty useful practical agents of community order, and even sometimes of justice. In the Bible, for example, there's a lot of language about the ideal judge being someone

who defends the interests of the weak and downtrodden against the tyranny of the powerful. The number of verses invoking fire and brimstone against “unjust judges” who “even rob the widows and fatherless children,” though, tells us that this ideal probably wasn’t always borne out in real life.

But then we come roaring into the present. Here in the US, we no longer live in a time where it’s typical for vigilantism and blood-feuds to break out on a large scale if the judge doesn’t make a decision the parties will willingly accept. Although in the case of, say, *Bush v. Gore*, that would have perhaps been a preferable outcome. So what function do judges perform now? Rather than just making pronouncements on what would be equitable in a particular dispute, judges are—theoretically—supposed to faithfully apply codified law. We’ve made a policy shift over the years that strongly favors ‘predictability,’ in place of ‘justice,’ as the chief virtue of the legal system.

It’s a well-accepted principle of the judicial craft that the important thing is to have a rule, rather than to necessarily have the right rule. Having the right rule is merely a subsidiary concern, if it’s a concern at all. We’d much rather have all similar cases or issues get decided the same way, instead of different ways, even if this leads to worse practical, real-world results overall for more individual people. Under this system, say, it’s much better if all US agents who kill people from inside US territory are deemed categorically ineligible to be sued, because this is predictable, and predictability is fair. To have a situation where some border guards are sueable and others aren’t, by contrast, is unfair. People would never know what to expect in a world like that! Except that there might, you know, occasionally be some consequences for people who slaughter other humans from a distance, but again, what do we know, we’re not judges after all.

The problem is that more than a few judges think that when they are anointed and ascend to that seat on high, some unidentified power causes their humanness to disappear and replaces it with a brand of lofty judicial insight that one can experience only if one’s posterior is affixed to the judge’s chair. Once in an empty courtroom I slipped up to the judge’s chair and sat down, firmly, and waited and waited. I never felt a bit smarter. Perhaps it was because I hadn’t donned the black robe.

Now, it’s possible you might think that I’m being unfair to judges here by expecting them to care about the same things—children being shot to death, poor people having their lives irreparably ruined by filing errors—that laypeople care about. The law is complicated, after all, and judges are legal experts. Isn’t it natural that judges would care about abstruse legal arguments that the rest of us can’t see the relevance of, because they understand the larger ramifications of each individual case for our great

legal system? Without this far-seeing vision, wouldn't our entire civilization go down in flames?

To this, we can only say that this is a terrible way to run a society, and this is not what actually motivates judges in 99 percent of cases. Judges are just ordinary people like you and me. They do not behave in the strange way they do because they are wise beyond the ken of mere mortals. They behave this way because our legal system has created a climate calculated to warp judges' minds. I once spoke to an immigration judge presiding over a court that was attached to a detention center. Her docket consisted largely of asylum-seekers who had been detained after crossing the border, and would appear before her—in jumpsuits and shackles—to try to argue their own cases without lawyers. The denial rate at this detention center was high. Most of these asylum-seekers would be sent back to countries where they claimed to fear for their lives, and the judge would never know their fates. I asked the judge:

“What's the hardest part of your job?”

She seemed to think for a moment.

“Our computer system crashes a lot. It's really annoying.”

The fact is that no judge or justice ever approaches a case with a genuinely open mind. They read briefs and hear arguments with brains shaped by Sunday school, military service, summers on Cape Cod, and years as a prosecutor or a parent. Researchers recently found that judges who had a daughter rather than a son were 16 percent more likely to decide gender-related civil rights cases in favor of women's rights. The effect appears to be driven primarily by male judges appointed by Republicans. One theory is that having a daughter helps these judges better understand the challenges that women face on issues like equal pay and reproductive health, giving them a perspective that they wouldn't otherwise have. All of this makes the lack of diversity on our present courts a major concern.

If the law consists of the decisions of the judges and if those decisions are based on the judge's hunches, then the way in which the judge gets his hunches is the key to the judicial process. Whatever produces the judge's hunches makes the law.

Thirty-two states hold elections for judges of state supreme courts, appellate courts, and trial courts. Nationwide, 87 percent of all state court judges face elections. This is in sharp contrast to other nations, where judges are typically appointed with the advice and consent of legislative bodies. No other nation in the world does this, because they realize you're not going to get fair and impartial judges that way.

“I think about the credos that I admire: Kant’s call to action for the betterment of man; Aquinas’s belief that every man’s job is to help every other man achieve his ends. When I grew up everything in my parents’ house had to be black and white. No interracial marriage, no booze, no sex, no voting for Democrats. I went to law school, and I thought: How does this narrow-minded horseshit aid in the callings of Kant and Aquinas? It can’t, because it’s too marginalizing.

But now look where I am, I’ve come full circle, because I see the people that I prosecute as case files, black ink on a white page. There’s so fucking many meth-heads, I can’t differentiate. I don’t get a chance to see them in their homes. I don’t really have time to see them even as people, because that’s not how I’m trained. So how have I evolved?

I haven’t. I devolved.”

State attorneys general, in charge of enforcing the rules by bringing lawsuits, are also subject to election and re-election, and they too are receiving increasing amounts of corporate money for their campaigns. An investigation by the New York Times in late 2014 found that major law firms were funneling corporate campaign contributions to attorneys general in order to gain their cooperation in dropping investigations of their corporate clients, negotiating settlements favorable to their clients, and pressuring federal regulators not to sue.

The attorney general of Utah, for example, dismissed a case pending against Bank of America, over the objections of his staff, after secretly meeting with a Bank of America lobbyist who also happened to be a former attorney general. Pfizer, the pharmaceutical giant, donated hundreds of thousands of dollars to state attorneys general between 2009 and 2014, to encourage favorable settlements of a case brought against the company by at least twenty states for allegedly marketing its drugs for unapproved uses. AT&T was a major contributor to state attorneys general who opted to go easy on the corporation after a multi-state investigation into the firm’s billing practices.

Trials are meant to be adversarial affairs, where one side argues for a person’s guilt regarding specific charges and the other side argues for a person’s lack of guilt (as opposed to ‘innocence’) regarding those specific charges. The entire judicial system is predicated on the belief that through such an adversarial proceeding, the truth will emerge. In reality, this is not always the case. The prosecution gets the first opening argument and the last rebuttal, so the prosecution has an advantage in any trial. In a

long trial, the prosecution can build their case for days or weeks before the defense has much to say about it. Although jurors are admonished not to form an opinion until both sides have been heard, it's human nature to do so. The defense can challenge the prosecution and cross-examine the witnesses to attempt to keep the defense's case alive, but if the defense attorneys are too aggressive in their questioning, this can turn off the jury before the defense has even been able to call its first witness.

Cross-examination, when an attorney has the chance to ask questions of a hostile witness, has been described as the "greatest legal engine ever invented for the discovery of the truth." An attorney conducting a cross-examination has four basic options: He can challenge the credibility of the witness; he can show that the witness made an honest mistake; he can spin damaging testimony in his client's favor; or he can ignore the testimony entirely. One of the strengths of cross-examination is that it is inherently adversarial,

The US legal system is organized as an adversarial contest: in civil cases, between two citizens; in criminal cases, between a citizen and the state. Physical violence and intimidation are not allowed in court, whereas aggressive argument, selective presentation of the facts, and psychological attack are permitted, with the presumption that this ritualized, hostile encounter offers the best method of arriving at the truth. Constitutional limits on this kind of conflict are designed to protect criminal defendants from the superior power of the state, but not to protect individual citizens from one another. All citizens are presumed to enter the legal arena on an equal footing, regardless of the real advantages that one of the parties may enjoy. The Constitution, therefore, offers strong guarantees for the rights of the accused, but no corresponding protection for the rights of crime victims. As a result, victims who choose to seek justice may face serious obstacles and risks to their health, safety, and mental health.

The oil industry pioneered, if not established, America's fondness for litigation.

For decades, the rules of civil litigation required that evidence collected during discovery be logged with the court, open to public scrutiny. Secrecy was the exception. In the 1980s and 1990s, rule changes moved discovery out of the courthouse and thus out of public view. Instead, the material was to be swapped privately between the lawyers involved. Companies eager to keep their records confidential had pushed for the change, but it also served the interests of judges and court clerks inundated with increasingly complex product-liability cases and huge caches of documents accompanying them.

The factors that play a role in our encoding of a memory are much more influential than we'd imagine. Simply by altering the conditions in which

a witness viewed a person, researchers were able to boost identification accuracy to 86 percent or drop it to 14 percent.

Stress affects memory as well, and violence is extremely stressful. Muskets have been found on Civil War battlefields with dozens of cartridges in their barrels, rammed home by soldiers who were too terrified to remember to fire each time they reloaded. Witnesses to violent crimes can be similarly unaware of their actions.

In particular conditions, such as the individual being anxious and the question coming from someone with authority—say, the lawyer in a court room—specific wording can create a memory. For example, if the lawyer asks:

“Was the defendant in the vicinity of the cheese store at the time of the great cheddar robbery?”

then the witness can answer yes or no, according to what he or she remembers. But if the lawyer asks:

“Where in the cheese store was the defendant at the time of the great cheddar robbery?”

this question asserts that the defendant was definitely there. The witness may not remember seeing the defendant, but the question, stated as a fact from a higher-status person, causes the brain to doubt its own records, and actually adjust them to conform to the new “facts” presented by this “reliable” source. The witness can end up saying something like, ‘I think he was standing next to the gorgonzola,’ and mean it, even though he or she witnessed no such thing at the time. That something so fundamental to our society should have such a glaring vulnerability is disconcerting.

Counterfeit memories are difficult to distinguish from memories of real events. This is a well-known bane of eyewitness identification and forensic interviewing, especially with suggestible children. Psychologists at the University of Arizona induced false memories in subjects to determine whether they would appear the same as true ones under a P300 paradigm. Using a well-established psychological test, they read to subjects a series of related words—‘prick,’ ‘thimble,’ ‘haystack,’ ‘thorn,’ ‘hurt,’ ‘injection,’ and ‘syringe.’ The word ‘needle’—a natural fit with the others—was not included. Yet when the investigators asked subjects whether it had been one of the words they had heard moments earlier, many participants answered yes. In P300 testing, those who reported feeling confident that “needle” had been among the original words showed the same pattern of brain electrical activity as they did when they were recalling the words they had heard.

Jurors believe confident witnesses, and investigators and prosecutors know this. The US Supreme Court stated that the “level of certainty of the witness” was an important factor in a 1972 case where a victim expressed “no doubt” in court that she recognized her own rapist. By contrast, most psychologists who testify as experts on eyewitness memory say that “an eyewitness’s confidence is not a good predictor of his or her identification accuracy.” In fact, mistaken eyewitness identifications, and their confident presentation to the jury, are the main cause of over 75 percent of wrongful convictions that are later overturned by DNA evidence.

Thinking in words about a person’s appearance can actually impair your ability to recognize that person later. Although this possibility was known in the 1950s, interest in it was revived by a series of experiments conducted in 1990, when it was given the new name “verbal overshadowing.” In one experiment, subjects watched a thirty-second video of a bank robbery that included a view of the robber’s face. One group of subjects then spent five minutes writing a description of the face “in as much detail as possible.” A control group spent five minutes doing something unrelated. Afterward, the subjects tried to pick the robber out of a set of photographs of eight similar-looking individuals, and then indicated how confident they were in their choices. The protocol used in this procedure mimics what happens in criminal cases. The police routinely ask witnesses to give detailed descriptions of suspects, and those same witnesses later try to identify a suspect in a photographic lineup. In the experiment, those subjects who did an unrelated task successfully identified the suspect 64 percent of the time. But what about those who wrote detailed notes about the suspect? They picked the right suspect only 38 percent of the time! The verbal information in the written notes overshadowed the nonverbal information captured by the initial visual perception of the face, and the verbal information turned out to be less accurate.

Ironically, our intuition tells us that analyzing a face will help us remember it better, but in this case at least, it is better for analysis to step back and let more automatic, pattern recognition processes take over. This experiment did not involve an emotional evaluation, only an objective test of memory, but reflective deliberation did not help.

A warning against the blind confidence in the observations of the average man: In a thousand courts in a thousand places all over the world, witnesses every day affirm by oath mixtures of truth and untruth, combinations of memory and of illusion, of knowledge and of suggestion, of experience and wrong conclusions.

We mistakenly think that memories are like carvings in stone; once done, they do not change. Nothing could be further from the truth. Memory

is not only selective; it is malleable. In the 1990s, there was much public concern and excitement about recovered memories. Authoritative figures published books and appeared in the media claiming that it was possible to completely repress memories of painful and traumatic events. Working with therapists, a number of patients discovered memories of such ghastly things as sexual abuse by their parents, cannibalism, satanic cults, and murder. Many families were destroyed and lives, both of the accusers and of the accused, ruined. Now that the panic has died down, we are ruefully admitting that there is no evidence at all that human beings repress painful memories. If anything, the memories remain particularly vivid.

Researchers have recently conducted a research project into the repressed-memory syndrome. Their interest was piqued by its sudden appearance in the late twentieth century. If the syndrome were hardwired into the human brain, then surely there would be evidence of its occurrence down through history. They found examples in nineteenth-century literature, but, although they offered rewards, they turned up no examples either in fiction or in nonfiction before 1800. They concluded that “the phenomenon is not a natural neurological function, but rather a ‘culture-bound’ syndrome rooted in the nineteenth century.” The preoccupation of the Romantics with the supernatural and the imagination, as well as later work, most notably that of Sigmund Freud, into the subconscious, predisposed us to believe that the mind can play extraordinary tricks on us.

We also polish our memories in the recounting. Primo Levi, who did so much to keep the memory of the Nazi concentration camps alive, warned:

“A memory evoked too often, and expressed in the form of a story, tends to become fixed in stereotype, crystallized, perfected, adorned, installing itself in the place of the raw memory and growing at its expense.”

As we learn more about the past, that knowledge can become part of our memory, too. The director of the Yad Vashem memorial to the Holocaust in Israel once said sadly that most of the oral histories that had been collected were unreliable. Holocaust survivors thought, for example, that they remembered witnessing well-known atrocities when in fact they were nowhere near the place where the events happened.

Our memories are not like digital photo albums that we can open and view perfectly preserved. Each time we retrieve a memory it is re-created anew. It’s more like going into a kitchen pantry and making your favorite meal: the essential ingredients are basically the same, but it tastes a little different each time you make it. When we remember things, we’re picking

out words and images, ideas and feelings, that seem to go together to re-create an experience in our brain. Each retrieval is re-created based on the last one, making memory an active and ongoing process.

We experience something and encode the facts and associated sensations, which remain stored until they are retrieved, reconsolidated as a memory, and then encoded again. Next time you tell the story, you're recalling the memory from the last version you told, not the original "hard copy." Remembering is an active process, which means we can introduce manipulations and interventions. It may be a little unsettling to think that your early memories have probably changed many times over the years.

Suggestion can create false autobiographical memories. A number of studies have shown how easy it is to plant false memories—everything from receiving a painful enema to meeting Bugs Bunny at Disneyland. One group of researchers found that they could get 50 percent of participants to remember all or part of a childhood hot-air balloon trip that never happened after showing the person a doctored photo of the event along with other real photos from the person's youth.

The less we know, the easier it is for us to produce a coherent story, and it is the consistency of the narrative that predicts how much confidence we will have in our assessment. The unfortunate result is that we may become overconfident precisely when we have limited or weak evidence. Consider the following two sentences:

1. When an elderly woman gets on the train, Carl immediately gives up his seat.
2. When an elderly woman gets on the train, Alex remains in his seat, reading his book.

Which man is likely to come to the aid of a passenger having a heart attack?

Easy, right? It is obviously Carl. But now look back at the sentences. They tell us almost nothing that would help us accurately forecast each man's future actions. Carl might not have seen the woman at all; he might have given up his seat after suddenly realizing it was his stop, or to move away from a crying child. And Alex might have remained seated because there were many open seats on the train, or because someone else offered the woman a seat and she refused, or because his back was turned. We took a few bits of information and then quickly filled in what was missing, so that we had a coherent story that allowed us to divine the men's characters and predict how they would behave. We do this hundreds of times a day.

Ignorance is not always bad however. The National Association of Medical Examiners encourages doctors to maintain their independence—for example, by avoiding interactions with investigating law enforcement officials before conducting exams. Such interaction can bias a doctor's conclusions. In fact, studies have shown that the more details crime lab analysts know about a case before conducting their analysis, the more likely they are to come up with false positives.

In one study, researchers asked two sets of experienced forensic clinicians to determine whether a particular mental patient with a violent history, Mr. Jones, ought to be released. Both groups were provided with a “state-of-the-art assessment” by a respected psychologist. The only difference was whether the psychologist chose to express the risk Mr. Jones posed to the public as a probability (“Patients similar to Mr. Jones are estimated to have a 20 percent probability of committing an act of violence”) or as a relative frequency (“Of every 100 patients similar to Mr. Jones, 20 are estimated to commit an act of violence”).

One might assume—quite logically—that the choice is of no consequence: the information is exactly the same and easy to understand in both cases. Yet it had a huge effect on the experts. Those who considered the risk in terms of 20 dangerous perpetrators out of every 100 were twice as likely to keep Mr. Jones confined in the mental hospital as those who pondered the 20 percent chance that he would engage in violence upon release. When the researchers probed more deeply, they found that people had a pretty benign picture of Mr. Jones with his future dangerousness conveyed as a probability, but if it was expressed as a frequency, they immediately thought of “some guy going crazy and killing someone”—and that potent image made them see Mr. Jones as more of a risk.

The actual likelihood of the threat is often not what matters most. If we have strongly negative feelings about something—like an assault by a pedophile—we will treat it as a significant risk regardless of how likely it is to occur. A one-in-five-million chance and a one-in-five-thousand chance look exactly the same to us.

In one recent study, researchers gave experts a DNA sample, telling them that it was part of a gang-rape case in which one of the perpetrators had accepted a plea deal and was testifying against the others. They needed to confirm that one of the suspects who denied any involvement had, in fact, taken part in the rape. As expected, the experts found that his DNA matched the sample, corroborating the witness's account and the prosecution's case. However, the researchers then took the same biological evidence and gave it to seventeen other DNA analysts without providing any backstory. What happened? Only one of the seventeen experts agreed

with the original group that the DNA was a match. Sequences of amino acids do not rearrange themselves to fit the prosecutor's frame, but that doesn't mean there is no room for bias. Someone has to interpret the results. And the first set of analysts couldn't help but be swayed by the information they had already been given.

Our justice system has an "expert paradox." We ought to defer to experts when they are more qualified to assess matters than we are, but we often get things backwards: we rely on our own skills of analysis where they are deeply flawed, and we embrace expert evidence when it is misleading and unhelpful.

"My sense is that judges, especially elected judges, find it very difficult to rule on these issues when it's going to seriously affect the prosecution in a high-profile case. They don't want to inject themselves into the case. It's just much easier to let two experts butt heads, and leave it to the jury to decide which one they believe."

Federal and state judiciaries should commit to the rigorous training of judges in assessing expert testimony. If a forklift operator has to reach a basic level of competency with the standard equipment for his job, why shouldn't a judge? A lack of proficiency can bring devastating consequences in both cases.

"I am afraid the education of many police and judges with regard to pathologists comes from paper-bound detective books and procedural TV shows wherein the pathologists make amazing and at times absurd deductions from minimal evidence and lacking any historical background of the case being studied. These examples, even though complimentary, are gross exaggerations of the actual practice of pathology."

Roughly one out of every three pretrial defendants believes incorrectly that if he remains silent after being arrested, his silence can be used against him at trial.

Police departments, for instance, teach investigators how to deliver a Miranda warning so that it is most likely to be misunderstood and ignored. Officers are encouraged to bring up the warning as a casual aside—and not at the moment of arrest, when a person is most likely to be considering his rights. When the Miranda doctrine was first introduced, cops were worried that it would severely limit their ability to gain confessions, but in fact it

has turned out to have a minimal effect on police work, precisely because it is so easy to work around.

The generally accepted gold standard, the Reid Technique of Interviewing and Interrogation, which has been used to train more than half of the police officers in the United States, not only fails to guard against false confessions but actually appears to encourage them. Using the Reid approach, when someone is brought in for questioning, detectives determine whether he is telling the truth through a nonconfrontational interview, and then, if he appears to be lying and his guilt is “reasonably certain,” they proceed to an aggressive interrogation designed to extract a confession. Unfortunately, police officers are no better than the rest of us at detecting deceit. And far from correcting officers’ erroneous intuitions about lying, the Reid technique relies heavily on unreliable gut instincts and dubious cues to deception.

When we view events as if standing in the shoes of the person experiencing them, we are much more likely to attribute the actor’s behavior to forces and constraints in the surrounding environment than when we adopt the perspective of an outside observer, in which case we tend to make attributions that focus on the individual’s disposition and character.

Imagine that you are impaneled on a jury and have to decide whether the defendant’s confession was voluntary or coerced by the police. As luck would have it, the entire interrogation was recorded, and you are provided with a videotape from one of three cameras in the room: a camera directed at the interrogator, a camera directed at the defendant, or a camera positioned to the side, showing both parties. It would seem reasonable to assume that regardless of the footage you were shown, you would come to the same conclusion, since all three cameras capture the exact same scene. When scientists conducted a number of studies using such a setup, however, they found that perspective made a big difference. By simply shifting the point of view from the person being questioned to the interrogator, researchers were able to significantly reduce the number of people who thought the resulting confession was coerced. Watching the interrogator through the eyes of the suspect, it was a lot easier to see—and feel—the menace and pressure. Those who watched the videotape that showed both sides made assessments that fell in between the two conditions.

Ironically, it may be harder to eliminate false confessions when there is an ineffective set of procedural rules aimed at preventing them than it would be if there were no protections at all. With elaborate structures in place, it appears that we’ve addressed the issue, and anything that is not barred at the gates is given little or no scrutiny—it’s assumed to be legitimate. The horrible truth is that in prohibiting the torture of suspects and requiring that arrestees be Mirandized, courts made lying to suspects

seem more justified—a necessary tool for the police whose work of keeping us safe became more difficult.

When the general population assumes that a popular police practice is prohibited because it's unfair, it should raise a red flag.

It stands as a warning to all of us. We have been lulled into thinking that discarding the rack and the back-room brute was enough. But all we have done is change the form of our coercion. The wounds and scars are now hidden, which leaves us in a far more precarious position. How do we spot a coerced confession when there are no bruises or welts? How do we know to sound the alarm bell when no one wears the torturer's cowl or beats out a confession, innocence be damned?

But we must also ask ourselves the broader question of whether seeking an admission of guilt is a proper approach for a just legal system. In the United States today, the vast majority of people charged with a crime are presented with a choice: say you did it and receive leniency, or maintain your innocence and suffer the consequences if a jury doesn't agree. Ninety to ninety-five percent admit guilt, which means no one ever has to come forward with any proof that the defendant is actually responsible, no jurors ever consider the evidence, and the trial process is completely short-circuited.

Let that sink in: nine out of ten prisoners are being punished based solely on their own admission of guilt. We've put away the breaking wheel, yes, but how far have we really come?

There's a real disconnect in this country between what people perceive is the state of indigent defense and what it is. I attribute that to shows like *Law & Order*, where the defendant says, 'I want a lawyer,' and all of a sudden Legal Aid appears in the cell. That's what people think.

In 2004, the American Bar Association released a report on the status of indigent defense, concluding that:

“All too often, defendants plead guilty, even if they are innocent, without really understanding their legal rights or what is occurring. Sometimes the proceedings reflect little or no recognition that the accused is mentally ill or does not adequately understand English. The fundamental right to a lawyer that Americans assume applies to everyone accused of criminal conduct effectively does not exist in practice for countless people across the United States.”

Tens of thousands of poor people go to jail every year without ever talking to a lawyer, and those who do meet with a lawyer for a drug offense often spend only a few minutes discussing their case and options before

making a decision that will profoundly affect the rest of their lives. As one public defender explained:

“They are herded like cattle into the courtroom lockup, up at 3 or 4 in the morning. Then they have to make decisions that affect the rest of their lives. You can imagine how stressful it is.”

Children routinely “waive” their right to counsel in juvenile proceedings. In some states, such as Ohio, as many as 90 percent of children charged with criminal wrongdoing are not represented by a lawyer.

“The kids come in with their parents, who want to get this dealt with as quickly as possible, and they say, ‘You did it, admit it.’ If people were informed about what could be done, they might actually ask for help.”

Prosecutorial overcharging is of two sorts: vertical overcharging, in which the prosecutor charges offenses for which he or she has insufficient proof to convict, and horizontal overcharging, in which the prosecutor charges a series of overlapping offenses arising from the same criminal act. In the latter type, prosecutors charge every offense for which a defendant might theoretically satisfy the offense definition, no matter how overlapping the offenses may be. Thus, a prosecutor might take a standard rape case—using force to compel intercourse—and add on assault, kidnapping, gross sexual imposition, et cetera. This is made possible because most American criminal codes, in which the state’s criminal laws are collected, grow over time to have a vast collection of overlapping offenses. Legislatures have been constantly adding new offenses, sometimes making the code seven or eight times longer than its original form based on the Model Penal Code, but without substantially expanding the code’s coverage.

So, for example, most states now have an offense of “carjacking,” after a series of newspaper headlines about such conduct. Does anyone doubt that such conduct was already punished severely as armed robbery (as well as auto theft, kidnapping, assault, et cetera)? Adding one more offense to charge was an act of potential showmanship, not criminal code improvement. The forests of overlapping offenses exist in large part because prosecutors have politically promoted them. Prosecutors have put political muscle into supporting a constant stream of new offenses that typically are just added on top of the old ones.

To protect this ability to bring multiple charges, they have repeatedly opposed criminal code reforms that would streamline codes and eliminate unnecessary overlaps. For example, in a new criminal law codification

undertaken in Illinois in 2003, which had as one of its primary aims the consolidation of overlapping offenses, the recodification was ultimately blocked by the political opposition of prosecutors. The prosecutors instead sponsored a new reform commission that kept the redundancies in the current code.

Strategic overcharging might seem to the uninitiated to be too unethical to be done openly. But the increasing game-like features of the system have dulled participants' sensibilities. Indeed, one need only look at similar manipulative conduct by federal judges before the Sentencing Reform Act of 1984 stopped the practice. Federal law at the time required that all offenders be eligible for early release by the United States Parole Commission no later than after serving one-third of their sentence. Judges who were uncomfortable with this early release could, and did, short-circuit the system by simply determining the sentence they really wanted, then tripling it. Thus, offenders would become eligible for release only after serving the full term the judges thought appropriate. Prosecutors may be making similar sorts of strategic manipulations when they overcharge. It was in part this judicial manipulative practice that contributed to the enactment of the "truth in sentencing" provisions of the Sentencing Reform Act of 1984. People had become increasingly skeptical of the sentences that were publicly imposed because they always ended in early release. The new act requires that an offender serve at least 85 percent of the sentence imposed—an attempt to earn back some credibility for the system.

Innocent parties can be compelled to plead guilty if they perceive the risk of going to trial as too high. When that happens, not only do we send an innocent person to prison, but we also close the case, which means that the police stop looking for the guilty party. The plea bargain, then, is best likened not to a shortcut but to a short circuit of our constitutional guarantees of due process. This presents a profound irony: while the adversarial system was introduced to protect defendants, the overwhelming resource requirements of that system have helped to drive a shift to plea bargaining, which has far fewer safeguards than a non-adversarial trial.

The practice of encouraging defendants to plead guilty to crimes, rather than affording them the benefit of a full trial, has always carried its risks and downsides. Never before in our history, though, have such an extraordinary number of people felt compelled to plead guilty, even if they are innocent, simply because the punishment for the minor, nonviolent offense with which they have been charged is so unbelievably severe. When prosecutors offer three years in prison when the penalties defendants could receive if they took their case to trial would be five, ten, or twenty years—or life imprisonment—only extremely courageous—or foolish—defendants turn the offer down.

The pressure to plead guilty to crimes has increased exponentially since

the advent of the War on Drugs. In 1986, Congress passed The Anti-Drug Abuse Act, which established extremely long mandatory minimum prison terms for low-level drug dealing and possession of crack cocaine. The typical mandatory sentence for a first-time drug offense in federal court is five or ten years. By contrast, in other developed countries around the world, a first-time drug offense would merit no more than six months in jail, if jail time is imposed at all. State legislatures were eager to jump on the “get tough” bandwagon, passing harsh drug laws, as well as “three strikes” laws mandating a life sentence for those convicted of any third offense. These mandatory minimum statutory schemes have transferred an enormous amount of power from judges to prosecutors. Now, simply by charging someone with an offense carrying a mandatory sentence of ten to fifteen years or life, prosecutors are able to force people to plead guilty rather than risk a decade or more in prison. Prosecutors admit that they routinely charge people with crimes for which they technically have probable cause but which they seriously doubt they could ever win in court. They “load up” defendants with charges that carry extremely harsh sentences in order to force them to plead guilty to lesser offenses and—here’s the kicker—to obtain testimony for a related case. Harsh sentencing laws encourage people to snitch.

While such conduct is deplorable, it is not difficult to understand. Who among us would not be tempted to lie if it was the only way to avoid a forty-year sentence for a minor drug crime? The pressure to plea-bargain and thereby ‘convict yourself’ in exchange for some kind of leniency is not an accidental by-product of the mandatory-sentencing regime. The US Sentencing Commission itself has noted:

“The value of a mandatory minimum sentence lies not in its imposition, but in its value as a bargaining chip to be given away in return for the resource-saving plea from the defendant to a more leniently sanctioned charge.”

Harsh mandatory minimum sentences for drug offenders have been consistently upheld by the US Supreme Court. In 1982, the Supreme Court upheld forty years of imprisonment for possession and an attempt to sell nine ounces of marijuana. Several years later, in *Harmelin v. Michigan*, the Court upheld a sentence of life imprisonment for a defendant with no prior convictions who attempted to sell 672 grams (approximately 23 ounces) of crack cocaine. The Court found the sentences imposed in those cases “reasonably proportionate” to the offenses committed—and not “cruel and unusual” in violation of the Eighth Amendment. This ruling was remarkable

given that, prior to the Drug Reform Act of 1986, the longest sentence Congress had ever imposed for possession of any drug in any amount was one year. A life sentence for a first-time drug offense is unheard of in the rest of the developed world. Even for high-end drug crimes, most countries impose sentences that are measured in months, rather than years. For example, a conviction for selling a kilogram of heroin yields a mandatory ten-year sentence in US federal court, compared with six months in prison in England. Remarkably, in the United States, a life sentence is deemed perfectly appropriate for a first-time drug offender.

The most famous Supreme Court decision upholding mandatory minimum sentences is *Lockyer v. Andrade*. In that case, the Court rejected constitutional challenges to sentences of twenty-five years without parole for a man who stole three golf clubs from a pro shop, and fifty years without parole for another man for stealing children's videotapes from a Kmart store. These sentences were imposed pursuant to California's controversial three strikes law, which mandates a sentence of twenty-five years to life for recidivists convicted of a third felony, no matter how minor. Writing for the Court's majority, Justice Sandra Day O'Connor acknowledged that the sentences were severe but concluded that they are not grossly disproportionate to the offense, and therefore do not violate the Eighth Amendment's ban on "cruel and unusual" punishments. In dissent, Justice David H. Souter retorted:

"If Andrade's sentence [for stealing videotapes] is not grossly disproportionate, the principle has no meaning."

Similarly, counsel for one of the defendants noted that the Court's reasoning makes it extremely difficult if not impossible to challenge any recidivist sentencing law:

"If these sentences aren't cruel and unusual punishment, what would be?"

First and second strikes are counted by individual charges, rather than individual cases, so a single case can result in first, second, and even third strikes. For example, a person arrested for possession of a substantial amount of marijuana, as well as a tiny amount of cocaine, could be charged with at least two separate felonies: possession with intent to sell marijuana, as well as possession of cocaine. Pleading guilty to each of these crimes would result in "two strikes." Fifteen years later, if the individual is arrested for passing a bad check, he or she could be facing a third strike and a life sentence. To make matters worse, sentences for each charge can run consecutively, so a

defendant can easily face a sentence of fifty, seventy-five, or one-hundred years to life arising from a single case. In fact, fifty years to life was the actual sentence given to Leandro Andrade, whose sentence for stealing videotapes was upheld by the Supreme Court.

Most people imagine that the explosion in the US prison population during the past twenty-five years reflects changes in crime rates. Few would guess that our prison population leapt from approximately 350,000 to 2.3 million in such a short period of time due to changes in laws and policies, not changes in crime rates. Yet it has been changes in our laws—particularly the dramatic increases in the length of prison sentences—that have been responsible for the growth of our prison system, not increases in crime. One study suggests that the entire increase in the prison population from 1980 to 2001 can be explained by sentencing policy changes.

About as many people were returned to prison for parole violations in 2000 as were admitted to prison in 1980 for all reasons. Of all parole violators returned to prison in 2000, only one-third were returned for a new conviction; two-thirds were returned for a technical violation such as missing appointments with a parole officer, failing to maintain employment, or failing a drug test. In this system of control, failing to cope well with one's exile status is treated like a crime. If you fail, after being released from prison with a criminal record—your personal badge of inferiority—to remain drug free, or if you fail to get a job against all the odds, or if you get depressed and miss an appointment with your parole officer (or if you cannot afford the bus fare to take you there), you can be sent right back to prison—where society apparently thinks millions of Americans belong.

Unless the number of people who are labeled felons is dramatically reduced, and unless the laws and policies that keep ex-offenders marginalized from the mainstream society and economy are eliminated, the system will continue to create and maintain an enormous system of injustice.

A little over one-hundred years ago, the English writer G. K. Chesterton was called for jury duty. After taking his oath, Chesterton sat back and observed the various characters in the unfolding drama: a woman accused of neglecting her children, a bicycle thief, a judge, assembled lawyers. From that intimate vantage point, he realized something that he had previously failed to grasp:

“The horrible thing about all legal officials, even the best, about all judges, magistrates, detectives, and policemen, is not that they are wicked (some of them are good), not that they are stupid (some of them are quite intelligent), it is simply that they have got used to it.”

As he explained, the problem with the system was that those in it were so acclimated to their surroundings, so set in their ways and assumptions, that “they do not see the prisoner in the dock; all they see is the usual man in the usual place. They do not see the awful court of judgment; they only see their own workshop.” For Chesterton, the solution was laymen jurors—outsiders, like him, who could:

“See the court and the crowd, and coarse faces of the policemen and the professional criminals, the wasted faces of the wastrels, the unreal faces of the gesticulating counsel—and see it all as one sees a new picture or a ballet hitherto unvisited.”

“Now, somebody has to say no to this. I can’t do it. The only thing I can do is ask you to do it. You have more power than the judge, and I don’t know many people who’ve got more power than the judge in this situation. You’ve got a lot more power than the prosecutors. You’ve got a lot more power than the police. You’ve got more power than the marshals. You’ve got more power than anybody because you can say no.

And not only that, but every one of you has that power, each of you individually, because the verdict has to be unanimous. So any one of you can say no and that is the end of the government’s case. People like George Washington sought to set up a federal government so you wouldn’t have to be afraid of it, that’s why our founders gave you that power, and that’s why you are so special.”

When a jury departs from the evidence and delivers a verdict that reflects some broader sense of justice, it is called “jury nullification.” Juries have used nullification to spare white men who were obviously guilty of lynching blacks, as well as to spare battered women who were obviously guilty of killing their husbands. Jury nullification, although treated warily by the courts, has traditionally been one way in which the “conscience of the community” can counteract the effect of an unpopular law.

The Seventh Amendment guarantees citizens the right to a jury trial. However, when the populace has no idea what’s in the Constitution—civic education has virtually disappeared from most school curriculums—that inevitably translates to an ignorant jury incapable of distinguishing justice and the law from their own preconceived notions and fears.

The best way to predict a jury’s ultimate verdict is to look at what the majority of jurors favor before deliberating, because that aligns with the outcome 90 percent of the time.

We are told to presume the defendant's innocence, and although it is an ideal we Americans embrace with pride, it cannot displace the knowledge we've gained from our own experience in life. That knowledge forms our attitudes in every case, and rarely does it presume innocence.

Visualization can be incredibly persuasive. The more a prosecutor can get a jury to visualize the defendant committing the crime, the easier it becomes to convince them that he's the culprit. One way to help them visualize the defendant committing the crime is to provide lots of detail. Particularly striking, powerful, or emotional details are especially effective. Like a big black man raping a little white girl with a broom handle.

"I tell my class: As a heterosexual male, it's not as if I won't be disgusted if you show me pictures of certain sexual acts between two males. The task for me is to say: What the hell does this have to do with my ethical beliefs? I tell them, the thought of two very ugly people having sex also revolts me, but that does not lead me to consider legislating against ugly people having sex.

The homeless are another group that people frequently speak ill of, probably because they, too, can trigger disgust alarms, making it easier for society to dehumanize them and find them guilty of crimes they didn't commit. My ethical duty is to make sure that this emotion doesn't influence me in a way it might actually tread on someone's humanity."

The highly disgusting also tend to be hard on crime; against casual sex, abortion, and gay rights; and authoritarian in orientation. For example, they're more inclined to think children should obey their elders without question and they place greater emphasis on social cohesion and following convention. Though the evidence is not as strong, there are even hints that those prone to disgust are more likely to be fiscally conservative (against taxation and government spending programs). There's a physiological angle to this story as well. When shown pictures of people eating worms and other revolting imagery, conservatives sweat more profusely than liberals (as measured by galvanic skin response). Their heightened reactivity, however, is not limited to disease-related dangers. Compared to liberals, they also react to loud noises with a more pronounced startle response. These twin observations may have direct bearing on a well-documented finding in political science: conservatives typically view the world to be a more threatening place than liberals. That, in turn, could influence their position on issues relevant to foreign policy. In addition to being more distrustful of foreigners,

they may be more willing to use force. Next to liberals, conservatives certainly are more outspoken in their support of patriotism, a strong military, and the virtue of serving in the armed forces.

A fear of germs does more than slant people's religious and political views. It literally leads them to think of morality in black-and-white terms—a finding with disturbing ramifications for the criminal justice system. You've likely noted that fairy godmothers always wear white and wicked witches black and, what's more, that the gun-toting heroes and villains in Westerns typically follow the same dress code. This seemingly trite observation raises an intriguing question: As a byproduct of being honed to spot contaminants, does the human mind actually encode black as sinful and white as virtuous?

Since the behavioral immune system operates at high speed to protect us from germs—indeed, some scientists liken it to a reflex—researchers grew increasingly confident that the subjects were relying on moral intuition rather than the slower process of conscious reasoning. If so, they theorized, people who were the fastest to link white to morality and black to immorality would be more concerned about germs and cleanliness. To explore this hunch, all the participants were asked to evaluate the desirability of cleaning products and other consumer goods at the end of the trial. Just as they anticipated, those whose test results suggested they might be germaphobic gave the most favorable ratings to cleaning products—especially items that were hygiene-related, like soap and toothpaste.

Since the tendency to see black as bad is heightened when moral issues are foremost on our minds, a courtroom is exactly the place where one would expect the cognitive bias to be most pronounced—unsettling news for people of color hoping for a fair trial. The darkness-contamination-evil link probably doesn't contribute as strongly to prejudice as the linking of ethnicity, poverty, and crime but it's concerning because all these negative biases might have an additive effect, raising the odds that a person of color will be found guilty or receive a harsher sentence.

Defense attorneys say there has long been a sentiment among some police and prosecutors that when it comes to babies who die unnatural deaths, “there are no accidents.” Someone killed the child, either willfully or through criminally negligent parenting. Babies don't die without someone being at fault. Therefore, somebody must be punished.

The greater value we place on young people's lives means we are also more motivated to seek justice on their behalf when they are killed. When an older man is murdered, research suggests that police officers will be less driven to track down his killer—even in situations where the murderer did not choose his particular victim and put everyone at risk, as with a remotely detonated bomb.

Passing a homeless drunk, we do not see a human being with a mind, feelings, needs, and ideas; we see him as if he were a mound of rags and trash, and that influences how we treat him. A pile of garbage can be left in the hallway for hours; it doesn't merit a police investigation; it doesn't need to be handled gently as it is lifted from the sidewalk.

The system failed them because of the psychological limitations of the people who operate it—limitations we all share. We see, in the words of the Bible, the speck in the eye of our brother but fail to notice the beam in our own eye. We blindly trust in the objectivity of our technologies and practices because they seem to deliver reality, when, in truth, they may distort our perspectives.

The reason it is important is this: Here is a group of people who have gathered to judge—and possibly execute—a fellow citizen. It's the highest calling there is and it has to be done well. A trial, however, is just a microcosm of the entire political system. When a democratic government decides to raise taxes or wage war or write child safety laws, it is essentially saying to an enormous jury, 'This is our theory of how the world works, and this is our proposal for dealing with it. If our theory makes sense to you, vote for us in the next election. If it doesn't, throw us out.' The ability of citizens to scrutinize the theories insisted on by their government is their only protection against abuse of power and, ultimately, against tyranny. If ordinary citizens can't coolly and rationally evaluate a prosecutor's summation in a criminal trial, they won't have a chance at calling to task a deceitful government. And all governments are deceitful—they're deceitful because it's easier than being honest. Most of the time, it's no more sinister than that.

The Sixth Amendment provides the defendant in a criminal trial with the right to "an impartial jury." It's a promise that we do not keep and may never be able to deliver.

People in almost every culture believe that one can spot liars through various cues—the way they avert their eyes, stutter, fidget, or touch their faces. Yet research does not support the validity of these signs. Numerous studies have shown, for example, that people who are lying are actually less likely to move their arms and legs (not more likely, as observers tend to assume), and averting one's gaze is not related to deceit. Even worse, when people are under a lot of pressure to appear trustworthy, that often exacerbates the behaviors that observers wrongly associate with lying. A truthful person who will calmly look you in the eye when discussing matters in her own home will stare down at her restless legs when called upon to defend herself in court.

There are surprisingly few useful clues for detecting when people are

lying. And even these cues are primarily verbal rather than nonverbal; for example, inaccurate statements are somewhat more likely to contain fewer details and more qualifiers ('I'm not positive, but I think that the bank-robber's shirt may have been blue') than accurate ones. Even trained security professionals, such as judges and police officers, rarely do better than chance at detecting lies.

And mechanical "lie detectors," are provably misnamed. Innocent people can fail to pass a polygraph test. And pathological liars, those with special training, and a small percent of the general population can beat the machine, i.e., tell a lie without indicating abnormal stress on the machine. Lastly, the integrity of the operator is key to a successful session. A faulty or dishonest operator can cause the person being tested such stress that a truth-teller can be made to look like a liar. Similarly, a dishonest operator can lessen the sensitivity of a machine such that a liar can look like a truth-teller. There are other concerns as well. Poor wording of questions and too many questions can adversely affect the usefulness of the test. For all these reasons and more, most states do not allow use of polygraph evidence in court. The primary use of such a machine is simply to scare criminals into a confession.

A memory of the perpetrator's face is just as susceptible to adulteration and misuse as a hair sample or partial fingerprint taken from a crime scene, but we don't treat it that way. We don't worry that it will get corrupted or lost or misreported. We don't subject it to careful monitoring or objective assessment. It makes little sense that a court should make the fullest use of all the modern scientific methods when, for instance, a drop of dried blood is to be examined in a murder case, while the same court is completely satisfied with the most unscientific and haphazard methods of common prejudice and ignorance when a mental product, especially the memory report of a witness, is to be examined.

We can expect to identify only a tiny percentage of the mistakes, biases, and acts of dishonesty marring the work of police officers, judges, jurors, and others. Most who have been wronged will never know it. Even if they do find out, the opportunity to remedy the problem is severely restricted: people often aren't aware of their rights, there aren't enough competent attorneys to file complaints and appeals, and there's frequently no hard evidence to convince a judge to address the issue. In only 5 to 10 percent of all cases, for example, is there a biological sample for DNA testing. And if a judge, two decades down the line, by some miracle, does acknowledge a suggestive eyewitness identification or a coercive interrogation and overturns a sentence, we still can't call it justice, for we placed an innocent man in a closet-sized cell for twenty years of his life.

We need to start thinking about witness mistakes in the way that we

think about other types of errors that individuals, groups, and institutions make. Studies of actual police lineups show that eyewitnesses select innocent people more than 30 percent of the time. Would we as a society tolerate the sale of a car whose brake lights malfunctioned on every third trip, or a hospital that handed out the wrong medicine to every third patient? Obviously not; we would demand immediate change. So why do we accept the claim that the legal system works just fine as it is?

It's true that, much of the time, when a witness picks out an innocent filler from a lineup, that person does not go on to be convicted of the crime. But given the tens of thousands of witness identifications annually, even a low percentage of truly consequential errors can produce an egregious level of harm. And consider that someone could offer the same rosy account of the hospital that gave every third person the wrong prescription: in most cases the patient would either notice before taking the medication or swallow it without experiencing any significant ill effects. But would we say to those who did suffer serious adverse reactions—or to the families of those who lost their lives: It's a shame about the error, but since our system works pretty well in general, we're not going to change it?

After receiving Kennedy Brewer's letter, the attorneys at the Innocence Project in New York agreed to represent him. Shortly after Brewer had been cleared by DNA testing, but well before he had been exonerated, his attorneys from both Mississippi and New York paid a visit to Forrest Allgood in Macon. The prosecutor had already announced that he planned to try Brewer again. The legal team wanted to make a personal plea to Allgood to drop the charges. What happened next, as recounted by André de Gruy and Peter Neufeld, was remarkable. The attorneys, along with Brewer himself, were to meet with Allgood in the jury room of a Noxubee County courthouse. Only after Brewer left the room did Allgood agree to talk. He then brought them back to an office in the courthouse and took a seat behind a desk. He leaned back, propped up his cowboy boots, and crossed his feet.

Neufeld carefully explained the science behind DNA testing, why the science in this case proved Brewer's innocence, and why the US Constitution compelled Allgood to drop the charges. When Neufeld had finished, Allgood slowly looked up from the floor, paused, and said, "You really believe in this science stuff, don't you?" Stunned, Neufeld replied that, indeed, he really did believe in DNA and in science. Allgood shrugged, took his boots off the table, and said, "Well I guess everybody's gotta believe in something."

"We had multiple experts saying this guy was innocent. We had two labs confirm the DNA tests. We were thinking: we just need to round up as many scientists as we can. More

confirmation, more tests, eventually we'd convince Allgood that our client is innocent. That conversation was such a revelation. The fact is, none of it mattered. We were dealing with a guy who thought science was just another set of beliefs, just another religion that wasn't his. You can see how a guy like that... how once he's convinced someone is guilty, he just isn't going to stop."

When asked about the conversation, Allgood denied making the first comment. "I have never disbelieved in DNA," he wrote, adding that he does sometimes object to how DNA test results are interpreted. He does recall making the second comment.

Because Brewer so rarely got emotional, de Gruy remembers vividly one of the few times he did. It was in 2007. Brewer had been released on bail but had yet to be formally exonerated. There was still talk of trying him again. New York Times reporter Shaila Dewan had come to Macon to write about Brewer's case.

"We were talking to Kenny at his mom's house, Shaila started asking Kenny about Christine Jackson, the little girl who was killed. And Kenny began to cry. I guess I just wasn't prepared for that. After all that time, it came out of nowhere. But there it was. He told Shaila that she wasn't his daughter, but he still cared for her. He started talking about how because he had been taken to jail so quickly, he never got to go to her funeral. All these years had gone by, and he still hadn't had a chance to visit her grave."

De Gruy says that's when he realized something important that he and Brewer's other attorneys had been overlooking.

"We were so busy trying to get Kenny out of prison, we had never really talked to him about Christine. It hit me that Kenny wasn't just a victim of a wrongful conviction; he was a victim of Justin Johnson, too. He was a victim of this crime just as much as anyone else in that little girl's life. And after all that had happened to him, he never really got the chance to heal."

It wasn't just the timing of the emotion that stuck with de Gruy, but the impetus for it.

"Here's a guy who had never gotten angry over being wrongly convicted for killing this little girl. Never got angry about being

put on death row. The one time he really broke down, it was because he never got to grieve for that little girl.”

Forrest Allgood has said on numerous occasions that although the system failed in the Brooks and Brewer cases, it also worked. What he means, of course, is that all things considered, the net result was what the process aspired to in the first place: the identification and apprehension of the real perpetrator. In a 2008 letter to the editor defending his prosecutions, Allgood argued that the fact that Brooks and Brewer combined spent nearly three decades in prison for crimes that they didn't commit was nothing more than truth being the “daughter of time.” Allgood isn't alone in his thinking. The late Supreme Court justice Antonin Scalia believed the same thing. In a 2006 opinion discussing the intersection of an inmate's claim of factual innocence and the death penalty, Scalia wrote that “the possibility that someone will be punished mistakenly is a truism, not a revelation.” For Scalia, Allgood, and many others, the moral hazards inherent in that position are worth the risk. But the risk is not an abstract one.

As we wait five or ten or fifty years for a finding to become incontrovertible, people's lives are being upended by legal rules, principles, and norms that often have no scientific basis at all.

It took the jury less than two days to deliberate, convict him based on bad scientific evidence, hear evidence on appropriate punishment, deliberate again, and sentence him to death. It took thirteen years for the courts to admit that a small portion of the bad evidence might have been scientifically unsound. It took another fourteen months for the trial court judge to agree to hold a hearing on the matter. It will be another fourteen months from that decision until the hearing itself. It's often said that the wheels of justice grind slowly. That isn't always true. When it comes to convicting people, they can move pretty swiftly. It's when the system needs to correct an injustice—admit its mistakes—that the gears tend to sputter to a halt. For now, he remains on death row.

In one case, a panel from the Fifth Circuit unanimously denied a new trial for a Louisiana man named James Koon, who had been convicted in 1996 of killing an infant. Steven Hayne was the state's expert witness. In his petition, Koon claimed that the recent revelations about Steven Hayne's credibility were newly discovered evidence. The panel unanimously rejected that claim. The panel also ruled that Koon should have discovered allegations made by Hayne's critics years earlier. But this particular opinion included two important words that proved Koon and appellants like him never really stood a chance:

“The evidence shows the witness for Louisiana, Dr. Steven Hayne, a now-discredited Mississippi coroner, lied about his qualifications as an expert and thus gave unreliable testimony about the cause of death.”

Now-discredited. This was the first time a majority opinion from an appeals court of any kind had acknowledged that Hayne had been “discredited.” Not only that, the opinion acknowledged that Hayne had lied about his credentials. Unfortunately, because of what that panel did next, the acknowledgment provided no relief for the people trying to get a new trial by challenging Hayne’s credibility. That’s because despite the fact that this was the first time an appeals court had described Hayne as discredited, it was already too late to do anything about it.

The federal district court judge who first ruled on Koon’s petition determined that despite the evidence that Hayne had been discredited:

“Dr. Hayne’s expertise was questioned by the Mississippi Supreme Court in an opinion published in May 2007; Justice Diaz’s Special Concurrence relied upon a magazine article published in 2006. In the absence of any evidence to the contrary, it is safe to conclude that a habeas petitioner exercising due diligence should have discovered this information well before the fall of 2011. In other words, this petition is clearly time-barred.”

The Fifth Circuit panel agreed. The panel noted that several media outlets had first begun to criticize Hayne between 2006 and 2008, that the Innocence Project had filed its complaint against Hayne in 2009, and that Mississippi Supreme Court Justice Oliver Diaz had criticized him in his concurring opinion in the Edmonds case in 2007.

“Koon’s assertion that he could not have learned of Edmonds from information in the Louisiana State Penitentiary law library is both implausible and immaterial in the light of the public information about Dr. Hayne that was available for several years prior to July 2011.”

Because Koon could have discovered these criticisms of Hayne much earlier, he had missed his deadline. He was out of luck. With a single short opinion, the Fifth Circuit admitted that the medical examiner Mississippi had been using for two decades was no longer a credible witness, but then slammed the door on anyone he had helped convict. Under a precise reading of federal law and the relevant case law, this was arguably correct. It was

also incredibly unfair and a stark illustration of just how ill-equipped the federal courts and federal law are to catch and correct quackery disguised as expertise.

Since the onset of DNA testing in the 1990s, the legal system has slowly been coming to terms with the fact that forensic analysts aren't nearly as accurate and reliable as they've often claimed to be. The problem has been documented in countless studies, reports, and law review articles, but the most damning evidence is the most straightforward: according to a 2007 study of the first two-hundred post-conviction exonerations, over half involved flawed forensic evidence. In the majority of those cases, the state's forensic witnesses gave inaccurate and unreliable testimony. And even as the criminal justice system can't seem to keep bad science out of its courtrooms, once someone is convicted, the same system then shifts to protect the "finality" of the verdict. Federal lawmakers have only made it worse with laws like AEDPA, altering federal code to make it ever more difficult to challenge state verdicts in federal court. The courts still let these witnesses testify at trial—as experts. But years later, when science proves them wrong, or the defendant finally finds funds to hire an expert to say as much, the system is all about protecting the verdict. At that point, it no longer wants to hear from experts.

Most of these more subjective forensics fields have largely avoided exposing themselves to scientific scrutiny. It's easy to see why. There's no incentive for them to do so. The purpose of forensics is to solve crimes. The end game is to testify in court and persuade a judge or jury. Once the courts begin accepting analysts from a new area of forensics as experts, there's no upside to those analysts then subjecting their methods and analysis to scientific scrutiny. They already have the only approval they need: that of the courts. If the science affirms their methods, they're no better off than they were before. At best, they get the benefit of telling the jury that their field is backed by scientific research. Of course, anyone can claim as much, regardless of whether it's true. But if their field doesn't withstand scientific scrutiny, it's free material for opposing attorneys. It could put their entire livelihood at risk—or at least it ought to.

Imagine that defendant "Johnny" is convicted based on handwriting analysis evidence. This particular variety of expert testimony has been criticized for many years but has only been acknowledged as invalid by government agencies in the last few years. Johnny now wants to file a post-conviction petition for a new trial based on the scientific consensus that the evidence used to convict him isn't scientifically reliable. At what point does the year-long window in which Johnny had to file his petition begin to take effect? Should it be after the first critical study? The second?

Is it once the scientific community has reached a consensus? What defines a consensus? How does one define the field of scientists among which such a consensus must arise? It isn't as if scientists take an annual vote on these things. These are critical questions, and they're essentially impossible to answer. The courts and Congress have set a trap for these defendants, and absent DNA evidence, there's really no escaping it. File your claim too soon—say, after the first few studies—and the courts could rule that you haven't presented enough evidence that the expertise used to convict you has been discredited. You now risk being barred from ever raising the issue again. But if you wait for a stronger scientific consensus before filing, the courts could rule that your deadline passed a year after those first few studies were published. Your window has closed. Here, too, you're now barred from raising that claim again.

And that's all just for the suspect fields of forensics. With individual experts, it gets even trickier. Michael West is a good example. Mississippi's courts, prosecutors, and attorneys continued to uphold and defend West's credibility well into the mid-2000s, despite the fact he had been repeatedly criticized and exposed going back to the mid-1990s. Mississippi attorney general Jim Hood finally conceded in 2008 that West wasn't a credible witness, telling the Jackson Free Press that West "is someone we have investigated, and I don't support him in any manner." But while Hood's office had by then stopped explicitly defending the substance of West's analyses in court, his office still continues to defend convictions won primarily on West's testimony. Instead of arguing that West is a credible witness, the office now argues that defendants are procedurally barred from raising West as an issue again, because most of them already challenged West's credibility and lost. It doesn't matter that even Hood acknowledges now that the courts back then were wrong.

But in cases like that of Hayne, the situation is more nuanced. The information trickles out over time. The gradual discrediting of Hayne took place over more than a decade. In November 2014, the Fifth Circuit Court of Appeals ruled that Steven Hayne had earned the label of 'discredited.' But exactly when did the court reach that conclusion? And how was James Koon supposed to have known? There was no announcement. There was no press release. There was no notice given to those who may have been convicted by Hayne's testimony that said, "Hey, you now have one year to file your claims."

The added indignity for someone like Koon is that Louisiana offers post-conviction indigent legal help only to those who have been sentenced to death. Koon was sentenced to life in prison, so once he lost his appeal, he lost his lawyer. He filed his post-conviction petition himself. The Fifth Circuit

ruling in his case essentially states that from his prison cell, an indigent defendant like Koon should not only have been following each revelation about Hayne's credibility as it happened but should have been able to discern the precise moment when those revelations tipped the scales to make Hayne 'discredited' in the eyes of the court—even though the court itself couldn't or wouldn't say precisely when that occurred. And Koon should have then filed his petition within a year of that magical moment. But it's even worse than that. Not only do the courts expect these defendants to abide by these dizzying rules to the letter, the courts refuse to hold themselves to the same standard. The Flaggs ruling that affirmed Hayne's credibility as an expert witness came in March 2013. That would be nineteen months after July 2011, which the same court declared was the very latest by which Koon should have already discovered the evidence that Hayne was not credible. There's just no way Koon could have gotten it right.

Finally, it's worth noting that the "discredited" acknowledgment in the ruling did not prevent Hayne from testifying in future cases in the Fifth Circuit—or anywhere else. It did not prevent Louisiana prosecutors from using him if they so desired, or even Mississippi prosecutors should the state change its laws. Ironically (or perhaps not), the only real consequence of the Fifth Circuit's acknowledgment that a longtime expert witness for the state was now discredited was to prevent criminal defendants from challenging that expert in federal court.

The system values process far more than justice.

Plant Wars

Witches and sorcerers cultivated plants with the power to “cast spells”—in our vocabulary, psychoactive plants. Their potion recipes called for such things as datura, opium poppies, belladonna, hashish, fly-agaric mushrooms (*Amanita muscaria*), and the skins of toads (which can contain DMT, a powerful hallucinogen). These ingredients would be combined in a hempseed-oil-based “flying ointment” that the witches would then administer vaginally using a special dildo. This was the “broomstick” by which these women were said to travel.

The challenge these plants posed to monotheism was profound, for they threatened to divert people’s gaze from the sky, where the new God resided, down to the natural world all around them. The magic plants were, and remain, a gravitational force pulling us back to Earth, to matter, away from the there and then of Christian salvation and back to the here and now. Indeed, what these plants do to time is perhaps the most dangerous thing about them—dangerous, that is, from the perspective of a civilization organized on the lines of Christianity and, more recently, capitalism. Christianity and capitalism are both probably right to detest a plant like cannabis. Both faiths bid us to set our sights on the future; both reject the pleasures of the moment and the senses in favor of the expectation of a fulfillment yet to come—whether by earning salvation or by getting and spending. More than most plant drugs, cannabis, by immersing us in the present and offering something like fulfillment here and now, short-circuits the metaphysics of desire on which Christianity and capitalism—and so much else in our civilization—depend.

But do not worry, though Christianity may be failing to do anything, capitalism has begun to embrace cannabis—with industrial growing, a mass diversity of products, and an increase in heavily-processed and -concentrated forms thereby rendering the drug more like alcohol, where one’s desire is to simply get ‘fucked up.’

There is a myth about natural cannabis: the user has an illusion of great insight, but it does not survive scrutiny in the morning. I am convinced that this is an error, and that the devastating insights achieved while high are

real insights; the main problem is putting these insights in a form acceptable to the quite different self that we are when we're down the next day. If I find in the morning a message from myself the night before informing me that there is a world around us which we barely sense, or that we can become one with the universe, or even that certain politicians are desperately frightened men, I may tend to disbelieve; but when I'm high I know about this disbelief. And so I have a tape in which I exhort myself to take such remarks seriously. I say, 'Listen closely, you sonofabitch of the morning! This stuff is real!'

Memory is the enemy of wonder, which abides nowhere else but in the present. This is why, unless you are a child, wonder depends on forgetting—on a process, that is, of subtraction. Ordinarily we think of drug experiences as additive—it's often said that drugs "distort" normal perceptions and augment the data of the senses—adding hallucinations, say—but it may be that the very opposite is true—that they work by subtracting some of the filters that consciousness normally interposes between us and the world.

In one way or another, all our experiences are chemically conditioned, and if we imagine that some of them are purely 'spiritual,' purely 'intellectual,' purely 'aesthetic,' it is merely because we have never troubled to investigate the internal chemical environment at the moment of their occurrence. Mystics have always worked systematically to modify their brain chemistry, whether through fasting, self-flagellation, sleeplessness, hypnotic movement, or chanting. The reason there aren't nearly as many mystics and visionaries walking around today, as compared to the Middle Ages, is the improvement in nutrition. Vitamin deficiencies wreak havoc on brain function and probably explain a large portion of visionary experiences in the past.

The brain can be made to drug itself, as seems to happen with certain placebos. We don't merely imagine that the placebo antidepressant is working to lift our sadness or worry—the brain is actually producing extra serotonin in response to the mental prompt of swallowing a pill containing nothing but sugar and belief. What all this suggests is that the workings of consciousness are both more and less materialistic than we usually think: chemical reactions can induce thoughts, but thoughts can also induce chemical reactions.

It does not seem to be an exaggeration to say that psychedelics, used responsibly and with proper caution, would be for psychiatry what the microscope is for biology and medicine or the telescope is for astronomy.

The reason research came to a halt was the drug war, not lack of potential in psychedelic compounds. The question is not do psychedelics cause harm in certain individual cases. So do automobiles, prescription drugs, mountain climbing, and love affairs—all more or less legal at this point. The question

is do you think it's justified to bring down the full institutional fury of the police state on citizens who want to explore these substances?

We already have a psychoactive drug sold on every street corner in America, one that's highly toxic and addictive, that's a major factor in violent crime, and that regularly destroys people's lives. Every year it kills more than ten times the people who died in the 9/11 attacks, and yet it's completely legal.

Of course I'm talking about alcohol. It should be the benchmark for any rational discussion of drug policy—this is the level of harm we as a society are willing to accept from a merely recreational drug. If some other drug creates far less harm and offers far greater potential benefits—as is the case with LSD or psilocybin—then at least let's not fool ourselves that loosing the police state on its users is motivated by altruistic concern for their well-being.

Throughout the 1980s, drunk driving was a regular topic in the media, and the term 'designated driver' became part of the American lexicon. At the close of the decade, drunk drivers were responsible for approximately 22,000 deaths annually, while overall alcohol-related deaths were close to 100,000 a year. By contrast, during the same time period, there were no prevalence statistics at all on crack, much less crack-related deaths. In fact, the number of deaths related to all illegal drugs combined was tiny compared to the number of deaths caused by drunk drivers. The total of all drug-related deaths due to AIDS, drug overdose, or the violence associated with the illegal drug trade, was estimated at 21,000 annually—less than the number of deaths directly caused by drunk drivers, and a small fraction of the number of alcohol-related deaths that occur every year.

In response to growing concern—fueled by advocacy groups such as MADD and by the media coverage of drunk-driving fatalities—most states adopted tougher laws to punish drunk driving. Numerous states now have some type of mandatory sentencing for this offense—typically two days in jail for a first offense and two to ten days for a second offense. Possession of a tiny amount of crack cocaine, on the other hand, carries a mandatory minimum sentence of five years in federal prison. Although drunk driving carries a far greater risk of violent death than the use or sale of illegal drugs, the societal response to drunk drivers has generally emphasized keeping the person functional and in society, while attempting to respond to the dangerous behavior through treatment and counseling.

Sure, its a problem that unethical chemists shotgun potentially dangerous, completely untested drugs out to a largely ignorant consumer base. But the lion's share of the blame belongs to the ongoing state of drug prohibition. If safer, more heavily studied drugs like MDMA weren't so illegal, there

wouldn't be a market for all of the weird little research chemicals meant for legitimate scientific study.

Black markets are inherently risky and dangerous since illegal contracts can only be enforced through violence or the threat of violence. This is an argument for regulating sales of things that attract eager buyers but pose minimal harm to the public, rather than trying to prevent them altogether.

For some types of meth, 'lab' is largely a misnomer. All that is truly necessary to make Nazi dope, in addition to the anhydrous ammonia and the cold pills, is a lithium strip from inside a battery (accessible by unrolling the layers of zinc and aluminum that lie beneath the protective sheath), some Coleman lantern fluid, and a ninth-grade knowledge of chemistry. Using a soda bottle instead of a pair of buckets rigged with surgical tubing is called the single-batch system, and it became popular once the police had begun raiding so many homes in search of meth labs. Single-batching was devised as a way to cook while riding mountain bikes. If they strapped a soda bottle onto a rack over the rear wheel, single-batchers believed that the constant movement—unlike in a home lab—would diffuse the smell of the process. They further believed that the police wouldn't suspect people on bikes of cooking meth.

But it didn't take long to catch on. In one story, a county sheriff's deputy pulls up to a kid sitting by the side of the road amid a wilderness of midsummer corn. His bike in pieces all around him, he has a soda bottle at his side, inside of which there is a small inferno of activity: he has decided, while he waits for his meth to cook, to take his bike completely apart and put it back together again. The boy asks the deputy why he stopped. "I got a call," says the deputy, in the bone-dry wit endemic to the Midwest, "that you needed to borrow a screwdriver."

Meth makes you do crazy shit. One story is of an ex-Marine sharpshooter who was also a prolific meth cook and lived alone with his teenage daughter. In 2003, increasingly paranoid that he would get caught making meth, the ex-Marine knocked out all the windows from his home and replaced them with black plastic garbage bags taped to the frames, thereby keeping people from looking in. They also provided a good way to defend the house, for he'd cut holes in the center of the bags from which he planned to shoot whoever came to shut down his lab. Near the windows, he had placed nineteen firearms of various kinds, along with seven-thousand rounds of ammunition. What one might find funniest about the story is not that the ex-Marine aroused his neighbors' suspicions by going outside in his underwear to dance in the street in the middle of the day; or that his daughter was home at the time, studying; or that the man, when the police came, tried to hide by lying still in the concrete gutter of the street, thinking he was camouflaged.

What may give some a good a laugh is that the man had the most firepower stacked around the house's highest windows, those in his daughter's room, which provided the best vantage points for shooting. There he had two AR-15 fully automatic assault rifles, a Remington 12-gauge shotgun, and seven-hundred rounds of ammunition. Commented one cop:

“Had he not decided to lay down and hide in the gutter there's no question he would have killed every single one of us.”

A meth user's feelings are reflected in what are called his executive actions—his ability to choose between what we all know to be good and bad. What feels good is tied directly to survival. The ability to make decisions, therefore, is in some ways controlled not by what people want, but by what they need. Meth hijacks the relationship between what is necessary and what is desired. The result is that when you take away meth, nothing natural—sex, a glass of water, a good meal, anything for which we are supposed to be rewarded—feels good. The only thing that does feel good is more meth. Moreover, there's a basic and lasting change in the brain's chemistry, which is a direct result of the drug's introduction. The ultimate effects are psychopathology such as intolerable depression, profound sleep and memory loss, debilitating anxiety, severe hallucinations, and acute, schizophrenic bouts of paranoia: the very things that meth, just eighty years ago, was supposed to cure.

Even if we get a hold of meth next month, we've already got three human stages of history to clean up. But seeing that we won't have it under control next month, we're going to have four, five, maybe six generations to deal with: the medical problems, the psychological ramifications—we don't even know what else. We've only settled into a long-term siege.

Consider Major, a former meth user. For Major, waiting to see what price his son would pay for his transgressions was a daily reminder of why he had to stay straight. But there was always the fear that one day, out of the blue, Buck would develop some kind of problem that was a direct result of Major's heavy meth use. The idea of this—and that it might, no matter how many strides Major made in his life, become a sudden and crushing reality—grew inside Major like a benign tumor that could, at any moment, metastasize into an inoperable cancer. The very notion that innocent, tiny Buck might be victimized by his father's past was still enough to make Major want to go and finish himself off with one last, superlatively freeing crank overdose.

The bad news, said Major, was that he lacked anything in which to believe. He was working hard—at staying clean, at raising Buck, at making

money. But without meth, Major found it impossible to feel, as he put it, “happy.” Even when Major did the right thing, he couldn’t quite believe in its rightness, for that thing didn’t satisfy him—meth did. To get back to normal—that is, to begin once again to derive meaning from the humdrum facts of life—might take years. Intellect cannot substitute for instinct—knowing is not feeling. Major’s self-admonishment that he ought to be grateful is no substitute for the neurotransmitters—and the feeling of well-being they create—that he can no longer produce. In the meantime, the gravitational pull of meth, with its pyrotechnic promise of biochemical ecstasy, could be overwhelming.

Contrary to what many people might think, the rural United States has for decades had higher rates of drug and alcohol abuse than the nation’s urban areas. If addiction has a face it is the face of depression.

Crack flooded the streets for as little as \$2.50 a rock. An addict broke into the home of eighty-one-year-old Rosa Parks and, even after recognizing her, stole fifty-three dollars and punched her in the face.

Not long after, Chino found his corner, and started selling his crack. And three years after that, when he was sixteen, he would smoke it for the first time.

“I wanted to know what my mom chose over me.”

And on the little table beside Hannah, there was her alcohol, and her heroin, and a needle. And Liz—who has never wanted to use drugs—looked at them and looked at Hannah and thought: ‘Which of these things on your bedside table can I give you to take your pain away?’

“And that was the moment I understood what addiction did for people.”

“When your kid’s dying from a brain tumor or leukemia, the whole community shows up. They bring casseroles. They pray for you. They send you cards. When your kid’s on heroin, you don’t hear from anybody, until they die. Then everybody comes and they don’t know what to say.”

In a country where doctors once feared opiates, a culture of aggressive opiate use was emerging by the mid-1990s.

“My fellowship director even told me, ‘If you have pain, you can’t get addicted to opiates because the pain soaks up the euphoria.’ Now you look back and it sounds so preposterous.

That's actually what people thought. You can think what you want in the face of ten-thousand years of reality."

Pain perception has a strong psychological component. The same incoming pain signal can be interpreted as painful or not, depending on what the patient is thinking. Pain requires conscious attention.

Drugs help attain the soothing hiss of oblivion. But when the drugs wear off, the vulnerabilities throb like a fresh surgical incision.

"Everything, bad or good, boiled back to the decade on the needle, and the years before that imbibing everything from cocaine to Romilar, pot to percs, LSD to liquid meth and a pharmacy in between: a lifetime spent altering the single niggling fact that to be alive means being conscious."

Behind every vice is an impulse. We can sate those impulses in ways that are healthy, that improve our ability to deal with the world, and that help us grow as people. Or we can sate those impulses in ways that numb us to the world and drive us deeper and deeper away from it.

In 1970, high-grade heroin and opium flooded Southeast Asia. Military physicians in Vietnam estimated that nearly half of all US Army enlisted men serving there had tried opium or heroin, and between 10 and 25 percent of them were addicted. Deaths from overdoses soared. In May 1971, the crisis reached the front page of the *New York Times*: "G.I. Heroin Addiction Epidemic in Vietnam." Fearful that the newly discharged veterans would join the ranks of junkies already bedeviling inner cities, President Richard Nixon commanded the military to begin drug testing. No one could board a plane home until he had passed a urine test. Those who failed could attend an army-sponsored detoxification program.

Operation Golden Flow, as the military called it, succeeded. As word of the new directive spread, most GIs stopped using narcotics. Almost all the soldiers who were detained passed the test on their second try. Once they were home, heroin lost its appeal. Opiates may have helped them endure a war's alternating bouts of boredom and terror, but stateside, civilian life took precedence. The sordid drug culture, the high price of heroin, and fears of arrest discouraged use, veterans told a sociologist who evaluated the testing program from 1972 to 1974. The findings were startling. Only five percent of the men who became addicted in Vietnam relapsed within ten months after return, and just 12 percent relapsed briefly within three years.

"This surprising rate of recovery even when re-exposed to narcotic drugs ran counter to the conventional wisdom that

heroin is a drug which causes addicts to suffer intolerable craving that rapidly leads to re-addiction if re-exposed to the drug.”

Scholars hailed the results as “revolutionary” and “path-breaking.” The fact that addicts could quit heroin and remain drug free overturned the belief that “once an addict, always an addict.”

It turns out that quitting is the rule, not the exception—a fact worth acknowledging, given that the official NIDA formulation is that “addiction is a chronic and relapsing brain disease.” The Epidemiologic Catchment Area Study, done in the early 1980s, surveyed 19,000 people. Among those who had become dependent on drugs by age twenty-four, more than half later reported not a single drug-related symptom. By age thirty-seven, roughly 75 percent reported no drug symptom.

The National Comorbidity Survey, conducted between 1990 and 1992 and again between 2001 and 2003, and the National Epidemiologic Survey on Alcohol and Related Conditions, conducted between 2001 and 2002 with more than 43,000 subjects, found that 77 and 86 percent of people who said they had once been addicted to drugs or alcohol reported no substance problems during the year before the survey. By comparison, people who were addicted within the year before the survey were more likely to have concurrent psychiatric disorders. Additionally, NIDA estimates that relapse rates of treated drug-addicted patients run from 40 to 60 percent. In other words, they are not representative of the universe of addicts. They are the hard cases—the chronic and relapsing patients. Yet these patients often make the biggest impressions on clinicians and shape their views of addiction, if only because clinicians are especially likely to encounter them.

Researchers and medical professionals err in generalizing from the sickest subset of people to the overall population of patients. This caveat applies across the medical spectrum. Just as the clinician wrongly assumes that all addicts must be like the recalcitrant ones who keep stumbling through the clinic doors, psychiatrists sometimes view people with schizophrenia as doomed to a life of dysfunction on the basis of their frequent encounters with those whose delusions and hallucinations don’t improve with treatment. The error of extrapolating liberally from these subsets of difficult patients is so common that statisticians gave it a name: the “clinician’s illusion.”

Unfortunately the brain-disease model has become dogma—and like all articles of faith, it is typically believed without question.

Before the Soviet invasion, Kandahar’s farmers produced an abundance of figs, melons, peaches, grapes, and pomegranates that were deservedly renowned for being the most delectable on earth. As part of the scorched-earth policy they implemented against the mujahedeen, however, the Soviets

not only obliterated these orchards and vineyards; they also destroyed the elaborate, centuries-old irrigation systems that had enabled the desert to bloom. To survive, the farmers started cultivating poppies instead, which needed to be watered only once every five days or so. And as the opium fields proliferated, militias vied to control the lucrative traffic in “flower oil”—a local euphemism for the gummy brown sap scraped from the plant’s seed capsules to produce heroin.

Once elected, Reagan’s promise to enhance the federal government’s role in fighting crime was complicated by the fact that fighting street crime had traditionally been the responsibility of state and local law enforcement. After a period of initial confusion and controversy regarding whether the FBI and the federal government should be involved in street crime, the Justice Department announced its intention to cut in half the number of specialists assigned to identify and prosecute white-collar criminals and to shift its attention to street crime, especially drug-law enforcement.

One senator insisted that crack had become a scapegoat distracting the public’s attention from the true causes of our social ills, arguing:

“If we blame crime on crack, our politicians are off the hook. Forgotten are the failed schools, the malign welfare programs, the desolate neighborhoods, the wasted years. Only crack is to blame. One is tempted to think that if crack did not exist, someone somewhere would have received a Federal grant to develop it.”

Until 1988, one year of imprisonment had been the maximum for possession of any amount of any drug.

In the 1980s, the US government helped fuel Central America’s dirty wars through its covert and overt support for brutal, drug-dealing Contras and repressive regimes in Honduras, Guatemala, and El Salvador. These wars killed and injured hundreds of thousands, frayed and destroyed social relations, and increased poverty, insecurity, and drug trafficking in the region. The wars also led to widespread forced migration, including widespread flight to the United States. These refugees typically ended up in the poor neighborhoods of cities like Los Angeles. Once there, many impoverished boys and young men (and, to a lesser extent, girls and young women) found themselves joining US-born-and-bred gangs. In addition to terrorizing US neighborhoods, these refugee gang members were often arrested and deported back to their home countries, where they soon established new branches of their US-based gangs. In turn, these gangs became centrally involved in the growth in drug trafficking in Central America—which the Contras helped kick-start—as drug traffickers took advantage of the region’s

poverty and instability to create a new transshipment hub between South American producers and North American points of sale.

The main result of the US drug war has been merely to shift transportation routes while increasing violence and doing little to affect consumption. Squeezing trafficking in one place has created a “balloon effect,” pushing the trade from the Caribbean to Honduras and other parts of Central America. Today, an estimated 90 percent of the cocaine shipped from Colombia and Venezuela to the United States goes through Central America, with more than one third of that total going through Honduras.

After the Cold War, the combatant command responsible for Latin America found itself marginalized and with little to do. Southcom discovered its salvation in disaster and drugs.

Many people believe that in times of war, democratic norms may be set aside. For this reason, the vocabulary used in the United States of a “war on drugs” is a clear signal that liberal democratic norms will be violated to deal with an emergency situation. In general, politicians are apt to appeal to the vocabulary of emergency in those situations in which they want to bypass democratic deliberation.

In a liberal democratic society, politicians will always make claims of exception for policies about which they care deeply. They will wrap these claims in the language of exception: “emergency manager,” as if the majority Black cities in the state of Michigan underwent tornadoes and floods; the “war on drugs,” as if drug use was an enemy outside. It is the job of the media in a democratic society to police politicians’ appeal to exceptions in the language of emergency.

Until recently, the financial incentives offered to local law enforcement to pump up their drug arrests have not been well publicized, leading the average person to conclude reasonably—but mistakenly—that when their local police departments report that drug arrests have doubled or tripled in a short period of time, the arrests reflect a surge in illegal drug activity, rather than an infusion of money and an intensified enforcement effort.

Although paramilitary units were often justified to city councils and skeptical citizens as essential to fight terrorism or deal with hostage situations, they were rarely deployed for those reasons but instead were sent to serve routine search warrants for drugs and make drug arrests. In fact police departments have an extraordinary incentive to use their new equipment for drug enforcement: the extra federal funding the local police departments received was tied to anti-drug policing. The size of the disbursements was linked to the number of city or county drug arrests. Each arrest, in theory, would net a given city or county about \$153 in state and federal funding. Non-drug-related policing brought no federal dollars, even for violent crime.

As a result, when Jackson County, Wisconsin, quadrupled its drug arrests between 1999 and 2000, the county's federal subsidy quadrupled too.

It was not until 1984, when Congress amended the federal law to allow federal law enforcement agencies to retain and use any and all proceeds from asset forfeitures, and to allow state and local police agencies to retain up to 80 percent of the assets' value, that a true revolution occurred. Suddenly, police departments were capable of increasing the size of their budgets, quite substantially, simply by taking the cash, cars, and homes of people suspected of drug use or sales.

One highly publicized case involved a reclusive millionaire, Donald Scott, who was shot and killed when a multi-agency task force raided his two-hundred-acre Malibu ranch purportedly in search of marijuana plants. They never found a single marijuana plant in the course of the search. A subsequent investigation revealed that the primary motivation for the raid was the possibility of forfeiting Scott's property. If the forfeiture had been successful, it would have netted the law enforcement agencies about \$5 million in assets.

Relatively little organized opposition to the drug war currently exists, and any dramatic effort to scale back the war may be publicly condemned as "soft" on crime. The war has become institutionalized. It is no longer a special program or politicized project; it is simply the way things are done.

A Black Lives Matter activist, confronting Hillary Clinton about her husband's crime policies in August of 2015, used the unfortunate words "unintended consequences" to describe mass incarceration. In fact, it was widely known at the time that the consequence of the crack/cocaine sentencing disparity was the mass incarceration of black drug users. This was one of the reasons the US Sentencing Commission tried to abolish the disparity in 1995, an action that Clinton and the Republican Congress overruled. It was also why the Congressional Black Caucus begged Bill Clinton not to overrule it—and why prison riots erupted when it became clear he was going to sign the bill overruling the recommendations of the Sentencing Commission.

"Let's be clear about what these policies have done. They have filled the nation's prisons with hundreds of thousands of young black and Latino men whose greatest crime is drug addiction. It is no wonder that one-third of black men in their 20s are under the jurisdiction of the criminal justice system. If we treated alcoholics and abusers of powdered cocaine this way, the nation's prisons would be bulging with white inmates."

Supreme Injustice

The Constitution, in Section 2 of Article 3, which establishes the judiciary branch, gives Congress the power to define and limit what the Supreme Court can and can't do. Here's part of the exact language:

“[T]he Supreme Court shall have appellate jurisdiction both as to law and fact, with such exceptions, and under such regulations as the Congress shall make.”

The Congress can control the terms and conditions under which the Supreme Court can rule? Yes, according to the Constitution. The framers of the Constitution wanted the greatest power to be closest to “We the People”—and that's why the entire House of Representatives and a third of the Senate is up for election every two years. Congress is the body in our representative democratic republic that is closest to the people, so that's where they wanted most of the power. That's also why Congress is defined in Article 1 of the Constitution, establishing it as the first among equals.

As Thomas Jefferson wrote in an 1820 letter to William Charles Jarvis, who thought Supreme Court justices should have the power to strike down laws:

“You seem to consider the judges the ultimate arbiters of all constitutional questions; a very dangerous doctrine indeed, and one which would place us under the despotism of an oligarchy. The Constitution has erected no such single tribunal. I know of no safe depository of the ultimate powers of the society, but the people themselves.”

Nowhere in the Constitution does it say that the Supreme Court can strike down laws passed by Congress and signed by the president. Nowhere.

In 1788, Alexander Hamilton wrote a newspaper article, now known as “Federalist No. 78,” stating:

“[T]he judiciary, from the nature of its functions, will always be the least dangerous to the political rights of the Constitution;

because it will be least in a capacity to annoy or injure them. The Executive not only dispenses the honors, but holds the sword of the community. The legislature not only commands the purse, but prescribes the rules by which the duties and rights of every citizen are to be regulated. The judiciary, on the contrary, has no influence over either the sword or the purse; no direction either of the strength or of the wealth of the society; and can take no active resolution whatever. It proves incontestably, that the judiciary is beyond comparison the weakest of the three departments of power; that it can never attack with success either of the other two.”

In 1803, a hard-right-wing Federalist chief justice named John Marshall—who’d been only eleven years old when the Declaration of Independence was written and signed—ruled, in the case of *Marbury v. Madison*, that the Supreme Court could strike down laws as “unconstitutional.” Although the power of “judicial supremacy” over the other two branches had been discussed extensively in the early days of the republic and debated in the constitutional convention, it had been rejected and does not appear in the Constitution. But Marshall took it onto himself and his court, instantly transforming the Supreme Court from “the weakest of the three” to the absolute overlord tribunal. John Marshall had, in effect, turned himself into a king, along with his colleagues on the Supreme Court. No matter what Congress and the president—the other two branches of government—did, the Supreme Court could overturn them. A tiny group of unelected lawyers who, like kings of old, had jobs for life, now controlled the fate and destiny of the United States.

President Thomas Jefferson went apoplectic. He wrote that if that decision wasn’t challenged by Congress:

“[T]hen indeed is our Constitution a complete *felo-de-se* [a suicide pact]. The Constitution, on this hypothesis, is a mere thing of wax in the hands of the judiciary, which they may twist and shape into any form they may please.”

Marshall and the court backed down, at least in appearance. For as long as Jefferson was alive, Marshall never again ruled a law unconstitutional. He never again said that a few unelected judges were the kings of America, with nobody else having the power to undo their decisions.

However most politicians weren’t seeing the long view—they never, in their wildest dreams, imagined that the court would become the final hurdle over which every single law passed by Congress and signed by the

president must leap. As mentioned, the Supreme Court was very wary about using judicial review in its first century. Mostly it just did what the Constitution says it should do—be the final court of appeals in legal disputes and criminal prosecutions, and in issues between the states. The buck has to stop somewhere, and that’s the Supreme Court. But striking down laws? That’s a power only kings have, and in the modern era even most kings in constitutional monarchies don’t have that power. In the United Kingdom, for example, not only does the king (or queen) not have the power to strike down laws, neither does the United Kingdom’s own supreme court. Ditto for the royal family and the supreme court of The Netherlands.

If the Supreme Court can’t decide what is and what isn’t constitutional, then what is its purpose? What’s it really supposed to be doing? The answer to that is laid out in the Constitution in plain black-and-white. It’s the first court where the nation goes for cases involving disputes about treaties, ambassadors, controversies between two or more states, between a state and citizen of another state, between citizens of different states, and between our country and foreign states. Read Article 3, Section 2 of the Constitution—it’s all there. Not a word in there about ‘judicial supremacy’ or ‘judicial review’—the supposed powers of the court to strike down (or write) laws by deciding what is and what isn’t constitutional.

President Thomas Jefferson was pretty clear about that—as were most of the Founders—and the court didn’t start seriously deciding “constitutionality” until after all of them were dead. But back in the day, here’s what Jefferson had to say:

“The Constitution has erected no such single tribunal, knowing that to whatever hands confided, with the corruptions of time and party, its members would become despots. It has more wisely made all the departments co-equal and co-sovereign within themselves. When the legislative or executive functionaries act unconstitutionally, they are responsible to the people in their elective capacity.”

Their elective capacity? That’s a fancy way of saying that the people can toss out on their ass any member of Congress or any president who behaves in a way that’s unconstitutional. The ultimate remedy is with the people—it’s the ballot box. If we don’t like the laws being passed, then we elect new legislators and a new president. It’s pretty simple.

But without the Supreme Court, some say, we never would have had *Brown v. Board of Education* in 1954, which ended apartheid in America, or *Roe v. Wade*, which ended restrictions on abortion in 1973. Maybe. Brown

v. Board of Education was mostly the Supreme Court reversing itself from its own 1886 *Plessy v. Ferguson* decision, which is what established legal apartheid in America. And if the Supreme Court hadn't decided *Roe v. Wade*—remember, the birth control pill had just been invented and brought to market thirteen years earlier and the women's movement in 1973 was in full bloom—then it would have been just a matter of a few years before Congress took care of it. The fact of the matter is that the Supreme Court has never found eternal truths in the Constitution—they just reflect current popular view, and they usually do that with about a twenty-year lag time.

Knowing that if the Supreme Court had not ruled the way they had in *Dred Scott v. Sandford*, the drums of war probably wouldn't be beating, Lincoln let his inner lawyer loose and said right out loud:

“[T]he candid citizen must confess that if the policy of the Government upon vital questions affecting the whole people is to be irrevocably fixed by decisions of the Supreme Court, the instant they are made in ordinary litigation between parties in personal actions the people will have ceased to be their own rulers, having to that extent practically resigned their Government into the hands of that eminent tribunal.”

Although he'd sugar-coated the statement, there it was. Lincoln knew that the entire concept that the Supreme Court could strike down laws passed by Congress and signed by the president was not one of the powers given to it by the Constitution.

Grant's successor, Republican Rutherford B. Hayes, took office under the most dubious of circumstances. Hayes had once been an advocate for enslaved black men seeking freedom. As an attorney in private practice, Hayes had argued dozens of cases on behalf of runaway slaves, often taking on clients offered to him by Levi Coffin, the president of the Underground Railroad. But Hayes sacrificed this principle in order to shore up his path to the White House. After Hayes lost the popular vote to Democrat Samuel Tilden and faced a highly disputed electoral vote, his supporters brokered a deal with Democrats: inaugurate Hayes, and the new president would end Reconstruction. As a result of this deal, federal troops stood down, Louisiana inaugurated a Confederate brigadier general as governor, and former slaves were left only with the Court's admonition to “look to the States” for protection. By the time the sun set on the Hayes administration, Southerners no longer lived under the Constitution of the United States. They lived under the white supremacist Constitution of John Archibald Campbell. And it wouldn't be long before the whole nation would live under the Constitution of Stephen Johnson Field.

On a porch in Colfax, Louisiana, eight wounded men lay shielded from the rain. Close to a decade earlier they'd been enslaved, toiling far away from the site where General Robert E. Lee would soon surrender his army. Five months earlier they'd cast ballots in a rigged election, then watched an ex-Confederate officer declare himself governor of their state. Two weeks back they'd been triumphant, emboldened by a federal judge's order to oust that false governor's loyalists and regain control of their local government from white supremacists. By morning, they would be gunned down by a racist mob.

Eight decades later, in the autumn of Jim Crow, this mob's descendants would erect a historical marker commemorating this massacre: "three white men and 150 negroes were slain" in what the marker deems the "Colfax Riot," bringing the "end of carpetbag misrule in the South."

The events this marker touts—the death of Reconstruction, the birth of Southern apartheid, and the near century of white supremacy that followed—did not simply emerge from a single day's slaughter. They were shepherded into being by one of the most powerful and most malign institutions in American history: the Supreme Court of the United States. Though a federal prosecutor achieved a nearly impossible task—he convinced a jury dominated by Southern white men to convict three members of the Colfax mob of violating the civil rights of African Americans—the Supreme Court tossed out these convictions in *United States v. Cruikshank* (1876). Less than eleven years after Lee's surrender at Appomattox Courthouse, the justices gave their blessing to the campaign of white-on-black terrorism that would define the South for generations.

Prior to the Civil War, most of the rights embraced by the Bill of Rights were not 'rights' in the way we understand that term today. Instead, the Constitution mostly prevented the federal government from taking certain actions against individuals. States, however, remained free to seize people's property without compensation, or to invade people's homes, or to establish an official state religion, just so long as the authorities did so in compliance with their own state's constitution. The Fourteenth Amendment declared, for the first time in the nation's history, that Americans enjoy a broad array of rights simply because they are Americans, and that they keep these rights even as they travel across state lines. In the amendment's words, "no State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States." To ensure that states did not deny these new citizenship rights to freedmen, the Fourteenth Amendment also declared that all persons born in the United States and subject to its laws "are citizens of the United States and of the State wherein they reside," regardless of the station of their parents. And it proclaimed that there are

some rights that citizens and foreigners both enjoy simply because they are human. No state may “deprive any person of life, liberty, or property, without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws.”

Though modern-day scholars disagree about what, exactly, the “privileges or immunities of citizens of the United States” are, the primary author of the Fourteenth Amendment had a fairly clear idea. In the words of that author, Ohio Republican Congressman John Bingham:

“The privileges or immunities of citizens of the United States, as contradistinguished from citizens of a State, are chiefly defined in the first eight amendments to the Constitution of the United States. These eight articles I have shown never were limitations upon the power of the States, until made so by the fourteenth amendment.”

Thus, Bingham believed that his amendment would, for the first time, forbid the states from violating the Bill of Rights. Yet Bingham’s amendment was also fundamentally flawed. Whatever the Ohio lawmaker might have wished it to accomplish, the amendment’s naked text offers no hint as to what the “privileges or immunities of citizens of the United States” could be. Similarly, it speaks in broad, undefined terms like “liberty” and “due process,” then leaves the reader to guess what exactly these words mean as well. By writing such open-ended language into the Constitution, Bingham and his fellow lawmakers delegated sweeping authority to the Supreme Court of the United States, as the power to interpret these and other ambiguous phrases within the Constitution ultimately rests with the justices who sit on that Court.

The few men and even fewer women entrusted with this power have not often wielded it wisely:

- The Court spent the first three decades after the Civil War paving the way for Jim Crow, and it spent the next four decades shielding employers from laws protecting their workers from exploitation.
- The justices held that Americans could be forced into concentration camps based on nothing more than their race, and that women could be sterilized at the state’s command.
- They held that children could be made to work in a cotton mill for as little as ten cents a day.

- They relegated countless adults to dank sweatshops and deadly factories, with neither a union nor a minimum wage to protect them.
- They gave billionaires a far-reaching right to corrupt American democracy, and neutered much of America's most important voting rights law.

And, throughout all of this history, the justices frequently ignored rights that are explicitly protected by the text of the Constitution. During World War I, for example, Congress enacted a sweeping censorship law that banned many forms of “disloyal” speech and even prohibited Americans from displaying the German flag. Yet the Supreme Court showed little sympathy for the view that the First Amendment’s “freedom of speech” protects individuals who speak out against their government during wartime. The Court held in a unanimous opinion:

“When a nation is at war, many things that might be said in time of peace are such a hindrance to its effort that their utterance will not be endured so long as men fight, and that no Court could regard them as protected by any constitutional right.”

The justices, in other words, have routinely committed two complementary sins against the Constitution. They’ve embraced extra-constitutional limits on the government’s ability to protect the most vulnerable Americans, while simultaneously refusing to enforce rights that are explicitly enshrined in the Constitution’s text. And they paved a trail of misery as a result. Few institutions have inflicted greater suffering on more Americans than the Supreme Court of the United States.

“A just court will, at times, order an infamous man or woman to be freed from prison. It will shield hated minorities from their community’s rage. And it will bring many of the nation’s wealthiest and most powerful interests to heel before the law.”

In 1899, Field joined the Supreme Court’s nearly unanimous decision in *Plessy v. Ferguson*, the segregated railcar decision that held that:

“The enforced separation of the races neither abridges the privileges or immunities of the colored man, deprives him of his property without due process of law, nor denies him the equal protection of the laws.”

An 1888 act prohibiting Chinese laborers who departed the United States from returning, even if they'd previously been issued a certificate by the federal government granting them permission to do so was upheld by the Supreme Court in a unanimous decision written by Justice Field.

We typically think of the Thirteenth as only abolishing slavery. Section 1 of the Thirteenth Amendment does so, and Section 2 empowers Congress to enforce Section 1. In 1866, Congress enforced the abolition of slavery by passing a Civil Rights Act, prohibiting actions that it deemed perpetuated the characteristics of slavery. Actions that made African Americans second-class citizens, such as racial discrimination in housing, were included in the ban. In 1883, though, the Supreme Court rejected this congressional interpretation of its powers to enforce the Thirteenth Amendment. The Court agreed that Section 2 authorized Congress to "to pass all laws necessary and proper for abolishing all badges and incidents of slavery in the United States," but it did not agree that exclusions from housing markets could be a "badge or incident" of slavery. In consequence, these Civil Rights Act protections were ignored for the next century.

There were many specific government actions that prevented African Americans and whites from living among one another, and I categorize them as 'unconstitutional.' In doing so, I reject the widespread view that an action is not unconstitutional until the Supreme Court says so—they don't have that right only the people do. Few Americans think that racial segregation in schools was constitutional before 1954, when the Supreme Court prohibited it. Rather, segregation was always unconstitutional.

Yet even if we came to a nationally shared recognition that government policy has created an unconstitutional, *de jure*, system of residential segregation, it does not follow that litigation can remedy this situation. Although most African Americans have suffered under this *de jure* system, they cannot identify, with the specificity a court case requires, the particular point at which they were victimized. For example, many African American World War II veterans did not apply for government-guaranteed mortgages for suburban purchases because they knew that the Veterans Administration would reject them on account of their race, so applications were pointless. Those veterans then did not gain wealth from home equity appreciation as did white veterans, and their descendants could then not inherit that wealth as did white veterans' descendants. With less inherited wealth, African Americans today are generally less able than their white peers to afford to attend good colleges.

If one of those African American descendants now learned that the reason his or her grandparents were forced to rent apartments in overcrowded urban areas was that the federal government unconstitutionally and unlawfully

prohibited banks from lending to African Americans, the grandchild would not have the standing to file a lawsuit; nor would he or she be able to name a particular party from whom damages could be recovered. There is generally no judicial remedy for a policy that the Supreme Court wrongheadedly approved.

But this does not mean that there is no constitutionally required remedy for such violations. It is up to the people, through our elected representatives, to enforce our Constitution by implementing the remedy. By failing to recognize that we now live with the severe, enduring effects of *de jure* segregation, we avoid confronting our constitutional obligation to reverse it. If I am right that we continue to have *de jure* segregation, then desegregation is not just a desirable policy; it is a constitutional as well as a moral obligation that we are required to fulfill. ‘Let bygones be bygones’ is not a legitimate approach if we wish to call ourselves a constitutional democracy.

More than five-hundred injunctions were issued against workers or labor unions just in the final two decades of the nineteenth century. By the 1920s, after watching an entire generation of judges’ efforts to thwart the labor movement, American Federation of Labor president Samuel Gompers warned:

“Those who seek to retain the injunction evil and to expand it are doing the greatest disservice to our system of jurisprudence, and in fact to our system of democratic government.”

To judges who shared Justice Brewer’s mindset, unions were no less odious than the governments that sought to control market forces—in fact they were in many ways viewed as more dangerous. Unions were not, in these judges’ minds, coalitions of labor market participants joining together to improve their position at the bargaining table; they were competitors to the judiciary itself. The judicial decisions of this era routinely used words such as ‘tyranny’ and ‘dictatorship’ to describe unions engaged in strikes or boycotts. Unions would declare employers to have sinned against the rights of workers, then impose sanctions upon those employers in much the same way that courts imposed consequences on lawbreakers. In this sense, Brewer and many of his fellow jurists perceived unions as creating their own alternative system of law—a law of labor, by labor, and for labor—that threatened to tear down the primacy of the law applicable in their courts. This is why Justice Brewer’s opinion in the *Debs* case proclaims that the American Railway Union exercised “powers belonging only to government” when it tried to separate the Pullman Company from the channels of interstate commerce. The courts must have the authority to reclaim their own dominance.

Yet, in endorsing the steps taken to put down the strike, the Court asserted a simply breathtaking vision of its own power. The lower court that issued the injunction against the union relied largely on the Sherman Antitrust Act to justify its decision. Justice Brewer's opinion, by contrast, relied on the law of "nuisance," a judge-made doctrine typically associated with property rights. Essentially, Brewer's opinion established that federal courts could issue sweeping injunctions with nationwide implications upon their own authority, regardless of whether elected officials had actually given them that power.

No fair judge could have laid the full blame for the strike's disruptiveness at the union's feet. Pullman's workers chose to strike, but the Pullman Company made the decision to slash wages and increase dividends. The union chose to boycott, but it was the Managers who decided to intentionally disrupt their own train lines in order to turn the public against the union. The first stone was cast, not by a striking worker, but by a nameless thug—and that stone was met by bayonets ordered onto the scene by the President of the United States himself. The workers and their union resorted to disruptive tactics only because they had nothing else to fall back on. And with each escalation, management met them with overwhelming, even deadly, force. When the Pullman Strike came to an end, Eugene Debs went to jail. The local union leaders were blacklisted. And Pullman's remaining workers returned at the same meager wages that triggered the strike. Meanwhile, the railroad barons went back to their mansions, where they remained among the wealthiest and most powerful men in the nation. And the Supreme Court said this was right. Justice Brewer's opinion in Debs was unanimous.

In the wake of the Pullman Strike, Congress enacted a law prohibiting railroads from firing workers solely because they belonged to a labor union. Because this law applied solely to railroads, which are, by their very nature, engaged in transportation and not manufacturing, it should have been well within Congress's authority even under the line drawn in the Sugar Trust Case. Yet the Court struck down this law in 1908, declaring that "labor organizations have nothing to do with interstate commerce" even if every single member of the union is engaged in interstate commercial activity.

Similarly, after Congress enacted a law protecting collective bargaining and similar rights for coal miners, the justices struck down this law, in 1936, on the grounds that mining coal has nothing to do with selling coal. Eleven years earlier, however, when a mining executive's attempt to de-unionize one of his mines broke out into an armed conflict between labor and management, the Supreme Court decided that it was perfectly acceptable for the federal government to regulate mining workers—at least when the regulation benefited management.

In the early years of the twentieth century, wedge-shaped buildings dotted the “hard coal counties” of Pennsylvania, where heavy lumps of anthracite coal were crushed into marketable pieces. There, at the top of each wedge, iron rollers broke the coal and elaborate screens sorted it by size. Meanwhile, underneath this operation, machines of a different kind culled rock and slate from an endless stream of crushed coal pouring down the inside of the wedge. There, engulfed by clouds of black dust, dozens of children filled each of these coal “breakers,” where they earned as little as forty cents a day for ten hours of labor. Chutes flowing with black anthracite formed the bowels of these breakers, while boys as young as eight years old sat on planks watching the stream of minerals flow by their feet. Their job was to spot stray pieces of slate and other detritus that could impurify coal shipments and decrease their value. Men with sticks patrolled the boys, smacking the heads or shoulders of any boy who appeared to be slacking.

Anthracite is difficult to distinguish from slate when it is constantly flowing by your feet in a rapidly moving stream—and when you are working in a room blackened with coal dust—so the boys bent low over the chutes to tell valuable coal from worthless slate. After just a few years of such labor, their backs began to hunch, their shoulders grew round, and their chests grew narrow. As one visitor to the breakers observed, “most of them become more or less deformed and bent-backed like old men.” When it was cold, the breakers were barely heated, so the boys donned scarves and hats and, if they could afford them, overcoats. Gloves, however, were forbidden, because the boys’ jobs depended so much upon their sense of touch. At the end of the workday, even if they were bathed and costumed in the garb of a mine owner’s son, a breaker boy could be immediately identified by his bleeding fingers and fingernails worn down to the quick by repeatedly plunging into the streams of hard coal. Many of these boys lost fingers. Some of them had entire limbs torn off by the machinery that drives the coal forward. Others slipped and fell down the refuse chutes—where, if they survived the fall, they were smothered to death by the piles of slate tossed in behind them.

Unlike the breakers, which operated only during the day, the silk mills ran day and night, with the girls divided into two twelve-hour shifts. The mills were kept moist and hot, and the girls emerged from this environment into the chilly Pennsylvania air at the end of their winter shifts. Tuberculosis and bronchial diseases ran rampant through the young workforce, as did anemia. And the work itself was no less physically demanding than the conditions imposed upon the breaker boys. As one girl described life in the mills:

“When I first went to work at night, the long standing hurt

me very much. My feet burned so that I cried. My knees hurt me worse than my feet, and my back pained all the time. Mother cried when I told her how I suffered, and that made me feel so badly that I did not tell her any more. It does not hurt so much now, but I feel tired all the time. I do not feel near as tired, though, as I did when I worked all night. My eyes hurt me, too, from watching the threads at night. The doctor said they would be ruined if I did not stop the night work. After watching the threads for a long time, I could see threads everywhere. When I looked at other things, there were threads running across them. Sometimes I felt as though the threads were cutting my eyes.”

In the unregulated stamping works of George Pullman’s Chicago, boys were handed a short iron poker and tasked with keeping an endless series of cans in line as they traveled through a vat of molten metal solder. Though the boys wrapped their hands in cloth to protect them from the melted metal, this shielded them from little more than the most minor burns. The briefest splash would often cost a young boy his hand.

Nicotine poisoning ran rampant through the children employed by Chicago’s nearby cigar factories, and the gilding that many child workers applied to picture frames stiffened their fingers and left them susceptible to throat disease. In the carpet factories of New York and Pennsylvania, child laborers soaked themselves in toxic dyes. One boy opened his shirt to a reporter to reveal a chest and stomach dyed a deep crimson. Others walked home night after night in clothes dripping with the red, blue, or green dye they’d worked with during their shift, leaving a brightly colored trail behind them in the snow. Children employed as varnishers in furniture factories inhaled poison fumes that led to a variety of intestinal maladies. Children in wallpaper factories slowly poisoned themselves with toxic paints. Naphtha fumes produced in the manufacture of rubber goods led to paralysis and decay. Children in leather works handled nauseating chemicals. Boys and girls working in match factories became sick with phosphorous necrosis—known as “phossy jaw”—a kind of gangrene of the lower jaw. Lead poisoning abounded in boys employed by foundries and stereotype printing operations.

And even in workplaces where the air was clean and the dangers were readily apparent, children were endangered by the sheer exhaustion their long shifts worked upon their growing bodies. In a 1909 court case, a thirteen-year-old boy employed by an Indiana steel mill literally passed out with his leg crossing the rail of a track used to transport iron to his employer’s furnaces. The boy had worked more than a week’s worth of

fourteen-hour night shifts in a row, and he remained unconscious with his leg across the track until it was crushed by a passing iron cart.

Child labor was as much a Northern problem as it was a Southern problem, but in the South, cotton mill managers spoke openly of their hope that someday nearly all men would be unemployed—replaced by relatively cheap women workers and even cheaper children. A young boy would enter the mill at age six, earning as little as ten cents a day for his labor, grow to become a father himself, and eventually be laid off and replaced by his own six-year-old son.

Though conditions inside the Southern mills were by no means harsher than those facing many child laborers in the North—indeed, they were often relatively safe compared to the poisonous, fire-filled environments of many Northern factories—conditions outside the mills gave the mill owners far greater ability to line their pockets at children's expense. Unlike the North, where decades of industrialization and railroad construction gave parents at least some ability to seek work in communities where they would not toil alongside their young children, much of the Southern economy was little more than poor farmers barely earning enough to feed and clothe their families. A handbill circulated by a North Carolina cotton mill relied on the misery of nearby farmers' lives to recruit entire families:

“While you are on the farm toiling in rain and snow, feeding away what you have made during the summer and making wood to keep fires to keep your family from freezing, you could at the same time be in a cotton mill and in a good comfortable room, making more than you can make in the summer time on the farm. At the mills, children over 12 years old, after they learn their job, can make more than men can make on farms.”

Northern capital had almost as much of a stake in the South's mills as did Southern investors. One investigation of twenty-four Alabama mills found that eleven of them were owned by Northerners—and the Northern-owned mills employed twice as many children under twelve as those owned by Southern capital. Massachusetts, which barred child labor outright before the age of fourteen, had some of the strictest child labor laws in the nation. But wealthy Bostonians could evade these laws simply by shipping their capital down South.

Senator Augustus Bacon, a Confederate army veteran representing the state of Georgia, warned that if Congress had the “arbitrary power” to address child labor, its ability to control American lives would be “practically unlimited.” This claim—that if Congress has the power to enact a particular

piece of legislation, then there would be no practical limit on its authority to enact other laws—would prove to be a common refrain repeated over and over again by opponents of progressive reform in the twentieth and twenty-first centuries.

Judges, and the lawyers who someday become judges, are creatures of precedents and common law rules that developed through a slow, deliberative process, often over the course of hundreds of years. This breeds a kind of conservatism that is less rooted in anti-government ideology than it is in traditionalism.

“Lawyers are secretly opposed to the instincts of democracy; their superstitious respect for what is old, to its love of novelty; their narrow views, to its grandiose plans; their taste for formality, to its scorn for rules; their habit of proceeding slowly, to its impetuosity. If you ask me where American aristocracy is found, my reply would be that it would not be among the wealthy who have no common link uniting them. American aristocracy is found at the bar and on the bench.”

Admittedly, the legal profession’s aristocratic character began to fade after state lawmakers started relaxing the requirements necessary to be admitted to the bar during the early 1800s. By the second half of the nineteenth century, however, these relaxed requirements led to a kind of class struggle between old-line aristocratic lawyers and the less-refined crop of men, many of them immigrants, who began earning a living as attorneys.

The American Bar Association (ABA) was founded in 1878 largely as an effort by the “best men” of the bar to reassert control over their profession, in part by raising the standards of legal education and other requirements necessary to become an attorney. Indeed, the ABA was largely the brainchild of one of the most pedigreed members of the legal profession—Simeon Baldwin, a Yale Law School professor and son of a former United States senator. Baldwin would go on to serve as chief justice and then governor of Connecticut. Laissez-faire attitudes were hardly uncommon among the men who heeded Baldwin’s call to organize America’s elite attorneys under a single bar association. Tiedeman and Brewer were both early members of the ABA, as were several very conservative lawyers who would later serve on the Supreme Court. But the prevailing attitude among these legal elites was less one of generalized skepticism about government and more a fear of rapid change. The first president of the ABA, compared the development of the law to the slow, Darwinian process of natural selection.

To legal elites who believed that the proper development of the law takes centuries, legislatures—with their power to cast aside longstanding principles

of the common law and replace it with an entirely novel legal regime—were downright terrifying. One early ABA president proclaimed that the United States could “endure all its other dangers with less apprehension than the action of its federal and state legislation inspires.” Another ABA president fretted that “when a state legislature meets, every great corporation within its reach prepares for self-defense, knowing by bitter experience how hospitably attacks upon its property are received in committees and on the floor.” ABA speakers labeled elected lawmakers as reckless politicians who truckled for the unthinking vote; social agitators who sought office for self advantage, not for the public weal; and professional demagogues who filled the land with ill-considered and impractical theories and engaged in gross, persistent, flagrant, and sometimes corrupt dereliction. The judiciary offered these legal elites the gradual, evolutionary process they found so comforting, whereas democracy represented the greatest single threat to this gradualism. In their minds, longstanding principles of the common law had served Americans and their English forefathers well for generations, so why should upstart lawmakers be allowed to simply cast these principles aside?

If there was any doubt left that the most well-to-do Americans had a friend in the Fuller Court, that doubt was eliminated by Fuller’s decision in *Pollock v. Farmers’ Loan & Trust*, which was handed down in the few short months between Debs and the Sugar Trust decision.

The income tax that Cleveland begrudgingly accepted as the price of tariff reform was quite modest. The tax exempted the first \$4,000 in income, more than \$100,000 in modern dollars, and only required taxpayers to contribute two percent of their income beyond that point. In total, only the wealthiest one-tenth of one percent of all Americans would pay this tax, contributing less than four percent of the nation’s revenues. Yet Fuller’s Court viewed even this modest tax as unconstitutional, and they relied on one of the Constitution’s most confusing distinctions in order to strike it down.

As originally drafted, the Constitution forbade any “direct” tax from being laid by Congress “unless in proportion to the census.” So if the state of New York housed seven percent of the nation’s population, its citizens must pay exactly seven percent of any direct taxes enacted by federal law. Thus, if an income tax qualified as a “direct” tax, such a tax would be practically impossible to administer in the United States, as it would require the federal government to calculate and recalculate how much money it could raise from each state and enact a different tax system in each state to achieve that goal.

Moreover, as Fuller’s opinion in *Pollock* makes perfectly clear, even the nation’s founders were unsure what constituted a “direct” tax as opposed

to some other form of taxation. Fuller devotes nearly fourteen pages of his opinion to conflicting quotes from prominent early Americans struggling to define the term ‘direct tax.’ Future Chief Justice Marshall defined a direct tax as a tax on “lands, slaves, stock of all kinds, and a few other articles of domestic property,” while Alexander Hamilton defined it more broadly to include “capitation or poll taxes, taxes on lands and buildings, general assessments, whether on the whole property of individuals, or on their whole real or personal estate.” Justice Samuel Chase, by contrast, doubted that taxes on “personal property” qualified as direct taxes. And Justice James Iredell seemed to agree that only a “land or poll tax” can be considered direct taxation. Theodore Sedgwick, a delegate to the Philadelphia Convention and future Speaker of the House, offered the unique view that taxes on “objects of luxury” could never be direct taxes—a view that was soundly mocked by James Madison.

In other words, the only thing that was clear from Fuller’s lengthy catalog of quotes from the framers and their contemporaries was that the Founding Fathers themselves had no clear idea what distinguishes a ‘direct’ tax from an ‘indirect’ one. And yet Fuller concludes his list of quotations with one of the least self-aware passages ever to appear in a Supreme Court opinion:

“From the foregoing it is apparent:

1. That the distinction between direct and indirect taxation was well understood by the framers of the Constitution and those who adopted it.
2. That under the state systems of taxation all taxes on real estate or personal property or the rents or income thereof were regarded as direct taxes.”

The upshot of this opinion was that income from capital—be it land, stock, or commodities—was immune to taxation, but income from wages was not. John D. Rockefeller could sit in his office watching money pour in from his investments, the whole time comfortable in the knowledge that this income could never be taxed. His lowest-paid worker enjoyed no such security. Indeed, in a concurring opinion, an elderly Justice Field was quite direct about the fact that he would declare this income tax unconstitutional specifically to protect the wealthy.

“The present assault upon capital is but the beginning. It will be but the stepping-stone to others, larger and more sweeping, till our political contests will become a war of the poor against the rich; a war constantly growing in intensity and bitterness.”

Pollock was a massive departure from precedent.

Six years after New York placed a limit on bakers' hours, the state fined a bakery owner named Joseph Lochner fifty dollars for overworking an employee. Four years later, Lochner's case reached the Supreme Court. Yet, despite the fact that it took a decade for the maximum-hours law to reach the justices, the fact that the law was doomed became obvious the moment Chief Justice Fuller announced that Justice Rufus Peckham would deliver the Court's opinion in *Lochner v. New York*.

Fuller and Peckham were, in many ways, ideological twins. Just as Fuller opposed the Emancipation Proclamation and tried to prohibit federal incursions upon slavery as an Illinois state lawmaker, the young Rufus Peckham was a Democrat who opposed secession but who also had no love for black slaves. "I am proud I believe in no negro equality," Peckham wrote his brother the same month Abraham Lincoln was elected president. Two years later he railed against "the radical abolitionists" who were "making it a war for the freedom of the slaves, in spite of the Constitution and if necessary in spite of the Union."

Peckham remained similarly dismissive of African Americans after becoming a judge. As a justice, Peckham voted to uphold segregation in *Plessy*. He sided with Alabama's suspicious decision to prevent over five-thousand black citizens from registering to vote. And he backed a Georgia county's plan to tax black families to pay for white schools without providing similar school facilities to black children—although, in keeping with the frequent disregard of turn-of-the-century justices for civil rights, the Court's decision in *Cumming v. Richmond County Board of Education* was unanimous.

His most revealing race case, however, may be a silent dissent Peckham offered on behalf of a skating rink owner claiming that a law prohibiting race discrimination in "places of amusement" violated the owner's supposed right to do what he wanted with his property. Though Peckham did not explain why he believed the rink owner should have the right to deny admission to black patrons, his dissenting vote matched a long record of skepticism regarding the power of elected officials to rein in business. Peckham's laissez-faire outlook animated even the most routine cases he heard as a state court judge. When a fourteen-year-old girl employed by a laundry crushed her hand between the two heavy rollers of a machine used to press collars, Peckham scoffed at the idea that her employer had any obligation to prevent such accidents or to compensate the victims of such injuries. By merely "accepting this work and entering upon the employment about this machine," the young girl assumed the risk that she might be injured by it. According to Peckham, workers like this permanently disabled girl "cannot call upon the defendant to make alterations to secure greater safety."

Justice Peckham, like Chief Justice Fuller, owed his high position to his friendship with the conservative President Grover Cleveland. Early in Cleveland's first term in the White House, the new president exerted his considerable influence in his home state of New York to help place Peckham on the state's highest court. Nearly a decade later, Cleveland favored his friend with an appointment to the nation's highest Court.

Yet, for all that the two justices shared in common, Peckham was, if anything, even more conservative than the chief justice. Seven years before *Lochner* reached the Supreme Court, a mine owner brought a similar lawsuit challenging a Utah maximum-hours law governing miners. Even Fuller agreed that this law was constitutional, joining six of his colleagues in deferring to the state legislature's determination that the hazards of mine work required a shorter work day. Peckham and the archconservative Justice Brewer found themselves in a lonely dissent.

And Peckham combined his staunch conservatism with an overarching distrust of democracy. When the city of Buffalo passed an ordinance replacing several gas street lamps with electric lighting, Peckham responded with a dissenting opinion, calling this act a "plain, bald, useless waste of the property or funds of the public" and insisting that his court should keep the gas lighting in place. To Peckham, even a question as routine as whether a particular avenue should be lit by gas flames or lightbulbs cannot be trusted to elected officials, and it was the sacred duty of judges to veto those officials' decisions if the judges deemed them unwise. No other judge joined Peckham's dissent in the electric lights case.

In other words, Peckham was the perfect justice to take up the crusade against "the absolutism of a democratic majority" and to write Justice Field's conservative vision into the Constitution. Six years after Field's death and just eight years after his retirement from the bench, *Lochner v. New York* would be more than just a victory for Joseph *Lochner*, it would be the culmination of Field's life's work.

Peckham's *Lochner* opinion in many ways maps the state court opinions invalidating attempts to better the lot of workers. Just as the Wisconsin justices read a right to be bound by some of the most oppressive labor contracts into their state constitution's invocation of the word 'liberty,' Peckham found a similar freedom from laws improving workplace conditions within the Fourteenth Amendment's vague language. "The general right to make a contract in relation to his business is part of the liberty of the individual protected by the Fourteenth Amendment of the Federal Constitution," Peckham wrote—despite the fact that this so-called right is never mentioned in this amendment—so judges must treat any effort to protect workers from exploitation with great skepticism.

Although the *Lochner* opinion did place some limits on this extra-constitutional right to contract, Peckham showed nothing but scorn for the idea that protecting workers is, in and of itself, a legitimate task for lawmakers. In Peckham's mind, "the question whether this act is valid as a labor law, pure and simple, may be dismissed in a few words. There is no reasonable ground for interfering with the liberty of person or the right of free contract" by preventing bakeries from overworking their bakers. Peckham also had no sympathy for the fact that a poor tenement dweller with no means to buy his own bread is hardly in a position to negotiate for decent wages or reasonable hours. "There is no contention," the *Lochner* opinion asserts, that bakers are unable to "care for themselves without the protecting arm of the State."

In reality, of course, New York's bakers worked fourteen-hour shifts in roach-infested basements, slept on their work tables, and then woke up the next day to do it again before the "protecting arm of the State" intervened.

Though *Lochner* deemed mere sympathy for workers to be an illegitimate impulse on the part of lawmakers, Peckham did leave the door open to some forms of labor regulation. Laws protecting the "safety, health, morals, and general welfare of the public" were still permitted under *Lochner*. So a state could still, in theory, protect workers from injury or disease.

Yet even this limited universe of health and safety laws could be vetoed by the courts. As Justice John Marshall Harlan explained in a dissenting opinion, many turn-of-the-century health researchers believed that bakeries were unusually unhealthy work environments, and that bakers' health risks were exacerbated by long hours.

"The constant inhaling of flour dust causes inflammation of the lungs and of the bronchial tubes. The eyes also suffer through this dust, which is responsible for the many cases of running eyes among the bakers. The long hours of toil to which all bakers are subjected produce rheumatism, cramps, and swollen legs. The intense heat in the workshops induces the workers to resort to cooling drinks, which together with their habit of exposing the greater part of their bodies to the change in the atmosphere, is another source of a number of diseases of various organs. Nearly all bakers are pale-faced and of more delicate health than the workers of other crafts, which is chiefly due to their hard work and their irregular and unnatural mode of living, whereby the power of resistance against disease is greatly diminished. The average age of a baker is below that of other workmen; they seldom live over their fiftieth year, most of them dying between

the ages of forty and fifty. During periods of epidemic diseases the bakers are generally the first to succumb to the disease, and the number swept away during such periods far exceeds the number of other crafts in comparison to the men employed in the respective industries. When, in 1720, the plague visited the city of Marseille, France, every baker in the city succumbed to the epidemic, which caused considerable excitement in the neighboring cities and resulted in measures for the sanitary protection of the bakers.”

Peckham, however, dismissed these risks.

“It might be safely affirmed that almost all occupations more or less affect the health, but there must be more than the mere fact of the possible existence of some small amount of unhealthiness to warrant legislative interference with liberty.”

Having dismissed the evidence that too many hours working in a bakery was unhealthy, Peckham then wrote the fear of democracy into the Constitution itself:

“It is unfortunately true that labor, even in any department, may possibly carry with it the seeds of unhealthiness. But are we all, on that account, at the mercy of legislative majorities?”

The upshot of this debate was that workplace health and safety laws were allowed, but only at the sufferance of unelected judges. Rufus Wheeler Peckham had no popular mandate to legitimize his exercise of power. He also had neither training as a physician nor any background in the sciences. Yet he took it upon himself to decide which workplaces were healthful and which ones dangerous enough to justify state intervention. And his opinion in *Lochner* was an invitation for every other judge in the country to do the same.

It is worth noting that not every judge, or even every justice who joined the majority opinion in *Lochner*, was as skeptical of government action as Justice Peckham. Though judges like Peckham weren't exactly rare during the decades surrounding the *Lochner* decision, a more subtle philosophy drove many of Peckham's contemporaries as well.

In the end, it took an alliance of two very different kinds of conservatives to produce opinions like *Lochner*: those who viewed democracy as a threat to liberty and those who believed, that society must show “infinite caution” before tearing down longstanding institutions. The lawyers and judges of

this era did not need to be disciples of Christopher Tiedeman—although many of them were—in order to stand athwart democracy and yell, “stop!” They just had to be protective of a legal regime that was designed for an era when it took four months to travel from New York to California.

The fact that not every justice who agreed with *Lochner*’s result shared an unforgiving ideology sometimes meant that plaintiffs invoking the so-called “liberty of contract” doctrine did not prevail. Indeed, *Lochner*’s most strident modern-day apologist defends the opinion on the grounds that the Supreme Court upheld most of the laws challenged under this doctrine. Yet, while this claim may be true, it is too dismissive of the sweeping impact of many decisions that did strike down laws protecting workers—or the completely arbitrary reasoning that the justices would often apply when deciding whether a law violates *Lochner*’s freedom to contract.

Carrie Buck was an imbecile, and the mother and the daughter of an imbecile to boot. In the words of the superintendent of the state mental institution where Buck was sent to live as a young woman, her family belonged “to the shiftless, ignorant, and worthless class of antisocial whites of the South.” And, perhaps worst of all, Buck was promiscuous—a trait that was alone sufficient reason to have her institutionalized. Indeed, the evidence of Buck’s promiscuity was hard to deny as it literally grew inside her. At the age of seventeen, Carrie Buck was pregnant, and she needed to be sent away. This is the picture of the young woman that would reach the justices sitting 150 miles away from her new institutional home near Lynchburg, Virginia. It also bore no resemblance to reality. Indeed, Buck’s case would come to symbolize the dangers of judicial inaction no less than *Lochner* stood for judicial overreach.

Taken together, the two cases reveal just how drastically judges empowered to decide the scope of constitutional rights can miss their mark. The justices invented a right to work long hours for little pay virtually out of thin air, yet they could not move themselves to stop one of the most intrusive invasions of a woman’s liberty in all of American history. Far from falling behind her peers intellectually, Buck performed quite well in school. Rather than claiming Buck could be intellectually disabled, a teacher wrote a note indicating Buck was a strong student—“very good-deportment and lessons”—her final year in school. Though Buck was forced to drop out during the sixth grade, this had little to do with her so-called “feeble-mindedness” and far more to do with her living conditions.

Carrie Buck’s father died shortly after her birth in 1906, and she was removed from her mother Emma’s care and placed in a foster home at the age of three. Her foster family, however, viewed her as little more than an indentured servant. The younger Buck’s foster parents, a couple named J.T.

and Alice Dobbs, pulled her out of school so she would have more time to focus on the household chores they assigned to her—and so that Buck could be loaned out to the neighbors. And Buck was not promiscuous. She was raped. By her foster mother’s nephew. Carrie Buck spent her entire young life being used for others’ purposes. She was used by the Dobbsses as an unpaid servant. She was used by Alice Dobbs’s nephew for sex. And she would soon be used to legitimize a nationwide effort to create an American master race.

Heredity, according to a Virginia law enacted just two months after Buck was institutionalized, “plays an important part in the transmission of insanity, idiocy, imbecility, epilepsy, and crime.” Therefore, the solution to imbeciles or criminals was to remove them from the gene pool entirely. Less than a year after arriving at the Virginia State Colony for Epileptics and Feeble-minded in 1924, Carrie Buck would be given a show trial intended to prove that she was genetically unsuited for breeding. Her attorney would be one of the state’s leading supporters of eugenics—selected for his willingness to collude with the Colony’s officials and to work against his client. One of the star witnesses at this trial was a nurse who would diagnose Carrie’s eight-month-old daughter as a “not quite normal baby” based upon little more than “a look about” baby Vivian Buck. Another key witness was a mental hospital director who moonlighted as a poet composing rhyming couplets about eugenics:

Oh why do we allow these people
To breed back to the monkey’s nest
To increase our country’s burdens
When we should only breed the best?

His testimony would liken Carrie Buck to a lame mare or a stunted pig—the farmer “breeding his hogs, horses, cows, or sheep selects a thoroughbred.” So why is it that “any sort of seed seems good enough” when human beings breed? In just five hours of testimony, lawyers, doctors, social workers, and eugenicists erased any trace of a perfectly intelligent young woman born into unfortunate circumstances, and recast her as the second of three generations of feeble-minded offspring. Yet, although the result of Carrie Buck’s trial was all but predetermined, her fate was sealed by a much higher Court. In its nearly unanimous decision in *Buck v. Bell*, the Supreme Court proclaimed that “three generations of imbeciles are enough.” Five months later, a surgeon cut Carrie open and removed her fallopian tubes.

In the end, Sutherland’s decisions, and the decisions of the other justices willing to declare forced sterilization sacred and the minimum wage profane,

reveals the tragic flaw at the core of the Fourteenth Amendment. By describing the scope of American's individual rights in such imprecise terms—What are the “privileges or immunities of citizens”? What is the “liberty” that cannot be denied “without due process of law”?—the drafters of this amendment delegated the power to define these rights to the nine justices on the Supreme Court. And those nine men were so inapt to the task that they placed the right to be exploited by a rapacious employer on a higher plane than a woman's right to do what she wants with her own body. The same justices who embraced *Lochner's* fabricated freedom to contract also placed this imaginary right on a higher plane than many rights that were explicitly laid out in the Constitution itself. The *Lochner* Era was not simply an age when the justices seized the power to censor economic regulation, for example; it was also one of the high points of an entirely different form of censorship. Though the Constitution's First Amendment explicitly protects every American's right to speak freely, the justices who were so active in striking down progressive labor laws could not actually be bothered to enforce the right to speak out against the government.

Congress voted by a wide margin to give Wilson his declaration of war, and then they gave him far more. By the time the Allied Powers met at Versailles to sketch out the terms of Germany's surrender, Congress had made it a crime to “willfully utter, print, write, or publish any disloyal, profane, scurrilous, or abusive language” about America's Constitution, its military, its flag, or its form of government. Or to argue against the draft. Or to publicly claim that Germany was on the right side of the First World War. Indeed, the mere act of displaying a German flag could be punished by up to twenty years in prison. “May God have mercy” on dissenters, Attorney General Thomas Gregory proclaimed, “for they need expect none from an outraged people and an avenging government.” At Gregory's urging, armies of volunteers arose not just to fight the enemy abroad, but to spy on potential dissidents at home. The American Protective League employed literally hundreds of thousands of members to report rumors of disloyal neighbors directly to the Justice Department. Other, smaller groups bore names such as the “Knights of Liberty,” the “Sedition Slammers,” and the “Boy Spies of America.” Gregory bragged that these domestic spies enabled the government to “to keep scores of thousands of persons under observation.”

The nation's judges were no more merciful than Gregory and his prosecutors. The editor of a Jewish socialist newspaper received ten years in prison for uttering these twelve words:

“I am for the people and the government is for the profiteers.”

Thirty German Americans were convicted for asking South Dakota's governor to reform Selective Service procedures and threatening to vote for his opponent if he refused to do so. A filmmaker, who produced a movie about the Revolutionary War that depicted British soldiers committing atrocities, received a ten-year sentence. "History is history, and fact is fact," the trial judge wrote about the film, but "this is no time" for films that may sow seeds of "animosity or want of confidence between us and our allies."

"To be consistent with its revolutionary character and true to its international principles the party is morally bound to stand squarely against every war save and alone the war against war, the war of the world's enslaved and exploited workers against the world's enslaving and exploiting masters.

I realize that, in speaking with you this afternoon, there are certain limitations placed upon the right of free speech. I must be exceedingly careful, prudent, as to what I say, and even more careful and prudent as to how I say it."

Nevertheless, Debs also acknowledged that he had freely chosen to go to jail before he would silently comply with the Wilson administration's censors:

"I would rather a thousand times be a free soul in jail than to be a sycophant and coward in the streets."

This was the law that the Supreme Court had made by the onset of the Great Depression. Dissent was dangerous. Sweatshops enjoyed the blessing of the courts. Children labored from dusk until dawn in the deadliest factories. And women could be mutilated according to the whims of the state.

As a 1930 report by a New York commission explained, "a very marked lessening of earning power begins around age 50," in large part because workers' worn-out muscles could no longer handle the kind of heavy labor that once supplied their livelihood. In some industries, men started to fall apart even younger.

"In the building trades, one-half of the workers have suffered partial or total impairment of earning power at age 54. Among glass blowers, this is true at age 51; among steel workers age 46, and among railway workers at age 39. The heavy industrial work that offered many fathers their only way to make a living simply burns men up."

Some of the elderly shut out by their own children wound up homeless, but a common fate was life in the poorhouse. Though the poorhouse faded from American memories many decades ago, every state but New Mexico had such homes at the dawn of the Franklin D. Roosevelt administration providing housing of last resort to individuals on the furthest margins of society. Most of the inmates in these houses—and poorhouse residents were typically labeled as “inmates”—were elderly. A 1910 report in Massachusetts, for example, found that 92 percent of poorhouse inmates took up residence after age 60. Though conditions varied, poorhouses were often wretched, dirty environments with little capacity for long-term care and few, if any, staff trained to provide for the infirm.

“With a few notable exceptions, our present public almshouse care of the aged is inadequate and altogether unsuited to meet the varying needs of the poor.”

Faced with such a future, some workers celebrated their retirement with suicide rather than spend the rest of their lives in a poorhouse. A sixty-year-old man in Cleveland threw himself from a bridge onto the street 125 feet below because he feared his own old age.

FDR did not come to Washington with a comprehensive plan. What he did promise the voters who placed him in office, however, was an entirely new approach to policymaking:

“The country demands bold, persistent experimentation. It is common sense to take a method and try it: If it fails, admit it frankly and try another. But above all, try something. The millions who are in want will not stand by silently forever while the things to satisfy their needs are within easy reach.”

Roosevelt’s plan to turn the government into a laboratory was wildly at odds with his predecessor Herbert Hoover’s vision, who warned in one of his final campaign speeches that his opponent would “destroy the very foundations of our American system” by extending “government into our economic and social life.” But, more important, Roosevelt’s ideas were a direct assault on the vision that dominated the Supreme Court. When the justices created a constitutional right to fire unionized workers, or when they declared the minimum wage to be off limits, or when they held the United States of America powerless to purge the nation of child labor, they did far more than simply set the nation’s labor policy. They declared that many of the most important and controversial questions left to lawmakers were instead answered by the Constitution itself, and that the kind of

experimentation Roosevelt proposed was strictly off limits. The battle that emerged between Roosevelt and the Supreme Court was about far more than whether the New Deal would stand or fall. It was about whether the solutions to America's most vexing problems were preordained—and whether the American people had the right to prefer Roosevelt's bold experimentation to Hoover's stoic confidence in the old ways.

Despite the very real likelihood that it would be struck down, President Roosevelt signed the Social Security Act. If the justices were going to doom another generation of the least fortunate seniors to the poorhouse, then they would have to do their own dirty work.

Mass inflation would result from excessive New Deal spending, many insisted, and the new benefits for unemployed and retired workers would be devoured by this inflation. Social Security, some warned, "is no more secure than the value of the dollar in which its benefits are payable." Such arguments are still in use and effective today, largely because people have no knowledge of history, and institutions like schools or the media do not actually educate and inform.

In his inaugural address, he offered a stern rebuttal to the justices who might try to strip him of the mandate a landslide election had given him—especially after the Liberty League had cast that election as a referendum on Roosevelt's understanding of the Constitution:

"This year marks the one-hundred-fiftieth anniversary of the Constitutional Convention which made us a nation. At that Convention our forefathers found the way out of the chaos which followed the Revolutionary War; they created a strong government with powers of united action sufficient then and now to solve problems utterly beyond individual or local solution. A century and a half ago they established the Federal Government in order to promote the general welfare and secure the blessings of liberty to the American people.

Nearly all of us recognize that as intricacies of human relationships increase, so power to govern them also must increase—power to stop evil; power to do good. The essential democracy of our nation and the safety of our people depend not upon the absence of power, but upon lodging it with those whom the people can change or continue at stated intervals through an honest and free system of elections. The Constitution of 1787 did not make our democracy impotent."

Roosevelt's words echoed General George Washington's much older

warning that “unless Congress have powers competent to all general purposes” then the blood spilt in the Revolution will “avail us nothing,”

The opposition to the Child Labor Amendment revealed two challenges facing anyone seeking to amend the Constitution. Constitutional amendments can have unpredictable results—just look at how the Supreme Court treated the Fourteenth Amendment—and this unpredictability can lead to opposition from unexpected sources. Conservative groups recruited parents to oppose the amendment by claiming that it would lead to a federal ban on household chores. One of the leading opponents of the amendment was the Catholic Church, which feared that it would allow Congress to regulate parochial schools on the theory that schoolwork was a form of labor. The Boston archdiocese even claimed that the Child Labor Amendment was “more in keeping with Soviet Russia than with the fundamental principles of the American Government.”

This tendency to stir opposition points to a related problem facing proponents of a constitutional amendment. No other constitutional democracy—nor, for that matter, any of the fifty states—has a constitution as difficult to amend as the United States Constitution. With rare exception, such as when Congress refused to seat senators or representatives from rebel states that refused to ratify the Fourteenth Amendment or the unusual case of Prohibition, the American Constitution is impossible to amend unless there is a widespread national consensus supporting the amendment across nearly every region and every sector of the nation. Determined opposition from an interest group that is powerful in just a small minority of states can be enough to derail an amendment.

Sham trials defined Southern justice for much of the twentieth century. From the era of the Pullman Strike until the early days of the Hoover administration, the number of lynchings in the South plunged more than 90 percent. A major factor in this drop, however, were state laws intended to placate white mobs by rushing black defendants from arrest to execution. Arkansas’s law, for example, provided that a trial must begin within ten days after a sheriff notified the local judge that the “crime of rape, attempt to commit rape, murder, or any other crime calculated to arouse the passions of the people” had occurred—the defendant’s right to secure counsel and prepare a defense be damned.

Once the trial began, defense attorneys rarely sought continuances for fear that their client would be murdered. Prosecutors told juries to convict in order to reward mobs for the restraint they showed by allowing the trial to move forward. Some governors even refused clemency requests on the grounds that a death sentence was necessary to ward off a lynching. This, in other words, was the world that had emerged from the Supreme Court’s

Reconstruction decision in Cruikshank. The lesson of the Colfax Massacre was that violent mobs could enforce white supremacy with near-impunity. And because Cruikshank effectively freed the states to ignore the Bill of Rights, nothing prevented states like Alabama from transforming their courts into agents of the mob.

When the newly constituted Warren Court met once again to discuss the fate of *Brown*, the new chief justice immediately cast his lot against Jim Crow. “We can’t set one group apart from the rest of us and say they are not entitled to the same treatment as all others,” Warren told his new colleagues. The Reconstruction Amendments “were intended to make equal those who once were slaves.” The significance of Warren’s pronouncement was obvious to each of the other eight justices. A year ago, under Vinson’s leadership, there were only four certain votes to end school segregation. Now the only question was whether the justices would stand together when they stuck the knife in Southern apartheid. The value of unanimity was not lost on the members of the Court. Justice Clark announced that he would support a decision striking school segregation—provided that the Court did not require the South to change too quickly—almost immediately after Warren’s vote made the outcome in *Brown* inevitable. Justice Frankfurter told a former law clerk that he feared a divided decision could trigger such resistance from the South that the Court’s order would become unenforceable. When Justice Reed was the lone holdout preparing a dissent upholding segregation, Warren dissuaded him with a warning—“Stan, you’re all by yourself in this now.” Not wanting to bear the blame for the South’s backlash against *Brown*, Reed signed onto Warren’s opinion.

What such actions clearly illustrate is that these individuals are nothing but unelected, job-for-life politicians in robes.

Although the Court was willing to declare school segregation unconstitutional, it wasn’t yet willing to do much about it. One year after *Brown*, the justices handed down another unanimous decision holding that desegregation need only move forward “with all deliberate speed.” Local judges, many of whom owed their jobs to their relationships with segregationist senators, would supervise school integration. And local officials would have the “primary responsibility” for determining how to implement *Brown* in light of the unique conditions within their school districts.

White Southerners received this decision as if Earl Warren had personally ridden on horseback to Appomattox Courthouse in order to surrender the Union’s armies. Florida lawmakers broke into cheers when they learned of the decision, and a Louisiana legislator labeled it “the mildest decree the Supreme Court possibly could have handed down.” A Virginia politician mused that “the court has not the courage of its previously avowed convictions,” and

a segregationist from Florida decided that the Court “realized it made a mistake in May and is getting out of it the best way it can.”

Though Southern resistance to *Brown* was inevitable, the Court’s timid implementation order undoubtedly emboldened the resisters. Eighty-one Southern members of Congress signed a “Southern Manifesto” pledging to “use all lawful means to bring about a reversal of this decision which is contrary to the Constitution.” Several schools in Virginia refused to open entirely rather than permit black students to be educated alongside white ones. After Governor Orval Faubus deployed the Arkansas National Guard to prevent nine black students from attending Little Rock Central High School, President Eisenhower had to deploy twelve-hundred paratroopers to Little Rock to protect the students. And the South’s campaign of resistance was wildly successful for many years. In 1959, just forty of North Carolina’s three-hundred-thousand African American students attended integrated schools. Forty-two of Nashville’s twelve-thousand black students attended desegregated schools in 1960.

Despite the Court’s initial reluctance to ensure that *Brown* would be meaningfully enforced, it is easy to imagine a much darker opinion emerging from the Court’s deliberations over public school segregation. If Jimmy Byrnes had remained on the Court, the vote Justice Minton cast for integration would have instead belonged to the man from South Carolina. Similarly, if President Herbert Hoover had succeeded in appointing Judge John J. Parker to the Court, that may have added another vote in favor of segregation. If Hugo Black had behaved more like a former Klansman might have been expected to behave, and if Chief Justice Fred M. Vinson had not died when he did, then *Brown v. Board of Education* might now be remembered as one of the greatest civil rights defeats of the twentieth century. Indeed, history would have been quite different if only President Eisenhower had been more diligent in screening his Supreme Court nominees. Although Eisenhower respected the rule of law enough to order troops to Little Rock in order to enforce the Supreme Court’s order, he was privately unamused by Chief Justice Warren’s most famous opinion. Southern whites, Eisenhower told Warren at a White House dinner, “are not bad people. All they are concerned about is to see that their sweet little girls are not required to sit in school alongside some big overgrown Negroes.” Eisenhower later described the Warren appointment as the “biggest damned-fool mistake I ever made.”

In spite of the slow progress achieved by *Brown*, the nearly sixteen years that Earl Warren served as chief justice were nonetheless one of the most transformative periods in American constitutional history. For the first time since Reconstruction, the justices gave real meaning to the Constitution’s

ban on racial apartheid. The Warren Court invigorated the Bill of Rights. It gave dissenting voices the freedom to speak openly without fear of arrest. It barred police from indiscriminately listening in on people's phone calls. And it restored democracy to states that had abandoned the basic rule that every person gets one, and exactly one, vote. Constitutional rights that had lain dormant for nearly a century roared back to life thanks to the Warren Court, and the Fourteenth Amendment finally represented something more than a shield over the rich and the powerful.

The Warren Court was one of the great anomalies of American history—a brief period when the Supreme Court read the Constitution and saw some of the many ways it was intended to make American lives better. And we owe this period to a series of historical accidents. If Byrnes had remained on the Court; if Black hadn't rejected his racist past; if Vinson hadn't died; or if Eisenhower hadn't made two damned-fool mistakes—he later listed his appointment of Justice William Brennan, a reliable vote in favor of the Warren Court's landmark decisions, as a second mistake akin to the Warren appointment—then the constitutional revival of the Warren era could have never happened. Like all anomalies, this revival could not last forever. Future presidents typically put a great deal more thought into their Supreme Court nominations than President Eisenhower did.

In the end, the most important thing the Warren Court did to advance racial justice was not the *Brown* decision. It was its willingness to get out of the way once Congress decided to confront Jim Crow. For protection against abuses by legislatures the people must resort to the polls and the streets, not to the courts.

For eighty-two long years, from 1875 until 1957, Congress did not pass a single civil rights bill. Indeed, this was true even when such legislation enjoyed majority support. Five civil rights bills passed the House between the end of World War II and 1957, but none of them survived contact with the Senate.

The reason for this inability to legislate was the filibuster, which allowed Southern white supremacists to block any bill they chose, so long as they could convince just a handful of conservatives outside the South to join their obstruction of the legislative process. Moreover, because Southern voting officials ensured that few black voters would actually get to cast meaningful ballots, white supremacist lawmakers faced no consequences for their opposition to civil rights.

The Jim Crow South was largely a collection of one-party states—between 1916 and 1944, for example, the Republican presidential candidate won more than five percent of the vote in South Carolina just one time. Thus, the winner of a Democratic primary in the South was virtually guaranteed

election, and general elections were largely formalities. For this reason, segregationists could exclude African Americans from the franchise entirely by preventing them from voting in Democratic Party primaries.

In 1923, one state tried to do just that by enacting a law providing that “in no event shall a negro be eligible to participate in a Democratic party primary election held in the State of Texas”—though this first attempt to suppress the black vote did not end well for Texas. The Supreme Court struck down the law in a unanimous opinion proclaiming that “it seems to us hard to imagine a more direct and obvious infringement of the Fourteenth [Amendment].” Even Justice James Clark McReynolds joined this opinion.

This decision, according to the Texas legislature, created “an emergency with a need for immediate action” and the lawmakers quickly replaced the unconstitutional law with a new one providing that “every political party in this State through its State Executive Committee shall have the power to prescribe the qualifications of its own members and shall in its own way determine who shall be qualified to vote or otherwise participate in such political party.” Not long thereafter, the state Democratic Party’s executive committee enacted a resolution providing that only “white democrats” may participate in their primary. Though the Court also struck this law down, in 1932, it did so over a dissent from McReynolds and the other members of the Four Horsemen. The Texas law itself, McReynolds claimed, “withholds nothing from any negro.” Instead, it merely recognized the Democratic Party’s power to “prescribe qualifications for membership.” According to McReynolds it was the Party, not the state, that denied voting rights to African Americans. And the Constitution has nothing to say about discrimination by a private organization such as a political party.

The obvious problem here is you have members of the club creating the laws the club must work within—highly problematic.

Three weeks after the Court’s second decision striking down Texas’s white-primary scheme, the state’s Democrats took matters into their own hands. Acting pursuant to no state law whatsoever, the Party enacted a resolution at its convention providing that only “white citizens” may vote in a Democratic primary. This time, the justices unanimously sided with the segregationists. Recall that the Fourteenth Amendment provides that “no state” shall “deny to any person within its jurisdiction the equal protection of the laws,” and the Fifteenth Amendment provides that “the right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of race, color, or previous condition of servitude.” In both cases, the amendments indicate that only government actors—a “state” or the “United States”—are bound by their prohibitions against race discrimination. Although the two previous white-

primary cases struck down a state law that mandated segregation—or at least entangled the state with the process that Texas Democrats used to exclude black voters—this case involved a political party acting on its own. “The qualifications of citizens to participate in party counsels and to vote at party primaries have been declared by the representatives of the party in convention assembled,” Justice Owen J. Roberts explained in *Grovey v. Townsend*, “and this action upon its face is not state action.”

The Texas Democratic Party was not an arm of the government, according to *Grovey*, and therefore it was immune to the Constitution’s prohibition on racial voter suppression. *Grovey* did not last long. Less than a decade later, the Supreme Court overruled it in the landmark *Smith v. Allwright* decision. But *Grovey* lasted just long enough to validate a strategy that animated the South’s resistance to black voting rights—if the court strikes down one voter suppression practice, just keep coming up with new ones until the courts back off.

The single most important thing the Supreme Court ever did for civil rights was not *Brown*. It was the Court’s decision to do absolutely nothing when first confronted with the Civil Rights Act of 1964 and the Voting Rights Act of 1965. Not long after President Johnson signed the Civil Rights Act into law, a motel in Atlanta and a barbecue restaurant in Birmingham filed a pair of lawsuits objecting to the law on similar grounds to the arguments raised by men like Rehnquist, Bork, and Goldwater. Nevertheless, the justices unanimously upheld the law. Less than two years later, they rejected a similar challenge to the Voting Rights Act. These three cases were the most important civil rights decisions of their era. By simply getting out of the way and allowing the federal government to do its job, the Warren Court did more to tear down Jim Crow than it could ever have accomplished on its own.

At the height of the Warren Court, many liberals gazed upon the Supreme Court with the same hunger to see their dreams made real by judicial decree that motivated union busters and Southern cotton mill owners during the *Lochner* Era.

The fact that contemporary judicial conservatives have not handed down a latter-day *Lochner v. New York* does not mean that they’ve failed to make an ideological mark on the law. In many cases, it simply means they are more subtle than their forebears. While justices like Field, Fuller, Brewer, and Sutherland read doubtful restrictions on government into the vaguest phrases of the Constitution, modern-day conservatives often prefer a different tactic. By reading civil rights laws narrowly, or by placing procedural barriers between workers and the courthouse door, or by shunting consumers into tribunals that are stacked in favor of the companies they are suing, the

Court can undermine progressive legislation just as surely as if they had declared it unconstitutional.

Moreover, as Congress grows more and more dysfunctional, the distinction between a Supreme Court decision reinterpreting the Constitution and another decision that achieves the same result by rethinking an ordinary statute matters less and less. Traditionally, the Court's constitutional precedents were understood to be particularly difficult to displace, because the difficulty of amending the Constitution makes the Court the only effective resort for changing obsolete constitutional doctrine. Court decisions interpreting acts of Congress, by contrast, could always be overruled by a new act of Congress. In an age when Congress and the president can barely agree upon whether or not to shut down the government, however, the idea that Congress will get its act together long enough to overrule a Supreme Court decision is largely a pipe dream. The justices are no longer simply the final word on the Constitution, they are typically the final word on everything that comes before them.

Once upon a time, it was generally understood that the police could not stop and search someone without a warrant unless there was probable cause to believe that the individual was engaged in criminal activity. That was a basic Fourth Amendment principle. In *Terry v. Ohio*, decided in 1968, the Supreme Court modified that understanding, but only modestly, by ruling that if and when a police officer observes unusual conduct by someone the officer reasonably believes to be dangerous and engaged in criminal activity, the officer "is entitled for the protection of himself and others in the area" to conduct a limited search "to discover weapons that might be used against the officer." Known as the stop-and-frisk rule, the *Terry* decision stands for the proposition that, so long as a police officer has "*reasonable articulable suspicion*" that someone is engaged in criminal activity and dangerous, it is constitutionally permissible to stop, question, and frisk him or her—even in the absence of probable cause. Justice Douglas dissented in *Terry* on the grounds that "granting police greater power than a magistrate judge is to take a long step down the totalitarian path." He objected to the notion that police should be free to conduct warrantless searches whenever they suspect someone is a criminal, believing that dispensing with the Fourth Amendment's warrant requirement risked opening the door to the same abuses that gave rise to the American Revolution. His voice was a lonely one.

A lower court broadly condemned "bus sweeps" in the drug war, comparing them to methods employed by totalitarian regimes:

"The evidence in this case has evoked images of other days,

under other flags, when no man traveled his nation's roads or railways without fear of unwarranted interruption, by individuals who had temporary power in Government. . . . This is not Hitler's Berlin, nor Stalin's Moscow, nor is it white supremacist South Africa. Yet in Broward County, Florida, these police officers approach every person on board buses and trains ("that time permits") and check identification, tickets, ask to search luggage—all in the name of "voluntary cooperation" with law enforcement.

The US Supreme Court reversed. The Court ruled that Bostick's encounter with the police was purely voluntary, and therefore he was not "seized" within the meaning of the Fourth Amendment. Even if Bostick did not feel free to leave when confronted by police at the back of the bus, the proper question, according to the Court, was whether "a reasonable person" in Bostick's shoes would have felt free to terminate the encounter. A reasonable person, the Court concluded, would have felt free to sit there and refuse to answer the police officer's questions, and would have felt free to tell the officer "No, you can't search my bag." Accordingly, Bostick was not really "seized" within the meaning of the Fourth Amendment, and the subsequent search was purely consensual. The Court made clear that its decision was to govern all future drug sweeps, no matter what the circumstances of the targeted individual. Given the blanket nature of the ruling, courts have found police encounters to be consensual in truly preposterous situations. For example, a few years after Bostick, the District of Columbia Court of Appeals applied the ruling to a case involving a fourteen-year-old girl interrogated by the police, concluding that she must be held to the same reasonable-person standard.

This is no secret to the Supreme Court. The Court long ago acknowledged that effective use of consent searches by the police depends on the ignorance (and powerlessness) of those who are targeted. In *Schneckloth v. Bustamonte*, decided in 1973, the Court admitted that if waiver of one's right to refuse consent were truly "knowing, intelligent, and voluntary," it would "in practice create serious doubt whether consent searches would continue to be conducted." In other words, consent searches are valuable tools for the police only because hardly anyone dares to say no.

So long as orders are phrased as a question, compliance is interpreted as consent. 'May I speak to you?' thunders an officer. 'Will you put your arms up and stand against the wall for a search?' Because almost no one refuses, drug sweeps on the sidewalk (and on buses and trains) are easy. People are easily intimidated when the police confront them, hands on their guns or

tasers, and most have no idea the question can be answered, ‘No.’

The upshot of the Court’s forced-arbitration cases is that the decision to employ them or not to employ them rests almost entirely with individual companies. And these companies can deny services or employment altogether to those who refuse to relinquish their ability to assert their rights in court. Forced arbitration, in other words, could potentially do just as much to undermine the rights of ordinary Americans as any decision handed down in the *Lochner* Era. What use is a minimum-wage law or a right to be free from discrimination if all of the judges who would enforce those rights are replaced by “arbitration mills” that exist solely to rule against workers and consumers?

The fact that one can imagine a slippery slope, however, does not mean that they will inevitably wind up at the bottom of it. Indeed, if the fact that a judge can envision a slippery slope were sufficient reason to declare a law unconstitutional, then it’s likely that all laws would have to be struck down. If Congress has the power to ban products like heroin and machine guns, it could also use that power to ban apple pie and ice cream! If Congress has the power to enact a ten-dollar minimum wage, it could use that power to enact a million-dollar minimum wage! If Congress can levy a 25 percent income tax, it could use that power to levy a 99.99 percent income tax! If Congress can ban child labor, it could ban all labor!

Moreover, there is something fundamentally aristocratic about the idea that judges must shrink federal authority in order to ward off the most horrible theoretical law those judges can possibly imagine. As Chief Justice Marshall explained in his opinion laying out the broad reach of Congress’s authority to regulate commerce, “the wisdom and the discretion of Congress, their identity with the people, and the influence which their constituents possess at elections are the restraints on which the people must often rely solely, in all representative governments.” The premise of any democracy is that the people must be trusted to make decisions for themselves, even if a small group of men with lifetime tenure believe that those people will come to regret their decision. If the Affordable Care Act—or any other law, for that matter—turns out to be a bad idea, the Constitution provides a very simple remedy. It’s called an election.

Two visions of the Constitution have struggled for dominance in the United States ever since Hamilton clashed with Jefferson over the constitutionality of the First Bank of the United States. In one, the United States should be governed by the men and women who are elected to govern, and, while the Constitution does place explicit limits on government that must be policed by the Supreme Court, it is not the job of the Court to micromanage decisions that belong to the people’s elected representatives. In the other

vision, the primary purpose of the Constitution is to restrain government action, even if lawmakers could easily act to prevent human suffering. As a Senator said in a 2010 lecture in which he argued that federal child labor laws are unconstitutional, the Constitution “was designed to be a little bit harsh.”

For the four Republican justices who voted to remove Obamacare from the books in its entirety, however, that truce is dead. They did not simply embrace a tenuous legal argument, they embraced a tenuous legal argument that ran headlong into one of Justice Scalia’s own opinions. And they voted to enact their political party’s number-one policy priority in the process. If the justices cannot be relied upon to set their partisan views aside in an easy case such as this one, how can they be trusted to interpret a Constitution that is absolutely riddled with vague and open-ended phrases? What are the “privileges or immunities of citizens of the United States”? What makes a search or seizure “unreasonable”? Which punishments are “cruel and unusual”? If the government wants to deny someone “liberty,” how much “process” is “due”? What is a “public use” of private property? How should the United States guarantee a “republican form of government”? What is the “general welfare of the United States”? Which laws are “necessary and proper” for carrying into effect Congress’s enumerated powers?

Many of these questions perplexed the very men who wrote these phrases into the Constitution. And yet we trust a Court with nine unelected judges and a terrible track record to issue binding pronouncements about what that Constitution means. This is the same Court that decided *Dred Scott* and *Cruikshank*. The same Court that invalidated the minimum wage and child labor laws. The same Court that held that a woman could be sterilized against her will. The same Court that upheld Japanese internment and that opened the doors to segregation. The same Court that gave us *Citizens United* and *Bush v. Gore*. And the same Court that nearly stripped health care from millions of Americans. We placed our Constitution in the hands of John Archibald Campbell, and we placed it in the hands of Stephen Johnson Field—and we gave them the ability to read whatever they chose into our founding document. Their successors enjoy that very same power to this day.

Chapter Twenty-nine

Imaginary Lines

Spartan teenagers were handed a dagger and sent off into the countryside to secretly stalk and murder the boldest local peasants in such a way that no man was able to say, either then or afterwards, how they came to their deaths. By ruthless Spartan logic, this was the perfect multipurpose path to citizenship: it kept insurrection at bay and turned young Spartans into masters of stealth and survival.

Even when two cultural norms are equally valid in theory, in the practical context of immigration it might still be justified to judge the host culture as better. Norms and values that are appropriate in one country just don't work well under different circumstances. Let's look closely at a concrete example. In order not to fall prey to well-established prejudices, let's imagine two fictional countries: Coldia and Warmland. The two countries have many cultural differences, among which is their attitude to human relations and interpersonal conflict.

Coldians are educated from infancy that if you get into conflict with somebody at school, at work, or even in your family, the best thing is to repress it. You should avoid shouting, expressing rage, or confronting the other person—angry outbursts just make things worse. It's better to work with your own feelings, while allowing things to cool down. In the meantime, limit your contact with the person in question, and if contact is unavoidable, be terse but polite, and avoid sensitive issues. Warmlanders, by contrast, are educated from infancy to externalize conflicts. If you find yourself in conflict, don't let it simmer and don't repress anything. Use the first opportunity to vent your emotions openly. It is OK to get angry, to shout, and to tell the other person exactly how you feel. This is the only way to work things through together, in an honest and direct way. One day of shouting can resolve a conflict that may otherwise fester for years, and though head-on confrontation is never pleasant, you will all feel much better afterwards.

Both these methods have their pros and cons, and it is hard to say that one is always better than the other. What might happen, though, when a Warmlander emigrates to Coldia, and gets a job in a Coldian firm? Whenever a conflict arises with a co-worker, the Warmlander bangs on

the table and yells at the top of his voice, expecting that this will focus attention on the problem and help to resolve it quickly. Several years later a senior position falls vacant. Though the Warmlander has all the necessary qualifications, the boss prefers to give the promotion to a Coldian employee. When asked about it, she explains: “Yes, the Warmlander has many talents, but he also has a serious problem with human relations. He is hot-tempered, creates unnecessary tensions around him, and disturbs our corporate culture.” The same fate befalls other Warmlander immigrants to Coldia. Most of them remain in junior positions, or fail to find any job at all, because managers presuppose that if they are Warmlanders, they would probably be hot-tempered and problematic employees. Since the Warmlanders never reach senior positions, it is difficult for them to change the Coldian corporate culture.

Much the same thing happens to Coldians who emigrate to Warmland. A Coldian starting to work in a Warmland firm quickly acquires the reputation of a snob or a cold fish, and makes few if any friends. People think that he is insincere, or that he lacks basic human-relation skills. He never advances to senior positions, and he therefore never gets the opportunity to change the corporate culture. Warmland managers conclude that most Coldians are unfriendly or shy, and prefer not to hire them to positions that require contact with customers or close cooperation with other employees.

Both these cases may seem to smack of racism. But in fact, they are not racist. They are ‘culturist’. People continue to conduct a heroic struggle against traditional racism without noticing that the battlefield has shifted. Traditional racism is waning, but the world is now full of culturists.

“Do you want to know the difference between Illegal Aliens and Politicians?

Well for starters they talk funny, and they can be pretty greasy. They are sneaky and ambitious about trying to get to where they want to go. They will lie, even fake being somebody else just to get a job. And when they do, they make a heck of a lot more money than those *illegals*.”

Most people from the US are taught that America is a melting pot—despite the fact that the name ‘America’ covers North and South and Central America, or that the metaphor glosses over bloody battles and the oppression of numerous people and groups.

Of course, there are only two types of people in the United States. People who are here because we allowed their families to come here, and people who are here because we somehow overlooked murdering their families. That’s it.

Families of immigrants and some descendants of the indigenous people we accidentally managed not to completely exterminate.

All people whose lives are impacted by the policies of a particular state, should have a say in how that state manages its affairs and particularly how it manages its entry requirements. In the absence of such an arrangement, what prevails at the level of international relations is a type of tyranny. In a global frame, what can democracy mean when the citizens of impoverished nations have no influence on the governmental policies that affect them most, in particular the immigration policies of wealthy nations?

Immigration has become a privilege of the elite and those useful to the elite instead of a right of the desperate. The world's people are being divided not into naturally forming communities but into corporate controlled economic markets. Governance by nation states is now as arbitrary and illogical as city states were earlier found to be.

Does US immigration policy simply allow our government to cushion itself from the effects of not adequately educating and supporting its own people?

The same sort of situation holds in all of the jobs that native born workers supposedly do not want: Native-born workers will wash dishes, clean toilets, and pick tomatoes for \$20 an hour. When the nanny state conservatives say that they can't find native-born workers for these jobs, they mean that they can't find native-born workers at the wages that they want to pay, just as most of us can't find native-born doctors or lawyers who are willing to work for \$15 an hour. The difference is that the nanny state conservatives get to bring in immigrants at low wages to meet their needs, whereas the doctors and lawyers can count on the nanny state to protect them from competition with immigrant workers.

The importation of low-paid labor is a tool of oppression that divides workers and benefits those in power. The proper response, therefore, is not abstract moralism about welcoming all migrants as an imagined act of charity, but rather addressing the root causes of migration in the relationship between large and powerful economies and the smaller or developing economies from which people migrate.

The comforting delusion that immigrants come here because they love America is incredibly naïve—as naïve as suggesting that the nineteenth-century Irish immigrants to England loved England. Most migrants emigrate out of economic necessity, and the vast majority would prefer to have better opportunities at home, among their own family and friends. But such opportunities are impossible within the current shape of globalization.

If open borders is “a Koch brothers proposal,” then what would an authentic Left position on immigration look like? In this case, instead of

channeling Milton Friedman, the Left should take its bearings from its own long traditions. Progressives should focus on addressing the systemic exploitation at the root of mass migration rather than retreating to a shallow moralism that legitimates these exploitative forces. This does not mean that leftists should ignore injustices against immigrants. They should vigorously defend migrants against inhumane treatment. At the same time, any sincere Left must take a hard line against the corporate, financial, and other actors who create the desperate circumstances underlying mass migration which, in turn, produces the populist reaction against it. Only a strong national Left in the small and developing nations—acting in concert with a Left committed to ending financialization and global labor exploitation in the larger economies—could have any hope of addressing these problems.

To begin with, the Left must stop ignoring the effects of immigration on domestic labor, especially the working poor who are likely to suffer disproportionately from expanding the labor pool. Immigration policies should be designed to ensure that the bargaining power of workers is not significantly imperiled. This is especially true in times of wage stagnation, weak unions, and massive inequality.

Employers, not immigrants, should be the primary focus of enforcement efforts. These employers take advantage of immigrants who lack ordinary legal protections in order to perpetuate a race to the bottom in wages while also evading payroll taxes and the provision of other benefits. Such incentives must be eliminated if any workers are to be treated fairly. They've also got websites, headquarters, warehouses, and factories and other physical infrastructure—they've got shit that's easy to find and take control of in response to injustice.

Trump infamously complained about people coming from third-world “shithole countries” and suggested Norwegians as an example of ideal immigrants. But Norwegians did once come to America in large numbers—when they were desperate and poor. Now that they have a prosperous and relatively egalitarian social democracy, built on public ownership of natural resources—though many of these harm developing nations by contributing to climate change, so in part the good life of Norwegians is subsidized by the poor elsewhere, as in all Western nations to varying degrees—they no longer want to. Ultimately, the motivation for mass migration will persist as long as the structural problems underlying it remain in place.

Reducing the tensions of mass migration thus requires improving the prospects of the world's poor. Mass migration itself will not accomplish this: it creates a race to the bottom for workers in wealthy countries and a brain drain in poor ones. The only real solution is to correct the imbalances in the global economy, and radically restructure a system of globalization

that was designed to benefit the wealthy at the expense of the poor. This involves, to start with, structural changes to trade policies that prevent necessary, state-led development in emerging economies. Anti-labor trade deals like NAFTA and its replacement must also be opposed and repealed. It is equally necessary to take on a financial system that funnels capital away from the developing world and into inequality-heightening asset bubbles in rich countries. Finally, although the reckless foreign policies of the George W. Bush administration have been discredited, the temptation to engage in military crusades seems to live on. This should be opposed. US-led foreign invasions have killed millions in the Middle East, created millions of refugees and migrants, and devastated fundamental infrastructure.

Indeed, smuggling people is as lucrative as smuggling drugs, and safer. There is not the worldwide concern for the transportation of illegal immigrants as there is for shipping narcotics, and in the unlikely event the organizers are caught, the penalties are much lighter.

Instead of simply sealing themselves off, affluent countries should be giving much more support to less affluent countries that are supporting large numbers of refugees: Lebanon, Jordan, Ethiopia, and Pakistan are obvious examples. Refugees living securely in countries that border their own are less likely to attempt hazardous journeys to remote regions and more likely to return home once a conflict is resolved.

But maybe you'd rather just continue your virtue signaling. And use things like drowned toddlers as simply another cog in your feel-good outrage machine.

Chapter Thirty

Starving for Justice

“Don’t tell us these racist lies, how we don’t care when someone black or brown dies in our community, that we only care when they’re the victim of a white police officer. My friend recently died. He left a hole in my heart. All right, a hole that can never be filled. And I’m speaking from my soul here. We cared when he died. We care when everyone dies.

But you know what the difference is, bigots of the world? That when those people die, if someone catches the ‘gangbanger’ or the individual who’s responsible for their murder on camera, he’s going to jail ninety-nine-point-nine-nine-nine percent of the time!

And when we catch an officer of the law, who’s supposed to know the law, and in my opinion should be held to that law to the highest standards, ninety-nine-point-nine-nine-nine percent of the time we hear excuses instead of hearing accountability.

And that’s all we’re saying. We want you to make it what you said it was on paper. Otherwise, it’s a lie. They think they can just close the door and have some kind of let-them-eat-cake Louis XVI party in there, while we starving out here. And when I say starving—I mean we got donuts—we starving for justice.”

We have not addressed the moral panics that sedimented over the past forty-five years into draconian laws. We have not curbed the zeal to punish. We have not restored what ought to be at the center of law: the idea that punishment has limits, and that the institutions have a responsibility to restore offenders to society in a better condition than when they were judged guilty of crimes. What is still urgently needed is a comprehensive approach to legal reforms, including laws that pertain to the most hated classes of offenders.

What follows is not a plan, but several questions and claims offered for serious consideration by those committed to justice and interested in dismantling mass incarceration. They are offered as conversation starters—

food for thought, debate, and—I hope—collective action. Each is a challenge to conventional wisdom or traditional strategies. Far more should be said about each point made, but, as indicated, this is meant to be the beginning of a conversation, not an end.

Ten-thousand years ago, there was no court or trial to ensure that a man accused of murder received due process—justice was the end of a spear. One-thousand years ago, proof of guilt was revealed when a woman’s hand festered after being burned with a hot iron. One-hundred years ago, black citizens could be barred from the jury box, bar, and bench on account of the color of their skin. And a decade ago, it was legal in the United States to execute someone who had committed his crime before he was eighteen.

Progress, certainly—but this has been no unbroken advance. It has been a journey, uphill and against the wind. It has entailed detours and backtracking—and our current vantage point has much to do with chance. History makes clear that our next destination may, or may not, lie up the mountain. The arc of history does not bend toward justice unless we bend it.

The best way to avoid known human biases or predictable errors in our criminal justice system may be to make changes outside of it. When confronted with a question like how to reduce the murder rate, we tend to recite the standard set of commonsense solutions: increase the number of officers in high-crime neighborhoods, crack down on drug gangs, and develop better tests to predict future violent behavior. But there may be other, less obvious responses that are more cost-effective and easily implemented. For example, a city could invest in trauma kits containing materials developed by the military for treating battlefield wounds and train all officers in how to address the major causes of preventable death in combat (a collapsed lung, airway obstruction, and hemorrhage from a limb), which also happen to be extremely common when someone has been shot in a drive-by or wounded in a robbery, or shot by police. Or we could have all hospitals and ambulances carry the inexpensive generic drug tranexamic acid, which is used to slow the bleeding of wounded soldiers—it’s estimated that every year this simple change could save the lives of up to four-thousand Americans who are the victims of violence. Before we go down the road of sanctioning invasive and problematic police actions to try to reduce gun violence (like “stop and frisk”) or invest immense time and energy in developing neuro-recidivism predictors that may never be accurate, we should see if there’s a simpler way to achieve our ultimate end: saving lives.

It is true that a virtual courtroom would remove a lot of the drama and excitement from the trial. But that is exactly the point: the elements that make for good television—bombastic attorneys, witnesses with shaky

hands, and defendants seemingly unmoved by the tearful testimony of the victim—make for poor justice.

The Supreme Court admonished in *Berger v. US* that the duty of a prosecutor “is not that it shall win a case, but that justice shall be done.”

We could adopt a similar approach in realigning the relationship between detectives and suspects. As we’ve seen, the commonly used Reid technique casts the two as adversaries. The resulting interrogations tend to be highly confrontational, focused on battering a suspect into submission and lying to him if necessary until he fesses up, which we know greatly increases the likelihood of a false confession. So, what if we recast the investigator’s objective, from obtaining an admission of guilt to simply gathering reliable information? Rosy claims to the contrary, the emphasis in our current approach is not on reaching an accurate account of what happened. That’s why detectives are permitted to offer the suspect potential motives and descriptions of how the crime went down—even if they’re entirely made up—to make it more psychologically palatable for him to accept responsibility. It’s an effective way to get to ‘I did it,’ but it’s a terrible way to get to the truth.

Our corrections hiring should target people well suited to rehabilitative work rather than disciplinarians ready for a fight.

We should also reduce the impenetrable divide between the public and the prison population. Although certain types of offenders are quite appropriately kept separate from the general public, many would benefit from closer ties with outside society. And the rest of us would benefit, too. If those convicted of crimes will walk among us again, we must begin preparing them today. We ought to help prisoners maintain family connections, allowing frequent interaction with loved ones so that they have support when they return. There is no justification for callous and shortsighted policies like limiting an inmate to a single phone call to his kids once every two weeks. Destroying families doesn’t prevent crime; it engenders it.

We can’t tie anchors around people’s waists, toss them in the deep end, and expect them to swim. If our goal really is for those who have committed crimes to become productive citizens, we’ve got to give them more help than other people, not less.

We can start by acknowledging that removing blame from our criminal justice system doesn’t mean that harmful conduct would suddenly become acceptable or that people who commit crimes would suddenly be free from sanction. The idea that if we stopped vilifying the criminal we’d have to treat rape victims and rapists exactly the same way is entirely false. Even without a legal framework grounded in personal volition and culpability, a serial rapist has still committed terrible acts that we would rightfully

denounce. But we'd no longer subject individuals to poor treatment and contempt on the grounds that they're bad people who deserve it. We'd get out of the payback business. Instead, we'd focus on remedying the harm, rehabilitating the criminal, discouraging others from taking similar actions, and treating the conditions that precipitated the crime in the first place.

The difficulty of justifying a democratic state is that its citizens must live in a society and be governed by laws to which they must adhere while simultaneously preserving their liberty. In order to preserve the liberty of action of its citizens, the laws of a democratic country must be laws to which those citizens in some sense agree, via a process of joint deliberation. A central question, or perhaps the central question, of democratic political theory is what makes a joint deliberative process fair. The question is complicated by the fact that citizens of a democratic state are typically born into a state with already existing laws. Because of this, the deliberative process must take into account the fact that the laws will apply to people who did not have the opportunity to participate in their formation. When crafting laws we must therefore take into account the views of those not yet born, as well as of children who, while not at that point capable of deliberation, one day will be among the people whose viewpoints need to be taken into account. What ideals should govern a deliberative process that results in laws of this sort, laws that can legitimately be taken as binding on individuals not yet born or too young to participate in their formation?

Democratic political theory has long favored another ideal, according to which a democratic community is one that fosters certain kinds of attitudes toward one's fellow citizens. In *The Souls of Black Folk*, Du Bois brings our attention to this normative ideal of public reason by describing the consequences of its complete failure in his description of the political state in the American South after the Civil War:

“Can we establish a mass of black laborers and artisans and landholders in the South who, by law and public opinion, have absolutely no voice in shaping the laws under which they live and work? Can the modern organization of industry, assuming as it does free democratic government and the power and ability of the laboring classes to compel respect for their welfare—can this system be carried out in the South when half its laboring force is voiceless in the public councils and powerless in its own defense? It is pitiable that frantic efforts must be made at critical times to get law-makers in some States even to listen to the respectful presentation of the black man's side of a current controversy. The laws are made by men who have little interest in the Negro;

they are executed by men who have absolutely no motive for treating the black people with courtesy or consideration; and, finally, the accused law-breaker is tried, not by his peers, but too often by men who would rather punish ten innocent Negroes than let one guilty one escape.”

As Martin Luther King Jr. writes in “Letter from a Birmingham Jail:”

“A law is unjust if it is inflicted on a minority that, as a result of being denied the right to vote, had no part in enacting or devising the law.”

But Du Bois is not merely making King’s point. He is rather bringing our attention to what he seems to regard as a more central reason the laws are not democratically legitimate. It is because those who created the laws did not have empathy for some of those subject to them, namely, their Black fellow citizens. The lack of empathy meant that the laws were crafted in such a way that did not reflect respect for the viewpoints of Black citizens; lawmakers will not listen to the “respectful presentation of the black man’s side of a current controversy.” Du Bois is arguing that the laws in the South are illegitimate, and they are illegitimate because:

1. Black citizens do not participate in their formation
2. Lawmakers will not take into account the reasonable perspectives of Black citizens
3. There is no empathy on the side of the lawmakers for the situation of Blacks subject to those laws

Du Bois is suggesting that underlying the kind of equal respect involved in taking into account reasonable perspectives of Black citizens is empathy.

A failure common in public discourse is the failure to see the point from the other man’s position. In making assertions that apply to everyone, utilize the safeguard of changing ‘you’ into ‘I.’ That way, one can more easily see whether the policy one is prescribing to others is a reasonable one.

What is most in need of reform is the legal system’s understanding of how the mind works. The police, the witnesses, the lawyers, the judges, and the jurors are all too susceptible to the illusions we have discussed. Because they are human, they believe that we pay attention to much more than we do, that our memories are more complete and faithful than they are, and that confidence is a reliable gauge of accuracy. The common law of criminal

procedure was established over centuries in England and the United States, and its assumptions are based precisely on mistaken intuitions like these.

It is relatively easy to convict an innocent person. Millions of defendants are processed through our courts each year, so it becomes nearly impossible to determine how many are actually innocent once they've been convicted. No one has the time or resources to examine the facts and backgrounds of those claiming to be wrongfully convicted. Actual wrongful conviction estimates range from two percent to ten percent, but no one really knows. These numbers may sound low, but when applied to a prison population of 2.3 million, they become staggering. Can there really be between 46,000 and 230,000 innocent people locked away? Those of us who are involved in innocence work firmly believe so. And, practically speaking, once an innocent person is convicted, it is virtually impossible to get them out of prison.

The US Constitution guarantees due process to anyone charged with a crime, and that means that everyone who is arrested is presumed to be innocent until found otherwise by a jury. Referring to the country's collective sacrifice during the American Revolution, a Massachusetts judge wrote that it was:

“Inconceivable that the people who depleted their resources in a long and bloody war to maintain their rights as freemen should have intended to deprive their citizens of an impartial trial before an unprejudicial jury.”

The prosecution, therefore, should labor under the implacably humane ideal that, as later expressed in a Supreme Court decision, “it is better that ten guilty persons escape than that one innocent suffer.” This is called the ten-to-one rule and can be traced through English common law all the way back to the Romans. The scales of justice—in theory, at least—are so heavily tilted in favor of the accused because it is thought that vastly more social harm results from jailing the innocent than from freeing the guilty. The reason that laws exist in the first place is to prevent social harm; so by definition those laws cannot cause more harm than the crimes they are meant to prevent.

If we become serious about dismantling the system of mass incarceration, we must end the War on Drugs. There is no way around it. The drug war is largely responsible for the prison boom and the creation of the new undercaste, and there is no path to liberation for communities of color that includes this ongoing war. So long as people of color in ghetto communities are being rounded up by the thousands for drug offenses, carted off to

prisons, and then released into a permanent undercaste, mass incarceration as a system of control will continue to function well.

Ending the drug war is no simple task, however. It cannot be accomplished through a landmark court decision, an executive order, or single stroke of the presidential pen. Since 1982, the war has raged like a forest fire set with a few matches and a gallon of gasoline. What began as an audacious federal program, has spread to every state in the nation and nearly every city. It has infected law enforcement activities on roads, sidewalks, highways, train stations, airports, and the nation's border. The war has effectively shredded portions of the US Constitution—eliminating Fourth Amendment protections once deemed inviolate—and it has militarized policing practices in inner cities across America. Racially targeted drug-law enforcement practices taken together with laws that specifically discriminate against drug offenders in employment, housing, and public benefits have relegated the majority of black men in urban areas across the United States to a permanent second-class status.

If we hope to end this system of control, we cannot be satisfied with a handful of reforms. All of the financial incentives granted to law enforcement to arrest poor black and brown people for drug offenses must be revoked. Federal grant money for drug enforcement must end; drug forfeiture laws must be stripped from the books; racial profiling must be eradicated; the concentration of drug busts in poor communities of color must cease; and the transfer of military equipment and aid to local law enforcement agencies waging the drug war must come to a screeching halt.

Public defender offices should be funded at the same level as prosecutor's offices to eliminate the unfair advantage afforded the incarceration machine.

In a nutshell, the following are your basic rights when it comes to interactions with the police as outlined in the Bill of Rights:

- You have the right under the First Amendment to ask questions and express yourself.
- You have the right under the Fourth Amendment to not have your person or your property searched by police or any government agent unless they have a search warrant authorizing them to do so.
- You have the right under the Fifth Amendment to remain silent, to not incriminate yourself and to request an attorney.
- Depending on which state you live in and whether your encounter with police is consensual as opposed to your being temporarily detained or arrested, you may have the right to refuse to identify yourself.

9 Principles for Policing by Consent

1. To prevent crime and disorder, as an alternative to their repression by military force and severity of legal punishment.
2. To recognize always that the power of the police to fulfill their functions and duties is dependent on public approval of their existence, actions and behaviour, and on their ability to secure and maintain public respect.
3. To recognize always that to secure and maintain the respect and approval of the public means also the securing of the willing cooperation of the public in the task of securing observance of laws.
4. To recognize always that the extent to which the cooperation of the public can be secured diminishes proportionately the necessity of the use of physical force and compulsion for achieving police objectives.
5. To seek and preserve public favour, not by pandering to public opinion, but by constantly demonstrating absolutely impartial service to law, in complete independence of policy, and without regard to the justice or injustice of the substance of individual laws, by ready offering of individual service and friendship to all members of the public without regard to their wealth or social standing, by ready exercise of courtesy and friendly good humour, and by ready offering of individual sacrifice in protecting and preserving life.
6. To use physical force only when the exercise of persuasion, advice and warning is found to be insufficient to obtain public cooperation to an extent necessary to secure observance of law or to restore order, and to use only the minimum degree of physical force which is necessary on any particular occasion for achieving a police objective.
7. To maintain at all times a relationship with the public that gives reality to the historic tradition that the police are the public and that the public are the police, the police being only members of the public who are paid to give full-time attention to duties which are incumbent on every citizen in the interests of community welfare and existence.
8. To recognize always the need for strict adherence to police-executive functions, and to refrain from even seeming to usurp the powers of the judiciary, of avenging individuals or the State, and of authoritatively judging guilt and punishing the guilty.

9. To recognize always that the test of police efficiency is the absence of crime and disorder, and not the visible evidence of police action in dealing with them.

We need an effective system of crime prevention and control in our communities, but that is not what the current system is. This system is better designed to create crime and a perpetual class of people labeled criminals, rather than to eliminate crime or reduce the number of criminals.

“These weren’t the kind of men you sent to jail. You don’t make the punishment fit the crime: you make the punishment fit the criminal.”

Colorblindness, though widely touted as the solution, is actually the problem. Civil rights leaders are quick to assure the public that when we reach a colorblind nirvana, race consciousness will no longer be necessary or appropriate. Far from being a worthy goal, however, colorblindness has proved catastrophic for African Americans. It is not an overstatement to say the systematic mass incarceration of people of color in the United States would not have been possible in the post-civil rights era if the nation had not fallen under the spell of a callous colorblindness. The seemingly innocent phrase, ‘I don’t care if he’s black. . .’ perfectly captures the perversion of Martin Luther King Jr.’s dream that we may, one day, be able to see beyond race to connect spiritually across racial lines. Saying that one does not care about race is offered as an exculpatory virtue, when in fact it can be a form of cruelty. It is precisely because we, as a nation, have not cared much about African Americans that we have allowed our criminal justice system to create a new racial undercaste.

The deeply flawed nature of colorblindness, as a governing principle, is evidenced by the fact that the public consensus supporting mass incarceration is officially colorblind. It purports to see black and brown men not as black and brown, but simply as men—raceless men—who have failed miserably to play by the rules the rest of us follow quite naturally. The fact that so many black and brown men are rounded up for drug crimes that go largely ignored when committed by whites is unseen. Our collective colorblindness prevents us from seeing this basic fact. Our blindness also prevents us from seeing the racial and structural divisions that persist in society: the segregated, unequal schools, the segregated, jobless ghettos, and the segregated public discourse—a public conversation that excludes the current pariah caste. Our commitment to colorblindness extends beyond individuals to institutions and social arrangements. We have become blind, not so much to race, but to the existence of racial caste in America.

More than forty-five years ago, Martin Luther King Jr. warned of this danger. He insisted that blindness and indifference to racial groups is actually more important than racial hostility to the creation and maintenance of racialized systems of control. Those who supported slavery and Jim Crow, he argued, typically were not bad or evil people; they were just blind. Even the Justices who decided the infamous Dred Scott case, which ruled “that the Negro has no rights which the white man is bound to respect,” were not wicked men, he said. On the contrary, they were decent and dedicated men. But, he hastened to add:

“They were victims of a spiritual and intellectual blindness. They knew not what they did. The whole system of slavery was largely perpetuated through spiritually ignorant persons.

This tragic blindness is also found in racial segregation, the not-too-distant cousin of slavery. Some of the most vigorous defenders of segregation are sincere in their beliefs and earnest in their motives. Although some men are segregationists merely for reasons of political expediency and political gain, not all of the resistance to integration is the rearguard of professional bigots. Some people feel that their attempt to preserve segregation is best for themselves, their children, and their nation. Many are good church people, anchored in the religious faith of their mothers and fathers. What a tragedy! Millions of Negroes have been crucified by conscientious blindness. Jesus was right about those men who crucified him. They knew not what they did. They were inflicted by a terrible blindness.”

King recognized that it was this indifference to the plight of other races that supported the institutions of slavery and Jim Crow. In his words:

“One of the great tragedies of man’s long trek along the highway of history has been the limiting of neighborly concern to tribe, race, class or nation.”

The consequence of this narrow, insular attitude “is that one does not really mind what happens to the people outside his group.”

If colorblindness is such a bad idea, though, why have people across the political spectrum become so attached to it? For conservatives, the ideal of colorblindness is linked to a commitment to individualism. In their view, society should be concerned with individuals, not groups. Gross racial disparities in health, wealth, education, and opportunity should be of no interest to our government, and racial identity should be a private matter,

something best kept to ourselves. For liberals, the ideal of colorblindness is linked to the dream of racial equality. The hope is that one day we will no longer see race because race will lose all of its significance. In this fantasy, eventually race will no longer be a factor in mortality rates, the spread of disease, educational or economic opportunity, or the distribution of wealth. Race will correlate with nothing; it will mean nothing; we won't even notice it anymore. Those who are less idealistic embrace colorblindness simply because they find it difficult to imagine a society in which we see race and racial differences yet consistently act in a positive, constructive way. It is easier to imagine a world in which we tolerate racial differences by being blind to them.

The uncomfortable truth, however, is that racial differences will always exist among us until we truly shatter the myth of race. We should hope not for a colorblind society but instead for a world in which we can see each other fully, learn from each other, and do what we can to respond to each other with love. That was King's dream—a society that is capable of seeing each of us, as we are, with love. That is a goal worth fighting for.

The notion that all of these reforms can be accomplished piecemeal—one at a time, through disconnected advocacy strategies—seems deeply misguided. All of the needed reforms have less to do with failed policies than a deeply flawed public consensus, one that is indifferent, at best, to the experience of poor people, especially those of color. As Martin Luther King explained back in 1965, when describing why it was far more important to engage in mass mobilizations than file lawsuits:

“We're trying to win the right to vote and we have to focus the attention of the world on that. We can't do that making legal cases. We have to make the case in the court of public opinion.”

King certainly appreciated the contributions of civil rights lawyers (he relied on them to get him out of jail), but he opposed the tendency of civil rights lawyers to identify a handful of individuals who could make great plaintiffs in a court of law, then file isolated cases. He believed what was necessary was to mobilize thousands to make their case in the court of public opinion. In his view, it was a flawed public consensus—not merely flawed policy—that was at the root of racial oppression.

Some might attribute the cyclical nature of racial progress to the “unstable equilibrium” that characterizes the United States' racial order. Under normal conditions, they argue, state institutions are able to normalize the organization and enforcement of the prevailing racial order, and the system

functions relatively automatically. Challenges to the racial order during these periods are easily marginalized or suppressed, and the prevailing system of racial meanings, identity, and ideology seems “natural.” These conditions clearly prevailed during slavery and Jim Crow. When the equilibrium is disrupted, however, as in Reconstruction and the Civil Rights Movement, the state initially resists, then attempts to absorb the challenge through a series of reforms that are, if not entirely symbolic, at least not critical to the operation of the racial order. In the absence of a truly egalitarian racial consensus, these predictable cycles inevitably give rise to new, extraordinarily comprehensive systems of racialized social control.

One example of the way in which a well established racial order easily absorbs legal challenges is the infamous aftermath of the *Brown v. Board of Education* decision. After the Supreme Court declared separate schools inherently unequal in 1954, segregation persisted unabated. The statistics from the Southern states are truly amazing. For ten years, 1954–1964, virtually nothing happened. Not a single black child attended an integrated public grade school in South Carolina, Alabama, or Mississippi as of the 1962–1963 school year. Across the South as a whole, a mere one percent of black school children were attending school with whites in 1964—a full decade after *Brown* was decided.

Brown did not end Jim Crow; a mass movement had to emerge first—one that aimed to create a new public consensus opposed to the evils of Jim Crow. This does not mean *Brown v. Board of Education* was meaningless, as some commentators have claimed. *Brown* gave critical legitimacy to the demands of civil rights activists who risked their lives to end Jim Crow, and it helped to inspire the movement (as well as a fierce backlash). But standing alone, *Brown* accomplished for African Americans little more than Abraham Lincoln’s Emancipation Proclamation. A civil war had to be waged to end slavery; a mass movement was necessary to bring a formal end to Jim Crow. Those who imagine that far less is required to dismantle mass incarceration and build a new, egalitarian consensus reflecting a compassionate rather than punitive impulse toward poor people fail to appreciate the distance between Martin Luther King Jr.’s dream and the ongoing racial nightmare for those locked up and locked out of American society.

Differences of opinion are inevitable about which reforms are most important and in what order of priority they should be pursued. These debates are worthwhile, but it is critical to keep in mind that the question of how we do reform work is even more important than the specific reforms we seek. If the way we pursue reforms does not contribute to the building of a movement to dismantle the system of mass incarceration, and if our advocacy does not upset the prevailing public consensus that supports the

new caste system, none of the reforms, even if won, will successfully disrupt the nation's class equilibrium. Challenges to the system will be easily absorbed or deflected, and the accommodations made will serve primarily to legitimate the system, not undermine it. We run the risk of winning isolated battles but losing the larger war.

All behavior is produced by chains of physical events that ultimately reach back to forces beyond the agent's control. There is an old French proverb—*Tout comprendre, c'est tout pardonner*—'To know all is to forgive all.' The ultimate hope is that society will discard blame-based punishment as a nasty relic and insert in its place penalties whose purpose is to shape future behavior.

Part III

Supremacist Ideology

How many roads must a man walk down
Before you call him a man?
How many seas must a white dove sail
Before she sleeps in the sand?
Yes'n how many times must the cannon balls fly
Before they're forever banned?
The answer my friend is blowin' in the wind
The answer is blowin' in the wind

Yes'n how many years can a mountain exist
Before it is washed to the sea?
Yes'n how many years can some people exist
Before they're allowed to be free?
Yes'n how many times can a man turn his head
And pretend he just doesn't see?
The answer my friend is blowin' in the wind
The answer is blowin' in the wind

Yes'n how many times must a man look up
Before he can see the sky?
Yes'n how many ears must one man have
Before he can hear people cry?
Yes'n how many deaths will it take till he knows
That too many people have died?
The answer my friend is blowin' in the wind
The answer is blowin' in the wind

Non-Human Relations

An Existential Loan

“A tree is a tree,” Ronald Reagan famously said in the midst of a pitched battle over logging rights. “How many more do you need to look at?”

The law locks up the man or woman
Who steals the goose from off the common
But lets the greater felon loose
Who steals the common from the goose

The Aliens Use Elites to Geoengineer/Methanate the Earth for Their Eventual Colonization Theory That Explains Everything:

- The Canadian Defense Minister stated some Aliens live now beneath the earth.
- Trees communicate through mycelium and trees’ constant banter might possibly drive the aliens mad with their noise. Also trees both oxygenate and remove CO₂ from the atmosphere and must die to make room for methane and eliminate any chance for our survival. See: rapid deforestation.
- Fracking, mining, hyperloops, et cetera are all methods for clearing more subterranean living space.
- Sinkholes are a means of exit to the surface once the methanation is sufficient.
- The uptick in objects blazing across the sky is a possible indication that more alien eggs are arriving or alternately, these “meteors” are atmospheric testing devices.

- The recent formation of companies that will provide space exploration for the wealthy 1% suggests the wealthiest are clearly in on the geo-engineering arrangement and have been promised a space refuge or mountain bunker.

This is the only rational explanation for not stopping climate change when the evidence was in 40+ years ago. Yes, you may say greed, but greed could never be this big or the 1% this greedy because the 1% have children too. It is all by design. There is a long-term plan.

Anthrohopelessness: The weariness that genuinely humane beings feel as they witness the collapse of much biology and beauty.

But what should we do with this fear that comes from living on a planet that is dying, made less alive every day? First, accept that it won't go away. That it is a fully rational response to the unbearable reality that we are living in a dying world, a world that a great many of us are helping to kill, by doing things like making tea and driving to the grocery store and yes, having kids.

“Whilst you rage against all of those who are to blame there is a case to examine our own culpability. We find it convenient to see ourselves as Victims, and as such we have had no control over our own individual decisions to comply.”

Excuse me, governments are to blame. They had information back in the early twentieth century from scientists. They had meetings about it in the 1960s. Thatcher was well aware of the issue, yet chose instead heavily to promote petrol-driven motor cars.

I can understand, being extremely generous, governments not acting on what scientists were telling them back then. But in recent decades, with climate science so much more developed, more instrumentation, more data being processed through computers, satellites recording methane billowing from the oceans and the face of the earth, data on coral reefs, acidification in the deep oceans being measured—there was no question about the gravest culpability on the part of governments, which continues today, for god's sake. Which continues today!

Had we lived through a period of genuine democracy, then yes, we people have a say in what happens. But for ever and a day we have to vote either left or right in a noxious dance between only two main parties. And even then, so what? We vote in one and they do nothing. We vote in the other—they do nothing.

How does it even matter which of the two main parties is in power? Neither does anything in any case, nor have they in any other country in a way which seriously reduces emissions. Capitalism holds sway across this earth and the Earth has been used as currency, it has been depleted, ripped out, torn down, damaged, and plundered, always with political approval in some endless quest for “economic growth,” whatever the fuck that means.

When it means the planet is now tipping into such tumultuous change that we have changed the entire atmosphere surrounding earth, the planet will heat up to the point of no return and much of life will become extinct in what we’re casually calling an ‘extinction event’—as if it’s simply a program on telly instead of the end of trillions of lives, a cessation of possibilities on a grand scale, the throwing of millions of years evolution into the dustbin—then economic growth is the greatest con trick ever known to mankind. It is no such thing, is it?! It has brought only vast wealth in its wake for the tiniest elite and destruction on a *vast* scale for everything and everybody else.

What is *my* culpability? I don’t drive, I don’t go on aeroplanes, I wear only secondhand clothes from charity shops, I am vegan, I wrap up in jumpers and coats rather than burn electricity, I have only one light on where I currently am with all others switched off and my only piece of technology is this PC which I turn off at night and one smartphone, where I take all the ‘apps’ off so the damned battery lasts longer.

And I have read and watched and learned about climate change for two decades and the frustration is off the scale, *off the scale*, with the total lack of action by politicians, who have our blood on their hands. When will it be their blood?

The Paris meeting was yet another fudge, another delay, another shrug-and-we’ll-deal-with-this-later, with delegates pretending they’d come to some kind of vital agreement when they had done nothing of the sort. They included in their global cuts of emissions technological solutions which have not even been *invented* yet.

But oh the horror when Big Bad Orange Man pulls the US out of this completely useless and inadequate process. It’s a game to them, when will you get it? They’re playing you. And oh how that righteous anger will flow should the people ever find themselves able to focus it on their real enemies, rather than simply tearing each other apart.

I don’t know how I will be able to contain my anger over the coming decade. I don’t. But I can tell you one thing. I *will* remain angry, because I’m damned if I’m going to subside into depression. I’m going to snatch every last damned minute of life in this exquisitely beautiful world, fully active and alert and functioning. And I will see to it that this shit is stopped—enough

is enough—even if it’s the last thing I do.

The fuckin’ plants are dying off and you’re pumped because ‘HUMANS NO. 1!’ And we’re not thriving really, not on our carbon-fuel, high-growth model of society. We’re taking out an existential loan against the odds of our own survival, trading away our atmosphere and ecosystems for a few decades of hyper-consumption.

We have to get over the old Cartesian paradigm of looking at the world as a machine which we get to control, which exists separately from us and can be manipulated without any unwanted repercussions. It’s a system we belong to, and like all functioning systems it has to self-regulate to stay alive.

The Agricultural Revolution seems to have been accompanied by a religious revolution. Hunter-gatherers picked and pursued wild plants and animals which could be seen as equal in status to *Homo sapiens*. The fact that man hunted sheep did not make sheep inferior to man, just as the fact that tigers hunted man did not make man inferior to tigers. Beings communicated with one another directly and negotiated the rules governing their shared habitat. In contrast, farmers owned and manipulated plants and animals, and could hardly degrade themselves by negotiating with their possessions. Hence the first religious effect of the Agricultural Revolution was to turn plants and animals from equal members of a spiritual round table into property.

To justify the carnage inflicted upon wildlife, Roman attitudes towards the natural world shifted markedly. During the early days of the Republic, Romans regarded the Mediterranean landscape as the sacred space of nature deities such as Apollo, god of the sun, Ceres, goddess of agriculture, and Neptune, god of freshwater and the sea. As Rome expanded, however, these religious beliefs became largely hollow rituals, disconnected from natural processes. During the high days of the empire, Stoic and Epicurean philosophies that legitimated the status-driven debauchery of the Roman upper classes prevailed. Orgies of conspicuous consumption, in which the wealthy would eat until they vomited, only to begin eating again, became common—this one is perhaps apocryphal, but illustrative nonetheless.

By the time Christianity became the official state religion of Rome in the late fourth century, there was little to differentiate Roman philosophy from the dominant attitude of the Judeo-Christian scriptures, in whose creation myth God grants human beings absolute dominion over the world he has made. Humanity, the Bible and Christian tradition held, was placed apart from nature by God, gifted with an immortal soul and a capacity for rational thought that legitimated the transformation of the natural world in the pursuit of human self-interest.

It was Western culture that first dreamed up the notion that ‘humans’ and ‘nature’ are somehow separate. This dichotomy holds that human beings are inherently superior to all other animals, alleging that we are the only ones capable of cognition or experiencing emotions. We’re told that efforts to communicate with other animals or to develop relationships that aren’t based on total domination are simply futile. Despite this very thorough conditioning, many people still desire a deeper connection with other animals and the more-than-human world, a connection that was implicit in all human lives before the dawn of ‘modern civilization,’ and the colonization and decimation of other cultures.

A closer look at the “crazed mob” on the beach that day seems to reveal this desire for connection: Notice that the people were not intentionally abusing the dolphin. There were cries among the crowd to place her back in the water. When she died, reportedly from dehydration, people came forward to tenderly stroke her, seemingly overcome with a dawning sense of sadness and regret. These are not the actions of monstrous people who should be condemned. These are the actions of people who are being taught to fundamentally misunderstand other animals, to treat them like objects rather than the aware, sensitive beings they truly are.

The incident illustrates one of the ways that Western culture mediates our relationships with other animals in order to reinforce the illusory barrier between ‘humans’ and ‘nature’—the performer metaphor, where humans are the spectators and nature is the entertainer. In North America at least, the language used to describe encounters with wild animals is largely linked to entertainment: ‘That whale really put on a show’ or ‘That bird is showing off.’ The examples are endless.

Companies like SeaWorld are simultaneously a symptom and a cause of this performer metaphor. Their facilities are sites where the collective misunderstanding of animals is acted out and disseminated into popular culture. Thousands of largely young and impressionable people who visit SeaWorld each year are exposed to the performative metaphor in its purest form: they, as the audience, applaud as the cetaceans are forced to go through their trained routines. They leave with the impression that what they have witnessed is part of the natural order of things: that this is how humans ought to relate to cetaceans and other animals. SeaWorld should have acknowledged the part their industry played in the death of the small Franciscana dolphin. Instead, they released a snarkily worded blog that admonished people for taking selfies with the dolphin. According to SeaWorld, one should not “pass around the animal like a prop to get a good selfie. And yes, taking a stranded young dolphin out of the water to take selfies with it falls under harassment.”

This may be true. But coming from SeaWorld, this advice is ironic since their entire business model is predicated on removing cetaceans from the oceans, forcing them to perform shows, and—wait for it—charging people money to take selfies with them. SeaWorld’s explicit acting-out of the performer metaphor is what helps transform dolphins, captive or stranded, into props for photos.

Of course, not everyone in Westernized culture views the more-than-human world through a performative lens. However, this perspective remains quite pervasive and it actively inhibits alternative ways of understanding and relating. The performer metaphor is so predominant in Western settings that at times we have a difficult time speaking, and perhaps even perceiving, differently. So, when we say things like, ‘those manatees enjoy performing for us,’ we may actually believe it. As cities grow larger and fewer people have the opportunity to develop their own perspectives, the performer metaphor’s influence may continue to grow.

Unfortunately, McKibben’s “war on climate change” only indirectly addresses the structural inequities. Although it might alleviate unemployment, “help ease income inequality,” and clean up the environment to some degree, simply replacing the toxic fossil fuel industry with a clean, green energy sector would do little to correct deeper, systemic problems—such as poverty, slums, our prison system, militarism—and other injustices emanating from our exploitative political economy; one that could be maintained by green cops, and by green armies, just as easily as by their fossil fuel counterparts.

All of this leads to a serious consideration. Instead of regarding the inability to act on climate change as a result of inertia or incompetence, perhaps we should begin to regard it as willful. After all, who now sincerely doubts that pollution and greenhouse gases create the conditions that produce the ecological calamities that largely harm the poor? And how can we overlook the related fact that the owners of the world have a substantial incentive in ridding the planet of the billions of people whose existence alone threatens their property and privileges? Indeed, allowing climate change to kill the poor would not only be more convenient than policing, fighting, locking out and locking up billions; by claiming that it’s inevitable, the owners of the world can watch the ecological holocaust unfold with a relatively good conscience.

When one considers this, along with the fact that the affluent classes dictate social policy as well as the regulation of the pollutants responsible for the climate calamities bombarding the poor, we may begin to see that the failure to halt the proliferation of notoriously toxic gases is comparable to a type of passive chemical warfare. Isn’t that what it amounts to? And, relevantly, there is a World War II precedent for just this type of inaction as

well. While the Red Army was losing millions in their march toward Berlin, the US intentionally delayed invading Europe in order to allow the Nazis to further weaken the USSR, which the US, Britain, and others regarded as a threat to their property—and the rule of money—ever since the October Revolution.

Although there is no evidence to suggest that climate inaction amounts to a willful omission designed to cull the world's poor, it is nevertheless difficult to deny that action is being both stymied and ignored. Obama, for instance, who promised in 2008 to vigorously tackle climate change, did nothing. And though some may argue that, whatever his shortcomings, McKibben should at least be commended for arguing for action, this argument is undermined by McKibben's approach which, at best, amounts to a plea for reform; and, at worst, comes off as a pitch for a business opportunity.

Rather than McKibben's "war on climate change," adequately mitigating the harms associated with climate change—which are inseparable from poverty and exploitation—requires an entirely new, emancipatory political economy, one that produces necessities for human flourishing for their own sake, rather than for exchange. Instead of producing new machines, what's more crucial is that we turn many of the existing ones—such as the war machine—off. And though McKibben is correct in pointing out that climate change involves war, he grievously misidentifies the enemy. Climate change is not the enemy; it's merely one of the many harmful effects of our political economic system. This is what needs to be eliminated. But such a transformation requires something greater than war. It requires peace.

Conveniently, you don't even have to read the piece, the headline tells you all you need and then some: "How To Make A Profit From Defeating Climate Change" really nails it. The entire mindset on display in just a few words. If that's what they went for, kudos are due.

That these problems originated in the same relentless quest for profit that they now claim will help us get rid of them, is likely a step too far for them; must have been a class they missed. 'We destroyed it for profit' apparently does not in their eyes contradict 'we'll fix it for profit too.' Not one bit. It does, though. It's indeed the very core of what is going wrong.

Profit, or money in general, is all these people live for, it's their altar. That's why they are successful in this world. It's also why the world is doomed. Is there any chance I could persuade you to dwell on that for a few seconds? That, say, Bloomberg and Carney, and all they represent, are the problem dressed up as the solution? That our definition of success is what dooms us?

Philosophers, religious people, or you and me, may struggle with the question, 'what's the purpose of life,' these guys do not. The purpose of life

is to make a profit. The earth and all the life it harbors exist to kill, drill, excavate, and burn down, if that means you can make a profit. And after that you repair it all for a profit. In their view, the earth doesn't turn of its own accord after all, it's money that makes it go round.

The lifestyles of the last ten generations of us, especially Westerners, are characterized more than anything else by the huge increase in the use of energy, of calories and joules. As we went from wood to peat to coal to oil and gas, the energy return on energy investment kept going higher. But that stopped with oil and gas. And from now on in it will keep going down.

'Free carbon excess' was a one-off gift from nature. It will not continue and it will not return. Different forms of carbon have offered us a one-time source of free energy that we will not have again. The idea that we can replace it with "clean energy" is ludicrous. The energy return on energy investment doesn't even come close. And you can't run a society with our present levels of complexity on a much lower net energy. We must dress down. No profit in that, sorry.

Ever wonder why everybody drives a car that is ten times heavier than her/himself and has a 10% efficiency rate in its energy use? Why there's an infrastructure everywhere that necessitates for every individual to use 1,000 times more energy than it would take herself to get from A to B on foot? Sounds a lot like deliberately wasteful behavior, doesn't it?

The essence here is that while we were building this entire wasteful world of ours, we engaged in the denying and lying behavior that typifies us as a species more than anything: we disregarded externalities. And there is no reason to believe we would not continue to do just that when we make the illusionary switch to "clean" energy.

The idea that "extinction does not carry moral significance, even when we have caused it"—that statement is a stranger to thousands of years of philosophy on moral agency and reveals an ignorance of human moral thinking. Moral agency issues from an ability to consider consequences. Humans are the species most capable of such consideration. Thus many philosophers consider humans the only creatures capable of acting as moral agents. An asteroid strike, despite its consequences, has no moral significance. Protecting bears by declaring Katmai National Monument, or un-protecting Bears Ears National Monument, are acts of moral agency. Ending genetic lineages millions of years old, either actively or by the willful neglect that many advocate, certainly qualifies as morally significant.

We have not done the things that are necessary to lower emissions because those things fundamentally conflict with deregulated capitalism, the reigning ideology for the entire time we have been struggling to find a way out of this crisis. We are stuck because the actions that would give us the best

chance of averting catastrophe—and would benefit the vast majority—are extremely threatening to an elite minority that has a stranglehold over our economy, our political process, and our major media outlets. That problem might not have been insurmountable had it presented itself at another point in our history. But it is our great collective misfortune that the scientific community made its decisive diagnosis of the climate threat at the precise moment when those elites were enjoying more unfettered political, cultural, and intellectual power than at any point since the 1920s.

The metaphor that we are part of the earth ecosystem is not a belief; it is a reality. We are tiny specks in a fabulous system, parts of something grand. We are part of what life has “learned” from its inception on earth and has genetically encoded in DNA that will be passed on until the sun goes out—hopefully.

Our economic system and our planetary system are now at war. Or, more accurately, our economy is at war with many forms of life on earth, including human life. What the climate needs to avoid collapse is a contraction in humanity’s use of resources; what our economic model demands to avoid collapse is unfettered expansion. Only one of these sets of rules can be changed, and it’s not the laws of nature.

We can’t will it to be otherwise. We can’t say, ‘Well, yes, our civilization is built on an evolutionarily unstable strategy but we can make it work anyhow, because we’re humans.’ The world will not make an exception for us. And of course what the Church teaches is that God *will* make an exception for us. God will let us behave in a way that would be fatal for any other species, will somehow “fix it” so we can live in a way that is in a very real sense self-eliminating. This is like expecting God to make our airplanes fly even if they’re aerodynamically incapable of flight.

“Yes, a new economic model is needed if catastrophic climate change is to be avoided. I do not know anything about the finer details of economics but can remember being highly skeptical when carbon pricing was suggested as a way to reduce emissions. It is quite obvious that it cannot work.”

Modern societies have always been hierarchical. With humans, wealth had come to be seen to be the symbol of high status and success. This would have been fine if it had been kept within the limits that the environment could sustain. Unfortunately, the Industrial Revolution opened the floodgates to environmental exploitation on a massive scale with its consequent emissions of CO₂ and other pollutants.

Every successive layer of society has more control over those beneath them and demands more rewards. The majority of humans are trapped by this system and many work to “better” themselves by moving up the social order by acquiring more wealth. Industry is geared to producing ever more products to enable people to get rich. The cost to the environment is totally ignored.

It is obvious that this economic model has led us onto the path to extinction. It is indisputable that the climate is set towards rapid change. That has always led to mass extinction events in the past. If anyone is not aware of the meaning of ‘mass extinction,’ it means that the vast majority of species on Earth will die, including humans.

A new economic model is needed. Ideally, the culture of acquiring wealth should be totally abandoned. I am very aware that that is very unlikely to happen but it could be the only way to save ourselves. Societies with a high disparity between the poorest and wealthy have, in the past, bred discontent and been overturned by revolutions. Unfortunately, the new rulers have always fallen into the same trap—that of acquiring wealth for themselves at the expense of others and the environment.

Human society has evolved to be this way over millennia. Unfortunately, there are not millennia available to create a fairer society less exploitative of others and resources. It would undoubtedly have been better if action to reduce fossil fuel use had been taken thirty or forty years ago instead of increasing their use in spite of warnings. The only real way to make a difference now is to cut fossil fuel burning to the barest minimum immediately which would mean creating a new economic model. Too much to ask?

Many people cannot see beyond the need to have work, any work, whatever the environmental cost. I am very far from being the cleverest person here but even I can see that there is a way, but it does mean that the wealthy would have to accept a lower standard of living. Surely, other people, very many of whom are a lot cleverer than me, can also see that? There are very many people who are perfectly happy with a considerably lower standard of living than even those who do not consider themselves to be wealthy, I am one of them. Wealth is not money or material possessions, it is having sufficient food to eat, a place to live, and social interactions with family and friends.

As climate change progresses, the first of those to go will be sufficient food to eat. That will cause huge disruption of the social order and economic collapse. Change is inevitable, surely it would be better to take decisive action now to reduce the impacts and to ensure an orderly transition rather than to let everything descend into chaos.

Of course, it is not helpful that there are still so many people who

dispute that climate change is a problem. That is akin to having the carbon monoxide alarm go off in their house and for them to say, ‘I can’t see anything, or smell anything so no worries, I’ll just wait to see if I die.’ The alarm is being sounded by scientists, who have been studying the climate full time for many years. They have been sounding the alarm for at least thirty years but emissions have been rising in that time. Not by a small amount, by around one third more. No meaningful action has been taken to halt these emissions. Time is running out very fast.

In pushing other species to extinction, humanity is busy sawing off the limb on which it perches.

The end of growth exposes the stupidity and ignorance of all but a precious few “leaders.” There is no other way this could have run, because an era of growth simply selects for different people to float to the top of the pond than a period of contraction does. Can we agree on that?

Growth leaders only have to seduce voters into believing that they can keep growth going, and create more of it. Anyone can do that. So anyone who’s sufficiently hooked on power games will apply. Contraction leaders have a much harder time; they must convince voters that they can minimize the suffering of the herd. Which is invariably a herd that no one wants to belong to. A tough sell.

At some point the whole ‘but it will create jobs’ thing doesn’t hold water. Jobs are only valuable if they contribute to the future. If the jobs, quite foreseeably, make the future worse then they have no value—perhaps even negative value once their externalities are factored in.

“Certain wolves I’ve known—they were better at being a wolf than I’ve been at being a person. Killing a wolf is like killing a brother.

I have lived to see state after state extirpate its wolves. I have watched the face of many a newly wolfless mountain, and seen every edible bush and seedling browsed to death, every edible tree defoliated to the height of a saddlehorn. Too much safety seems to yield only danger in the long-run. Perhaps this is the hidden meaning in the howl of the wolf, long known among mountains, but seldom perceived among men.”

Wolves became werewolves, dangerous dogs became chupacabras, human-eating snakes became dragons, narwhal horns became unicorns, mastodon became cyclops, squids and octopi became sea monsters, and even Thomas Jefferson in the 1790s introduced the megalonyx, which he believed to be a

great cat-like creature based on the discovery of a large claw—it turned out to belong to a sloth. All to be defeated at the hand of humans.

People continue to tame and subjugate nature, but when we visit the few remaining scraps of wilderness where bears roam free, we can still feel an instinctive fear. How precious that feeling is.

We are each newly arrived and temporary tourists on this planet, yet we find ourselves custodians of the world for all people yet unborn. A little humility, and forbearance, might comport.

This we know: the Earth does not belong to man, man belongs to the Earth. All things are connected like the blood that unites us all. Man did not weave the web of life, he is merely a strand in it. Whatever he does to the web, he does to himself.

Traditionally, when a great crime such as a murder occurs, people make a great effort to apprehend the guilty party. A murder is a great grievance, but it is a minor one compared to the loss of a species, especially one that is part of a cultural and ecological web that encompasses millions of people, performs ecological services on a near global scale, and enriches the enjoyment of life not just for the living but for all generations to come.

Neither ignorance nor personal justification can be a defense when it comes to heinous crimes leading to genocide, ecocide, or the extinction of species. Effects really matter, and any chemical that is synthesized—meaning that it has never before existed as a component of an ecosystem—should be assumed harmful on an ecosystem level until proven otherwise. This is not wild extrapolation; it is commonsense biology. And by common sense it is also obvious that ‘the market’ as such will not solve the problem but will create and maintain it, if left to run free like a high-tech car without a steering wheel or brakes.

It’s not that anyone thinks humans have not greatly changed the world, or will stop changing it. Rather, as the great wildlife ecologist Aldo Leopold wrote in his 1949 classic, *A Sand County Almanac*:

“To keep every cog and wheel is the first precaution of intelligent tinkering.”

Diversity is a survival factor for the community itself. A community of a hundred-million species can survive almost anything short of total global catastrophe. Within that hundred-million will be thousands that could survive a global temperature drop of twenty degrees—which would be a lot more devastating than it sounds. Within that hundred-million will be thousands that could survive a global temperature rise of twenty degrees. But a community of a hundred species or a thousand species has almost no survival value at all.

It is holy work. The more competitors you destroy, the more humans you can bring into the world, and that makes it just about the holiest work there is. Once you exempt yourself from the law of limited competition, everything in the world except your food and the food of your food becomes an enemy to be exterminated.

As you see, one species exempting itself from this law has the same ultimate effect as all species exempting themselves. You end up with a community in which diversity is progressively destroyed in order to support the expansion of a single species.

We—especially economists—need to realize that the global economy is a subsystem of our global ecology. There can be no economy without exploitation of the natural world and the global economy can never be larger than the size of the natural resources that Earth once held because ecology indicates the boundaries of where our economy can reach. There are ecological limits. Human capital and natural capital are not interchangeable in any tangible sense. The eco-capitalist mindset unfortunately fails to understand this very basic, and self-evident, observation.

The metaphors we use to describe the natural world strongly influence the way we approach it, the style and extent of our attempts at control. It makes all the difference in and to the world if one conceives of a farm as a factory or a forest as a farm.

The potential for us to make progress with environmental issues is limited by the basic assumptions that we make about nature, the unspoken, often unrecognized perspective from which we view our environment. If there is any hope of dealing with our global environmental crisis we must first break free of old assumptions and old myths about nature and ourselves.

Forest = Forest
Cattle Ranch = \$

Yes. Sadly. Natural resources are ruthlessly exploited by predatory capitalism and turned into money. But money is without life and without value outside a very limited cultural setting. Our hoarding economy has turned everything it touches into money. Money is stored as figures in a bank. It is just some bytes in a computer. Utterly useless unless reinvested in something that sustains life. But all the hoarders do is invest their money to make—wait for it—more money. Just rewrite the accounts and give everyone billions each. Flood the earth with digital wealth if that is so special. It is only of symbolic value. It is not real for fucks sake! And this is to say nothing of the incredible loss of biodiversity that goes along with the destruction of forest. Given how consistently researchers discover powerful

new pharmaceutical compounds in exotic rainforest plants, we may have already sacrificed a cure for cancer for the sake of our Big Macs.

Forest is very much real, very much of unique value. not just forest but a rich environment full of ever evolving life forms. With inherent value, the inalienable value of life. Who knows what wonders come from such forest? Once upon a time in a forest an ape climbed down from a tree and stood upright on the earth and walked forward into a future which created you and me. Why might such forests not generate more new life at least as wonderful as human beings? Let's keep as much biodiversity as possible. For our present benefit and for the future.

To exchange life for money is insane, simply insane.

If there is danger in the human trajectory, it is not so much in the survival of our own species as in the fulfillment of the ultimate irony of organic evolution: that in the instant of achieving self-understanding through the mind of man, life has doomed its most beautiful creations.

I thought of the long ages of the past during which the successive generations of these things of beauty had run their course with no intelligent eye to gaze upon their loveliness, to all appearances such a wanton waste of beauty. This consideration must surely tell us that all living things were not made for man. Their happiness and enjoyments, their loves and hates, their struggles for existence, their vigorous life and early death, would seem to be immediately related to their own well-being and perpetuation alone.

Anthropocentrism, the idea that humankind is the most important element of existence, is another unique facet of the human/nature divide that has colonized much of the world today. Simply put, anthropocentrism is narcissism on a cultural scale.

This is manifested when, for example, entire landscapes are transformed to be suited to the needs of modern civilization, done at the expense of both human and nonhuman. The opinions, desires, and needs of indigenous communities, of cetacean communities, of the multitude of other-than-human communities, are unequivocally and thoroughly dismissed.

Some say that the selfie is the epitome of individual narcissism. The rise in selfie popularity seems to align with the trajectory of Western anthropocentrism, as both climb to a fevered pitch. Gone are the days when people were content to take photos where the landscape or other animals were the central features.

Now, humans are often centered in these shots, as though the scenes would be meaningless without a human face. The world increasingly exists as a mere backdrop for the comings and goings of Westernized humanity.

Selfies can be inflammatory, and for good reason. Many animals have died for selfies, but billions more have died from rampant human self-

centeredness. Selfies bring into visceral focus our ailing relations with the more-than-human world, and this focus is uncomfortable to reckon with.

But reckon with it we should. We can do this by first recognizing where the problems lay: within the Western framing of the world we experience. Only when we have done this can we begin imagining alternative ways of being together, where we can co-create a more compassionate and understanding world for all species.

Only when we put down the selfie stick and really look at the ‘more than human’ world will we begin to reclaim the connections that Western culture has hidden from us. There is a whole Universe that awaits us beyond the illusion.

Of course, the same arbiters of moral importance will heatedly defend a favorite delicacy, a piece of finery, a bloody recreation, or whatever else, as if all the world depended on it. How do we convey to them the truly finer things, such as a sense of fraternity with fellow creatures, bound for dust as we are, and the self-restraint and mercy in which we show the real glory of humanity?

It cannot be the right of masses of people who can afford it to take vacations in whatever part of the planet they choose regardless of many factors including environmental ones. Just because corporations increasingly have the human right to exploit resources wherever and whenever they choose, does not mean we should be extending that right to all individuals at the level of total vacation destiny rights. We should be challenging the destructive rights of the corporations.

We all need to start understanding the true value of things rather than the price of things. Sometimes something simply should not have a price tag.

“It’s basically dealing with itself as we deal with basic human needs. As countries develop, fertility rates are dropping worldwide, and many developed countries are already below replacement rates.”

The problem with “developed” countries is that they use a perfectly insane amount of resources and depend on suffering to maintain their standard of living. As more countries become “developed” this puts more pressure on the rest of the world’s natural resources.

“If you want global population to drop, the best thing we can do is help keep the developing countries on that track.”

It's not a lack of development, it's a lack of a cultural value that comprehends and respects the future and decent behavior toward non-human beings and ecosystems. It's egotistical insanity and a fundamental lack of morality.

The question is, do we want to continue eating meat, or do we want to make room for a couple billion more people? The all-encompassing question is, do we want to give up X, so that we can fit Y number of people on the planet?

A lot of people like to talk about how there's plenty of room for so many more people. But it seems as if they don't really think about quality of life questions, because they'll also tell you that taking daily showers is bad, having a lawn is bad, driving a car is bad, owning a single family home is bad, not living in an urban area in general is bad. But none of these things are objectively 'bad,' it's just that they are starting to butt up against questions like 'Is there enough for everyone?' and, 'Can we keep doing this to the planet?'

And those are great questions to be asking. Because in many ways, there isn't enough for everyone, and we can't keep doing this to the planet. And while I certainly don't advocate lavish, wasteful, destructive lifestyles, I do see the almost every form of personal cut-backs as nothing more than a stopgap solution, a warning. I mean, if me changing from 15 minute showers to 10 minute showers is what's necessary today, what's necessary tomorrow? Even the big offenders, like dairies or California almonds, don't provide unlimited water for an unlimited population.

The usual next argument is that the global population will reach some kind of equilibrium, both by a general decrease in birth rates for first world countries, and by the simple fact that we will eventually run out of resources to feed, clothe, shelter everyone. And I believe that, but what I don't want is a world continuously on the brink. I don't want just enough water for people to drink. I don't want just enough tigers to maintain a viable population. I don't want just enough National Park space to accommodate every visitor, as long as the park is at 100% capacity every day. It's not about any one of these things, but it's about all of them, and many more.

Would I literally kill someone for a steak or the freedom to take a nice 30 minute shower after a long day? No. And eugenics scares the shit out of me. I'm just confident that the key to human prosperity and happiness and safety lies in a reasonable population. And that's what I think more people should be talking about.

Our planet is not fragile at its own time scale, and we, pitiful latecomers in the last microsecond of the planetary year are stewards of nothing in the long-run. Yet no political movement is more vital and timely than

modern environmentalism because we must save ourselves—and our neighbor species—from our own immediate folly.

Many people argue in a dramatically flawed way, yet many will not realize it. We find ourselves arguing over non-issues, not the real issues. One may be arguing that conservation hunting is fantastic, it helps support the animals when no other funding is provided. The other may be arguing over the immorality of killing the animal for money. They're not having the same argument in most cases. Does the supporter believe this is the best or correct way to be doing it? We don't know. Is the opponent against it always? Simply arguing that while it is the only option available now, because the system is flawed? Neither is necessarily examining the real issue, while wasting time and energy on unimportant distractions.

Other Nations

The root of all of our myths containing various humanoid, human-like, primate-esque monsters is our genetic cousins which our ancestors made extinct.

When we wound the planet grievously by excavating its treasures, destroy its ability to breathe by converting forests into urban wastelands, poison its waters with toxic wastes, and exterminate other living organisms, we are in fact doing all this to our own bodies. All other species are to be enslaved or driven to extinction if need be in the interests of human “progress.” We are part of the same web of life—where every difference we construct artificially between ‘them’ and ‘us’ adds only one more brick to the mausoleum of humankind itself.

“They are in all ways like me, but the thing that has failed them is luck, and they are as unlikely to escape theirs as I am to forfeit mine. The poachers are just uneducated young men. They’re as smart as we are; they’re being used by evil people because they have nothing to lose except their lives.”

When a poacher kills an elephant, he doesn’t just kill the elephant who dies. The family may lose the crucial memory of their elder matriarch, who knew where to travel during the very toughest years of drought to reach the food and water that would allow them to continue living. Thus one bullet may, years later, bring more deaths. Watching dolphins while thinking of elephants, what I realized is: when others recognize and depend on certain individuals, when a death makes the difference for individuals who survive, when relationships define us, we have traveled across a certain blurry boundary in the history of life on Earth—‘it’ has become ‘who.’

Grief doesn’t require understanding death. Humans certainly grieve, but they disagree on what death is. People learn widely varying traditional beliefs—in heaven, hell, karmic reincarnation, and other devices for keeping the deceased undead. The main thing humans seem to believe about death is: you never really die. A minority believe that we simply end, ceasing to exist. But most people find that notion inconceivable. ‘I believe in life everlasting’ are words many are taught to repeat in church. So when a chimpanzee or dolphin carries its dead baby, does it understand any less about death than does the pope? When an elephant fondles the bones of its dearly departed, does it understand more?

Is it because I speak to you, that you judge that I have feeling, memory, ideas? Well, I do not speak to you; you see me going home looking

disconsolate, seeking a paper anxiously, opening the desk where I remember having shut it, finding it, reading it joyfully. You judge that I have experienced the feeling of distress and that of pleasure, that I have memory and understanding.

Bring the same judgment to bear on this dog which has lost its master, which has sought him on every road with sorrowful cries, which enters the house agitated, uneasy, which goes down the stairs, up the stairs, from room to room, which at last finds in his study the master it loves, and which shows him its joy by its cries of delight, by its leaps, by its caresses.

Barbarians seize this dog, which in friendship surpasses man so prodigiously; they nail it on a table, and they dissect it alive in order to show the mesenteric veins. You discover in it all the same organs of feeling that are in yourself. Answer me, machinist, has nature arranged all the means of feeling in this animal, so that it may not feel? Has it nerves in order to be impassible? Do not suppose this impertinent contradiction in nature.

We say ‘humans and animals’ as though life falls into just two categories: ‘us’ and ‘all of them.’ Yet we’ve trained elephants to haul logs from forests; in laboratories we’ve run rats through mazes to study learning, let pigeons tap targets to teach us Psychology 101; we study flies to learn how our DNA works, give monkeys infectious diseases to develop cures for humans; in our homes and cities, dogs have become the guiding protectors for humans who see only by the light of their four-legged companions’ eyes. Throughout all this intimacy, we maintain a certain insecure insistence that ‘animals’ are not like us—though we are animals. Could any relationship be more fundamentally miscomprehended?

“Realizing we are not so different to the rest of the animal kingdom could have profound implications on how we treat our closest living relatives. Is it acceptable to continue to carry out invasive medical trials? Or lock up our primate cousins in zoos for our entertainment?”

Sentences like this are so depressing to read. First, because yes, obviously. Anyone with a heart would agree that medical experiments and locking up animals for our entertainment is grotesque, selfish callousness on the part of humans. But also—yes, we *know* that there is a very faint dividing line between human and animal behaviour. Anyone who’s ever owned a pet knows that.

I have only known cats. But the psychological connection, the understanding between them and me, their emotional need for me to show them love, their need to love me back, and a whole range of other behaviours

means they are not simply objects, or even ‘animal-objects,’ but living thinking sensing emotional beings—like me, except with fur and different shaped bodies.

I’ve had cats who are clearly intelligent, others who are a little dim. I’ve had cats play tricks on me, or come up with strategies, such as systematically knocking books off a shelf and peering around to notice my reaction, when they want to jostle me into getting up from the computer and giving them breakfast. I usually feed my cats at 8:00. If I’m sitting at my computer at 7:45 and one of my two cats decides he’s impatient for breakfast, that’s what he does. Or reaches out and slightly nudges a coffee cup.

I could cite hundreds of examples of what my cats do. And they’re “just” cats. Monkeys, apes—are vastly more similar to us human beings, obviously. To trap an animal used to roaming in the wild in a cage is grotesque stupidity on the part of humans—very cruel, a horrific punishment for an animal who has done nothing but be himself. I will never forget Guy the Gorilla at London Zoo, sitting hunched in front of the bars of his cage, grumpy and depressed, getting angry with people gesticulating in front of his face and masturbating wildly when angry.

Climate change threatens the existence of all of us on this planet. I often think how very much I would like a moratorium for animals across the world, even just one fucking week, before we wipe out life on earth, where they can just be left alone. Not boiled alive in Asia, not have their horns ripped off in Africa, not cut up and drugged and trapped in machines in the West, not shoved in their thousands into pens so tiny they can’t even turn around and as a result compulsively peck out their feathers.

The way humans treat the natural world goes beyond obscenity. It is sick, sick, sick behaviour. Our comeuppance is this: because we can treat the natural world as we do, because we can treat living creatures the way we do, means that our mental faculties are far too limited to understand the way that human beings naturally slot into the world. Which means we are too ignorant to understand how to protect our natural living world. Which is why we have done nothing about climate change and why we have already locked into the system, with our out of control emissions, temperature rises of at least four degrees or more.

Our sociopathy is too advanced for the survival of the natural world on this planet. And too advanced for the survival of our own selves. It’s very depressing.

Whenever people say, ‘We mustn’t be sentimental,’ you can take it that they are about to do something cruel. And if they add, ‘We must be realistic,’ they mean they are about to make money out of it. These slogans have a long history. After being used to justify slave traders, ruthless industrialists,

and contractors who had found that the most economically realistic method of cleaning a chimney was to force a small child to climb it, they have now been passed on, like an heirloom, to the factory farmers.

This isn't the first time science has seen such a pervasive collapse of rigor. A century ago, scientists believed that northern Europeans were the most intelligent of our species, thanks to a big fat dose of bias. Such bias is now seen as antiquated, but comparative psychology is applying the same bias to cross-species comparisons between humans and apes.

In one set of studies, researchers compared children raised in Western households, steeped in the cultural conventions of nonverbal signaling, with apes raised without the same cultural exposure. But then they were all tested on Western conventions of non-verbal communication. Of course the human children are going to do better. I would like to see them put the human kids in the wild and see them forage for food and communicate with other apes; who'd outperform there?

Of the approaches so far in measuring apes' abilities, the only firm conclusion that can be made is that apes not raised in Western, postindustrial households do not act very much like human children who were raised in those specific ecological circumstances, a result that should surprise no one.

We need another and a wiser and perhaps a more mystical concept of animals. Remote from universal nature and living by complicated artifice, man in civilization surveys the creature through the glass of his knowledge and sees thereby a feather magnified and the whole image in distortion. We patronize them for their incompleteness, for their tragic fate for having taken form so far below ourselves. And therein do we err. For the animal shall not be measured by man. In a world older and more complete than ours, they move finished and complete, gifted with the extension of the senses we have lost or never attained, living by voices we shall never hear. They are not brethren, they are not underlings: they are other nations, caught with ourselves in the net of life and time, fellow prisoners of the splendour and travail of the earth.

We have to remember that what we observe is not nature itself, but nature exposed to our methods of questioning. It is a simple truth of field biology that it is easy to miss and hard to figure out what, exactly, an animal is doing. And what animals do may be more complex than the descriptions we apply or the measurements we devise.

We are sometimes at a loss in trying to describe such events because we unthinkingly imagine the animals as instinctual. We are suspicious of motive and invention among them. The lesson of evolution with the muskox, an animal that has changed little in two-million years, is that whether it is witty or dull in its deliberation, a significant number have consistently

chosen correctly.

Whenever we seek to take swift and efficient possession of places completely new to us, places we neither own nor understand, our first and often only assessment is a scientific one. And so our evaluations remain unfinished.

Ecosystems are not only more complex than we think. They're more complex than we can think.

Assessing the mind of a creature this alien demands that we be extraordinary flexible in our own thinking. Imagine the way someone like an octopus might attempt to measure our brainpower: How many color patterns an octopus might wonder, can your severed arm produce in one second? On the basis of that answer, an octopus could reasonably conclude we humans were stupid indeed—so dumb that they could steal a bucket of fish from us in full view.

“What if the catalyst or the key to understanding creation lay somewhere in the immense mind of the whale? Suppose if God came back from wherever it is he's been and asked us smilingly if we'd figured it out yet. Suppose he wanted to know if it had finally occurred to us to ask the whale. And then he sort of looked around and he said, 'By the way, where are the whales?'”

A lot of flowers have patterns on their petals that reflect UV light, the reason being that bees can see UV, and use that information to better figure out which flowers are good to harvest. We can't see UV light, so we see flowers differently than bees do. It doesn't matter to you whether that flower would rather be pollinated by a bee or a hummingbird or a butterfly, because you're much more interested in looking at my face and figuring out whether my smile is genuine or if I'm scamming you. So bees see flowers in a special way but my face is just another vaguely-round blob, while your senses can instantly process an incomprehensible amount of information about my facial expression but can't distinguish flowers as well as a bee can.

What is a flower really like? What is a face really like? What the bee sees? What we see? To understand what a flower is, you have to understand it objectively, completely abandoning the idea of sight, or what a flower looks like, what it smells like, what it feels like. We are incapable of doing that.

The duration of the beat of a hummingbird's wing is as concealed to our sensory organs as is the drifting of the continents.

The labeling of objects is very much part of language, and we should not forget that once upon a time linguists defined language simply as symbolic

communication. Only when apes proved capable of such communication did they feel the need to raise the bar and add refinements such as that language requires syntax and recursivity. Syntax is what tells us that a Venetian blind is not a blind Venetian. Many communication experts consider syntax to be the defining characteristic of true language.

Critical pieces such as power alliances (politics) and the spreading of habits (culture), as well as empathy and fairness (morality), are detectable outside our species. The same holds for capacities underlying language. Honeybees, for example, accurately signal distant nectar locations to the hive, and monkeys may utter calls in predictable sequences that resemble rudimentary syntax.

The most intriguing parallel is perhaps referential signaling. Vervet monkeys on the plains of Kenya have distinct alarm calls for a leopard, eagle, or snake. These predator-specific calls constitute a life-saving communication system, because different dangers demand different responses. For example, the right response to a snake alarm is to stand upright in the tall grass and look around, which would be suicidal in case a leopard lurks in the grass.

Science increasingly views human speech and birdsong as products of convergent evolution, given that songbirds and humans share at least fifty genes specifically related to vocal learning. No one serious about language evolution will ever be able to get around animal comparisons.

Even with respect to my fellow humans, I am dubious that language tells us what is going on in their heads. I am surrounded by people who study members of our species by presenting them with questionnaires. They trust the answers they receive and have ways, they assure me, of checking their veracity. But who says that what people tell us about themselves reveals actual emotions and motivations? This may be true for simple attitudes free from moralizations ('What is your favorite music?'), but it seems almost pointless to ask people about their love life, eating habits, or treatment of others ('Are you pleasant to work with?').

It is far too easy to invent post hoc reasons for one's behavior, to be silent about one's sexual habits, to downplay excessive eating or drinking, or to present oneself as more admirable than one really is. No one is going to admit to murderous thoughts, stinginess, or being a jerk. People lie all the time, so why would they stop in front of a psychologist who writes down everything they say? In one study, female college students reported more sex partners when they were hooked up to a fake lie-detector machine than without it, thus demonstrating that they had been lying before.

“My distrust of language goes even deeper, because I am also unconvinced of its role in the thinking process. I am not sure that

I think in words, and I never seem to hear any inner voices. This caused a bit of an embarrassment once at a meeting about the evolution of conscience, when fellow scholars kept referring to an inner voice that tells us what is right and wrong. I am sorry, I said, but I never hear such voices. Am I a man without a conscience, or do I think in pictures? Moreover, which language are we talking about? Speaking two languages at home and a third one at work, my thinking must be awfully muddled. Yet I have never noticed any effect, despite the widespread assumption that language is at the root of human thought. In his 1973 presidential address to the American Philosophical Association, tellingly entitled ‘Thoughtless Brutes,’ the American philosopher Norman Malcolm stated that ‘the relationship between language and thought must be so close that it is really senseless to conjecture that people may not have thoughts, and also senseless to conjecture that animals may have thoughts.’”

How much different is you rehearsing your presentation in your mind, anticipating and answering potential questions, than the wolf imagining eating just before beginning to chase the elk? Does one require more intelligence? Does one demonstrate more intelligence?

Since we routinely express ideas and feelings in language, we may be forgiven for assigning a role to it, but isn’t it remarkable how often we struggle to find our words? It’s not that we don’t know what we thought or felt, but we just can’t put our verbal finger on it. This would of course be wholly unnecessary if thoughts and feelings were linguistic products to begin with. In that case, we’d expect a waterfall of words! It is now widely accepted that, even though language assists human thinking by providing categories and concepts, it is not the stuff of thought.

We don’t actually need language in order to think. The Swiss pioneer of cognitive development, Jean Piaget, most certainly was not ready to deny thought to preverbal children, which is why he declared cognition to be independent of language. With animals, the situation is similar. The obvious—and I should have thought sufficient—refutation of the claim that natural languages are the medium of thought is that there are non-verbal organisms that think.

“I very rarely think in words at all. A thought comes, and I may try to express it in words afterwards.”

If it’s true that children lack inner speech, the implications are far-reaching. No one should conclude from this that children don’t think, but

they do seem to lack a mode of thinking that dominates the consciousness of many adults. That's just one of several reasons for concluding that a small child's mind is a strange place to be. Language, then, does not give the child thought; rather, it transforms whatever intellectual capacities are present before language comes along.

“Famous cases include Koko, the sign-language gorilla spontaneously combining the signs for ‘white’ and ‘tiger’ upon seeing a zebra, and Washoe, the chimpanzee pioneer of this entire field, labeling a swan a ‘water bird.’ I am prepared to interpret this as a hint of deeper knowledge, but only after I see more evidence than we have today. It is good to keep in mind that these animals produce hundreds of signs every day and have been studied for decades. We’d need to know more about the ratio between hits and misses among the thousands of utterances recorded. How are these fortuitous combinations different from, say, Paul the octopus (nicknamed Pulpo Paul) who rose to fame after a string of correct predictions during the 2010 World Cup? In the same way that no one assumes that Paul knew much about soccer—he was just a lucky mollusk—we need to compare striking animal utterances with the probability of them coming about by chance. It is hard to evaluate linguistic skills if we never get to see the raw data, such as unedited videotapes, and hear only cherry-picked interpretations by loving caretakers. It also doesn’t help that whenever apes produce wrong answers, their interpreters assume that they have a sense of humor, exclaiming ‘Oh, stop kidding around!’ or ‘You funny gorilla!’

I consider us the only linguistic species. We honestly have no evidence for symbolic communication, equally rich and multi-functional as ours, outside our species. It seems to be our own magic well, something we are exceptionally good at. Other species are very capable of communicating inner processes, such as emotions and intentions, or coordinating actions and plans by means of nonverbal signals, but their communication is neither symbolized nor endlessly flexible like language.

For one thing, it is almost entirely restricted to the here and now. A chimpanzee may detect another’s emotions in reaction to a particular ongoing situation, but cannot communicate even the simplest information about events displaced in space and time. If I have a black eye, I can explain to you how yesterday I walked into a bar with drunken people and so on. A chimpanzee

has no way, after the fact, to explain how an injury came about. Possibly, if his assailant happens to walk by and he barks and screams at him, others will be able to deduce the connection between his behavior and the injury—apes are smart enough to put cause and effect together—but this would work only in the other’s presence. If his assailant never walks by, there will be no such information transfer.”

We put so much added value on being able to explain how to do something than actually doing it. But which is actually more valuable? It depends. Just because an animal cannot explain why or how they do something does not imply any lack of complexity or ability or intelligence.

We judge heroism not by what is thought but what is done. What are firefighters thinking when they rush into a burning room to rescue a stranger’s child and there is no time to think? If a hero is someone who risks their life for the life of another, then as for Triangle, the sickly little-brother wolf who saved his big sister—you tell me.

We tend to give our words and abstract thoughts a little too much credit for our more visceral feelings. We tend to overestimate how different the core of our subjective experience is from other animals, particularly other mammals. There are definite, large differences between humans and even their closest kin, but they don’t completely overpower the similarities. A lot of what drives you on a fundamental level developed well before our lineage split from others.

Dogs especially were domesticated from a very social species, and bred to become even more socially focused. They may not have some of the more intellectual reactions we do, they don’t contemplate ‘loving all mankind,’ but that gut-level emotion that makes you care so much about another person that you really do value their well-being as highly as your own? That’s something they’ve been driven to over-develop across millennia.

“Dogs never let you down. You can lock your wife in your trunk, you can lock your dog in your trunk, and you open the trunk—your wife’ll be mad, the dog will be glad to see you.”

You can look at a dog and say they don’t have ‘real sadness,’ or ‘real joy’ or any of that, but after a certain point it’s just like looking at other humans and saying that. You can’t know another’s mind for sure, but their behaviour can give you some pretty strong hints as to how much you have in common.

Dolphins and humans have not shared a common ancestor for tens of millions of years. Yet for all the seeming estrangement of lives lived in

liquid, when they see us they often come to play, and we greet them and can recognize in those eyes that someone very special is home. There is someone in there. It's not a human, but it is a someone.

Just about every animal—not just mammals and birds—can learn, recognize individuals, and respond to empathy.

Octopuses realize that humans are individuals too. They like some people; they dislike others. And they behave differently toward those they know and trust. The idea of octopuses with thoughts, feelings, and personalities disturbs some scientists and philosophers. Only recently have many researchers accorded even chimpanzees, so closely related to humans we can share blood transfusions, the dignity of a mind.

The belief set forth by French philosopher René Descartes in 1637, that only people think—and therefore, only people exist in the moral universe (*Je pense, donc je suis*)—is still so pervasive in modern science that even Jane Goodall, one of the most widely recognized scientists in the world, was too intimidated to publish some of her most intriguing observations of wild chimpanzees for twenty years. From her extensive studies at Gombe Stream Reserve in Tanzania, she had many times observed wild chimpanzees purposely deceiving one another, for example stifling a food cry to keep others from discovering some fruit. Her long delay in writing of it stemmed from a fear that other scientists would accuse her of anthropomorphizing—projecting “human” feelings onto—her study subjects, a cardinal sin in animal science. There's always an effort to minimize emotion and intelligence in other species.

Hormones and neurotransmitters, the chemicals associated with human desire, fear, love, joy, and sadness are highly conserved across taxa. This means that whether you're a person or a monkey, a bird or a turtle, an octopus or a clam, the physiological changes that accompany our deepest-felt emotions appear to be the same. Even a brainless scallop's little heart beats faster when the mollusk is approached by a predator, just like yours or mine would do were we to be accosted by a mugger.

You have to deeply deny the evidence to conclude that humans alone are conscious, feeling beings who can enjoy living and desire to continue doing so. In other words, life, liberty, and the pursuit of happiness. People who play with a dog—or a squirrel or a rat—and then believe that the animal lacks consciousness, themselves lack a certain consciousness. Such people certainly lack, in a peculiarly human way, the wider empathy that our dogs and others so generously, so naturally grant to us.

By veiling their vocal repertoire with our one-size-fits-all words—‘bark,’ ‘rumble,’ ‘howl,’ et cetera—that don't actually fit all, we hobble our understanding of their understanding of what they mean.

“Nonhuman animals may arrive at beliefs based on evidence, but it is a further step to be the sort of animal that can ask oneself whether the evidence really justifies the belief, and can adjust one’s conclusions accordingly.”

Yet it is many humans who are demonstrably incapable of asking whether evidence justifies their beliefs, then adjusting their conclusions. Other animals are great and consummate realists. Only humans cling unshakably to dogmas and ideologies that enjoy complete freedom from evidence, despite all evidence to the contrary. The great divide between rationality and faith depends on some people choosing faith over rationality, and vice versa. Other animals’ actions and beliefs are evidence-based; they don’t believe anything unless the evidence justifies it. Other animals attribute awareness only to things that are actually aware. While a dog might bark to rouse someone sleeping on the living room couch, they never seek assistance from the sofa itself. Or from volcanoes. Or from bearded dudes floating in the clouds. They easily discriminate living things from inanimate objects and even from impostors.

Do humans really have a better-developed theory of mind than other animals? People watching a cartoon of nothing more than a circle and a triangle moving around and interacting almost always infer a story, involving motives and personalities and genders. Children talk to dolls for years, half-believing—or firmly believing—that the doll hears and feels and is a worthwhile confidant. Many adults pray to statues, fervently believing that they’re listening.

All of this indicates a common human inability to distinguish conscious minds from inanimate objects, and evidence from nonsense. Children often talk to a fully imaginary friend who they believe listens and has thoughts. Monotheism might be the adult version. We populate our world with imaginary conscious forces and beings—good and evil. Most present-day people believe they’re helped or hindered by deceased relatives, angels, saints, spirit guides, demons, and gods. In the world’s most technologically advanced, most informed societies, a majority of people take it for granted that disembodied spirits are watching, judging, and acting on them. Most leaders of modern nations trust that a sky god can be asked to protect their nation during disasters and conflicts with other nations.

All of this is “theory of mind” gone wild, like an unguided fire hose, spraying the whole universe with presumed consciousness. Humans’ “superior” theory of mind is in part pathology. The oft-repeated line, “humans are rational beings,” is probably our most half-true assertion about ourselves. There is in nature an overriding sanity and often, in humankind, an

undermining insanity. We, among all animals, are most frequently irrational, distortional, delusional, worried.

Belonging to the World

Plants and animals have been mechanized. Around the time that *Homo sapiens* was elevated to divine status by humanist religions, farm animals stopped being viewed as living creatures that could feel pain and distress, and instead came to be treated as machines.

The process of taming almost always involves the castration of males. This restrains male aggression and enables humans to control the herd's procreation.

Today, the motto of the more efficient, inseminating, vertically integrated mega-farmer could be: More handjobs on the farm, fewer farmhands on the job. Farmers with know-how and pride got eliminated. This kind of farming doesn't take any talent. The company gives you a plan, a consultant, the feed, and the pigs. All you have to do is follow the plan. This system also required farmers to subtly shift the way they looked at their animals. The good farmer had to know his animals. The successful Smithfield producer has to know his inputs, death rates, and his feed conversion ratios.

Our children's books, our iconography, and our TV screens are still full of giraffes, wolves, and chimpanzees, but the real world has very few of them left. There are about 80,000 giraffes in the world, compared to 1.5 billion cattle; only 200,000 wolves, compared to 400 million domesticated dogs; only 250,000 chimpanzees—in contrast to billions of humans. Humankind really has taken over the world.

Today, the majority of large animals on planet earth are domesticated farm animals that live and die as cogs in the wheels of industrial agriculture. The disappearance of wildlife is a calamity of unprecedented magnitude, but the plight of the planet's majority population—the farm animals—is cause for equal concern. In recent years, there is growing awareness of the conditions under which these animals live and die, and their fate may well turn out to be the greatest crime in human history. If you measure crimes by the sheer amount of pain and misery they inflict on sentient beings, this seemingly radical claim is not implausible.

Much of the vaunted material wealth that shields us from disease and famine was accumulated at the expense of laboratory monkeys, dairy cows, and conveyor-belt chickens. Over the last two centuries, tens of billions of them have been subjected to a regime of industrial exploitation whose cruelty has no precedent in the annals of planet Earth. If we accept a mere tenth of what animal-rights activists are claiming, then modern industrial agriculture might well be the greatest crime in history.

You could call factory-farm animals evolution's greatest success story, if

all that mattered were reproduction and population, but what is that worth when individually it means a life subjected to extreme cruelty? The animal kingdom has known many types of pain and misery for millions of years, yet the Agricultural Revolution created completely new kinds of suffering, ones that only worsened with the passing of the generations.

From the viewpoint of the herd, rather than that of the shepherd, it's hard to avoid the impression that for the vast majority of domesticated animals, the Agricultural Revolution was a terrible catastrophe. Their evolutionary success is meaningless. A rare wild rhinoceros on the brink of extinction is probably more satisfied than a calf who, after being ripped from his mother, spends its short life inside a tiny box, fattened to produce juicy steaks. The contented rhinoceros is no less content for being among the last of its kind. The numerical success of the calf's species is little consolation for the suffering the individual endures.

This discrepancy between evolutionary success and individual suffering is perhaps the most important lesson we can draw from the Agricultural Revolution. When we study the narrative of plants such as wheat and maize, maybe the purely evolutionary perspective makes sense. Yet in the case of animals such as cattle, sheep, and *Sapiens*, each with a complex world of sensations and emotions, we have to consider how evolutionary success translates into individual experience.

Hyper-bred in industrial facilities, separated at once from their mothers, denied the outdoors and anything resembling a natural life, confined without relief between bars, mutilated, experiencing no touch of human kindness before it all ends in the mayhem of slaughter, these creatures still have the social natures of their own distant wild ancestors. Each one still has the emotions, the desires, the need for play, companionship, and maternal care that allowed their kind to flourish over millions of years before humans took charge of their existence. Each one can be happy, sad, lonely, and afraid.

A detail has always stayed with me, from a visit years ago to the world's largest abattoir for hogs, that somehow stirs fellow-feeling as much as any other: The vast plant floors—scene of 2,000 kills every hour, if you can picture that pace—must be constantly washed clean of waste, because in terror so many of the pigs lose control of their bowels.

“You're not wrong. But you've failed to convince me as to why you are not taking it a bit too far. The line between species might be gray, but you can't deny that with distance the distinction is there, or you'd stop eating plants too.”

I agree. There are also differences between members of a given species,

human or other. But in the ways that matter to the question ‘Should I kill this person?’ humans are mostly pretty similar, and I don’t see how the differences between us and the animals that we use for food are important to the question either.

It’s pretty well established that most of the species Americans regularly eat are conscious, feel pain, and even have emotions. These qualities are, to me, the important common things that make killing wrong. Basically, I think we should try to avoid killing things that want to live, and we should try to avoid making things suffer. It is also pretty well established that plants—at least the ones we know of—aren’t conscious and can’t suffer, so the same concerns don’t apply there. They can react to their environment, but they don’t have minds and don’t experience pain or sadness, so they not only don’t care what we do with them, they can’t care.

“To use chickens as an example, so long as they’re healthy and not in pain, I fail to see the problem of responsible chicken farming.”

A slaughtered chicken might not be in pain, but it’s definitely not healthy. If you’re talking about just farming for eggs and not killing the chickens, there are a few practical problems. Hens’ productivity naturally goes down as they age, so if you don’t kill them, eventually you’re taking care of these animals and getting nothing in return. Additionally, if you’re breeding the chickens in order to keep your farm running for more than five years, you’ll find that half of the chicks are male and can’t lay eggs. A popular solution is to kill all the male chicks immediately so they don’t drain your resources, but that’s not an option on a no-kill farm.

So being cold, starving, terrified, in constant pain, deprived of dignity, prodded and beaten as you’re moved into and between cages; all for a prolonged and sustained period; and finally killed slowly and painfully to satisfy a belief system. This is a holocaust when it happens to homo sapiens, but a valid farming method when applied to animals? If so these are classic sociopathic tendencies. I’m of course not in any way trivializing the holocaust. Human dignity could be argued to more conscious of such dire situations, and thus suffer more. But no one knows what the animals in these conditions experience, and only a fool considers it to be a categorical difference.

All humans are Nazis when it comes to animals for their suffering is an eternal Treblinka. I sit in witness to the greatest machines of death and suffering known to man. I sit in relatively sparse company. I must construct a reality or narrative which will allow me to function within such a world.

We presently keep hundreds of millions of other sentient beings in unimaginably frightful conditions. We do so for no better reason than to satisfy our culinary tastes. It has aptly been remarked that if animals had a conception of the Devil, he would surely have human form. Alas this is no mere rhetorical conceit. Contemporary humans deliberately incarcerate and butcher our fellow creatures in a vast, state-sanctioned apparatus of concentration and extermination camps. They are run with mechanized horror for profit.

In retrospect, our descendants may view them as a defining feature of our age in a way akin to our own conception of the Third Reich. Analogously, their sheer viciousness and even existence is usually camouflaged behind a morass of bland euphemism. Fortunately for our peace of mind, at least, we find it hard properly to conceive of what we're being spared. Conditions inside the camps and factories are frequently so gruesome that the public have to be barred from watching the atrocities that go on inside them.

What we are doing in the death-factories is so vile that a few lines of text can scarcely even hint at its ghastliness. Nevertheless, we are so inured to the notion of exploiting and killing other sentient beings to titillate our palates that many otherwise "sophisticated" people will find the starkness of expression of these paragraphs somehow sensationalist; or perhaps "emotive," as if the reality of such suffering could properly be otherwise.

We avoid grieving for animals in order to function and even the most committed animal advocates must regularly engage in disavowal. There is an impulse to recoil from all of the grief and loss of being 'animal' in a human world, the incomprehensible, interminable record of irreparable harms. It is worth doing almost anything to suppress this terror.

What would it mean to comprehend the reality when walking down the grocery aisles? Suddenly, the scene in front of you shifts. No longer are you seeing normal products of everyday existence. In front of you is the violent reality of animal flesh on display: the bones, fat, muscles, and tissue of beings who were once alive but who have been slaughtered for the parts of their body. This scene overtakes you, and suddenly you tear up. Grief, sadness, and shock overwhelm you, perhaps only for a second. And for a moment you mourn, you mourn for all the nameless beings in front of you.

Since the ultimate result of the factory farm victim is death and dismemberment, is the practice not *more* horrific and indefensible than slavery and the slave trade?

- **Families broken up:** Both
- **Seen as subhuman:** Both
- **Abuse:** Both
- **Murder:** Factory Farm
- **Selective breeding:** Factory Farm

The thing is, once a town accepts CAFOs, it's impossible to confine their ugliness. Flies can't be caged. Neither can odors. Cruelty also tends to spread. Once farmers become hardened to animal pain, it's a smaller step to also seeing their workers as unfeeling machines. Researchers have found that in 85 percent of households where animals are subjected to violence, there are also incidents of domestic abuse. Violence radiates out through society. As does poverty. These days middle class family farmers must make ever riskier bets to stay afloat, and their farms demand menial laborers—often undocumented and always poor—who claw at the slippery foot of the American dream, sometimes driven to drugs and crime by the hopelessness of the endeavor.

It is a system that, in pursuing one kind of efficiency, has embraced other inefficiencies: Pollution, and all forms of waste, is by definition inefficient. Suffering is inefficient. Is it possible to fashion an economy that saw the efficiency in keeping families together, the efficiency of healthy people, and perhaps even—dare I ask it—the efficiency of beauty and pleasure?

Together with our obligation to use the earth's goods responsibly, we are called to recognize that other living beings have a value of their own. In our time, the Church does not simply state that other creatures are completely subordinated to the good of human beings, as if they have no worth in themselves and can be treated as we wish. The Catechism clearly and forcefully criticizes a distorted anthropocentrism:

“Each creature possesses its own particular goodness and perfection. Each of the various creatures, willed in its own being, reflects in its own way a ray of God's infinite wisdom and goodness. Man must therefore respect the particular goodness of every creature, to avoid any disordered use of things.”

And that's coming from the folks that ran (run?) the world's largest 'kiddie diddler' cover-up operation.

“I have no obligation to eat substitutes just to satisfy bleeding hearts. When I can go moose hunting, kill a great source of very lean and healthy meat—enough meat to feed a few families and have a vacation at the same time—I have no moral dilemma about it. I thoroughly enjoyed our pork roast wrapped in bacon tonight, the steaks on the weekend. I am going to have a great time with the annual fish fry this Saturday of all the fish caught this winter. We plan on doing a whole lamb over a pit at the first corn roast and so on.

Can I do all this? Yes. Should I? Hell ya cause it all tastes so damn good. I have no problem killing for food. And to answer something you asked earlier, if it meant the difference between my kids eating or starving to death I would have no problem killing to get someone's food supply. So you enjoy your protein shake and I will enjoy my steak."

A cow's desire to continue living is greater than my desire for a slightly tastier meal.

Quale nie ein Tier zum Scherz denn es fühlt wie du den Schmerz—Never do something to torture an animal because it feels the pain like you. He drilled the ethics of hunting into me, and the only time when I ever saw him show anger toward me was when as a preteen in the 1950s I tried to kill a skunk with my slingshot to impress my peers. That was not all right. It was disgusting. He felt justified to kill birds for a museum where they would be preserved forever, as some feel justified to eat fish, chicken, or other meat that is digested in hours. Which is more justified? And even if necessary, how do you justify? Those who are familiar with ancient folklore, or are up above the rest of us a moral notch or two, kill "respectfully" by offering prayers or apologies, in the hope that animals will "offer themselves" up to be voluntarily killed. However, it is a sad fact that no animal cares if those who might eat them invent reasons to justify their acts to make themselves feel good.

I am going to assume you live in the first world. As a first world individual, you eat meat, not to survive, but because you like it. Unless you get lost on your moose hunt and are hunting food until you're rescued, meat is a luxury, not a necessity.

It seems you use survival as a way to legitimize what might otherwise be a troubling act. But be honest and recognize it is a conscious choice, to choose the luxury food item which cost a feeling, emotive creature its life so you could feel a momentary surge of happy chemicals in your brain from the oh so tasty meat—and yes, it *is* very tasty, we agree here. You can certainly make that choice, put happiness over others, but you can't hide behind survival of you and your family to do it. There are certainly some who—for various environmental or societal reasons—essentially have to eat meat or they'll die, I'm just betting you're not in that camp.

And while your last line was likely just meant in a lighthearted fashion, it does highlight something interesting. You enjoy your consensual intercourse, I'll just keep using the force. You go ahead and not beat bags of puppies to death, I'll be getting my happiness from doing so and then maybe I'll BBQ them after. You go ahead with paying your workers, I'm gonna keep mine

as property, it's easier that way. You go ahead with killing your livestock before butchering, I like to watch mine squirm and it makes the meat taste better. These don't seem like acceptable compromises in our society, what makes yours different?

“Are you really going to compare eating meat to slavery? Eating meat to BBQ live puppies? That my friend is called a straw man argument. Try again.

Self righteous vegetarians like you make everyone else look like a lunatic by association.”

Well remember, I beat those bags of puppies to death first, before BBQing—I'm not a monster. Also: You haven't articulated a difference. You've simply acted as if the difference is obvious. If it is so obvious, would you care to point it out? At one time the inferiority of the African race was seen as the obvious order of things, you probably disagree and have reasons for doing so.

I'm simply seeking an explanation, in no way am I self righteous, though if you would care to point out instances of that I would be happy to reevaluate. I have not forced you to hear my views, standing outside your place of work or play, shouting. You chose to read them, simply ideas, questions, and criticisms. Perhaps the lack of concrete answers is simply because you lack them, and your negative opinion of me is because these shortcomings have been highlighted in your own mind? We are all ignorant of much, we would be wise to remember this.

“I am not obligated to educate you. The obvious difference is, if I eat meat in the park it's called a picnic. If I BBQ a puppy in the park I would be arrested, reviled, or possibly lynched. This is called reality.

The reason you are a self righteous lunatic is exactly because you compare normal behavior to psychotic behavior as though there is no difference.

If you're a seeker of truth as you claim, you'd do well to avoid insulting everyone around you by drawing such ridiculous analogies. But that's the thing with self righteous people who think they know better. You are patently incapable of understanding that reality is integral to philosophy.”

Who creates this reality? You act as if I want my human arms to allow me to achieve flight unaided, and I am simply a fool because I refuse to

acknowledge gravity. But much of what you are likely calling reality is simply something a hairless member of the great ape family decided, at some point in the past.

Who defines psychotic behavior? The majority? That would seem to retroactively legitimize quite a few horrors in history.

If one were to have stolen you from the hospital shortly after birth, one could theoretically mold you into the leader of some extremist vegan terror organization. Your mind craves stories, especially at a young age, and your society just feeds them to you in order to perpetuate itself. Just like how most US citizens are perfectly fine with their government engaging in genocide from its inception—because of course they would not call it genocide, it was Manifest Destiny.

Your society is powered by exploitation and abuse, without it, your “civilization” comes crashing down.

“The boy to be initiated is dressed in leaves and given drugs to keep him awake. Drums beat through the night until, before dawn, the boy is led into a special area of forest, where he’s obliged to confront two chimpanzees. Some of what follows seems to be symbolic enactment, some of it blood-real. A gong is sounded, a voice calls out from the forest, and two chimpanzees respond. The male chimpanzee comes out first and touches the boy’s head. The female chimpanzee emerges minutes after and the boy is expected to kill it. At dawn the boy bathes, then stays awake until late afternoon, pacing and expectant, at which point the circumciser comes at him with a homemade knife. ‘I nursed my wound for 45 days after,’ one initiate said. But now he was a man, no longer a boy. Until recently, the Bakweles have been using chimps for this ritual. They claim two chimps could be used for circumcision of as many as 36 people. They amputate the arms of the chimps. This part of the animal is eaten by elders of the village. Of late, however, due to the scarcity of chimps, Bakweles go for gorillas.”

We would do well to remember that the lens through which we view the world is only one type of lens, there are many different ones that exist, some completely unlike the lens we are familiar with. If I give you a lens that doesn’t allow you to see yellow, if most everyone has those lenses, you will never know yellow exists. You may even find someone to be crazy if they told you about it, for you had never seen it or know anyone serious who claims to believe in yellow.

What biases are you not even aware of? What concepts have you not been given or thought of yourself? What concepts *have* you been given or thought of that then influence others? Is there some information, some experience, you lack?

We are limited by the constructs we possess at the time. This applies to everyone so you must question the fundamentals of your ideology periodically. As a social animal, we are also limited by the way the majority of the culture thinks, especially if the majority culture is overtly hostile towards the ideas—animals being in any way equal to humans being a prominent example.

Not participating in an act which results in the needless misery and suffering is not making a sacrifice. You are assuming that you already have an inherent right to do as you please to less powerful beings. By giving up meat, you are not making a sacrifice as you are not giving up any right of yours.

And if you're being entirely honest about it, the best 'animals dead versus calories available' ratio is probably covered by whaling. You get an absolutely huge amount of calories from one whale, and it only nets you one animal death—you can't even get that ratio from wheat.

Sure, if you believe that the lives of whales and slugs have equal value then this is still problematic. Unfortunately, that isn't how the vast majority of people look at it. We find it unethical to kill organisms that we perceive to be conscious, and don't really mind killing simple organisms that don't have properties we associate with consciousness.

Instead, imagine an XY coordinate plane with all sorts of organisms plotted: level of consciousness (or awareness, or whatever you'd like to call it) on the X-axis, and the number of human-digestible calories available on the Y-axis. Organisms on the left side (e.g. corn, wheat) are going to have a drastically different calories to consciousness ratio than organisms on the right side (e.g. humans, whales). If you take Y / X you'd see an incredibly simple trend: the ratio of calories to consciousness is high on the left, and exponentially decreases as you move to the right.

The meta-trend of vegetarianism and veganism isn't to end all suffering, it's to trend leftward on the continuum as far as is practical.

The vegan paradigm is first and foremost centered on a steadfast recognition that animal lives have intrinsic value. That is, their value doesn't derive from the economic worth humans assign to them. Sentient beings have an interest in living, and thus, they have the right not to be treated as human property. If this basic point is lost in any animal advocacy, then the advocate must retool or else risk contributing to continuing animal exploitation.

I've been finding it increasingly bizarre that, in 2020, relatively wealthy and comfortable humans are still having to argue about whether non-human animals should have any moral considerations. It makes me think that, from an outside perspective, perhaps we're not worthy of such consideration ourselves? As little as 0.3% of the population of the UK is actively trying to avoid animal abuse, commodification, and exploitation, at least to a degree that mildly inconveniences them. At times, it feels as though at least 75% of the population enjoys taking the piss out of them.

'Can animals suffer' is no longer a question. 'Should we be deliberately causing billions of animals to suffer each year for our own short-term benefit' shouldn't still be a question either. If we extrapolate from the past, I think we can say with certainty that our decedents and descendants will look back at the piggeries, hatcheries, fur farms, cosmetic labs, and the rest, with shame and embarrassment.

We are much more like a pig, than a pig is like a toad—their hearts can function in us. Watch just five minutes of undercover footage from a large piggery. It's heartbreaking. It should make you want to cry. People writing, 'Fuck vegans! Bacon is amazing lol,' on videos of animal agriculture are standing on the wrong side of history, arguing in favor of abuse and oppression. I'm sorry, but they're gonna look like right dickheads.

It shouldn't just be vegans and animal rights activists who are calling for the abolition of these factory farms. It's the McRibs, and the pepperoni on a Domino's that are keeping them open. We should all take a look at how these intelligent and social creatures are being ruthlessly exploited for profit and cheap, unhealthy meat, and collectively say: 'No. Fuck This. This is horrible,' and begin the process of shutting them down—now, in our lifetime—before our great-grandchildren have to do it for us and whilst doing so lose all respect for us.

We weren't meant to be demons to these creatures. And we don't have to be any longer.

“What is it made of if it doesn't come from animals? You cant synthesize animal protein, and plants severely lack the nutrients only found in animal protein that we need. I am *never ever* taking supplements for the needs that plants cannot meet because it is either made from the natural source, defeating the supposed 'cruelty free' purpose, or it is made of something that just shouldn't be in our bodies, much like how typical margarine (a supposedly healthy dairy alternative) is one molecule away from either plastic or diesel fuel, depending on whether you

remove or add a molecule. I hate margarine for that reason, although I sometimes have to eat it because it is cheaper.

Furthermore, there are very few unbiased studies that find evidence for veganism, and many that find evidence against it. It is undeniable, and we are on the high end of the food chain. Even monkeys and apes eat meat and meat-like foods occasionally, from insects to other mammals. The people who make the vegetarian or fruititarian claims can go bother someone who is gullible enough to believe it. I have eaten deer, freshly killed. Yet I love fawns. I eat beef, but I think calves are cute. I eat pigs, but the sight of piglets make me squeal with delight (no pun intended). I eat chickens, but chicks make me awww really loudly.

See, we are all hypocrites regarding food. Vegans can claim their lifestyle is cruelty free, but animals still die for it, even if unintentionally. Field mice, insects, rabbits, raccoon, coyotes, et cetera are killed by farmers every day to protect crops and the farm animals, as well as unintentionally during harvesting (in the case of field mice). You can pretend not everyone kills something, but you're living a lie. I'm an advocate for natural food sources, and sustainably raised livestock. I'm not now, nor will I ever be, an advocate for going against nature in any way, and that includes trading healthy options for synthetic crap."

Meat and other non-human animal products are not a magic substance. Your human body needs certain components of these, this is correct, you are correct. It's not protein though—all protein is plant protein remember. However, we are aware of what those substances are. They are not some mystical energy force that dwells within non-human animals. So if you synthesize those components, using either artificial or simply using the natural processes of non-complex lifeforms, you then get to not die and not kill complex life in order to do so. Now of course even a vegan diet kills—insects on crops, bacteria, et cetera—so they are not bloodless either.

"You say that meat protein is not required for survival yet you go on about ways to substitute for them."

Substitute for the small number of nutrients found only in animal products? Yes, required. But if you can make the substitution, then the meat is no longer required. Just like if you have electricity, you don't need to light your house with whale oil lanterns.

Just because a particular trait served one well in previous historical eras, does not necessarily mean it is useful now. The same holds true for our cultural memes, much of which are ancient technology at this point.

We often wonder how people of the past, including the most revered and refined, could have universally engaged in conduct now considered unconscionable. While retrospective judgment tends to make us feel superior to our ancestors, it should really evoke humility. Surely some contemporary practices will be deemed equally abominable by succeeding generations. The only question is: Which ones?

I've long thought it will be our treatment of animals. I'm convinced that our great-grandchildren will find it difficult to believe that we actually raised, herded, and slaughtered them on an industrial scale—for pleasure.

“The hypothetical nation of tree-hugging, vegan, pacifists unfortunately did not survive history. This was not an accident. If they ever existed, they were eaten by the reality that is this world.”

There certainly may have been a culture like you describe, certainly ones that would have had at least some aspects. Their destruction was no accident. A culture which easily otherizes and believes it is moral to inflict violence on others intentionally did so, whether directly or indirectly.

Waking up angry every single day, decrying what our culture likes to think are the great civilizers of the world (ourselves)—what many think Western Civilization is. The great lie is that it is civilization. It's not civilized. It has been literally the most bloodthirsty brutalizing system ever imposed upon this planet. That is not civilization. That's the great lie: that it represents civilization.

Sometimes society as a whole can be viewed as a quasi-conglomerate form of legitimized morality but even that can go awry when that particular society holds beliefs that are later deemed horrific by the greater societies of the future—like a society that accepts and perpetuates slavery or the murder of a particular people-group. If you and I could agree on a certain moralistic framework then I could answer your question based off of those parameters but unless God exists and there really is a natural framework then to what avail is doing that?

“For one, you should note that I do not consider vegetarians nearly as silly. it's the extra step of no animal products no matter how acquired that tips the scale for me. The notion of refusing to eat unfertilized chicken eggs, honey, or milk even

when you know they were humanely acquired is a nigh fanatical or religious approach to the philosophy that strikes me as ridiculously unnecessary (hence: silly).”

What does humane mean to you? With eggs we run into what happens to the male chicks in egg-laying bird hatcheries, what happens to the individuals once they no longer produce eggs, the morality of keeping another imprisoned to be used as a resource.

“The claim that we, as omnivores who are naturally evolved to eat meat, are wrong when we do so also strikes a funny bone when we are still animals and have every right to eat another animal as the cheetahs or lions do.”

Wild animals kill to survive. They must kill to eat, otherwise they would die. Whether they kill on instinct or are aware of their predicament is irrelevant, we are not in their situation. If you live in modern society and have access to crops, vegetables, fruit, grains, et cetera, then you have no obligation or need for animal products. Also, lions exhibit all kinds of behavior that you would seek to avoid, for instance, violent territorial disputes, and in some cases a male lion will kill the cubs of a female he wishes to mate with because she won't mate while she has cubs around. Lions are not good ethical role models.

“There are also other considerations to think about. Like the fact that some people might see even a poor existence as superior to non-existence. As such, these industries have given the experience of life (good or bad) to countless more critters than could possibly have lived life without being a commodity and that might be seen as a net positive for the animal than nonexistence or nothingness.”

The animal can't conceptualize this and you can't harm someone who doesn't exist.

“There are also populations—like deer or kangaroos—that have to be controlled or they will destroy the environment and starve other animals in the area in the process and so might as well be consumed as a beneficial byproduct of their culling.

How would you feel about a cow that was free roaming but tripped and fell in such a way that it died? Would it be ethical to eat it? Of course by most moral constructs it wouldn't be any

problem and is just taking advantage of a bad situation. But a Vegan places a hard line at it just not being animal based at all which side-steps morality/ethics and finds itself in non-sense ideological fanaticism territory.”

That would be fine. If you think veganism is against that, then you misunderstand veganism. As for the culling: what predator did you exterminate that allowed the populations to rise unchecked?

Moral agency is the ability to know whether an action is right or wrong. For example, if a bear kills a person, there is no moral issue because that’s just how bears operate—not that this fact always stops the death squad goons of Wildlife Services—but, if a person kills a person, they need to hire a lawyer because people typically have more options than bears do, which means they can be held responsible for their actions. Murder is not just killing—murder is having a choice not to kill and killing anyway. Without moral agency, there is no murder. In fact, the whole idea of ‘justice’ assumes that moral agency exists, which is why most legal systems do not prosecute kids or folks with certain mental illnesses—if someone lacks the ability to do the right thing, it is pointless to punish them for not doing it.

You seem to fall into the typical trap of the technology-dominated culture. That just because you can do something means you should.

Lions very well may, if given the opportunity, domesticate gazelles and farm. Perhaps they might settle down, build more permanent shelters, and maybe even start to eat a few specific kinds of plants, just a few of them at first of course. Then maybe those plants make those lion offspring stronger, more likely to reproduce. Maybe then some genetic copying glitch results in some more complex cognition, leading to better hunting tactics. Soon more of those individuals are part of the lion pride. Maybe thousands of generations later, in the shade of a tree, members of a species descended from those lions are sitting in a complex nest, discussing whether or not a dolphin would farm a tuna if it could and whether it was morally right to eat gazelles.

If it is human nature to eat meat, then it must also be human nature to question the morality of doing so, it must also be human nature to not eat meat. Because humans do all these things. So human nature is not a rational argument, it is simply invoking a different kind of faith or embracing one’s ignorance as a virtue.

Do you not realize that you are the only omnivorous species with a choice? I really don’t understand the logic behind comparing your actions with that of a much less capable (in this regard) species. I guess it’s easier that way. But the truth is that you are part of the only species with a choice,

and you used your power to cause more suffering. No other carnivores or omnivores are in any position to make a choice, they don't even have a place in this debate.

It's the human way—'kill what you don't like,' whereas it should be 'live with what belongs here.' Animals don't behave like men. If they have to fight, they fight; and if they have to kill they kill. But they don't sit down and set their wits to work to devise ways of spoiling other creatures' lives and hurting them. They have dignity.

Predators cull the weak, man culls the healthy.

"You completely miss the point. Nature is all about survival of the fittest. Pure and simple. Humans as a species in order to survive have used our mental fitness to domesticate and dominate.

You need to understand, those that can not accept that, don't belong. If truly humans fell into survival of the fittest, the population of humans would be a small fraction of what it is."

You are utilizing a common misconception of exactly what 'survival of the fittest' means. In terms of evolution, it doesn't mean the strongest biggest brutes that can dominate all the others survive and thrive. A lot of evolutionary biologists actually shy away from the term, and Darwin himself was said to regret coining the phrase as it became so misused by the public.

What 'survival of the fittest' refers to is the fact that the genetic variances that are most well adapted to a given environment are the most likely to be passed along to future generations. A genetic mutation doesn't need to provide an advantage to get passed on. Most such mutations are actually neutral, they don't help or hinder us. Some genes are disadvantageous—for instance, the BRCA-2 mutation that greatly increases the chance of breast cancer—but are still able to be passed on because they do not prevent the organism that has it from being able to survive childhood and reproduce, or because they are recessive genes that are only expressed if both parents carry them, thus a parent can be a carrier for a condition like Tay Sachs that kills children at young ages.

However, some genes provide a clear advantage to a given species in a given location. A classic example is moths in a white birch forest. If you have a group of brown moths, and a gene enters the population that causes a moth to be white, that gives it a huge advantage because that moth is much less visible to predators. That moth is much more likely than his brown moth brethren to survive longer and make more moth babies. Thus the 'white moth' gene is far fitter than the 'brown moth' gene, and more

likely to be passed on. Survival of the fittest refers to how advantageous the white moth gene is to a moth in a forest full of white trees. It in no way indicates that white moths are the biggest, baddest, strongest moths out there and that is why they survived.

I'm quite aware of your point. It is simply what I view as a barbaric and misguided one. Survival of the fittest is part of the story humans tell themselves about their world. It is part of how the dominant human culture comes to understand things. Natural law, as most prominent Western philosophers see it, is based on primitive understandings of our world.

There is no biological law which states that one must value one's life or that of one's fellow species members over members of another species. The dominant culture shaped your view of the world much more than your biology has in all likelihood. You can use a basic understanding of human biology and psychology to mold a mind to believe almost anything given the proper conditions.

As a male of a sexually reproducing species, the law of nature seems to state that I can force myself on a member of the opposite sex. Yet I doubt you would be advocating for this. Accept that part of your nature is that you have the cognitive capability to explore concepts that allow you to expand beyond your biology-influenced tendencies.

“So by whose morals are we supposed to live our lives? Yours? Ain't gonna happen! What you seem to forget is that we have the ability and right to set our own moral compass. You may not like it but mine is just fine as is.”

I would like us all to honestly develop and continuously refine our moral compass as new information becomes available to us. We can do this both together and apart. But we must be honest and not accept answers which simply make us feel good and allow us to get through the day.

The same urges and ideologies which otherize the non-human to another category of being are the ones which have the potential to hurt you and your family.

“All your arguments are based on your morals. Sucks to be you. My morals are different and you do not have the power to tell me what is moral and what is not.”

I walk up and put a .22 into the head of a lamb. You see a morally corrupt act. I see charcoal roasted leg of lamb. I don't have to justify or rationalize this for any reason. I find it morally acceptable.

There are species that eat and ones that get eaten. Welcome to life.”

I was more interested in finding out the underpinnings of your morals than forcing mine on you. After all, text would be a very poor medium to do so—in fact I’m not even quite sure how I might go about it.

It is likely that you—directly or by proxy—force your moral views on others quite often. If one were to hurt your family, I imagine you would either take matters into your hands or expect the “authorities” to do so for you. But what if the perpetrator does not see it as a wrong act? Is it because you live in a country that allows you to vote and influence your laws, the ‘public morals?’ What if we voted that it was OK to hurt you, is that still a valid forcing of morals when they involve harm to another?

It makes me quite sad to see someone so willing to settle for such non-answers. And to use them to justify such harm. History will judge us all harshly. I think we owe it to your kids and everyone else’s to do better.

Remember, much of the foundations of what we believe, what we accept, how we view the world and our place in it, were laid by individuals who were often far more ignorant than even the average individual today. It would be good, both for your fellow humans, as well as the non-human animals, to question the validity of those foundations.

Using your logic, I can eat you, if you fail to defend yourself adequately. Now you may protest and state that eating humans is wrong. Why is that though? Why pork but not people? There must be some characteristic, some ability, some trait, you had to have chosen something as a defining difference, what is it? Or is it simply going with the flow and if people were an acceptable menu item in society you’d order some Pedro Parmesan with a Little Timmy meat sauce?

The issue with animal experimentation is the lack of consent. We should condemn the practices, if done without informed consent, regardless of the species. Given that it is likely impossible to bridge the communications gap to the extent of conveying such abstract concepts, it will always be impossible and therefore immoral to engage in any animal experimentation, regardless of how many lives stand to be saved.

As for animal testing and its role in civilization (though I’d argue its completely uncivilized but for this point we’ll use the generally accepted use of civilization): If you do not defecate on your food supply and in your water supply. If you have basic antibiotics. And you have a rough understanding of what viruses and bacteria are. Your society will be better off than most others in recorded history. This technology and information all exists already. We have sacrificed millions upon millions of animal lives

to acquire it. You can continue to have all of this without another animal death. Do you get to cure all cancers? Probably not. Still gonna have loved ones die of some diseases? Probably. But just as the absence of slaves may have had a negative effect on some individuals' lives did not mean that it was moral to continue the practice, it does not mean you get to inflict fear, pain, imprisonment on another creature for your "benefit."

Racists violate the principle of equality by giving greater weight to the interests of members of their own race when there is a clash between their interests and the interests of those of another race. Sexists violate the principle of equality by favouring the interests of their own sex. Similarly, speciesists allow the interests of their own species to override the greater interests of members of other species. The pattern is identical in each case.

"I have it figured out. You struggle with morals all the time. You actually lack moral conviction and strength. I see people like you all the time. Weak people like you cannot understand how people like me can be so strong and certain. You believe because you struggle that everyone struggles. Not the case, as I have yet to find myself with a moral dilemma. Strength of character, you should try it.

A lot of it is confidence and not giving a rat's ass what you or anyone thinks of me.

As for my kids, they all love animals and they all love to hunt, fish, and eat what was killed. Wouldn't have it any other way.

You also use the word 'violence' like it is a bad thing. Why?"

Even the choice of the words you use to describe me are so infected with the ideology of the dominant culture. I'm weak because I'm uncertain about potentially taking a life—a permanent act—or causing another unnecessary harm? It seems you have quite a narrow and primitive definition of strength sir.

Confidence can come from knowledge, but it can also—and more often does—come from ignorance. Many ignorant individuals are too ignorant to know what they do not, and too confident about what they do—or think they do—know. One could argue it takes a certain level of confidence in oneself to admit one's shortcomings.

Violence is an act which results in great harm being done, by definition. Why would one want great harm to be done, unnecessarily? You, however, seem to choose to engage in, and glorify, the unnecessary use of violence. Why do you see it as so good—excluding the easy and inapplicable out of

‘survival’? Your children will grow up in a world where someone can label them as the spawn of animals, not worthy of protection, of life. Some could build a following around that, an ideology which puts your children at the bottom. And then your children and others pay the price of your “strength” and moral certainty.

Be aware: the fact that you do not have moral struggles is unlikely to be a sign of your great character, though your society is heavily invested in you seeing it as such.

But, it is likely you already have the moral belief system that it is wrong to cause unnecessary harm to animals. Most people refrain from causing unnecessary harm to humans because they recognize that humans are capable of suffering in the same way that they are. Most animals show all of the same signs that humans do that they are experiencing suffering—they avoid painful stimuli, they might yelp or grimace when hurt, pain is evolutionarily advantageous for them since they can move away from the stimuli, et cetera.

If you wouldn’t punch a stranger in the face, you ought not punch a puppy in the face. Similarly, if you wouldn’t eat a human because you know it would be wrong to cause it unnecessary harm, since you can just eat something else, you ought not eat a cow because you know it would cause it unnecessary harm. And yes, eating animals is almost always unnecessary because of the cost to your health, the cost to the environment, and the cost to your fellow humans that are exposed to environmental health hazards such as pollution, antibiotic resistant bacteria, food-borne illness. Your interest in satisfying your taste buds—and that is the only benefit to eating animals, as I’ve elaborated—by eating an animal does not trump the animal’s interest in being alive and avoiding suffering.

“Society developed this way for a reason. Humans are naturally hunters and predators. Over time they built up a system of laws and rules that keep them from slaughtering each other over a piece of bread. These laws rightly consider actions that are damaging to society as a whole to be vile. Things like rape, murder, and slavery. Other actions are not considered as vile or even at all vile, like eating meat, driving on a Sunday, and line dancing.

The process of figuring out what is and is not permissible is constantly evolving and is by no means perfect. You have no idea what would happen if you try to impose the moral supremacy of one imbecile on an entire population. The moral ramifications of doing that, by the way, far outclass the rights of a chicken not

to be eaten. So, if you think you know better than 6,000 years of evolution I will leave you to that delusion.”

You and I are both products of a single human culture. Your views of the world 6,000 years ago—while unfortunately not uncommon—are simply one way to look at it, interpret it. The story of Western civilization is what you know, what you speak of in all likelihood. At times it can be a very unflattering story, but it is undeniably one which holds progress up as its main theme. It explains your place in the world, how awful things were before the great gift of civilization as you know it, and on and on your culture sings to you.

You speak of one imbecile imposing views, painting it negatively, and surely it is. But that is largely what has happened—millennia ago—just on a slightly grander scale. That one imbecile is simply one small culture, that conquered and stole and manipulated its way to be the dominant one that essentially influences everything today.

Evolutionarily speaking, you are born with much the same hardware as your distant ancestors, its just that your stories have gotten more complex. While the exact implementations of an ideology may change—sometimes in large ways—the fundamental features are still present. Superiority over others, might makes right, technological progress over social progress. Why should I have any faith that someone with access to far less information about the world would have gotten *any* of the foundations of their society correct? And since we have the same exact hardware as them, but much more information, why would we not assume we might have a higher—though still not perfect—likelihood of getting things more right?

If you care about animals and are bothered by the abuse they endure, the only consistent response is to go vegan, because all animals—including humans—have an equal desire to live free from domination, other-inflicted exploitation, death, and other harms, by virtue of us all being sentient.

“You do understand that if we go vegan those animals we cultivate, exploit, eat are not going to be ‘free from domination, other-inflicted exploitation, death, and other harms,’ they would just never be born in the first place.”

Just as we understand that we don’t have a right to create humans for purposes of killing them to harvest their organs at age 18—no matter how “happy” their lives until then—we also don’t have the right to decide for other animals for what purpose they live, and when they die.

The consequence of that of course is that there will be fewer non-human animals around—at first—but the only reason they are brought into existence

in the first place is because the economic cost of feeding them is thought to be outweighed by the benefit of being able to use and kill them, to sell them as commodities. Ignoring externalities, that is—as AGW is not counted as a ‘cost’ of animal agriculture; nor is societal ill-health, to the extent that this is caused by the consumption of animal products. If we would decide to stop participating in the latter, do you really think we’d still be producing all that food and shelter and pasture for them to live on?

“Maybe if you ask the animals that are born to be eaten by us whether they would rather never be born, well they might just prefer to have been born and to know what life is, don’t you think? In addition if we kill them in humane ways, what’s not to like?”

I can only ask human animals whether they would appreciate being killed because someone would like to use their body for some purpose or other; thus far, nobody signed up for it. I would point out, furthermore, that you’d also need to ask the mothers whether they want to be impregnated to mother offspring who are to be killed.

We assume that we may decide for them that they would prefer living at all, but morally, that’s just vacuous, because thinking you are in the right, then acting on that, without checking our, by definition unverifiable, belief doesn’t fly, and is just another case of using words to obfuscate the fact that we are deciding for other animals how they are used, when they die, when they are destroyed, just as we do for anything we consider our property. Sentience has evolved to increase our chance of continued existence, and it allows us to choose our actions. So why choose to use and harm other animals—who want to continue to live just as much as we do—when we don’t have to? It makes no sense to me anymore, since I found out that animal use for food is nutritionally unnecessary.

As for “humane killing,” it is an oxymoron, which moreover evades or ignores the central issue—why do we believe we have the right to decide when another animal dies—without it being a case of self-defense in which there are no non-lethal alternative courses of action available—in the first place?

“Three points:

1. Animals are not humans so asking a human how they would feel if treated as an animal makes no sense. There is no moral equivalence. Pretending otherwise is mere moral one-upsmanship not morality.

2. Virtually all animals, including humans, depend on other animals for food. Even cute little birdies eat bugs. It's just nature. Why do humans not realize that they are part of nature?
 3. I realize I am part of nature and I love burgers. I am no more likely to allow a vegan to deprive me of that pleasure than I am to allow a Saudi cleric to deprive me of the pleasure of pork in hot garlic sauce. One pleasure hating moralist is equivalent to another.”
1. Humans are animals, it's just that we use 'animals' as short-hand for nonhuman animals. We are all equal in that we all desire to live our lives, and to not be harmed. Sure, we all experience that differently, but that's a separate, and morally irrelevant issue.
 2. This is not the way I would phrase it. Alternative: We are human; we are part of nature; we are able to reflect on our behavior and choose our actions. Hence being able to choose is not “unnatural.” The question then becomes who to count as part of the moral sphere. When it comes to sentient beings who we classify as humans, possession of 'sentience' is a sufficient reason to include them in the moral sphere. Sentience in large part refers to having a desire to continue to live, to evaluate one's surroundings, and to avoid dangers. Other animals also possess sentience, and also subjectively experience these desires, even though they experience them quite differently from us. So what reason do we have for excluding them from the moral sphere, other than that we feel we have the right to exclude them, which is a wholly circular justification for doing so?
 3. Why are you talking about others not “allowing” you to do things? The only person who decides what you allow yourself to do is you—no law can stop you—hence all the problems we have with violence even though we have laws.

As for your remark about “pleasure-hating moralists”—I am sad that you choose to characterize any/all vegans that way, not least because as I have tried to explain, the question whether we derive pleasure from eating animals is besides the point.

To offer an analogy: would you also characterize someone who argues for an end to sexual violence a ‘pleasure-hating moralist’? Note that I am not equating these—merely trying to explain via analogy why I think

that unnecessary; and animal use for food indeed is wholly unnecessary, distribution issues, which are political choices, aside. Violence towards other animals is morally indefensible.

“No one, absolutely no one, living in a current first world country has any right to claim superior morality. I find any action in claiming superior morality for life choices like veganism or vegetarianism hilarious. Do you really think you can remove yourself from affecting the environment, negatively, by a mere choice of food? You would have to live in a hut, built by your hands; eat food grown by yourself; weave textiles into clothing, et cetera. It simply doesn’t exist except in areas like Africa—yet the African tribes eat meat! So are you claiming environmental superiority versus Africans simply because they eat meat? Animal testing is what let the likes of you live above the age of 35. How do you think we develop drugs? Do you think mining is less invasive than nurturing animals on a farm? What about pesticides and fertilizers used on vegetables? You think growing corn and soy monocultures is less detrimental than cows? Maybe so, maybe not, but believe me when I say that no one has the right to claim any sort of superiority when they are part of the system.

Drive through the Midwest and look at those endless fields of corn, wheat, and soybeans and ask yourself how many animals live in those fields now, compared to how many animals lived in those fields in the past. Modern mass farming is the most ecologically damaging form of food production and requires the literal extermination of all other life forms to make room for it. There is nothing ethical about modern vegetable food production.”

Where am I talking about, let alone (personally) claiming moral superiority?

All I did is say that we have the ability to not use animals for food, and ask why we would then choose to continue to use animals, given that they are also sentient, also desire to live, and, most importantly, given that we—and especially those who live in the West—unlike other animals, have the ability to choose what we eat. And to preempt another common objection: no, a diet that consists of starches, legumes, and greens plus some fruits is not elitist. Animal agriculture is many times more resource and water intensive.

And, while I don't necessarily disagree that mass farming is an ecological disaster, please keep in mind that a very large part of US and worldwide production of soy, corn, wheat, alfalfa, and other grains is for use as fodder. In the case of soy, 98% of US soy meal goes to feed pigs, chickens, and cows. The figures for corn and wheat are somewhat lower—it's about 70% of corn, 25–33% of wheat—but still, an enormous amount of acreage is dedicated to the production of nutritionally unnecessary “food,” in the form of animals and animal products such as dairy, eggs.

“It's almost like you don't understand equations. If everything moved from meat to soy, then that ‘96% soy production is for feed’ would then read ‘96% of soy is for meat substitutes.’ You cannot get away from man being a heavy consumer of food products.”

I don't get it, all this worldliness and hostility, presumably because you have it in your head that I want to harm other humans to “save animals,” or whatever—yet at the same time you don't know that any animal will need to eat many times their slaughter weight in feed to attain that weight, just like we humans need many times our adult weight in food to grow and continue living. And the efficiency case is even worse when it comes to dairy and eggs.

If you have worries, I would appreciate it if you could express them clearly, rather than asking me to distill the worries from a response in which you impute all kinds of thoughts to me that are inaccurate or besides the point.

“I hear you, but still I can't help finding you so cruel for wishing all those piglets, chicken, what have you, not to be born, not to experience life, the tenderness of their mothers bosom, the running and squeaking and pickings with siblings, the staring at the moon and the night sky, the feeling of a full stomach, just because they were born to be eaten by us. You want to erase billions of sentient brains from the face of the Earth, just because someone will eat them once they are ripe for the serving.”

I am confused. Are you truly arguing that raising an animal for the express purpose of using them until it serves us better to kill them, all so long as, and to the extent that, one can make money out of it—or otherwise gain status—is morally neutral or good, but pointing out to people that this is morally odious is “cruel” because they might decide to stop participating

in the former? Forgive me, but that really makes no sense to me whatsoever, and I hope you can understand why.

“I didn’t say anything about money. I said it is cruel to wish for so many animals not to be born, not to experience life, just because they are born to be eaten.

Consider that before they are killed and eaten, they experience many small and rewarding pleasures of life for months or even years, such as having a meal, interacting with others, sleeping together, and perhaps pondering about the nature of life, yes including in those industrial factory farms, ignorant of what’s coming to them, in blissful ignorance shall we say.

You want to deny them everything, you want they were not born because you, having experienced life, judge their lives not worth living. Think about it beyond your preconceptions.”

I do hope you realize that you’re now basically using the same argument anti-abortion activists make to argue for denying women the right to have abortions—who are convinced that the right to life of unborn, not-yet-sentient offspring outweighs the right of the mother to decide what to do with her body? You’re arguing that one shouldn’t argue against animal use because the consequence might be that as-yet-unborn beings—who by definition cannot bear rights—would remain unborn, which is a harm?

“I’ve seen quite a few factory farms and also small scale traditional farms. In my childhood we used to kill pigs and sheep for festivities with family, in the case of sheep we called it the Crucifixion because we roasted them with arms and legs spread in a cross, standing upwards.

We didn’t enjoy killing them, some of them sheep and pigs and chicken had been with us over several summer seasons and they were part of our troop, but still we knew we were going to eat them. My grandpa gave me wine to drink, he said I was too brainy, needed to tone it down a bit, and I asked him about all the animals that lived with us but that we eventually killed and ate. He was a wise man, and he said do you wish that they were not born? Do you think their lives are not worth living? How arrogant of you. Or something like that. I thought he was right. Even living in a crowded factory floor with no room to spread wings or to run around is better than not to be born at all, a meal or two per day, time to grow, seeing things, breathing, who

am I to judge those things not worth the time they take before heading to the conveyor belt?

Besides, in the near future, factory farms will not raise individual animals, they will raise steaks, chicken breasts, ribs, et cetera, directly, by cell cultivation. The factory farm floor will be a thing of the past. Then this chicken Auschwitz cry will cease I guess.

Why do we have to go full vegan? My chickens live the life of Ryan, and we do joke about the soup we are going to make when they stop laying (and we are near the end now) but we know they are just going to die of old age or misadventure and get a half-decent burial.

Sheep wool, chickens eggs, cows milk—not seeing the inhumanity in that. Meanwhile we bomb the shit out of actual people that we don't even intend to honor by eating.”

As I tried to indicate above, the main reason is that anything less is inconsistent, because any type of institutionalized use is guaranteed to involve harm, because it all happens in the context of satisfying human needs at the cost of others—whether human or nonhuman—and because people are just blind to the ‘harm’ issue since we’re so used to seeing it. Even in mostly benign cases, such as that of backyard chickens, male chicks are generally killed because they can’t be sold—because people want eggs, and quiet. And while some people don’t, only very few people don’t out of a desire to respect their needs—mostly it’s only because they don’t feel comfortable with it. Which is fine as far as it goes, but it makes for a terrible moral principle.

In the case of dairy, this means forcibly impregnating cows to stimulate milk production, removing the calves after birth—either to be killed or to be raised on formula as the next-gen dairy cow—so that we can use their milk, and repeat every year, because only then does the milk production stay at a level at which economic exploitation “makes sense.” Generally cows can stomach about 4–7 “cycles” of this before their milk production drops below about 8000 liters/year, at which point the cost attached to keeping the cow alive and in production becomes too high, so the cow is sold to a butcher, and replaced by the next generation.

The figures for “happy” exploitation, and “organic” cows are marginally less worse, but the economic logic is the same—it’s all only and wholly about what suits us even when we decide for sentimental reasons to keep an animal around. Please understand I don’t mean this as an accusation, I’m just trying to make it clear how little our thinking has to do with actually

taking seriously the interests of nonhuman animals who we consider our property.

Similar things apply to our use of chickens for eggs, of sheep for wool—we keep them alive until it makes more economic sense to replace them than to let them live.

Five Freedoms was a set of guiding welfare principles articulated in the UK during the 1960s in response to increasing public concern about animal suffering caused by industrial-farming methods, such as battery cages for chickens and gestation crates for pigs. The Five Freedoms included freedom from fear, hunger, distress, and pain, and the freedom to engage in at least some species-specific behavior—for example, birds must be able to stretch their wings. These freedoms were suggested as ideals toward which to strive, with the built-in assumption that the things to which we expose animals under our “care” make achieving the freedoms difficult, if not impossible. The most striking thing about the Five Freedoms formulation is the cruel irony that what animals used in human industry most lack is freedom. Their lives are not their own.

No member of the animal kingdom nurses past maturity
 No member of the animal kingdom ever did a thing to me
 It's why I don't eat red meat or white fish
 Don't give me no blue cheese
 We're all members of the animal kingdom
 Leave your brothers and sisters in the sea

Isn't man an amazing animal? He kills wildlife—birds, kangaroos, deer, all kinds of cats, coyotes, beavers, groundhogs, mice, foxes, and dingoes—by the million in order to protect his domestic animals and their feed. Then he kills domestic animals by the billion and eats them. This in turn kills man by the million, because eating all those animals leads to degenerative—and fatal—health conditions like heart disease, kidney disease, and cancer. So then man tortures and kills millions more animals to look for cures for these diseases. Elsewhere, millions of other human beings are being killed by hunger and malnutrition because food they could eat is being used to fatten domestic animals. Meanwhile, some people are dying of sad laughter at the absurdity of man, who kills so easily and so violently, and once a year, sends out cards praying for “Peace on Earth.”

“This ability to predict the long-term future is reliant on memory. In fact, that's really the main evolutionary use for memory, as a storehouse of the information needed to predict

the future. With memory and cognition, our brains became time machines—we could travel back and forth in time. This mental time travel is a human capacity, distinguishing us from other animal. Scrub jays, oddly, seem to demonstrate similar abilities, but proof of mental time travel in animals is hard to come by as yet.”

Why is it assumed that they do not have it until proven that they do? Why is the assumption based on the idea that humans are special, advanced, unique?

We shouldn't assume that animals—or, for that matter, lovers, spouses, kids, or parents—must be thinking and feeling just as we would if we were them. They're not us.

Certainly, projecting feelings onto other animals can lead to us misunderstanding their motivations. But denying that they have any motivation guarantees that we'll misunderstand it.

A critique of empathy for animals' kinship bonds is that it reflects sentimentality and anthropomorphism. But in fact, it is natural to interpret what looks and sounds like sociability as sociability, just as it is intuitive to understand the expression of grief and loss as grief and loss. The radical projection in operation is the contrary: that animals do not suffer, despite what they show us. In a context wherein animals' yearnings are anxiously disavowed, the mother orca balancing her dead calf on her nose, refusing to let her go, summons us to reassess our assumptions.

What if the danger is not applying “human” qualities, abilities, dispositions to non-humans, but the elevation of such things to be the unique realm of humans? If one anthropomorphizes a tree, are they actually being irrational or was it those who placed the tree in the category of other, lesser, below, that are irrational? For some of the most basic functions of life is the prudent course not to assume that other creatures, other life, has the same abilities though perhaps differently expressed, emphasized?

The use of ‘anthropomorphism’ as an objection is quite problematic. Though it was standard in science until recently, it's actually a gross violation of Occam's Razor. It rests on an unsupported assumption that humans are utterly unique in the animal kingdom.

Realistically, we're evolved animals; it makes much more sense to assume that *all* human traits have precedents among other animals. That's especially true of our nearest relatives, of course, but in truth much of what we do is a variation on basic animal, or at least basic vertebrate. Humility turns out to be a scientific principle.

The stipulation ‘over-sentimental’ indicates, I assume, impatience with anthropomorphism. I’m impatient with that impatience. Anthropomorphism is our best first guess. We share almost all our anatomical and physiological hardware and software with non-human mammals and birds, and we know that animals have emotions too—ask Darwin, who wrote a very good book on the subject. If you want to know what an animal is feeling, start by asking how you’d feel.

Which requires a greater leap of faith?

- Humans are unique, with biological processes and abilities that are completely foreign to non-human animals.
- Humans are simply another variation of mammal, evolved with abilities and biological processes that make it more capable than other non-human animals in some situations and less capable in others but whose foundations can be found in many other creatures.

And what is the key distinction which makes the human more valuable than the non-human animal?

Is it that they can make technology? What level is required? Does every member of the species have to be able to create this tech?

Is it that they must have games with clearly defined rules?

Is it because they can communicate using symbols on pieces of paper? Can communication via symbols be sufficient if it’s in the dirt or on a tree and not paper? In what way would territorial markings be fundamentally different?

Is it that humans look like me?

I mean one could go on and on—entire books written, libraries filled—regarding what the potential difference between human and non-human animals is. So you should have lots of reference material should you not have the answers to my questions yourself.

Much of what makes my own life worthwhile—joy, play, meaningful work, loving relationships—is shared widely across species. The hard line between human and nonhuman that many seek to draw is blurrier than it appears.

A fundamental obstacle of how we view the world, and thereby, construct our stories, ideologies, scientific understanding, et cetera about it, is the differentiation between that which is done by us, and that which is done by them (animals). We speak to each other, they vocalize, call, howl. We make decisions, they are governed in many ways by instincts. We are one class of being, they are others, all lesser.

Are we different than other animals? Certainly, no one can dispute that basic, general claim. However we are not fundamentally different from all

animals, though of course there are some we are less alike than others. All of our skills, talents, abilities exist simply on a continuum, no one animal possesses a truly unique biological ability. Our intelligence, while high, is not some unique trait only possessed by humans. Others have intelligence as well, all seeming to be at a level less than ours but of course that is plagued by potential species-biases, human supremacy, et cetera. Others make and use tools but they don't make something like a laptop. Others form complex social groups, others care for their young, others experience fear.

Fear. To some extent a universal experience. Downplayed by even so-called unbiased science, it is something that at least every healthy organism will experience. Perhaps not experienced in the way that a textbook might define it, but experienced in a way that a child would likely describe as fear. And in some cases, the perceived—and to some extent actual—ignorance of a child guides us towards what may be true. We are certainly able to use our large, powerful brain hardware to render up some negative future scenarios that will create fear in the here and now, something current science seems to believe others do not do. Of course cognitive ability can often be difficult to determine given the largely foreign world of the others to many modern-day humans. At first it was simple ignorance that created the gap between Us and Them, now it is “scientifically proven” to most that our mental experience simply cannot compare to theirs.

We have equated the ability to make trinkets with intelligence. While these trinkets may certainly be complex, much of which is outside the ability of most of them, the trinkets are largely not unique. Others build houses, others build devices that allow them to take flight, others wear clothes and protective gear. What could be described as unique is simply our wide array of trinkets. But this is largely due to the fact that we have writing, another unique ability we are told. Certainly writing itself is a unique specific skill, but it is simply a form of inter-generational information transmission, something huge numbers of animals possess. As with many human skills, writing is simply one end of the continuum as it currently stands (according to human knowledge and construction).

These distinctions are all part of a process—likely begun by ignorance and continued by both ignorance and malice—to draw hard lines between us and them, to wall off our species—and by extension, civilization—from them. A dirty past, a dangerous past, a savage past, that is what we have left behind we are told. A savage knife-edge we no longer live on. However the savagery was never quite as bad as claimed, just as our absence of savagery now isn't quite as great as claimed. It's savage to kill another man, not an other. It's savage to take someone's land with guns, not with a court order. It's savage to blow up others along with yourself, not with precision bombs

from high in the air. Attempt to make connections between overt, covert, subtle savagery is met with derision, accusations of demeaning, belittling “true” savagery.

One of the biggest mistakes may be the argument that “articulating and defending a conception of their own interests” is specific to humans. Animals consistently voice preferences and ask for freedom. We deliberately have to choose not to hear when the lobster bangs on the walls from inside a pot of boiling water or when the hen who is past her egg-laying prime struggles against the human hands that enclose her legs and neck. We have to choose not to recognize the preference expressed when the fish spasms and gasps for oxygen in her last few minutes alive. Considering animals voiceless betrays an ableist assumption of what counts as having a voice.

The differences between humans and nonhumans, in moral capacities as in all else, exist on a continuum. This observation goes back to Charles Darwin, and some contemporary animal behaviorists, such as Frans de Waal, argue forcefully against ranking humankind at the top of some evolutionary ladder of intelligence.

Instead, there are a variety of intelligences, not all of which humans excel at. De Waal goes so far as to call for a moratorium on declaring any defining difference between human and animal, as so many past attempts—such as defining humans by tool use—have been handily disproven.

Charley doesn’t have our problems. He doesn’t belong to a species clever enough to split the atom but not clever enough to live in peace with itself. If chimps or other apes are to gain personhood, it likely won’t be due to anything extra that they can do that we haven’t already seen. Personhood for chimps will finally be realized not through more cognitive tests or changes in evolutionary timelines, but through a reimagining of what it really means to be a person.

Living diversity is astonishing, but as you peel layers of difference, you encounter similarities more stunning. The extreme shrinkage of hind limbs that granted whales their swimming bodies was largely accomplished by the loss of one gene. In your body, this same gene gave you normal limbs. Normal for a human, that is. If you look at side-by-side drawings of human, elephant, and dolphin brains, the similarities overwhelm the differences. We are essentially the same, merely molded by long experience into different outer shapes for coping with different outer surroundings, and wired inside for special talents and abilities. But beneath the skin, kin. There is no other animal like us. But don’t forget: there are no other animals like each of them, either.

Zoos aren’t prisons? You can *maybe* make that argument in the insect house, but remember, your ‘consciousness,’ ‘mind,’ ‘brain,’ whatever label

you want, is simply a different version of ones other non-human animals have. So if I locked you up in a nice house, with free medical care, food, toys, don't let you leave, and let a bunch of people observe your life, you'll likely use your quite-capable human version to see your situation as horrible, but so will most of the non-human animals in the zoo, just likely to a lesser extent.

Dropped into a completely alien—not green men, just radically different to your own—culture, not knowing the language, customs, et cetera, you would find that you may react in similar ways to Harambe, even with all that intelligence to sort out “right” and “wrong” actions. Would you be so supportive of putting down the dangerous creature then? Or would you perhaps want more leeway provided, more potential danger to others exist, to hopefully get you through alive?

“In his deepest being, Sultan is not interested in the banana problem. Only the experimenter's single-minded regimentation forces him to concentrate on it. The question that truly occupies him, as it occupies the rat and the cat and every other animal trapped in the hell of the laboratory or the zoo, is: Where is home, and how do I get there?”

Likewise, the melancholic bellowing of oxen separated from their kin and driven to the cattle trains heading for slaughter:

“And the worst of all is the stampede of homesick cattle. A yearning bull when it gets out of hand turns into a wild animal. I find that homesickness in an animal is even worse than in people.”

In such places, where animals are simply penned up, they are almost always more thoughtful than their cousins in the wild. This is because even the dimmest of them cannot help but sense that something is very wrong with this style of living. When I say that they are more thoughtful, I don't mean to imply that they acquire new powers of reasoning. But the tiger you see madly pacing its cage is nevertheless preoccupied with something that a human would certainly recognize as a thought. And this thought is a question: Why? ‘Why, why, why, why, why, why?’ the tiger asks itself hour after hour, day after day, year after year, as it treads its endless path behind the bars of its cage. It cannot analyze the question or elaborate on it. If you were somehow able to ask the creature, ‘Why what?’ it would be unable to answer you. Nevertheless this question burns like an unquenchable flame in its mind, inflicting a searing pain that does not diminish until

the creature lapses into a final lethargy that zookeepers recognize as an irreversible rejection of life. And of course this questioning is something that no tiger does in its normal habitat.

We know now from over a century of observing animals in captivity that when they are deprived of their natural habitat, they will often develop symptoms that look like extreme forms of despair. Parrots will rip their own feathers out. Horses will start unstopably swaying. Elephants will start to grind their tusks—their source of strength and pride in the wild—against the walls of their cells until they are gnarled stumps. Some elephants in captivity are so traumatized they sleep upright for years, moving their bodies neurotically the whole time. None of these species ever behave this way in the wild. Many animals in captivity lose the desire to have sex—that’s why it’s so hard to get animals to mate in zoos.

I acknowledge the benefits they provide. I simply don’t believe those benefits outweigh the negatives. Sure, there are great zoos out there that are absolutely dedicated to conservation and humane treatment of animals, but for every one of those, there are so many that provide little towards conservation efforts and mistreat the animals.

Studies have repeatedly shown how difficult and usually unsuccessful attempts are to reintroduce captive animals into the wild, so their claim of restoring wild populations of endangered species is lacking results. Not to mention that many zoos don’t have a diverse enough population of any given species to support their forced breeding programs of these endangered species, nor access or resources to coordinate with others, so they turn to inbreeding which only causes more issues for the animals.

The education argument is incredibly weak, because once again studies have shown that zoo patrons spend little to no time reading the available information on any animal. The average time spent at any individual enclosure was not nearly long enough to read and retain any information if an individual even bothered to read the signs.

The behavioral problems animals show in captivity alone is enough to make me detest zoos. Animals in zoos display behavior not typical of their wild counterparts, including self harm.

One of my biggest issues with zoos, however, is that they distract from the real issue. We are the ones causing so many species to go extinct. We are destroying their habitats and poaching them for their hides, horns, et cetera. The mass amount of funding zoos receive could do so much more good fighting those issues rather than holding these animals captive largely for our enjoyment.

In captivity, these animals will only ever get to experience a small fraction of what their lives could have been. In the wild, they would have

had miles and miles of ice to roam across and enjoy the thrill of hunting and interacting in family and social groups. Their lives would have had a very distinct meaning and purpose entirely of their own volition. Instead, they are confined to a glorified prison cell that is artificially cooled and packed with ice to keep them “comfortable.” The extreme boredom and frustration with this tiny ice box will likely lead them to exhibit stereotypical behaviors such as pacing or head bobbing. These pointless, repetitive actions are thought to be physical manifestations of extreme mental distress. According to Polar Bears International:

“Some 85 percent of North American polar bears [in zoos] do it, devoting nearly a quarter of their “active day” (i.e. the time they spend alert and moving) to this behavior.”

It occurred to me that the frogs and their progeny, if they had any, and their progeny’s progeny, if they had any, would never again touch the floor of the rainforest but would live out their days in disinfected glass tanks.

A century from now, pandas and tigers and rhinos may well persist only in zoos or in wildlife areas so small and heavily guarded they qualify as quasi-zoos.

We should see ourselves in our brothers and sisters, but we do not. Taken from her natural context, adequately cared for at best, slavery and imprisonment always, she labors alone. Or perhaps with a few companions. A hall closet compared to her true home. But hey, we feed and provide safety for her, she wouldn’t move as much if she didn’t have to. You wouldn’t mind submitting to this completely unwarranted lifetime house arrest then would you? Don’t worry, we’ll make sure you’re fed and watered and maybe give you a beach ball or something to play with. A home filled with family. Oh and yeah, sorry, didn’t say your house did I? Nope, so yeah, meet Billy and Sam, and you’ll be living with them in Texas. Maybe we’ll give Billy a handy and you can make a cute kid we can put on billboards. Have fun.

Resigned to a remaining life in captivity. Alone, at best coping and socializing with other damaged distant kin. One day she snaps. She goes on a rampage against her oppressors. No more concern for her body, no one but her had cared for a long time anyway. Damage. Rage. Frustration. Destroy. It’s close to over now, flesh pierced along with the air. No clean shots, but she doesn’t have much strength now. Down she goes, one eye pressed into the dirt, no energy to lift it even once more in what has become her long, troubled life. The other eye focuses on the small figures. Breathing hard now, breathing is hard now. No more small figures now.

Just as our big-eared brothers and sisters fall, so too do our small-eared brothers and sisters. They struggle each day against their own captors.

Their cages different but no less existent. Some die in captivity of “natural causes,” some few—unlucky ones if viewed honestly—of truly natural causes, some in fits of rage against their oppressors. Revolutionaries are not limited to one species, though popular propaganda would like you to believe so. Fighting. Dying. Risk. She lost it all. But she had lost it already, a life in captivity is not a life. You do not need to be a hairless ape to recognize these facts. An animal in a trap will seek to get out of the trap, to the point of removing its limb in order to survive at least a bit longer. Would you do anything close? Perhaps a lack of forethought promotes this, perhaps a wisdom that is clouded from view by your “superior intelligence.”

She is hopeless. They are hopeless. Brothers and sisters everywhere are hopeless, they despair. But they could be going through so much worse you say. How does this make it better? You are aware it could be worse yet do nothing to make it better? Great, they should feel lucky they didn’t live then? What purpose does this serve in discussing legitimate grievances? None, it is simply a tool used by the oppressors and their supporters, whether ignorant or informed. It applies to irrational fears, the type of fears promoted by the oppressors, and nothing more.

The largest extinction of our brothers and sisters is occurring as this is written, transmitted, read, stored. We poison them, murder them, experiment on them. We have the ability to communicate over long distances what we do to them. We can create arguments justifying all manner of violence against them. We can study the most ideal ways to exterminate them. We will do it publicly, privately, no matter.

It will be done.

It must be done.

You will not stop it.

Perish.

How does he feel about capturing animals in the wild and sending them to a life in captivity? He has no regrets:

“They’re ambassadors from the wild. Unless people know about and see these animals, there will be no stewardship for octopuses in the wild. So knowing they are going to accredited institutions, where they are going to be loved, where people will see the animal in its glory—that’s good, and it makes me happy. She’ll live a long, good life—longer than in the wild.”

A bear biologist writes:

“Every time I chase an animal to put a dart in it, I am in conflict. How can I justify getting the information like this?”

One of them had once come upon a female nursing her cubs. Unaware of his presence, she had settled back against a bank of snow with them and was staring calmly out across the empty sea ice.

“I saw that, and I said to myself, why in God’s name am I bothering these animals?”

Most humans believe we are superior, perfected, destined to rule. In truth other living things are as much of the world and have as much claim to the Earth as do we. And they cause far less trouble. Humans are by far the most compassionate and creative and violent and destructive species in the history of our planet. And because we have put the whole living world into accelerating decline—forests, waters, air, oceans, species—with zero consideration for other species and for people who will come after us, our moral landscape—if there is one—needs a total makeover.

Organisms don’t have to show their human equivalence—as conscious agents, intentional communicators, or ethical subjects—to count.

One measure of human moral progress—amid and despite the savageries we visit upon each other—is how we treat the innocent in our care. And none are more innocent than these.

When people would ask me why I’m concerned about animals in the face of widespread human suffering, I respond: ‘Compassion is an action word with no boundaries.’

If it is in our power to prevent something bad from happening, without thereby sacrificing anything of comparable moral importance, we ought, morally, to do it. By “without sacrificing anything of comparable moral importance” I mean without causing anything else comparably bad to happen, or doing something that is wrong in itself, or failing to promote some moral good, comparable in significance to the bad thing that we can prevent.

This principle of altruism requires us only to prevent what is bad and it requires this of us only when we can do it without sacrificing anything that is, from the moral point of view, comparably important. Thus, all things being equal, there is no moral excuse for not doing what we can to alleviate the suffering of people who are dying from lack of food, shelter, and medical care, regardless of geographical proximity or distance. Just because they might be thousands of kilometers away, for example, doesn’t mean that we are not obliged to take the money that we would have spent on a luxury item and instead donate it to an international relief agency.

The extension of the principle of altruism to non-humans—not species, but individual animals—seems to be trivial. After all, once again, there is

no morally relevant difference in terms of the capacity to suffer. In other words, we are obliged to help a starving polar bear.

What happened to this animal? Did the witnesses of its suffering intervene? Did the videographer and his crew take any steps to save it? Usually such efforts on behalf of this or that particular animal meet resistance, even discouragement, on the grounds that we should not intervene as nature ‘takes its course.’

Now put aside the fact that nature is taking such a course only because it has been altered, perhaps irrevocably, by irresponsible human activity, to the detriment of the members of other species (not to mention our own). Even so, how much weight should we give to this ‘leave nature alone’ argument? Here is an animal that is suffering. Should we—or the people who take such videos—do anything to help it?

From an ethical perspective, the answer seems to me to be clear: yes, absolutely. Anyone who accepts the arguments that we are morally obliged both (a) not to treat animals in a certain way, because of their capacity to suffer, and (b) to relieve the suffering of human beings as long as it does not involve a comparable loss on our part must also grant (c) that we are morally obliged also to relieve the suffering of non-human animals when it is possible to do so and without comparable loss on our part.

Of course, we do often acknowledge such a duty to help animals that suffer, especially when it is clear that such suffering is directly related to human activity. We typically come to the aid of waterfowl harmed by oil spills, sea mammals incapacitated by plastic floating in the oceans, and animals injured by vehicles. But here is the sticking point: why should it be any different with animals whose suffering is less obviously or directly related—and perhaps not related at all—to human activity, suffering for which we less clearly bear responsibility, or for which we bear no responsibility at all?

A failure to help that polar bear—or any individual animal in a comparable condition, regardless of our responsibility, direct or indirect, for that suffering—is callous and morally wrong. Nor can lack of action be defended by some alleged concern for the course of nature (‘We must not interfere!’) or the gene pool of the species (‘Let the weak die!’). Consider someone who would use those same arguments to justify not intervening to help relieve the suffering of particular human beings during a famine or after a tsunami, or someone who would use such arguments to say that we should not give antibiotics to a child with pneumonia. Such an attitude, reminiscent of various Charles Dickens characters, would be rejected out of hand as immoral. If the only morally relevant factor is, ‘can they suffer,’ there is no relevant moral difference when animals suffer pain that we can

alleviate.

Hell, even the climate-change-denying Australian government airdropped some carrots and sweet potatoes to animals affected by bushfires. You want to be worse than those assholes?

If we don't get our act together and come in commonality and understanding with the organisms that sustain us today, not only will we destroy those organisms but we will destroy ourselves. We need to have a paradigm shift in our consciousness. What will it take to achieve that?

If I die trying but I'm inadequate to the task to make a course change in the evolution of this planet...okay I tried. The fact is, I tried. How many people are not trying. If you knew that every breath you took could save hundreds of lives in the future had you walked down this path of knowledge, would you run down this path of knowledge as fast as you could? Or would you hide, in fear of what else might be lurking along it, waiting for you?

I believe nature is a force of good. Good is not only a concept it is a spirit. So hopefully the spirit of goodness will survive.

Human beings will only be as kind or respectful to each other as they are kind and respectful to animals and nature.

The Sapiens regime on earth has so far produced little that we can be proud of. We have mastered our surroundings, increased food production, built cities, established empires and created far-flung trade networks. But did we decrease the amount of suffering in the world? Time and again, massive increases in human power did not necessarily improve the well-being of individual Sapiens, and usually caused immense misery to other animals.

Humans seem to be more irresponsible than ever. Self-made gods with only the laws of physics to keep us company, we are accountable to no one. We are consequently wreaking havoc on our fellow animals and on the surrounding ecosystem, seeking little more than our own comfort and amusement, yet never finding satisfaction. Is there anything more dangerous than dissatisfied and irresponsible gods who don't know what they want?

According to Taker mythology, every civilization anywhere in the universe must be a Taker civilization, a civilization in which people have taken the life of the world into their own hands. That's so obvious it doesn't need to be pointed out. Hell, every alien civilization in the history of science fiction has been a Taker civilization. Every civilization ever encountered by the USS Enterprise has been a Taker civilization. This is because it goes without saying that any intelligent creature anywhere will insist on taking his life out of the hands of the gods, will know that the world belongs to him and not the other way around.

It's not man who is the scourge of the world, it's a single culture. One culture out of hundreds of thousands of cultures. *Our* culture. And here is

the best of the news I have to bring: We don't have to change humankind in order to survive. We only have to change a single culture.

We now stand where two roads diverge. But unlike the roads in Robert Frost's familiar poem, they are not equally fair. The road we have long been traveling is deceptively easy, a smooth superhighway on which we progress with great speed, but at its end lies disaster. The other fork of the road—the one less traveled by—offers our last, our only chance to reach a destination that assures the preservation of the earth.

Fundamentally, the task is to articulate not just an alternative set of policy proposals but an alternative worldview to rival the one at the heart of the ecological crisis—embedded in interdependence rather than hyper-individualism, reciprocity rather than dominance, and cooperation rather than hierarchy. This is required not only to create a political context to dramatically lower emissions, but also to help us cope with the disasters we can no longer avoid. Because in the hot and stormy future we have already made inevitable through our past emissions, an unshakable belief in the equal rights of all people and a capacity for deep compassion will be the only things standing between civilization and barbarism.

Writing in 1808, British abolitionist Thomas Clarkson described the battle over the slave trade as:

“A contest between those who felt deeply for the happiness and the honour of their fellow-creatures, and those who, through vicious custom and the impulse of avarice, had trampled underfoot the sacred rights of their nature, and had even attempted to efface all title to the divine image from their minds.”

Right from the beginning, everything that ever lived belonged to the world—and that's how things came to be this way. Those single-celled creatures that swam in the ancient oceans belonged to the world, and because they did, everything that followed came into being. Those club-finned fish offshore of the continents belonged to world, and because they did, the amphibians eventually came into being. And because the amphibians belonged to the world, the reptiles eventually came into being. And because the reptiles belonged to the world, the mammals eventually came into being. And because the mammals belonged to the world, the primates eventually came into being. And because the primates belonged to the world, *Australopithecus* eventually came into being. And because *Australopithecus* belonged to the world, man eventually came into being. And for three-million years man belonged to the world—and because he belonged to the world, he grew and developed and became brighter and more dexterous

until one day he was so bright and dexterous that we had to call him *Homo sapiens sapiens*, which means that he was us. And that's the way the we lived for three-million years—as if we belonged to the world. That's how we came into being. We know what happens if you take the Taker premise, that the world belongs to man. That's a disaster. If you take the Leaver premise, that man belongs to the world, then creation goes on forever.

Changing the World

The Human Super-Organism

“I am pessimistic about the human race because it is too ingenious for its own good. Our approach to nature is to beat it into submission. We would stand a better chance of survival if we accommodated ourselves to this planet and viewed it appreciatively instead of skeptically and dictatorially.”

ORDER IS DISTURBED BY LOSS OF PLACE.
ORDER IS DISRUPTED BY LOSS OF BALANCE.
ORDER IS DESTROYED BY LOSS OF DIVERSITY.

I have come to the conclusion that capitalism is successful primarily because it can impose the majority of the costs associated with its economic activities on outside parties and on the environment. In other words, capitalists make profits because their costs are externalized and borne by others. In the US, society and the environment have to pick up the tab produced by capitalist activity.

In the past when critics raised the question about external costs, that is, costs that are external to the company although produced by the company's activities, economists answered that it was not really a problem, because those harmed by the activity could be compensated for the damages that they suffered. This statement was intended to reinforce the claim that capitalism served the general welfare. However, the extremely primitive nature of American property rights meant that rarely would those suffering harm be compensated. The apologists for capitalism saved the system in the abstract, but not in reality.

For example, very little, if any, of the real estate development underway would be profitable if the external costs imposed on existing property holders had to be compensated. Consider just a few specific instances. When a taller house is constructed in front of one of less height, the view of the latter is preempted. The damage to the property value of the house whose view has

been blocked is immense. Would the developer build such a tall structure if the disadvantaged existing property had to be compensated for the decline in its value? When a house is built that can sleep 20 or 30 people next to a family's vacation home or residence, the noise and congestion destroys the family's ability to enjoy their own property. If they had to be compensated for their loss, would the hotel, disguised as a 'single family dwelling' have been built?

Walton County, Florida, is so unconcerned about these vital issues that it has permitted construction of structures that can accommodate 30 people, but provide only three parking spaces. Where do the rental guests park? How many residents will find themselves blocked in their own driveways or with cars parked on their lawns? As real estate developers build up congestion, travel times are extended. What formerly was a five minute drive from Inlet Beach to Seaside along 30-A can now take 45 minutes during summer and holidays, possibly longer. Residents and visitors pay the price of the developers' profits in lost time. The road is a two-lane road that cannot be widened. Yet Walton County's planning department took no account of the gridlock that would emerge.

As the state and federal highways serving the area were two lanes, over-development made hurricane evacuation impossible. Florida had to pay for turning two lane highways into four lane highways in order to provide some semblance of hurricane evacuation. After a decade, the widening of highway 79, which runs North-South is still not completed to its connection to Interstate 10. Luckily, there have been no hurricanes. If developers had to pay these costs instead of passing them on to taxpayers, would their projects still be profitable?

Now consider the external costs of offshoring the production of goods and services that US corporations, such as Apple and Nike, market to Americans. When production facilities in the US are closed and the jobs are moved to China, for example, the American workers lose their jobs, medical coverage, careers, pension provision, and often their self-respect when they are unable to find comparable employment or any employment. Some fall behind in their mortgage and car payments and lose their homes and cars. The local and state governments lose the tax base as personal income and sales taxes decline and as depressed housing and commercial real estate prices in the abandoned communities depress property taxes. State and local infrastructure declines. Possibly crime rises. Safety net needs rise, but expenditures are cut as tax revenues decline. Municipal and state workers find their pensions at risk. Education suffers. All of these costs greatly exceed Apple's and Nike's profits from substituting cheaper foreign labor for American labor. Contradicting the neoliberal claims, Apple's and Nike's

prices do not drop despite the collapse in labor costs that the corporations experience.

A country that was intelligently governed would not permit this. As the US is so poorly governed, the executives and shareholders of global corporations are greatly enriched because they can impose the costs associated with their profits on external third parties. The unambiguous fact is that US capitalism is a mechanism for looting the many for the benefit of the few. Neoliberal economics was constructed in order to support this looting. In other words, neoliberal economists are agents of injustice just like the Western print and TV media. Because of these influential propagandists you will hear those who are being looted praise the merits of “free market capitalism.”

So far we have barely scratched the surface of the external costs that capitalism imposes. Now consider the pollution of the air, soil, waterways, and oceans that result from profit-making activities. Consider the radioactive wastes pouring out of Fukushima since March 2011 into the Pacific Ocean. Consider the dead zones in the Gulf of Mexico from agricultural chemical fertilizer run-off. Consider the destruction of the Apalachicola, Florida oyster beds from the restricted river water that feeds the bay due to over-development upstream. Examples such as these are endless. The corporations responsible for this destruction bear none of the costs. If it turns out that global warming and ocean acidification are consequences of capitalism’s carbon-based energy system, the entire world could end up dead from the external costs of capitalism.

Free market advocates love to ridicule economic planning; Alan Greenspan and Larry Summers actually said that “markets are self-regulating.” There is no sign anywhere of this self-regulation. Instead, there are external costs piled upon external costs. The absence of planning is why over-development has made 30-A dysfunctional, and it is why over-development has made metropolitan areas, such as Atlanta, Georgia, dysfunctional. Planning does not mean the replacement of markets. It means the provision of rules that produce rational results instead of shifting costs of development onto third parties. If capitalism had to cover the cost of its activities, how many of the activities would be worth it? As capitalists do not have to cover their external costs, what limits the costs? Once the external costs exceed the biosphere’s ability to process the waste products associated with external costs, life ends.

We cannot survive an unregulated capitalism with a system of primitive property rights. Ecological economists understand this, but neoliberal economists are apologists for capitalist looting. In days gone by when mankind’s footprint on the planet was light, what some arrogantly call an

“empty world,” productive activities did not produce more wastes than the planet could cleanse. But the heavy foot of our time requires extensive regulation. The Trump administration’s program of rolling back environmental protection, for example, will multiply external costs. To claim that this will increase economic growth is idiotic. The measure known as Gross Domestic Product (GDP) is so flawed that we do not know whether the increased output costs more to produce than it is worth. GDP is really a measure of what has been looted without reference to the cost of the looting. Environmental deregulation means that capitalists can treat the environment as a garbage dump. The planet can become so toxic that it cannot recover.

In the United States and generally across the Western world, property rights exist only in a narrow, truncated form. A developer can steal your view forever and your solitude for the period his construction requires. If the Japanese can have property rights in views, in quiet which requires noise abatement, and in sun fall on their property, why can’t Americans? After all, we are alleged to be the “exceptional people.” But in actual fact, Americans are the least exceptional people in human history. Americans have no rights at all. We hapless insignificant beings have to accept whatever capitalists and their puppet government impose on us. And we are so stupid we call it Freedom and Democracy.

“Basically the entire global economy rests on how quickly we can get carbon out of the ground and put it in the atmosphere. That’s basically the global enterprise. And there’s a lot of people doing it. Geologically, it’s a really impressive effort.”

Global warming has improbably compressed into two generations the entire story of human civilization. First, the project of remaking the planet so that it is undeniably ours, a project whose exhaust, the poison of emissions, now casually works its way through millennia of ice so quickly you can see the melt with a naked eye, destroying the environmental conditions that have held stable and steadily governed for nearly all of human history. That has been the work of a single generation. The second generation faces a very different task: the project of preserving our collective future, forestalling that devastation and engineering an alternate path. There is simply no analogy to draw on, outside of mythology and theology—and perhaps the Cold War prospect of mutually assured destruction.

Annihilation is only the very thin tail of warming’s very long bell curve, and there is nothing stopping us from steering clear of it. But what lies between us and extinction is horrifying enough, and we have not yet begun

to contemplate what it means to live under those conditions—what it will do to our politics and our culture and our emotional equilibria, our sense of history and our relationship to it, our sense of nature and our relationship to it, that we are living in a world degraded by our own hands, with the horizon of human possibility dramatically dimmed. We may yet see a climate *deus ex machina*—or, rather, we may yet build one, in the form of carbon capture technology or geoengineering, or in the form of a revolution in the way we generate power, electric or political. But that solution, if it comes at all, will emerge against a bleak horizon, darkened by our emissions as if by glaucoma. Those who have imbibed several centuries of Western triumphalism tend to see the story of human civilization as an inevitable conquest of the earth, rather than the saga of an insecure culture, growing, like mold, haphazardly and unsurely upon it.

Humans, like all mammals, are heat engines; surviving means having to continually cool off, as panting dogs do. For that, the temperature needs to be low enough for the air to act as a kind of refrigerant, drawing heat off the skin so the engine can keep pumping. At seven degrees of warming, that would become impossible for portions of the planet's equatorial band, and especially the tropics, where humidity adds to the problem. And the effect would be fast: after a few hours, a human body would be cooked to death from both inside and out. At eleven or twelve degrees Celsius of warming, more than half the world's population, as distributed today, would die of direct heat. Things almost certainly won't get that hot anytime soon, though some models of unabated emissions do bring us that far eventually, over centuries.

But at just five degrees, according to some calculations, whole parts of the globe would be literally unsurvivable for humans. At six, summer labor of any kind would become impossible in the lower Mississippi Valley, and everybody in the United States east of the Rockies would suffer more from heat than anyone, anywhere, in the world today. New York City would be hotter than present-day Bahrain, one of the planet's hottest spots, and the temperature in Bahrain would induce hyperthermia in even sleeping humans. Five or six degrees is unlikely by 2100. The IPCC furnishes us with a median prediction of over four degrees, should we continue down the current emissions path. That would deliver what today seems like unthinkable impacts—wildfires burning sixteen times as much land in the American West, hundreds of drowned cities. Cities now home to millions, across India and the Middle East, would become so hot that stepping outside in summer would be a lethal risk—in fact, they will become that way much sooner, with as little as two degrees of warming. You do not need to consider worst-case scenarios to become alarmed.

A sentiment exists—particularly among non-scientists—that the idea of humans seriously disrupting the planet on a geological scale is mere anthropocentric hubris. But this sentiment misunderstands the history of life. In the geological past, seemingly small innovations have reorganized the planet's chemistry, hurling it into drastic phase changes. Surely humans might be as significant as the filter-feeding animals of the Cambrian Explosion. Here's an example where, 500 million years ago, something very similar happened. There's plenty of talk today about comparing rates of extinction in the mass extinctions of the past with the rate at which we're driving species extinct today, and it's all through the evolution of new behaviors and ecosystem engineering. Like the Cambrian burrowers that reshaped the microbial mat world to their own ends, humans have converted half the planet's land surface to farmland. We're even beginning to change the chemistry of the ocean, acidifying it with carbon dioxide and turning whole swaths of the continental shelves anoxic with the deluge of nitrogen and phosphorus fertilizers pouring out of our agricultural heartlands. And the dizzying arsenal of our modern technology is a leap in innovation perhaps matched in the entire history of life only by the eruption of biological invention at the Cambrian Explosion. At the very least, it's not a stretch to think we might be as important as penis worms.

This is an example from the past when an ecological crisis happened because of ecosystem engineering. And we shouldn't be too surprised or too staggered or too blown away by the fact that maybe it's happening again. Biological organisms are an incredibly powerful geological force.

Sam Hill—the man, not the old-timey euphemism for hell—spent his career building roads across the Pacific Northwest. He didn't actually build them; huge teams of laborers did that. But Sam owned the company they worked for, and he got rich enough off the profits that he was able to commission his own damn Stonehenge as a monument. That's a bellwether of human progress: What was once the labor of generations can now be built at the whimsy of a rich man. In fairness to Sam, his motivations for building a fake Stonehenge were rather nobler than 'upstage those shiftless cavemen.' He wanted to create a monument to the millions of young men who died fighting in World War I. At that point, the prevailing belief was that Stonehenge had been built as a sacrificial altar. In Hill's mind, World War I was an altar upon which millions had been sacrificed, pointlessly. A full-scale replica of history's most famous pagan murder shrine seemed a fitting tribute.

How far back can we date the large-scale impact of *Homo sapiens* on the planet? According to some, the pivotal moment was the human development of language, and with it a capacity for conscious intentionality. Beginning

roughly 60,000 years ago, they argue, the origin of language and intentionality sparked a prodigious capacity for innovation that facilitated adaptive changes in human social organization. This watershed is marked in the archaeological record by a vast expansion of artifacts such as flints and arrowheads. With this “great leap forward,” *Homo sapiens* essentially shifted from biological evolution through natural selection to cultural evolution. Yet, tragically, our emancipation as a species from what might be seen as the thrall of nature also made us a force for planetary environmental destruction.

In tandem with this great leap forward in social organization and killing capacity, humanity expanded across the planet. From our ancestral home in Africa, we radiated outward, colonizing all the world’s major ecosystems within the span of 30,000 years. We spread first to Eurasia, then, around 50- to 60,000 years ago, to Australia and New Guinea, then to Siberia and North and South America around 13,000 years ago (though perhaps this one has changed yet again—what year is it?), and then, most recently, to the Pacific Ocean Islands only 4,000 years ago. At the same time, humans underwent a massive demographic boom, expanding from a few million people 50,000 years ago to around 150 million in 2000 BC.

The late Pleistocene wave of extinctions cannot be understood in separation from this spatial and demographic expansion of *Homo sapiens*. In most places around the planet, the megafauna extinctions occurred shortly after the arrival of prehistoric humans. On finding fresh hunting grounds, our ancestors encountered animals with no evolutionary experience of human predators. We quickly obliterated species that didn’t know how to stay out of our way. The susceptibility of creatures who were unfamiliar with humans is evident from what biologists call the filtration principle: the farther back in time the human wave of extinction hit, the lower the extinction rate today. This filtration effect means that in our ancestral home, Sub-Saharan Africa, only 5% of species went extinct, while Europe lost 29%, North America 73%, and Australia an astonishing 94%.

Ecologists have a label for such an event. They call it an outbreak. This use of the word is more general than what’s meant by an outbreak of disease. You could think of disease outbreaks as a subset. Outbreak in the broader sense applies to any vast, sudden population increase by a single species. Such outbreaks occur among certain animals but not among others. Lemmings undergo outbreaks; river otters don’t. Some kinds of grasshopper do, some kinds of mouse, some kinds of starfish, whereas other kinds of grasshopper, mouse, and starfish do not. An outbreak of woodpeckers is unlikely. An outbreak of wolverines, unlikely. The insect order Lepidoptera (moths and butterflies) contains some notable outbreakers—not just tent caterpillars of several kinds but also gypsy moths, tussock moths, larch

budmoths, and others. Those are exceptions, though, to the general rule even for lepidopterans. Among all the forest-dwelling species of butterfly and moth, about 98 percent maintain relatively stable populations at low density through time; no more than two percent ever experience outbreaks. What makes a species of insect—or of mammal, or of microbe—capable of the outbreak phenomenon? That’s a complicated question that the experts are still trying to answer.

From the ecological point of view an outbreak can be defined as an explosive increase in the abundance of a particular species that occurs over a relatively short period of time. From this perspective, the most serious outbreak on the planet earth is that of the species *Homo sapiens*. In 1987, the world’s human population stood at 5 billion. We had multiplied by a factor of about 333 since the invention of agriculture. We had increased by a factor of 14 since just after the Black Death, by a factor of 5 since the birth of Charles Darwin. That growth curve, on a coordinate graph, looks like the southwest face of El Capitan.

Another way to comprehend it is this: From the time of our beginning as a species (about 200,000 years ago) until the year 1804, human population rose to a billion; between 1804 and 1927, it rose by another billion; we reached 3 billion in 1960; and each net addition of a billion people, since then, has taken only about thirteen years. In October 2011, we came to the 7-billion mark and flashed past like it was a ‘Welcome to Kansas’ sign on the highway. That amounts to a lot of people, and certainly qualifies as an explosive increase within a relatively short period of time. The rate of growth has declined within recent decades, true, but it’s still above one percent, meaning that we’re adding about 70 million people yearly.

So we’re unique in the history of mammals. We’re unique in the history of vertebrates. The fossil record shows that no other species of large-bodied beast—above the size of an ant, say, or of an Antarctic krill—has ever achieved anything like such abundance as the abundance of humans on Earth right now. Our total weight amounts to about 750 billion pounds. Ants of all species add up to a greater total mass, krill do too, but not many other groups of organisms. And we are just one species of mammal, not a group. We’re big: big in body size, big in numbers, and big in collective weight.

We’re so big, in fact, that biologist Edward O. Wilson felt compelled to do some knowledgeable noodling on the matter. Wilson came up with this:

“When *Homo sapiens* passed the six-billion mark we had already exceeded by perhaps as much as 100 times the biomass of any large animal species that ever existed on the land.”

Wilson meant wild animals. He omitted consideration of livestock, such as the domestic cow (*Bos taurus*), of which the present global population is about 1.3 billion. We are therefore only five times as numerous as our cattle—and probably less massive in total, since they’re each considerably bigger than a human. But of course they wouldn’t exist in such excess without us. A trillion pounds of cows, fattening in feedlots and grazing on landscapes that formerly supported wild herbivores, are just another form of human impact. They’re a proxy measure of our appetites, and we are hungry.

We are prodigious, we are unprecedented. We are phenomenal. No other primate has ever weighed upon the planet to anything like this degree. In ecological terms, we are almost paradoxical: large-bodied and long-lived but grotesquely abundant. We are an outbreak.

When all the big game was gone, our ancestors were forced to find alternatives to their millennia-old hunter-gatherer survival traditions. Combined with climatic and demographic changes, the megafauna extinctions catalyzed one of humanity’s first food crises. Pushed by crisis conditions, humanity underwent what may be seen as its second great transition: the Neolithic Revolution. Given conducive environmental conditions—including plant species that could be domesticated, abundant water, and fertile soil—human beings shifted from nomadic to sedentary modes of food production. This shift happened remarkably rapidly, from about 10,000–8,000 BC.

The Neolithic Revolution also generated a fateful metamorphosis in humanity’s social organization. Intensive agriculture produced a food surplus, which in turn permitted social differentiation and hierarchy, as elite orders of priests, warriors, and rulers emerged as arbiters of the distribution of that surplus. Much of subsequent human history may be seen as a struggle over the acquisition and distribution of such surplus.

Farming was invented around 10,000 years ago (about 300 generations ago; world population: 1 million), transforming some regional landscapes as human-bred plant varieties replaced wild flora. Around 5,500 years ago (world population: 5 million), cities were built and the first great civilizations emerged. The Industrial Revolution in Europe and North America, which replaced the labour of humans and beasts with machines, started having a measurably global impact about 150 years ago (world population: 1 billion), as large volumes of carbon dioxide from fossil fuels were released into the atmosphere.

It took 50,000 years for humans to reach a population of 1 billion, but just the last ten years to add the latest billion.

As the Epic of Gilgamesh documents, the Mesopotamian city-states found themselves grappling with a scarcity of timber resources. The sweep-

ing deforestation of the region also contributed to the secondary effects of soil erosion and siltation that plagued irrigation canals, as well as having a significant impact on the biodiversity of the region. As the Sumerian city-states grew, they were forced to engage in more intensive agricultural production to support the booming population and the increasing consumption of the civilization, with its mass armies and state bureaucracy. The Sumerians sought to cope with this ecological crisis by bringing new land into cultivation and building new cities. Inevitably, however, they hit the limits of agricultural expansion. Accumulating salts drove crop yields down more than 40% by the middle of the second millennium BC. Food supplies for the growing population grew inexorably scarcer. Within a few short centuries, these contradictions destroyed ancient Sumerian civilization. The deserts that stretch across much of contemporary Iraq are a monument to this ecological folly.

Not all ancient societies went the way of Sumer. For about 7,000 years after the emergence of settled societies in the Nile Valley (around 5500 BC), the Egyptians were able to exploit the annual flood of the Nile to support a succession of states, from the dynasties of the Pharaonic Era, through the Ptolemaic kings of the Hellenistic Period, to the Mamluk Sultanate, and the Ottoman Era. The stability of Egypt's agricultural system originated in the fact that the Nile Valley received natural fertilization and irrigation through annual floods, a process that the Egyptians exploited with only minimal human interference.

Within decades of the introduction of dam-fed irrigation by the British in the nineteenth century, in order to grow crops like cotton for European markets, widespread salinization and waterlogging of land in the Nile Valley developed. The Aswan dam, begun by the British in the late nineteenth century, regulated the Nile's flood levels and thus protected cotton crops but undermined the real secret of Egypt's remarkable continuous civilization by retaining nutrient-rich silt behind the dam walls. As a result, the natural fertility of the Nile Valley was destroyed, replaced by extensive use of artificial, petroleum-derived fertilizers that placed Egypt even more deeply in thrall to the global capitalist economy.

It is only with the invention of hierarchical societies such as the Sumerian Empire that practices of defaunation and habitat destruction became so sweeping as to degrade large ecosystems to the point of collapse. The history of Egypt suggests that under the right material and cultural circumstances, human beings can achieve relatively sustainable relations with the natural world. It is the combination of militarism, debauched and feckless elites, and imperial expansionism, through which the Sumerians laid waste to much of the Fertile Crescent in pre-modern times, that renders ecocide so toxic as

to destroy the very civilizations that carry it out. The collapse of ecocidal imperial cultures should serve as a potent warning to the globe-straddling world powers of today.

In the first of his accounts of his voyages to the New World, Christopher Columbus describes the island he named Española as an Edenic land whose “mountains and plains, and meadows, and fields, are so beautiful and rich for planting and sowing, and rearing cattle of all kinds, and for building towns and villages.” Greed and lust for power drip from Columbus’s pen as he describes a marvelous land of abundant harbors and many rivers, “most of them bearing gold,” and populated by naïvely generous inhabitants “so liberal of all they have that no one would believe it who had not seen it.” For Columbus, the biodiversity of this new world is equally notable, for, as he notes the islands are “covered with trees of a thousand kinds of such great height that they seemed to reach the skies,” trees in which “the nightingale was singing as well as other birds of a thousand different kinds.” Columbus’ breathless description of the material riches to be found in the “New World” set the tone for the European imperial expansion in the subsequent five centuries.

If human beings have engaged in notable forms of ecocide throughout our history, it is only with the expansion of Europe and the development of modern capitalism that ecocide has taken on a truly global extent and planet-consuming destructiveness. As Europeans subjugated and colonized “virgin” lands, they dramatically augmented processes of environmental degradation and extinction. The expansion of capitalist social relations through European colonialism and imperialism pushed what had previously been regional environmental catastrophes to a planetary scale. In addition, by transforming nature into a commodity that could be bought and sold, capitalist society shifted humanity’s relations with nature into a mode of intense ecological exploitation unimaginable in previous epochs.

Capitalism is not necessarily more immoral than previous social systems with regard to cruelty to humans and the gratuitous destruction of nature. As a mode of production and a social system, however, capitalism requires people to be destructive of the environment. Three destructive aspects of the capitalist system stand out when we view this system in relation to the extinction crisis:

1. Capitalism tends to degrade the conditions of its own production
2. It must expand ceaselessly in order to survive
3. It generates a chaotic world system, which in turn intensifies the extinction crisis

By wrenching specific elements out of the complex ecosystems in which they are intertwined and turning them into commodities, capital remorselessly breaks down the complex natural world into impoverished but exchangeable forms, simultaneously discarding all those elements that don't appear to have immediate exchange value.

As Europeans colonized other parts of the world, they took cultural beliefs with them that legitimated their conquests. These ideologies of domination, intended to justify European expropriation of indigenous people and their land, also established an exploitative attitude towards flora and fauna in the colonies. The English philosopher John Locke, for example, argued that God intended the land to belong to those who were "industrious and rational." These attributes were manifested in Europeans' "improvement" of the land through their labor, development work that, he argued, removed the land from its original communal state and made it the property of the Europeans. As Locke remarked:

"He that in obedience to this command of God, subdued, tilled, and sowed any part of [the land], thereby annexed to it something that was his property, which another had no title to."

In other words, since indigenous people weren't using the land properly, it didn't really belong to them and they could be dispossessed with no problem. Not coincidentally, Locke owned plantations in English colonies in Ireland and Virginia.

The scientific method generated a model of patriarchal mastery over a passive feminized nature that set the terms for subsequent notions of progress through domination of the natural world. Doctrines of the objectivity and disinterestedness of the scientific method helped to obscure the potentially ecocidal, patriarchal, and racist character of techno-science, until the social movements of the late twentieth century arose to challenge science's role in legitimating colonialism, in depriving women of control of their bodies, and in creating deadly chemicals such as DDT.

Capitalism is dependent on the conditions of production that it relentlessly degrades. By fecklessly consuming the environment, capital is figuratively sawing off the tree branch it is sitting on. But it does so because it must: it is a system based on ceaseless accumulation. Capitalists must constantly reinvest their accumulated profits if they are to survive against competitors, or at the very least, lose their wealth to inflation, driving capital to expand at a compound rate.

"Their skin would turn yellow and at that moment they knew it was time to die, which they did without much protest."

We called them the ‘yellow canaries.’ In other jobs I had with chemical companies, I learned to breathe—almost instinctively—with only the upper part of my lungs.

Trying to make a workplace safe isn’t easy, for it takes a lot of dollars. Money, not human health and welfare, is the heart and soul of that corporate business. People are cheap these days. The chemical industry can kill as many workers as they have at any one time, yet there are still more workers waiting outside to take their place. And the government always looks the other way while the worker gasps for breath.”

The spread of industrialization in the nineteenth and twentieth centuries was a cancer. Industrialization in its present form, is a process of uncontrolled, unsustainable growth that eventually destroys its host—the biosphere.

When something precious is at stake, why not slow down and consider the options, not just for yourself but for a future that you will never see? In a time when we’ve never had more knowledge to inform our actions, we’ve never been more heedless. You are living for the moment while everything else around you is living in geological time.

The earth’s resources are not just scarce. They are finite. Classical economics encourages both producers and consumers to use up resources as fast as possible in pursuit of greater profits and growth. Mainstream economics as practiced today celebrates values—selfishness, gluttony, competitiveness shortsightedness—that were once viewed as cardinal sins, and in the process provides intellectual justification for capitalism’s disastrous pillage of the planet.

Can capitalist society reform itself sufficiently to cope with the extinction crisis? This is not simply unlikely. It is impossible in the long-run. While it is true that the environmental movement did manage to push corporations and the state into cleaning up local crises from the late 1960s onwards, climate change and extinction suggest that the capitalist system is destroying its ecological foundations when viewed on a longer temporal scale. Recall that capital’s solution to periodic systemic crises is to initiate a new round of accumulation. Capital essentially tries to grow itself out of its problems. But, as we have seen, the extinction crisis is precisely a product of unchecked, blinkered growth. In such a context, conservation efforts can never be more than a paltry bandage over a gaping wound.

As laudable as they are, conservation efforts largely fail to address the deep inequalities that capitalism generates, which push the poor to engage in deforestation and other forms of over-exploitation. Many of today’s major

conservation organizations were established in the last half of the twentieth century: the Nature Conservancy (1951), World Wildlife Fund (1961), Natural Resources Defense Council (1970), and Conservation International (1987). Yet during this same period, a new round of accumulation based on neoliberal principles of unrestrained hyper-capitalism has engulfed the planet. The neoliberal era has seen much of the global South become increasingly indebted, leading international agencies such as the World Bank to force debtor nations to harvest more trees, mine more minerals, drill for more oil, and generally deplete their natural resources at exponentially greater rates. The result has been a steeply intensifying deterioration in global ecosystems, including a massive increase in the rate of extinction.

Despite this dramatic collapse of global ecosystems, the climate change crisis has unleashed a fresh round of accumulation, obscured by upbeat language about the investment opportunities opened up by the green economy. Neoliberal solutions to the climate crisis such as voluntary carbon offsets are not only failing to diminish carbon emissions, but are also dramatically augmenting the enclosure and destruction of the global environmental commons. Such programs allow polluting industries in wealthy nations to continue emitting carbon, while turning the forests and agricultural land of indigenous people and peasants in the global South into carbon dioxide “sinks” or biodiversity “banks.” Under the green economy, vast numbers of people, plants, and animals are being sacrificed as collateral damage in the ecocidal exploitation of the planet. Capitalism, it is clear, cannot solve the environmental crises it is causing.

The massive wave of defaunation that has swept the globe over the last half century challenges the very idea of an unspoiled nature. There is no safe refuge from anthropogenic extinction. Indeed, the wilderness that remains has been so significantly degraded that we suffer from change blindness: as the planet’s remaining wilderness is degraded, each generation grows up with an increasingly impoverished view of natural biodiversity, so that human experience itself is undergoing a form of extinction.

In 2009 the European Commission and World Bank published a study that showed a mere 10 percent of the earth’s land today qualifies as “remote,” meaning it takes more than forty-eight hours to travel to it from a city.

Our planet is increasingly being made artificial through human-driven climate change. At least 80 percent of the earth’s land surface is directly influenced by humans. Why does that number matter? Because it indicates that humans are controlling the climate and environment on a scale unprecedented in earth’s history. If we have taken over as creators, those directing the evolution or extinction of life on the planet, how are we to be humble? What stands over us? Humility is important for thinking about

environmental values because it is what shows us our place in relationship to life. Without humility, it is too easy to underestimate or overestimate our value in relationship to the universe. This is far from a new idea—humility has long been an element of the preservationists' argument for caution in altering nature—but at a time when our technological powers have reached heady heights, perhaps this word is at its weakest.

Deserts are spreading across savannahs, forests are drying and being logged. Wildlife is being hunted and dying because of habitat loss and climate change, pushing the planet towards the sixth mass extinction in its history. Meanwhile, we are causing the proliferation of our domesticated species and indiscriminately scattering others around the globe. We are disemboweling the Earth through mining, drilling, and other extractions, littering the planet with novel compounds and materials, devices and objects, that could never have occurred naturally.

For almost all of the planet's 4.5 billion-year history, the atmosphere has been lit solely by extraterrestrial flares, like suns or meteors, or by electrical storms. Now, the skies are infused with artificial lights of different wavelengths as our devices communicate with each other and with us. And that's just in the invisible spectrum. In the visible spectrum we have lit up our world so brightly that towns and cities made of glass, steel, concrete can be seen from space at night and, for city dwellers, the stars fade into oblivion.

We now support a massive global population, but we have not simply multiplied the number of small hunter-gatherer communities. More than half of the world's people now live in cities—artificial constructs of densely packed, purpose-built living spaces, which act as giant factories consuming the planet's plants, animals, water, rocks, and mineral resources. Humanity operates on an industrial scale, and has needs—currently, eighteen terawatts of the energy at any time, 9 trillion cubic meters of fresh water per year and 40% of the global land area for food. It has become a super-organism, a creature of the Anthropocene, a product of industrialization, population expansion, globalization, and the revolution in communications technology. The intelligence, creativity, and sociability of this human super-organism is compiled from the linked-up accumulation of all the human brains, including those from the past who have left a cultural and intellectual legacy, and also the artificial minds of our technological inventions, such as computer programs and information libraries like Wikipedia.

In the Anthropocene, our Earth-moving capabilities have become truly planetary in scale: we now move more rocky materials through mining and other extractions than do glaciers and rivers combined.

Humanity currently uses 30% more natural resources a year than the

planet can replenish.

The idea that scarcity of natural resources poses limits to growth seems logical—indeed, the end of unsustainable capitalism has been predicted for centuries now—except that every time humanity is said to be on the brink of collapse, we find a way around the problem. The Green Revolution that tripled agricultural yields in the 1970s saw off one predicted crash. There was a huge fear in the nineteenth century that New York City and London would drown in their transport pollution (horse manure), or that they would run out of transport fuel (horse feed). The invention of the motor car laid those concerns to rest within a decade, but gave rise to other worries, like rubber and oil shortages. The new explosion in fracking, whereby engineers tap previously inaccessible horizontal drill sites deep underground, has increased global supplies of natural gas from decades to centuries. Such game-changing discoveries are hard if not impossible to predict. So should we rely on them to get us out of other resource shortages?

Like every other life form on this planet, humans are limited to whatever is contained on Earth and its atmosphere, with only solar energy being limitless. Humans are masters of conversion and adaptation. We will always find a solution to mineral shortages, but the problem is that the price for extracting scarce materials is usually paid for in environmental terms, whether it is the huge energy and water costs—and pollution—involved, or the destruction of precious landscapes. Humanity now uses roughly half of global natural production. Every other species that achieves this level of “success,” from bacteria to rats, reaches a tipping point at which its population size outstrips its ability to feed itself. Humanity is reliant on food, but also on external energy and other materials. The crash could be far more severe for us.

The self-awareness that comes with recognizing our power as a planetary force also demands we question our new role. Are we just another part of nature, doing what nature does: reproducing to the limits of environmental capacity, after which we will suffer a population crash? Or are we the first species capable of self-determination, able to modulate our natural urges, our impacts and our environment, such that we can maintain habitability on this planet into the future? And what of our relationship to the rest of the biosphere? Should we treat it as an exploitable resource to be plundered mercilessly for our pleasures and needs, or does our new global power imbue us with a sense of responsibility over the rest of the natural world? Our future will be defined by how we reconcile these two opposing, interwoven forces.

The entire concept of ‘us’ versus ‘nature’ is flawed since we too are part of nature. But why then is a bird’s nest or a beaver’s lodge and dam

considered natural, whereas human houses are not? If we are part of the natural world, why is what we produce—the artificial or cultural—deemed any more or less worthy of admiration, awe, and respect than what we deem naturally produced by planetary forces or evolution? When people make that distinction between humans and the natural world, surely what they mean is that we are capable of dramatically and deliberately choosing and altering the environment in a way that other species cannot. We can change and enhance nature—even the biology we are born with—and exceed natural physical limitations in a way no other species can.

Are we still “natural,” then, in the Anthropocene? Throughout civilization, humans have worried about our progress away from nature, while scorning or fetishizing societies who live most basically with nature. In the Anthropocene, as the last of these natural cultures now face extinction, it perhaps confirms that humans are not just changing the natural environment, but that we now operate on the planet as a very different animal.

There comes a time in a child’s life when they first realize that the food they enjoy—the meat they eat—comes from an animal. That the lovely fluffy mammal they pet is also food. Some children become vegetarian and refuse to eat meat again. Most do not. At this moment in our history, we are like children, realizing that the things we enjoy in life, that we depend upon, from energy to water to consumables, all come with environmental and social consequences that affect us. How we struggle to resolve this issue will determine the trajectory of the Anthropocene for years to come.

No single person or community came up with the idea to put the greenhouse gas carbon dioxide into the atmosphere. The oil-based market-driven economy is a characteristic of civilization that arose out of the human love of energy and its promise of power and wealth. One gallon of oil contains an amount of energy that would take a man eight days of labour to produce. What is wealth if not the key to freedom, a way of throwing off the shackles of labour and the circumscribed life—the liberty to have, be, and do as you choose; the dream of no man having dominion over you? It’s intoxicating stuff.

One of the most unjust aspects of climate disruption (and there are many) is that our actions as adults today will have their most severe impact on the lives of generations yet to come, as well as kids alive today who are too young to impact policy. These children have done nothing to create the crisis, but they are the ones who will deal with the most extreme weather—the storms and droughts and fires and rising seas—and all the social and economic stresses that will flow as a result. They are the ones growing up amidst a mass extinction, robbed of so much beauty and so much of the companionship that comes from being surrounded by other life forms. It is

a form of theft, of violence—slow violence. A clean, vibrant planet is the birthright of all living beings.

Humans aren't the first species to alter the atmosphere; that distinction belongs to early bacteria, which, some two-billion years ago, invented photosynthesis. But we are the first species to be in a position to understand what we are doing.

The Great Oxidation Event occurred after cyanobacteria evolved photosynthesis. Photosynthetic creatures spread through the oceans, excreting oxygen all the while. The flood of oxygen permanently changed the surface of the earth, the composition of the oceans, and the functioning of the atmosphere. Most scientists believe it made the vast majority of the world's land and sea uninhabitable for the vast majority of the planet's living creatures. The resultant slaughter was an oxygen holocaust. Over time, minerals absorbed much of the gas, stabilizing it at about 21 percent of the atmosphere—a good thing, because if the level had risen much more our air would have had so much oxygen that a single spark could have set the planet afire.

The Great Oxidation Event has lessons for today. The first is that people who think that living creatures can't affect the climate have no idea of the power of life. The second is that the onset of climate change means that *Homo sapiens* is getting into the biological big leagues—we are tiptoeing into the terrain of bacteria, algae, and other truly important creatures. The third is that species, like sullen teenagers, don't pick up after themselves. Cyanobacteria sprayed their oxygen garbage all over Earth without concern for the consequences—littering on an epic scale. People are doing the same with carbon dioxide.

The Ad Hoc Study Group on Carbon Dioxide and Climate, or the Charney panel, as it became known, met for five days at the National Academy of Sciences' summer study center, in Woods Hole, Massachusetts. Its conclusions were unequivocal. Panel members had looked for flaws in the modelers' work but had been unable to find any. "If carbon dioxide continues to increase, the study group finds no reason to doubt that climate changes will result and no reason to believe that these changes will be negligible," the scientists wrote. For a doubling of CO₂ from preindustrial levels, they put the likely global temperature rise at between two-and-a-half and eight degrees Fahrenheit.

The panel members weren't sure how long it would take for changes already set in motion to become manifest, mainly because the climate system has a built-in time delay. The effect of adding CO₂ to the atmosphere is to throw the earth out of "energy balance." In order for balance to be restored—as, according to the laws of physics, it eventually must be—the

entire planet has to heat up, including the oceans, a process, the Charney panel noted, that could take “several decades.” Thus, what might seem like the most conservative approach—waiting for evidence of warming to make sure the models were accurate—actually amounted to the riskiest possible strategy: “We may not be given a warning until the CO₂ loading is such that an appreciable climate change is inevitable.” It is now more than twenty-five years since the Charney panel issued its report.

A tipping point takes a small nudge to the climate system and amplifies it into a big change. Compare the climate system to a rowboat: You can tip and then you’ll just go back. You can tip it and just go back. And then you tip it and you get to the other stable state, which is upside down.

We’ve never conducted this experiment, and we only get to conduct it once; we don’t have a duplicate planet.

Extinction is truly forever; once a group dies out, the hundred-thousand unpredictable stages that led to its origin will never be repeated in precisely the same way.

The story of the great auk is a dark comedy. A flightless bird that once likely numbered in the millions, they were hunted by Native Americans and eaten by tenth-century Icelandic settlers in a manner not unlike how an exhausted parent goes out and grabs a rotisserie chicken from the grocery store today. They were quick in the water, but vulnerable when they tottered onto land to breed. By the early sixteenth century, European sailors, craving fresh meat after the long voyage to Newfoundland, would herd hundreds of them onto their boats before digging in.

Then the auk began to be used for more than food. Their feathers were perfect for pillows and mattresses. One sailor distastefully noted that a common tactic was to pluck the best feathers off before leaving the bird to “perish at his leisure.” Their meat could be used as fishing bait, and if you found yourself without wood, you could just light up an auk or two and let their body oils produce a flame for you. That is not a joke.

Only a handful of islands suited the auks’ mating needs, and by the late 1700s, those islands were being decimated. Going to the ill-named Funk Island and plucking birds all summer to fuel the ceaseless demands of the feather industry was the eighteenth-century equivalent of working at the local water park. In 1718, Funk Island was described as so overrun by auks that you couldn’t put your foot between them. By 1810, the place was barren.

There were efforts to save the auk. A petition led to a 1775 law that made taking an auk’s eggs or killing it for its feathers punishable by being beaten in public (certainly puts ideas like a carbon tax in perspective). But it was still legal to kill them for their meat, and in a dark irony, their growing

rarity made rich collectors willing to pay as much for a specimen as a skilled worker would make in a year. Who wouldn't risk a public flogging if you could cover 12 months of bills in a few days' work?

But there are two incidents that truly stand out in the annals of stupidity. In 1840, sailors snagged an auk from an island off Scotland, only to superstitiously stone it to death four days later amid a terrible storm, no doubt prompting a sailor to drunkenly slur, 'More like the not so great auk!' before offering up high-fives. It was the last auk seen in Great Britain, and by 1844, the auks were down to one lonely colony off the coast of Iceland.

One day, three men rowed out there, captured and strangled a pair of auks, left their cracked egg behind, and sold the bodies to a dealer. And that was the last time anyone ever saw a living great auk.

The earth has experienced five mass extinctions before the one we are living through now, each so complete a wiping of the fossil record that it functioned as an evolutionary reset, the planet's phylogenetic tree first expanding, then collapsing, at intervals, like a lung:

- 450 million years ago, 86 percent of all species dead
- 70 million years later, 75 percent
- 125 million years later, 96 percent
- 50 million years later, 80 percent
- 135 million years after that, 75 percent again.

Unless you are a teenager, you probably read in your high school textbooks that these extinctions were the result of asteroids. In fact, all but the one that killed the dinosaurs involved climate change produced by greenhouse gas. The most notorious was 250 million years ago; it began when carbon dioxide warmed the planet by five degrees Celsius, accelerated when that warming triggered the release of methane, another greenhouse gas, and ended with all but a sliver of life on Earth dead. We are currently adding carbon to the atmosphere at a considerably faster rate; by most estimates, at least ten times faster. The rate is one-hundred times faster than at any point in human history before the beginning of industrialization. And there is already, right now, fully a third more carbon in the atmosphere than at any point in the last 800,000 years—perhaps in as long as 15 million years. There were no humans then. The oceans were more than a hundred feet higher.

Many perceive global warming as a sort of moral and economic debt, accumulated since the beginning of the Industrial Revolution and now come

due after several centuries. In fact, more than half of the carbon exhaled into the atmosphere by the burning of fossil fuels has been emitted in just the past three decades. Which means we have done as much damage to the fate of the planet and its ability to sustain human life and civilization since Al Gore published his first book on climate than in all the centuries—all the millennia—that came before. The United Nations established its climate change framework in 1992, advertising scientific consensus unmistakably to the world; this means we have now engineered as much ruin knowingly as we ever managed in ignorance.

Global warming may seem like a distended morality tale playing out over several centuries and inflicting a kind of Old Testament retribution on the great-great-grandchildren of those responsible, since it was carbon burning in eighteenth-century England that lit the fuse of everything that has followed. But that is a fable about historical villainy that acquits those of us alive today—and unfairly. The majority of the burning has come since the premiere of *Seinfeld*. Since the end of World War II, the figure is about 85 percent. The story of the industrial world's kamikaze mission is the story of a single lifetime—the planet brought from seeming stability to the brink of catastrophe in the years between a baptism or bar mitzvah and a funeral.

Though the coral reefs of the Triassic flourished under a much higher atmospheric CO₂ regime than present, scientists are quick to dismantle what could be used as a strawman argument by skeptics:

“Although modern corals arose in the mid-Triassic and lived under much higher atmospheric CO₂ there is no evidence that they lived in waters with low-carbonate mineral saturation. It is the rapid unbuffered increase in atmospheric CO₂ and not its absolute values that causes important associated changes such as reduced carbonate ions, pH, and carbonate saturation of seawater.”

Though it might take only a few decades for us to wipe out coral reefs, if the End-Triassic mass extinction is any guide, these ecosystems will take not decades, centuries, or even millennia, but millions of years to restore. The decisions made in the next few years by the energy industry and the governments that regulate them will leave a record in the rocks that will last for hundreds of millions of years. Considering how much we've already done to dismantle coral reefs, and projecting these trends forward into anything resembling geological time, it becomes clear why it's not unreasonable to compare what is going on today with the worst disasters in earth's history.

Although this wave of mass extinction is global, the vast majority of species destruction is concentrated in a small number of geographical

hotspots. This is because biodiversity is unevenly distributed. On land, tropical rainforests are the primary nursery of biodiversity. Although they cover only six percent of the Earth's surface, their terrestrial and aquatic habitats harbor more than half the known species on the planet. The tropics are the leading abattoir of extinction, their great verdant expanses chopped up into quickly dwindling fragments, their plant and animal species struggling to adapt to habitat destruction, overharvesting, and, increasingly, anthropogenic climate change.

In the planet's tropical latitudes, there is a catastrophic convergence, a supremely destructive alignment of three factors:

1. Militarization and ethnic fragmentation related to the legacy of the Cold War in postcolonial nations
2. State failure and civil discord linked to the structural adjustment policies imposed on the global South by institutions like the World Bank in the name of debt repayment since the 1980s
3. Climate change-fueled environmental stresses such as desertification

But the picture of the stresses affecting the global South is incomplete without a consideration of the relations between humanity and the natural world in its fullest sense. We cannot understand the catastrophic convergence, that is, without discussing the decimation of biodiversity currently unfolding in the global South. Nor, conversely, can we understand extinction without an analysis of the exploitation and violence to which postcolonial nations have been subjected.

Extinction is the product of a global attack on the commons: the great trove of air, water, plants, and collectively created cultural forms such as language that have been traditionally regarded as the inheritance of humanity as a whole. Nature, the wonderfully abundant and diverse wild life of the world, is essentially a free pool of goods and labor that capital can draw on. Aggressive policies of trade liberalization in recent decades have been predicated on privatizing the commons—transforming ideas, information, species of plants and animals, and even DNA into private property.

There are at present no effective institutions to deal with the cancerous degradation of the global environment that is brought about by capital's need for continuous exponential growth.

Extinction is both a material reality and a cultural discourse that shapes popular perceptions of the world, one that often legitimates an inegalitarian social order. In order to respond adequately to this planetary crisis, we need

to transgress the boundaries that tend to keep science, environmentalism, religion, philosophy, and radical politics separate.

As millions of species are snuffed out, the biodiversity that supports the planetary ecosystem as we and our ancestors have known it is imperiled. This catastrophe cannot be stemmed—let alone reversed—within the present capitalist culture. We face a clear choice: radical political transformation or deepening mass extinction.

The notion that extinction is the death of a species is a far from adequate understanding of what is happening today. Extinction is the slow unraveling of delicately interwoven ways of life, generations of learning interrupted and lost from the world.

“Let us beware of needlessly destroying even one of the lives—so sublimely crowning the ages upon ages of evolving. The beauty and genius of a work of art may be reconceived, though its first material expression be destroyed; a vanished harmony may yet again inspire the composer; but when the last individual of a race of living beings breathes no more, another heaven and another earth must pass before such a one can be again.”

They didn't leave a heritage. They didn't leave a building you could look at or dig a big hole or put in a dam. I guess the first rain that came along after the last one was caught washed out his tracks, and that was about the only sign they were there. We'll never have them again.

Climate change has become an unplanned experiment with the biodiversity of the planet. It is a major selective force and there's a lot of debate out there about how much different species can adapt. It's not easy to predict. What might be important for one organism is not the same as another. Seasonality, moisture, it might be for some that climate effects create a competitive balance or mutualism. It's extremely complicated. Consider, as an example, the ecological relationship between a bird and its prey, in this case a moth. If the peak season of moth hatching and abundance shifts as a result of climate changes, they may no longer be able to support birds that require them as food for their own reproductive cycles. When the speed of evolutionary change is mismatched between any two interdependent species, it could decrease abundance or lead to extinction.

The Volterran principle predicts, for instance, that if the populations of predators and their prey are more or less in balance with one another, and something happens to disturb their joint environment, then there will be a disproportionate decline in the number of predators. Surprisingly, this is precisely what happens. If herbivorous insect pests in a crop field are being

eaten by other predatory insects and the farmer sprays the entire area with a broad spectrum pesticide, a similar proportion of each population will die. But the crop-eating prey, whose death rate has been reduced by a shortage of predators, recovers more quickly than the predators, who initially can no longer find sufficient prey. So the farmer's even handed assault on the system seems only to make his pest problem worse. This is not what he intended or what we might expect, but it happens all too often, both with pesticides and to our ideas of how we think things ought to work.

For almost two centuries the Hudson Bay Company in Canada has been keeping records of the furs sold to them by hunters and trappers who work on islands in the bay. These purchases consist largely of lynx and their favorite food, the snowshoe hare. The records show that populations of the two species fluctuate, with a peak of abundance and therefore of fur sales, about every ten years. The population curves more or less coincide, with lynx numbers rising to their high point slightly after the hares. All very nice and tidy, just what one would expect if well-fed lynx tend to raise more litters, who eat more hares, leading to an eventual parallel decline in both populations. But the problem is that on some islands where there are no lynx, hare populations fluctuate anyway and in precisely the same way.

Recent studies have produced a more surprising Volterran suggestion. The snowshoe hare, it seems, is another species that reacts badly to overcrowding. It goes into a form of shock that the researchers diagnose as "hormone-mediated idiopathic hypoglycemia." What that means is that hares suffer from stress which damages their livers in ways from which they cannot recover, even if they are removed from the situation. They have an endocrinal response which controls their own population size. And, as it happens, those snowshoe hares which are most resistant to such stress, and therefore form a larger proportion of the surviving hare pool, also carry a virus that may produce a debilitating lynx disease. This predator-prey relationship is nothing like we imagined. It is actually the hares that assault the lynx.

In any biological community there are shifting configurations, many of which are going to be as complex and as unexpected as this. It is seldom as simple as 'who eats whom,' or of removing just those species that we find dangerous or inconvenient. Doing so can cause the community as a whole to change, like pulling the keystone out of a soaring arch brings the whole structure tumbling down. There are such species and their identification has become vital to ecology, which needs to be very concerned about extinctions now that we may be losing as much as a species every second from the biosphere.

There's a great political cartoon where a guy at a climate summit is

saying to his compatriot:

“What if it’s a big hoax and we create a better world for nothing?”

It all sounds so obvious, and too familiar. And that’s the problem: the things that should have us on fire demanding change somehow fail to rouse we, the people, to the passion that could free us from our dependence on our pushers.

Even though it’s a matter of physics that carbon dioxide makes the planet warmer, and even though, because of burning oil and coal, our atmosphere now contains a third more carbon dioxide (and climbing) than it did at the start of the Industrial Revolution, many people just won’t believe we have a big problem. People have a lot of kooky notions, but many who are disconnected from reality on this issue are running or aspiring to run the government of the United States of America.

“Our ancestors had seen the hunger for oil when the Yankee whalers came in the nineteenth century. They came for the whale oil and wiped out the whales. Whole villages that had relied on whales for food disappeared, Then six years ago we saw the hunger for oil coming back. We started to think, ‘This time we will go extinct.’”

As the whalers were stuck in their remorseless havoc, so we have stuck ourselves, with oil.

Though the world has relied on petroleum as a major industrial fuel for only a little over a century, people have been using petroleum for over six-thousand years. The Sumerians, among others, mined shallow asphalt for caulking boats and for export to Egypt, where it was used to set mosaics to adorn the coffins of great kings and queens. In about 330 BC, Alexander the Great was impressed by the sight of a continuous flame issuing from the earth near Kirkuk, in what is now Iraq; it was probably a natural gas seep set ablaze. The Chinese, around 200 AD, used pulleys and muscle labor to pump oil from the ground, send it through bamboo pipes, and collect it for fuel. Not until the 1800s did the West catch up to this level of oil drilling.

People being what we are, the potential for petroleum-based weapons was recognized early on. Arabs used petroleum to create flaming arrows used during the siege of Athens in 480 BC. The Byzantines in the seventh and eighth centuries hurled pots filled with oil ignited by gunpowder and fuses against Muslims. Similar bombs used at close range nearly destroyed the fleet of Arab ships attacking Constantinople in 673. Bukhara fell in 1220

when Genghis Khan hurled pots of naphtha at the city gates, where they burst into flame.

During the Renaissance, oil and asphalt from shallow pools discovered in the Far East found their way to Europe, and traders soon established routes to the West. By the 1600s, petroleum was lighting streets in Italy and Prague. By the end of the Napoleonic Wars, asphalt was being used extensively to build roads. In the New World, natives in what is now Venezuela used petroleum to caulk boats and baskets, and for lighting and medicines. In 1539, a barrel of Venezuelan oil was sent by ship to Spain to soothe the gout of Emperor Charles V. In North America, certain natives used oil in rituals and for making paints.

The modern commercial petroleum era began in 1820, when a lead pipe was used to bring gas from a natural seep near Fredonia, New York, to nearby consumers and a local hotel. In 1852, Polish farmers in Pennsylvania asked a local pharmacist to distill oil from a local seep. They were hoping to make vodka, but the result was undrinkable. It burned, though, and so they invented kerosene. The invention of the kerosene lamp two years later created a mass market for commercial kerosene, and soon towns everywhere were glowing with the light of petroleum. In 1858, Colonel Edwin Drake pounded a well sixty-nine feet into the ground near Titusville, Pennsylvania. It produced a continuous flow of oil, and within a short time kerosene replaced whale oil for lighting lamps.

In the early 1900s, wooden oil derricks popped up so fast in Los Angeles that streets looked like a surreal forest painted by Picasso. Some two-hundred oil companies drilled more than two-thousand wells into scores of different oil fields. The frenzy turned the city into a “vibrant oil-soaked little canyon.” Early homeowners gamely hosted wooden derricks in their backyards and disposed of oil-field waste in their basements. Oil wells planted in cemetery plots allowed the dead to provide income for the living, in the form of royalty checks. The thirty-year-long boom manufactured big fortunes for Union Oil, Getty Oil, and Atlantic Richfield. The flowing oil dollars in turn fueled the state’s Wild West car culture and enriched evangelical churches. Petrodollars supported the upstart film industry and a raft of corrupt real estate deals. Oil turned California into an early American Kuwait.

In the 1880s, the first oil tanker began carrying oil across the ocean. By the 1970s, the seas began bearing thousand-foot-long supertankers capable of containing 800,000 tons of oil. Today oil accounts for over half the tonnage of all sea cargoes. Petroleum didn’t really get big until the internal combustion engines of the twentieth century and the autos, tractors, trucks, and, eventually, aircraft they powered. Middle East oil ramped up rapidly in the late 1940s. Oil was discovered in Iran in 1908, in Iraq in 1927, and in

Saudi Arabia in 1938. By the 1970s, the oil fields of the Middle East were producing about half the world's oil. Between 1950 and 1970, annual world oil production surged from 500 million to 3 billion tons. Today there are more miles of petroleum pipelines than of railroads.

In 2007, the US government collected \$9 billion in royalty payments from Big Oil on just the drilling done in the Gulf of Mexico. In reality, we should have earned a lot more, but the United States ranks ninety-third in the world in how much revenue it extracts from oil and gas extraction compared with the profits these industries enjoy. That has something to do with Ronald Reagan. Between 1954 and 1983, the average lease for federal land was \$2,224 per acre. But after Reagan, between 1983 and 2008, the average lease was just \$263 an acre.

In addition, in 1995, Congress decided to reduce the government's royalties on oil and gas extracted from deep water. The goal and result: more drilling encouraged. But other nations charge more. Oil taxes and royalties in the United States are considered much lower than elsewhere in the world. Our country should benefit financially, as the oil companies do. And what else isn't fine is that this encouraged more and riskier drilling but not more safety. Industry assurances that deepwater drilling was safe rocked a willing Congress to sleep on the issue. The fact that accidents are rare and unpredictable has substituted for the obvious truth and certainty that accidents do happen.

In 2005, despite high oil prices and even President George W. Bush saying oil companies needed no further drilling incentives, the Republican-dominated Congress again lowered the royalties oil companies are required to pay our national Treasury. That's nonsensical but part of the ideology appears to be a desire to starve the government so there is scant money for wasteful social programs like education, health, and environmental protection. And while, yes, there are excessive regulations, there is also excessive greed. Regulations don't threaten business; they threaten greed, the greed that threatens both us and our nation's economy. In 2006, Louisiana's congressional delegation supported giving a share of oil royalties to states that allowed drilling. This means using national oil revenue directly to achieve state policies that benefit Big Oil. Nice giveback. Clever.

“There must have been—I speculate—tremendous damage to sheer numbers of those eggs and larvae. We should also bear in mind, however, that the numbers of eggs and larvae are always far in excess of what the system can support. The competition and struggle for existence is so intense that under normal, healthy circumstances, only one fish egg in millions wins

the lottery ticket for becoming an adult. That is where a lot of the resiliency comes from. There may be enough survivors to let the Gulf recover quickly.”

Of course such positive thinking ignores the fact that these millions of losers do not simply poof out of existence like they’re in some Hollywood CGI-fest. They’re eaten, they provide nourishment, homes, nurseries, fertilizers. If they’re just poisoned before they can grow and do any of this that is a problem.

But the worst environmental disaster in history isn’t the oil that got away. The real catastrophe is the oil we don’t spill. It’s the oil we run through our engines as intended. It’s the oil we burn, the coal we burn, the gas we burn. The worst spill—the real catastrophe—is the carbon dioxide we spill out of our tailpipes and smokestacks every second of every day, year upon decade. That spill is changing the atmosphere, changing the world’s climate, altering the heat balance of the whole planet, destroying the world’s polar systems, killing the wildlife of icy seas, killing the tropics’ coral reefs, raising the level of the sea, turning the oceans acidic, and dissolving shellfish. And as the reefs dissolve and the productivity of oceans and agriculture destabilizes, so will go the food security of hundreds of millions of people.

Boiling Frogs

“Behind the lectern, a broad banner was adorned with the young company’s logo—the letters GCOS forming the spokes inside a sharp-toothed bucket wheel, the massive machine that chewed bitumen from the earth out in the mine like a hungry dog gnawing at a gristled bone. Above the logo, a semicircular arch of text read ‘Man Develops His World.’ It was an incontrovertible statement of fact in this otherworldly prefab temple to the genius of engineering. This was the purpose of civilization, modernity’s very apex. Man Develops His World!”

The idea of nature as a storehouse to feed human needs and a treasure trove to feed human ambitions is a pillar of Western civilization.

The average 797 dump truck will make four trips to the shovel and back per hour, roughly thirty to fifty total trips per shift by each driver. On average, each 400-ton load will produce 172 barrels of oil. In the giddy days of \$120-per-barrel oil in 2008, a driver might have hauled a million dollars’ worth of oil in a single twelve-hour shift. In 2015, with oil stuck in the doldrums of \$50 or less, the total was between \$250,000 and \$450,000.

Here are immaculately landscaped lawns and parks, brand-new schools and recreation facilities. Here are the YMCA and the Suncor Energy Centre for the Performing Arts and the Multicultural Association of Wood Buffalo. Here are lavishly equipped big-box gyms, where men doing solo twenty-and-tens, their families back in Quebec or Prince Edward Island, spend their very little downtime working out, counting reps in lieu of counting the days till they head home again. Here are strip malls with long-established bars featuring karaoke nights and down-home fiddle bands tucked between Lebanese-run donair places and dental offices. Here’s a sign advertising ‘Tar Sand Betties Roller Derby’ in front of a hockey arena.

Here, on the very western edge of Timberlea, is the Syncrude Athletic Park, as new and lavish a collection of sports fields as you’ll find in any small city in the country. Beer-league softball teams fill a half-dozen baseball fields with friendly chatter, alongside four soccer pitches where cheers ring out in at least that many languages, alongside Fort McMurray’s first-ever cricket pitch, put in after the rest of the park had been built at the behest of the city’s first-ever cricket club.

Here, on MacDonald Island, which lies across the river just north of downtown and just south of the highway exit leading to Thickwood, is maybe the most elaborate multipurpose recreational centre a company town has ever built, finished in 2009 at a cost of \$127 million. Here, surrounding a

wide parking lot, is upper-middle-class suburban leisure at its High Modern apex and in many of its most popular forms. Here is the Miskanaw Golf Club, its clubhouse staring across the parking lot at Shell Place, a brand-new outdoor stadium and concert venue. In between the stadium and golf course is the enormous Suncor Community Leisure Centre. Its marquee facility is the Syncrude Aquatic Centre, an expansive, tropical-themed retreat from the merciless boreal winter, climate-controlled and artificially humid and equipped with several pools and multiple waterslides. There is also the CNOOC Nexen Field House (for basketball and other court sports), the CNRL Arena (for hockey and figure skating), the Total Fitness Centre (named for the French oil company, not the comprehensiveness of its workout gear), and the Oilsands Curling Club. The city's public library, with its Total Aboriginal Cultural Corner and Syncrude Corner, is on the second floor. MacDonald Island is a sober middle-class pleasure dome.

The hub of Calgary's business district is, rather fittingly, an artificially lit, climate-controlled homage to suburban retail commerce. There is an obvious practicality to the Plus 15 network. Winters are long and sometimes harsh here where the prairie meets the Rockies, the streets and sidewalks filling with snow that turns to slush and back again when a warming winter chinook wind blows through. But the Plus 15 represents as well a rejection of place, a suburbanite's thermostat-controlled denial of the realities of the local climate. Fifteen feet above the sidewalk, weather has been rendered irrelevant. The landscape is a picture framed by an office tower's window. The heart of the city, the main street where you bump into an old friend or pick up your dry cleaning, is an indoor concourse lined with retail outlets, set to a soundtrack of office-tower HVAC white noise. All of it gets locked up at night, and much of it is a desolate ghost town on the weekends. From suburban garage to heated underground parking lot, from meeting to lunch to a quick haircut, the white-collar oil sands employee's working day can transpire entirely, effortlessly indoors.

Is this progress? The grand High Modern project begun under a makeshift bubble tent as the Great Canadian Oil Sands in 1967 is a roaring success by the only definition known to everyone who was there that day. But it has come at a significant price to land, water, animals, and people, a cost tallied by varying measures over the years and understood to be far too high by those who now articulate a competing definition of progress. Those who subscribe to this competing view tabulate environmental costs not only uncounted but totally unconsidered at the project's launch. They delineate social costs that expand in lockstep with the scale of the Patch itself. And they ultimately assess hydrocarbons as a fuel source of the past and emissions reduction as the sine qua non of any sustainable definition of

progress in the twenty-first century.

In a large color ad taken out in *Life* magazine in 1962 by ExxonMobil's precursor, Humble Oil, a small, smartly dressed cartoon character saluted a photograph of a majestic glacier. "Each Day Humble Supplies Enough Energy to Melt Seven-Million Tons of Glacier!" the ad's headline declared.

A good way to understand the full impact of this burning of fossil fuels and forests is to compare it to volcanoes. Volcanoes have an immediate and literally chilling impact on climate, followed by a slower warming effect. However, these human sources of global warming gases are much, much larger—between 100 and 150 times bigger—than anything belched out by volcanoes, ultimately overpowering any cooling effect of volcanic dust and ash. Put another way, to match the CO₂ and other greenhouse gases that people are pouring into the atmosphere, Mount St. Helens would have to erupt every two-and-a-half hours, every day, forever.

"I may be talking to you here today, and in a month you may hear the news that I have disappeared. I ask myself: Am I scared? I am. I am a human being, I get scared. But it doesn't make me shut my mouth! As long as I am able to walk, I will be denouncing those who hurt the forest. The trees in the Amazon are my sisters. I am a son of the forest. I live off them, I depend on them, I am part of them. When I see one of these trees on top of a truck going to the sawmill, it gives me such pain. It's as if I were watching a funeral procession, taking the dearest person I've got. Why? It's life. It's life to me. It's life to all of you who live in cities! Because the forest is purifying the air, it is giving us a return. And the crimes of a group of people, who can think only of profit, of themselves, and not of future generations or anything else—they are doing whatever they want in our town. It's a shame because nobody takes any brave steps to solve this problem. This is the obstacle."

Although the age of permafrost is difficult to determine, most of it in Alaska probably dates back to the beginning of the last glacial cycle. This means that if it thaws, it will be doing so for the first time in more than one-hundred-twenty-thousand years.

It's very difficult to look at trends in air temperature, because it's so variable. So one year you have around Fairbanks a mean annual temperature of zero Celsius and you say, 'Oh yeah, it's warming,' and other years you have mean annual temperature of minus six Celsius and everybody says, 'Where?

Where is your global warming?’ In the air temperature, the signal is very small compared to noise. What permafrost does is it works as low-pass filter. That’s why we can see trends much easier in permafrost temperatures than we can see them in atmosphere. In most parts of Alaska, the permafrost has warmed by three degrees since the early 1980s. In some parts of the state, it has warmed by nearly six degrees.

Like all climate models, GISS’s divides the world into a series of boxes. Three-thousand-three-hundred-twelve boxes cover the earth’s surface, and this pattern is repeated twenty times moving up through the atmosphere, so that the whole arrangement might be thought of as a set of enormous checkerboards stacked on top of one another. Each box represents an area of four degrees latitude by five degrees longitude. The height of the box varies depending on altitude. In the real world, of course, such a large area would have an incalculable number of features; in the world of the model, features such as lakes and forests and, indeed, whole mountain ranges are reduced to a limited set of properties, which are then expressed as numerical approximations. Time in this grid-world moves ahead for the most part in discrete, half-hour intervals, meaning that a new set of calculations is performed for each box for every thirty minutes that is supposed to have elapsed in actuality. Depending on what part of the globe a box represents, these calculations may involve dozens of different algorithms, so that a model run that is supposed to simulate climate conditions over the next hundred years involves more than a quadrillion separate operations. A single run of the GISS model, done on a supercomputer, usually takes about a month.

Very broadly speaking, there are two types of equations that go into a climate model. The first group expresses fundamental physical principles, like the conservation of energy and the law of gravity. The second group describes—the term of art is ‘parameterize’—patterns and interactions that have been observed in nature but may be only partly understood, or processes that occur on a small scale and have to be averaged out over huge spaces.

Imagine that we were looking down at the earth from a spaceship hovering above the North Pole. It’s springtime, and the ice is covered with snow, and it’s really bright and white. It reflects over 80 percent of the incident sunlight. The albedo is around 0.8, 0.9. Now, let’s suppose that we melt that ice away and we’re left with the ocean. The albedo of the ocean is less than 0.1; it’s like 0.07. Not only is the albedo of the snow-covered ice high; it’s the highest of anything we find on earth. And not only is the albedo of water low; it’s pretty much as low as anything you can find on earth. So what you’re doing is you’re replacing the best reflector with the worst reflector.

The most significant indirect effect is known as “water-vapor feedback.”

Since warmer air holds more moisture, higher temperatures are expected to produce an atmosphere containing more water vapor, which is itself a greenhouse gas.

Q: “What is it like to know that the country in which you were born will no longer exist?”

A: “It is painful. We are talking about the loss of a culture that goes back perhaps 5,000 years, the loss of a unique language, of fairy stories and songs. I would hope that our population can all move together somewhere else, but it is likely that we will be split into small groups here and there wherever we can be accommodated. Older people tell me they would rather die under the waves than leave their homes, the place of their ancestors and the graves of their loved ones. It is likely many will die of grief rather than move on.

This is the biggest global emergency of our time—bigger than terrorism. People that continue to emit greenhouse gases, they are climate terrorists. We are the first to go. But others will come after us.”

The trick you’ve got to remember is that climate is multivariate. The plant species are having to respond both to temperature changes and to moisture changes and to changes in seasonality. It makes a big difference if you have a drier winter versus a drier summer, because some species are more attuned to spring and others to fall. Any current community has a certain mixture. If you start changing the climate, you’re changing the temperature, but you’re also changing moisture or the timing of the moisture or the amount of snow and, bingo, species are not going to move together. They can’t.

But even for those with more mobility, such long-distance migrations are likely not practical in a fragmented landscape like today’s. Many organisms now live in the functional equivalent of oceanic islands or remote mountain tops. Certainly, our knowledge of their past response may be of little value in predicting any future reactions to climate change, since we have imposed totally new restrictions on their mobility.

Bones of fish and whales are made of calcium carbonate, and researchers have found that ocean acidification is altering bone formation, particularly in the delicate ear bones, which fish use to navigate and sense speed and direction. Fish are not just disorientated by acidification: biologists have discovered that their neurotransmitters are also disrupted, changing their behaviour. Acidification also changes the way sound waves travel through

the water. A 0.3 decrease in pH allows sound to travel 70% further in the water—the ocean is becoming louder in the Anthropocene, perhaps confusing animals that communicate through sound, like cetaceans.

Noise polluters are like bullies in a school yard. They are basically saying, ‘I don’t care about you and the effect my noise has on you.’ It’s a power issue.

Fishermen often take the largest specimens of salmon or trout from streams and rivers. Fish usually need to reach a certain size before becoming sexually mature and capable of reproduction, after which growth slows down. Like other animals, fish show a trade-off between large size and time of reproduction: if you wait to be large before producing offspring, you probably will be able to produce more of them, and having greater numbers of offspring is favored by evolution, but you also risk dying before you are able to reproduce at all. But where overfishing has removed a substantial portion of a population, the average size of fish is now substantially smaller, because the fishermen have inadvertently selected for earlier reproduction, and evolution has favored fish that get to the business of sex sooner. It’s not just that the larger fish have all been taken; it’s that the fish are not reaching such sizes to begin with. The genes responsible for regulating growth and size at sexual maturity are now different because evolution has occurred. To bring back the jaw-dropping trophy fish of decades past, scientists say, people will have to change their ways.

The first-ever systematic estimate of the size of the annual global capture of wild fish calculates the total in the order of one trillion, although it could be as high as 2.7 trillion. To put this in perspective, the United Nations Food and Agriculture Organization estimates that 60 billion vertebrate land animals are killed each year for human consumption—the equivalent of about nine animals for each human being on the planet.

Global annual fish consumption is now approaching 20 kg per person per year—four times as much as in the 1950s—even though global fish stocks have continued to decline. Humans are now the biggest ocean predator, making oceans less biodiverse and disrupting food chains. It is likely the only fish that people will eat, further into the Anthropocene, will be farmed. Entire species will never be seen, let alone tasted. Vast areas of the seabed of the Mediterranean and North Sea already resemble a desert, expunged of fish by Europeans using increasingly efficient methods such as bottom trawling.

The open ocean, that vast and lawless no-man’s-land of international waters where factory-fishing fleets the size of small cities trawl with giant nets and drag longlines studded with millions upon millions of hooks. These operations are ruthlessly efficient strip miners; a decade-long study found

that 90 percent of the global sea's large, predatory fish has been wiped out in the last fifty years.

And at what point would the hunting stop? When all the sharks were gone? There certainly wasn't an endless supply. Nature doesn't dole out apex predators at the same rate that it provides us with, say, pigeons. White sharks, like tigers and lions, reproduce slowly, giving birth to live young. Their gestation period has not been precisely determined, but it's thought to be close to eighteen months and result in only a handful of pups.

Strip away the top of the food chain and the bottom is likely to sprawl, with opportunistic animals (fish-devouring sea lions, for example) dominating and breeding unchecked, worms, viruses, parasites, and their ilk having a high old time.

Whales are social mammals with big brains, capable of enjoying life and of feeling pain—and not only physical pain, but very likely also distress at the loss of one of their group. Whales cannot be humanely killed—they are too large, and even with an explosive harpoon, it is difficult to hit the whale in the right spot. Moreover, whalers do not want to use a large amount of explosive, because that will blow the whale to pieces, and the whole point of whaling is to recover valuable oil or flesh from the whale. Hence harpooned whales typically die slowly and painfully.

Causing suffering to innocent beings without an extremely weighty reason for doing so is wrong, and hence whaling is unethical. But the Japanese whaling fleet will still kill about 1,000 whales, mostly minke whales. It justifies its whaling as “research” because a provision in the rules of the International Whaling Commission allows member nations to kill whales for research purposes. But the research seems to be largely directed to building a scientific case for a resumption of commercial whaling, so if whaling is unethical, then the research is itself both unnecessary and unethical.

The Japanese do have one argument that is not so easily dismissed. They claim that Western countries object to Japanese whaling because for them whales are a special kind of animals, as cows are for Hindus. Western nations should not, the Japanese say, try to impose their cultural beliefs on them. The best response to this argument is that the wrongness of causing needless suffering to sentient beings is not a culturally specific value. It is, for example, one of the first precepts of one of Japan's major ethical traditions, Buddhism. But Western nations are in a weak position to make this response, because they themselves inflict so much unnecessary suffering on animals. The Australian government, which has come out so strongly against whaling, permits the killing of millions of kangaroos each year, a slaughter that involves a great deal of animal suffering. The same can be said of various forms of hunting in other countries, not to mention the vast

quantities of animal suffering caused by factory farms.

Polyester garments release around 1,900 plastic fibers each time they are washed, which are being eaten by marine animals and getting into the food chain in measurable amounts.

Human changes to the marine environment may lead to a tipping point in which jellyfish rather than fish dominate the oceans of the Anthropocene, much as they did hundreds of millions of years ago in pre-Cambrian times. Jellyfish are simply better prepared than other marine life for Anthropocene conditions—warmer temperatures, salinity changes, ocean acidification, and pollution work to their advantage. Jellyfish can cope far better with anoxia (low oxygen) than muscular fish. Even our infrastructure—pontoons, piers, and drilling platforms—is a boon for jellyfish, providing an anchor for polyps.

As places get richer they begin outsourcing the dirty, polluting parts of making stuff to poorer countries. Most of China's pollution—filthy emissions, discoloured rivers, poisoned soils and ravaged wildlands—is associated with the recent fabrication of goods for export to the West.

The television in my living room, appears nowhere on Canada's emissions ledger, but rather is attributed entirely to China's ledger, because that is where the set was made. And the international emissions from the container ship that carried my TV across the ocean—and then sailed back again—aren't entered into anyone's account book. This deeply flawed system has created a vastly distorted picture of the drivers of global emissions. It has allowed rapidly de-industrializing wealthy states to claim that their emissions have stabilized or even gone down when, in fact, the emissions embedded in their consumption have soared during the free trade era.

China has followed Europe's example and outsourced its dirty industry from the wealthy cities, such as Beijing and Shanghai, inland to rural and less developed central and western areas, as well as to poorer countries, such as Indonesia. In doing so, China's air quality will improve, just as Europe's has, while the atmosphere of developing countries will worsen.

Pushed into a smaller and smaller range by the encroaching shrimp farms, he was hungry. Late at night he would prowl into the nearby village, and any domestic animal not locked away might be taken. Yet for all his power, this big cat was at a loss, unable to fight back against the rolling changes that threatened not just him but his whole species. Our human species is wandering along a different path, seemingly oblivious to the warnings echoing around us. The crisis of global warming is much bigger than that tiger, the Sundarban forest, Bangladesh, global slavery, or any single one of us. It's a runaway train and we're all standing right in its path—unaware that we have in our hands a way to reduce global warming immediately and effectively. End slavery. One of the key causes of global warming is the

destruction of the world's forests, a process enabled by slave labor.

Slavery flourishes where old rules, old ways of life break down. The frontier can be swept by several waves of exploitation, the first which sweeps away the old forest, another which is the leading edge of the alien planting, a third rolls through when the alien forests are cut. Inside the wave of destruction laws disappear. Once trapped within one of these waves a person is beyond social norms and protection. The only road in is an isolated dirt track. This track stops at the line where old forest ends and new destruction begins. It is the first tentacle of change, moving ahead with the wave. The people caught up and forced to carry out the destruction of the forests live without electricity, running water, or communication with the outside world. They are completely under the control of their masters. As the wave passes, it carries slavery with it. The land ahead is still exploitable, the land behind is stripped, and when all the land is stripped the slaves will be dumped.

We tend to think of environmental destruction as huge bulldozers gouging their way through pristine forests, crushing life under their steel tracks, scraping away nature in order to cover the land with concrete. In fact the process is more insidious. The people who live in the forest and rely on it are usually forced to destroy it. Tree by tree, the hands of slaves wrench the life out of their own land and prepare it for a new kind of exploitation. The slavery of Brazil is a temporary slavery because environmental destruction is temporary: you only get to ruin a forest once and it doesn't take that long.

Logging operations bring roads and workers and firearms into the depths of the forest; dead wildlife consequently travels out.

Road creation is the primary driver of deforestation. Whether it is to provide access for mines and dams or to link towns and villages, a road enables loggers, animal poachers and traffickers, and small-time miners to enter virgin territory. Following in their wake are the farmers, who deforest for cropland, and drug growers and processors. Scientists have shown that 95% of all deforestation takes place within twenty-five kilometers of a road and, on average, every road carved into the Amazon—and there have been 50,000 kilometers built in the past three years—is followed by a fifty-meter-wide halo of deforestation.

It is because of this that they recommend establishing a railway or using the river networks to support large planned hydrodams and mines in the forest. The Camisea gas project at Las Malvinas in Peru, for example, in a sensitive area of the Amazon, has no road connections and operates like an industrial island where everything leaves or arrives by boat, air, or underground pipeline, which hugely limits its impact on the forest. Other ways of mitigating the disturbance include narrower roads that retain tree canopy

above, or rope bridges which reduce roadkill deaths by allowing animals to cross safely. Ground-dwelling creatures can benefit from underpasses—an elephant underpass built in 2011 under a busy road in Kenya has been used by hundreds of elephants and helped reunite separated herds, preventing conflict with farmers and road users.

For the individuals who carve away at the great tropical forests, their piecemeal destruction of a few acres for timber, crops, or ranching are livelihood improvements that make negligible impact on the enormity and permanence of a forest that extends further than they will usually have traveled in their lives. But the accumulation of millions of such forest-eaters, in addition to the large-scale commercial enterprises, are steadily eroding vast areas that have been forested for millennia. The accumulation of small-scale logging operations have a footprint that is twenty times larger than the more obvious wholesale deforestation. Even so-called sustainable logging practices—such as selective logging, in which one or two lucrative hardwoods are chopped down, leaving the rest intact—are enormously detrimental to the forest. On average, for every selectively logged tree, another thirty are severely damaged, increasing fire risk, worsening soils and impacting biodiversity.

Gilberto was a slave. His job was destroying the forest:

“My family, like most families, had no land. Sometimes we would try to ‘earn the land.’ That meant finding a piece of public land, or unused land, and planting a crop on it. Once we got some land cleared and the crop started, and then a big farmer came and said the land was his. We had no way of knowing if this was true. He said we could stay and he would pay us for harvesting ‘his’ crop.

Then someone came from the Ministry of Labor and stopped us farming there altogether. They said the conditions were too bad, and it was true we had no water, no toilets, and not really any shelter. We mostly just slept in the field, some people had pieces of plastic sheet to sleep under. We were hungry all the time, and the ants were biting us. We tried planting some vegetables, but got pushed off before we could harvest them. When the corn we had planted was ready, we went back to harvest it. We worked through the field pulling the ears of corn and then stripping away the outer leaves. The big farmer paid us about 5 reais [\$2] for every 130 pounds of shucked corn. This was all of us working, even the small children worked.

After this I went off with my cousin looking for work further north, up near the forest. This is where the gato caught me. The gato is like an actor, he comes along and is very nice, he understands how much you need a job, and he says he can help. He'll recruit several young men at a time in town, but when you get to the countryside, up on the edge of the forest, the gato becomes a villain.

When he recruited me, he said I would be paid 12 reais [about \$7] for every 'line' of trees I cut. A 'line' was about 50 square meters, and was about all you could cut if you worked hard from four in the morning until sundown. This is the raw forest, and the vegetation is very thick, some of the trees are enormous, but there are others of every size, along with thornbushes, vines, snakes, and lots and lots of insects. To do the work we had to buy equipment from the gato, boots, knives, hooks, machetes, and axes, and they were really expensive.

When we started to work there, we realized this was a bad situation. For breakfast the gato only gave us a little coffee and some manioc flour, at lunchtime there would be a small amount of rice, maybe some beans if we were lucky. Working this hard we were really hungry, and after a couple of days we just said, 'Forget it! We want to leave.' But the gato said, 'No! You owe me money, a big debt for the tools and the food and the cost of bringing you out here.' And then he showed us his gun. So we thought, 'Okay, we'll work out this debt and go,' but the debt just kept getting bigger and bigger. And the situation just got worse, our only shelter was a little bit of plastic over sticks, rats were running over us in our sleep, our only water was from a dirty pond, and our only toilet was the forest.

One of the worst things was what the gato was doing to two young guys who were thirteen or fourteen. At night he would come to the shelter and take one of them away at gunpoint. Off in the middle of the forest, he'd put his gun to the boy's head, and rape him, forcing him to do things. Sometimes he'd hit him with his pistol as well. It was terrible, we wanted to help them, but we were afraid that he'd shoot us. These boys were in bad shape.

After five months I had just had enough, and I told my cousin I was going to run for it. He was frightened and told me that I would be killed. By this time the gato had two other men watching over us with guns. But I was determined and willing

to take the risk. So, on a Sunday afternoon I walked about five miles through the jungle and found a road. It is hard to believe, but I actually met a guy I knew on the road. When he heard what had happened he gave me 30 reais and I was able to get a bus into Açailândia. There were men hanging around the bus station, so I asked some of them where I should go to report what had happened. 'Don't bother going to the police,' they said, 'they won't do anything. You've got to go to the Center for Defense of Life and Human Rights.'

At the center I met Brígida, a specialist who seemed to know all about what had happened to me, she said it was happening to a lot of young men. She took down all the details and where the men were being held and started a report to the Special Mobile Inspection Group so they could raid the site and rescue them. She told me it would be several days, possibly even weeks, before there could be a raid.

When she told me this I started to worry about my cousin. He was pretty sick when I left and I didn't want him to die there. So, I went back to help him. The gato was angry, but also very surprised to see me come back. I told him I had gone off to see a girl, and he just sent me back to work. I think it was the water, but now everyone was getting really sick, and my cousin was getting worse. He was so sick the gato didn't care when I asked to take him out to the road, so I got him off and he made it home. I stayed around waiting for the mobile squad to show up. I wanted to see what would happen, and be there to tell the truth. Finally, one day, the mobile squad arrived at about noon. The gato ran out with his gun, but realized the soldiers were a lot stronger, so he had to surrender. The workers started shouting, they were very happy, and were rushing to meet the mobile squad. The farmer who owned the land had to pay us 'back wages' immediately, and most of the workers left for their homes.

We told the police that the gato had raped those two teenagers, but he wasn't arrested, I don't know why. Somebody said that they couldn't physically prove he'd raped them, but I feel like those boys were victims and their word should have counted. The rest of us had seen the gato take the boys away, and then we had been with the boys when he brought them back. I don't understand why the gato wasn't punished for that.

Most of the men returned to the south, but when I got to Açailândia, I looked for work. I also met my wife; she was working in a restaurant. We hit it off right away, and got married not long after the raid. She still works in that restaurant and I'm working in a big kitchen. Everything is different now, I've got a whole new life."

I would dwell on darkness. A kind of darkness, for example, that afflicts the Kaminuriak caribou: excess killing at the hands of Eskimos, in modern times. Everyone is afraid to say something about it, for fear of being called a racist. It is easier to let the animals go than to confront that dark region in ourselves. The darkness of politics, in the long hours, runs into the darkness of the land. Into anger.

I would think of the Eskimo. The darker side of the human spirit is not refined away by civilization. It is not something we are done with. Eskimo people, in my experience, have, still, a sober knowledge of their capacity for violence, but are reluctant to speak of it to whites because they have been taught that these are the emotions, the impulses, of primitives. We confuse the primitive with the inability to understand how a light bulb works. We confuse the primitive with being deranged. What is truly primitive in us and them, savage hungers, ethical dereliction, we try to pass over; or we leave them, alone, to be changed. They can humiliate you with a look that says they know better.

How are we going to survive? Is deforestation viable? No! The forest is viable when it is standing! You don't have to water or fertilize the forest. All you have to do is go there and gather what it produces. The forest is twice as sustainable when it is standing because when you cut it down, you have only one chance, whereas when you leave it there, you will always have it. You will have it today, tomorrow, when you're gone, other people stay there and they will enjoy the forest the same way you did and they will live well.

For example, an untouched forest yielding Brazil nuts and other products can easily generate as much or more income as what can be made from cattle. If the naturally occurring forest products are complemented with a few cocoa and açai berry trees, the yield can be double or triple what a family might earn from cattle. But the cultural imperative is very strong, and the uneducated rural poor will tell you: "Cattle make a man rich." So, the forest dies and all but the cattle barons are impoverished.

Let's assume that only 40 percent of deforestation is accomplished with slavery—this is a conservative figure. What does that mean in terms of CO₂ emissions? To answer that question we have to determine how much

deforestation adds to the total CO₂ emissions each year, but on that point there isn't clear agreement. The amount of CO₂ scientists say comes from deforestation runs from 17 percent to 20 percent to 25 percent to "almost 30 percent." I'm going to go with the 20 percent estimate because that number is supported by more of the scientific research institutes around the world. So, if 40 percent of deforestation is slave-based, then slavery is responsible for 2.54 billion tons of CO₂ per year, not counting the scrubbing capacity that is lost when the trees are cut. For 2010 that amount of greenhouse gas is also greater than the emissions of all the countries in the world except China and the United States, the world's largest emitters. That's worth saying another way. If slavery were a country, it would have the third largest CO₂ emissions on the planet.

Wouldn't it be wonderful if bringing slavery to an end also helped curb the global warming that threatens the lives of our children and their children? After all, we know that slavery can be brought to an end. The 35 million slaves in the world today make up the smallest fraction of the global population to ever be in slavery, and the \$150 billion in slave production each year is the tiniest proportion of the global economy ever represented by slavery. Slavery is illegal in every country and rejected by all religions and political groups. It has been pushed to the very edges of our global society, where it hides and hurts the poor and vulnerable. We know how much it would cost to bring slavery to an end—about \$11 billion over a period of twenty to thirty years. And it is worth remembering that in the scale of the world economy \$11 billion is chicken feed. In fact, it is less than the amount that Great Britain alone will spend on chicken feed over the same period. Eleven-billion dollars is also the amount that the World Bank says is lost to the global market every year because of illegal logging. Like smallpox, with commitment and resources, slavery can be eradicated—reduced from millions in bondage to just a few isolated cases.

From the beginning of human history, slaves have been used to make bricks. Stories in the Bible attest to Hebrew slaves making bricks for their Egyptian masters. Egyptian tomb paintings from 2000 BC show slaves at work in brick kilns. When hundreds of thousands of African-Americans were re-enslaved after the Civil War in the peonage system, many were consumed by brick kilns.

"Gangs of prisoners sold from the pestilential city stockade on Bryan Street dug wet clay with shovels and picks in nearby riverbank pits for transport to the plant. There, a squad of men pushed clay that had been cured in the open air into tens of thousands of rectangular molds. Once dried, the bricks were

carried at a double-time pace by two dozen laborers running back and forth—under almost continual lashing by English’s overseer, Capt. James T. Casey—to move bricks to one of nearly a dozen huge coal-fired kilns, also called ‘clamps.’ At each kiln, one worker stood atop a barrel, in the withering heat radiating from the fires, furiously tossing the bricks into the top of the ten-foot-high oven.”

The scale of the operation was mind-boggling: in the twelve months ending in May 1907, these slaves produced nearly 33 million bricks, and Mayor James W. English pocketed the equivalent of \$1.9 million in today’s money.

And jumping forward to the present day we see that nothing much has changed:

“Between these two crews, more slaves, often children, are feeding the fire, clambering over the top and around the kiln in the intense heat. The air temperature here is well over 130 degrees, and the workers, including the children, wear sandals with thick wooden soles against the heat of the kiln. For all their heavy footgear, the workers tread lightly, and the smaller children have an advantage, for as the fires rage in the kiln below them sometimes the top level of bricks gives way. When this happens a person can fall through. If they fall completely into the kiln there is no hope for them: the temperature inside is more than 1,500 degrees and they are instantly incinerated. If only a leg or a foot pushes through, there may be hope depending on how quickly they are pulled up and out. But their burns will be serious and life-changing.

The roiling black smoke from burning tires carries polycyclic aromatic hydrocarbons: dioxin, benzene, styrene, phenols; as well as heavy metals, and butadiene into the air. If you’re not familiar with these chemicals, the key thing you need to know is that they make you sick, give you cancer, and once in the water or soil are almost impossible to get rid of. In addition to the smoke, when you burn a tire, about two gallons of oil melts and drains away, carrying the same mixture of toxic compounds into the soil and groundwater. In the United States a tire fire is officially classified as an environmental crisis, and tire fire sites end up so poisoned they qualify for Superfund cleanup status.”

But it's fair to ask if all these slaves were set free wouldn't the kilns keep running and polluting with free workers? In a word, no. You can make a profit making bricks using thousand-year-old, Bible-era technology if you use slaves, but not if you have to pay the workers. Small, efficient, mechanical brick molders and kilns are readily available, and are ultimately more profitable than slave-based brick-making. Slaveholders, however, don't see the need to invest in new machines when they have slaves. So once again—stop the slavery and the pollution and CO₂ will drop dramatically.

When a “dig and wash” open-pit mine begins, clear-cutting the trees is just the overture of a four-act environmental tragedy. Act One is the removal of all life, plant and animal, to expose the sandy clay or stone below. Act Two is digging out great pits and trenches, and land near streams and rivers is especially sought after. Some riverbanks are excavated to a depth of one-hundred feet with the pits extending into the surrounding forest for another two-hundred feet. This converts a living river into a stagnant, dead pond writhing along the bottom of a barren ditch.

Act Three is the poisoning, the leeching and seeping of mercury, and the spread of death to the animals, birds, reptiles, amphibians, fish, and insects in the surrounding forest. Act Four of this tragedy is the abandonment. When the gold peters out, the slaveholders take their slaves and walk away. Piles of rubbish and mineral tailings are left where they sit. Soil, pushed to one side when the pits are opened, is never spread back over the scarred land. Streams and rivers, wrenched from their natural banks, are left trapped in pools or diverted in ways that further erode the forest. If the land can recover, which is often not possible, it will take decades, if not centuries.

“Climbing down into one of these pits, I gag on the acrid stench, a mix between that of a latrine and an oil refinery. At the bottom of one hole, as wide and deep as a house, is a small pool of water, fed from the trickling stream used to wash the gold on the long sloping tables. It is the color of this pool of water that stops me in my tracks. Beneath a patchy layer of scum it is magenta, fading to a dull metallic blue at the edges. Putting my face down to the pool's surface I see that even the ubiquitous mosquitoes aren't breeding here, and after a single sniff I jerk back from a coppery reek of sour metal.

On one edge of the abandoned site and surrounded by forest is another pit. The floor of this pit is wide and flat; time and weather have left the surface windswept, a soft and smooth layer of mud and fine sand. I carefully climb down because this is a perfect place to record animal, bird, and insect life. Testing the

surface with my fingertips, it is clear that anything that might crawl, walk, or land here would leave a trace as clear as ink on paper. But searching the pit, I find nothing—no bird’s footprint or animal track, not the weaving line of a snake, or even the tiny skittering trail of a beetle. After covering a large area, I found a single track, the hoofprints of three small deer crossing one far edge of the pit, not running, but stepping carefully across six feet of sand from one arm of the forest to another. In the midst of lush and fertile highland jungle, this is a dead zone.”

We look back to the destruction of the Great Plains ecosystem and shake our heads, blaming the ignorance of our ancestors and their rapacious disregard for nature and indigenous peoples. We can say that they didn’t understand what they were doing, believing that “development,” civilization, and their own betterment went hand in hand. That they didn’t understand that mature and highly evolved grassland was a treasure. They didn’t grasp that forcing its development meant ruin, and in the case of the Great Plains actually released more CO₂ into the air than cars or coal-fired power plants. But today we do understand.

We know that trying to turn a grasslands ecosystem into plowed fields is just as stupid and destructive as turning a forest into grassland for grazing cattle. We might as well make umbrellas out of toilet paper, or shoes out of concrete. We understand that it takes hundreds of thousands of years of evolution to assemble an ecosystem that works, one where plants and animals and insects and climate and weather and soil and water are fitted together into something that flourishes and produces, that is stable and maximizes the conversion of sunlight (our main energy source) into everything that makes life possible.

There is a human contradiction to these facts, but it is venal and ugly. It is the argument used by some individuals that their immediate desire for riches is more important than anything else, and one of the favorite rationalizations for this greed is the worn-out lie of development. If this sounds a little cosmic, if it sounds like a mystical call for tree hugging, it’s not. This is not the call of the Ghost Dance, an anguished last song when all was already lost. This is the living testimony of people like Cláudio and Maria, whose words and actions demonstrated the possibilities of a sustainable partnership with the forest. It is, however, a dangerous message, and it is no coincidence that Cláudio and Maria, like the Ghost-Dancing Sioux, were murdered when they stood in the path of greed.

Oregon, 1942: A Japanese floatplane launched from a submarine unsuccessfully attempts to start a forest fire in the mountains of southern Oregon.

This small incident begins an intensification of US Forest Service governance in which the campaign against forest fires is pursued with military-like discipline and zeal. In 1944, as fears of Japanese fire bombs over Oregon forests circulate, Smokey Bear becomes a symbol of fire protection as homeland security.

One eastern Cascade forester recalled, in the vision of that period:

“Forests of the future would be dominated by a mosaic of 25 to 40 acre even-aged stands of healthy and intensively managed young-growth.”

What went wrong with the post-war vision? Ponderosa was increasingly logged out, and it did not grow back, at least not readily. It was missing fire. The great ponderosas in their open parks had emerged together with Native American fire regimes, in which frequent burning of the underbrush encouraged browse for deer and berries for fall picking. Fire burned out competing conifer species while allowing the ponderosas to thrive. But whites drove out Native Americans in a series of wars and relocations. The Forest Service stopped not only their fires but all fires. Without fire, flammable species such as white fir and lodgepole grew up under the ponderosas. When the ponderosas were removed through logging, these other species took over. The open character of the landscape disappeared as small trees grew in. Pure stands of ponderosa became rare. The landscape looked less and less like the open ponderosa forests of the early twentieth century—and less and less like a landscape of interest to the timber industry.

In dispossessing Native peoples from the lands they had made so inviting, white loggers, soldiers, and foresters destroyed the park-like forests they had wanted so badly.

By using fire to create habitat for the animals they hunted, the Indians controlled—or at least acted upon—their environment. There was also, contrary to the conventional wisdom, widespread agriculture throughout the Americas. When a wave of microbes, advancing ahead of white settlers, demolished these civilizations the animal populations they had managed boomed. Suddenly deregulated, ecosystems shook and sloshed like a cup of tea in an earthquake. The passenger pigeons that blocked out the sun, the bison that shook the earth for hours on end, the profusion of shellfish in Cape Cod—all of which Europeans took as evidence of nature’s virgin bounty, might instead have been symptoms of a radically destabilized environment.

Myth: Fuel build up is responsible for large blazes.

A conventional narrative is that wildfires in the western US are unprecedented and more extensive than in the past. This increase in fire acreage is attributed to “fuel build-up,” presumed to be the result of successful fire suppression. However, such assertions lack context. Compared to the past, we still have a fire deficit.

For example, between 1900 and 1940, as many as 50 million acres burned annually. One of the largest wildfires in historic times, the 1910 Big Burn, raced across 3.5 million acres of northern Idaho and western Montana occurred in this period, long before anyone can argue there was fire suppression contributing to fuel build-up.

During the period between the 1940s and late 1988, when Yellowstone burned, there were few large fires due to Pacific Decadal Oscillation—an ocean current that brought cooler, wetter weather to the West. The lack of large blazes during these decades is attributed to successful fire suppression; however, it was also a period of cooler and moister climate. Nature was successful at putting out blazes. Then beginning in the late 1980s, the climate warmed considerably with historic drought conditions across many parts of the West, and large wildfires once again became common—in spite of even better firefighting ability and equipment. With climate change we can expect larger blazes to become more common.

A further nuance is that fuel build-up to the degree it has occurred due to fire suppression likely only applies to some ponderosa pine communities; not all ponderosa pine are characterized by high frequency and low severity fire—80% of the higher elevation ponderosa pine stands in the Colorado Front Range are characterized by high severity blazes. Most plant communities in the West burn at long intervals and often at high severity. This includes chaparral, juniper, sagebrush, all hemlock, most fir, aspen, and many higher elevation pines, including lodgepole pine and western white pine. All have fire rotations often running from many decades to hundreds of years.

Lodgepole pine in Yellowstone typically experiences large blazes every 200–400 or more years. Therefore, it is entirely natural for “fuels” to build up over this time, and given a window of hundreds of years, even if fire suppression were successful, it would not have any influence on fuels since dead materials in these forests naturally accumulate over many decades.

Myth: Active forest management will protect communities.

It is often assumed that logging projects, including thinning, around the West will stop large blazes during extreme fire weather conditions and/or reduce smoke and therefore protect communities. However, large blazes are controlled by top-down influences like climate/weather, not fuels.

All large fires burn during extreme weather conditions of low humidity, high temperatures, drought, and, most importantly, high winds. Under less than extreme conditions, most fires are easily contained; the majority of these blazes are small, burning less than 100 acres. For instance, a total of 56,320 fires burned over 9 million acres in the Rocky Mountains between 1980–2003. 98% of these fires (55,220) burned less than 500 acres and accounted for 4% of the area burned. By contrast, only 2% of all fires accounted for 96% of the acreage burned. And 0.1% (50) of blazes were responsible for half of the acres charred.

The overwhelming observation is that under extreme fire weather, no amount of logging/thinning significantly influences fire behavior. Under wind-driven conditions, embers are tossed miles ahead of a fire front. For instance, the Eagle Creek Fire in the Columbia Gorge jumped the mile and half wide Columbia River to ignite fires on the opposite shore. The landscape burned by the Camp Fire that destroyed Paradise, California had two previous fires in the past ten years (fuel reduction), had been extensively logged on private lands (fuel reduction), while the Forest Service had done hazardous fuel reductions on public lands.

In much of the West, the largest blazes are not even in forests. The 282,000-acre Thomas Fire that charred the hills around Santa Barbara, as well as the recent 98,000-acre Woolsey Fire that burned near Los Angeles, was in chaparral. The 558,198-acre Long Draw Fire that was the largest in Oregon history occurred in sagebrush.

In a 2017 letter to Congress, more than 250 scientists opined that logging and thinning were ineffective. To quote from their message:

“Thinning is most often proposed to reduce fire risk and lower fire intensity. However, as the climate changes, most of our fires will occur during extreme fire-weather (high winds and temperatures, low humidity, low vegetation moisture). These fires, like the ones burning in the West this summer, will affect large landscapes, regardless of thinning, and, in some cases, burn hundreds or thousands of acres in just a few days.”

The idea that fuel reduction from logging/thinning or even prescribed burning is effective is questioned by many researchers.

“Extreme environmental conditions overwhelmed most fuel treatment effects. This included almost all treatment methods, including prescribed burning and thinning. Suppression efforts had little benefit from fuel modifications.”

This view was echoed by the Congressional Research Service (CRS), which stated in a report to Congress:

“From a quantitative perspective, the CRS study indicates a very weak relationship between acres logged and the extent and severity of forest fires. The data indicate that fewer acres burned in areas where logging activity was limited.”

One of the problems is that our western landscapes are so vast, and predicting exactly where a fire might ignite is impossible. Research has shown that the probability of a fire encountering a ‘fuel reduction’ during any period when it might be useful is less than 1%. Plus, thinning/logging opens up the forest to greater heating and wind penetration, often exacerbating the conditions that encourage blazes. One study of 1500 fires found that actively managed forests—logged/thinned—tend to burn at higher severity than protected landscapes where presumably fuels are greater.

Myth: Dead trees contribute to larger blazes.

Another assumption is that dead trees resulting from insects, disease, or previous fires will contribute to more massive fires. Yet research from throughout the West shows that forests experiencing insect outbreaks or other sources of mortality are less susceptible to fire. This is because what burns in a blaze are fine fuels like needles, cones, small branches, shrubs, grass, and other easily burnable materials. This is why we get snags after insect outbreaks or fires. The larger trunks that remain lack the fine fuel to carry crown fires.

Ecologically speaking, dead trees are critical to healthy forest ecosystems. More wildlife species depend on dead trees for their survival than green trees. The second-highest biodiversity found in forests after old-growth stands occurs in the snag forests that result from high severity blazes.

Myth: Logging forests before they can burn helps fight climate change.

Burning forests release relatively small amounts of carbon. Most carbon remains on site in snags, roots, and burnt wood. Charcoal that results from high severity fires is one of the best carbon storage mechanisms available. By contrast logging and wood processing releases far more carbon. For instance, an Oregon Global Warming Commission 2018 report found that even in very active wildfire seasons, wildfires average around 10% (some years as low as 3%) of the states’ total greenhouse gas emissions. By comparison, logging contributed to more than three times more emissions.

Several Oregon State researchers concluded that:

“Logging harms our carbon balance for decades. By accounting for more of the benefits and costs involved in reducing the risk of crown fires, modifying storage in long- and short-term products, and in substituting wood products for fossil fuel (biomass), we find that thinning existing forests to reduce crown-fire risk increases net carbon emissions to the atmosphere for many decades.”

For every dollar it received in timber sales in 2010 the US Forest Service spent \$8.60 on fire suppression. Although environmental goals have changed Forest Service rhetoric, district offices are still evaluated by the board feet of timber they generate.

Nearly all timber sales on public lands lose money. The Forest Service (FS) tries to hide this fact with dubious accounting methods which the General Accounting Office (GAO) labeled as “unreliable overall” and had “significant reporting errors in its financial statements” and “lacked financial systems that could accurately track revenues and costs.”

Worse than the economic subsidies is the failure of the FS to truly acknowledge and account for the ecological impacts of its timber program. Ultimately the ecological impacts of logging are more costly to society than the welfare we give to the timber industry.

Unlike the God whose name begins with a capital letter, our gods are not all-powerful. Any one of them can be vanquished by a flamethrower or a bulldozer or a bomb—silenced, driven away, enfeebled. Sit in the middle of a shopping mall at midnight, surrounded by half a mile of concrete in all directions, and there the god that was once as strong as a buffalo or a rhinoceros is as feeble as a moth sprayed with pyrethrin. Feeble—but not dead, not wholly extinguished. Tear down the mall and rip up the concrete, and within days that place will be pulsing with life again. Nothing needs to be done, beyond carting away the poisons. The god knows how to take care of that place. It will never be what it was before—but nothing is ever what it was before. It doesn’t need to be what it was before. You’ll hear people talk about turning the plains of North America back into what they were before the Europeans arrived. This is nonsense. What the plains were five-hundred years ago was not their final form, was not the final, sacrosanct form ordained for them from the beginning of time. There is no such form and never will be any such form. Everything here is on the way. Everything here is in motion.

The only essential difference between rock, water, air, life, galaxies, economies, civilizations, plastics is the rate of flow.

Over millennia we fed, petted, and sheltered the dogs that knew what we were thinking, and we killed, beat, and exiled the dogs that were oblivious to our desires. This gives modern-day dogs an amazing ability to read human thoughts, although not in the mysterious telepathic sense. Instead they read our nonverbal cues, such as gaze and pointing.

But why did dogs start looking less like wolves and more like dogs? That happened on its own, too. Animals with genes for friendliness look different. The same genes that deliver desire for friendly contact with humans bundle a raft of stowaway physical traits. In discussing selective breeding in domestic animals, Darwin in the first chapter of *On the Origin of Species* noted:

“If a man goes on selecting he will almost certainly modify unintentionally other parts of the structure, owing to the mysterious laws of correlation.”

Weirdly, in various mammals (not just dogs), genes that create the hormones that reduce fear and aggression and increase friendliness also create floppy ears, curly tails, blotchy markings, shorter faces, and rounder heads.

Making worlds is not limited to humans. We know that beavers reshape streams as they make dams, canals, and lodges; in fact, all organisms make ecological living places, altering earth, air, and water. Without the ability to make workable living arrangements, species would die out. In the process, each organism changes everyone’s world. Bacteria made our oxygen atmosphere, and plants help maintain it. Plants live on land because fungi made soil by digesting rocks. As these examples suggest, world-making projects can overlap, allowing room for more than one species.

Humans, too, have always been involved in multi-species world making. Fire was a tool for early humans not just to cook but also to burn the landscape, encouraging edible bulbs and grasses that attracted animals for hunting. Humans shape multi-species worlds when our living arrangements make room for other species. This is not just a matter of crops, livestock, and pets. Pines, with their associated fungal partners, often flourish in landscapes burned by humans; pines and fungi work together to take advantage of bright open spaces and exposed mineral soils. Humans, pines, and fungi make living arrangements simultaneously for themselves and for others: multi-species worlds.

Twentieth-century scholarship, advancing the modern human conceit, conspired against our ability to notice the divergent, layered, and conjoined projects that make up worlds. Entranced by the expansion of certain ways of life over others, scholars ignored questions of what else was going on.

Although a PVC duck in the bathtub may well be harmless to your child, no one really knows how the post-consumer plastics that escape the landfill are altering the chemistry of the environment. The accidental experiment, which began a century or so ago, is ongoing.

Since the 1980s, Almería in southern Spain has developed the greatest concentration of greenhouses in the world, covering 26,000 hectares. Dubbed the sea of plastic, this Anthropocene landscape is remarkable not only because Europe's driest desert now produces millions of tonnes of fruit and vegetables, but also because the greenhouses reflect so much sunlight back into the atmosphere that they are actually cooling the province. While temperatures in the rest of Spain have climbed faster than the world average, meteorological observatories located in the plastic expanse have shown a decline of 0.3C per decade. It turns out that the plastic acts like a mirror, reflecting sunlight back into the atmosphere before it can reach and heat up the ground. At a local level, the plastic greenhouses offset the global greenhouse effect.

“This new, Anthropocene field of geoengineering is a fascinating area of research and the scientists working in it are some of the most remarkable and thoughtful people I've encountered. It is eerily reminiscent of the atomic research carried out in the 1940s—today's geoengineers are working at the cutting edge in an exciting, entirely new science, spending their lives making discoveries and designing amazingly powerful technologies that they fervently hope will never be deployed.

However, the predicament that humans currently find themselves in—facing catastrophic climate change and yet increasingly reliant on the fuels that exacerbate the problem—means that planetary cooling techniques are likely to be seriously considered. It is, after all, what humans have always done when presented with a challenge—engineer a way through it.”

The concept of artificially cooling the atmosphere is highly controversial, given the atmosphere is a global commons. Perhaps it is because the intent is so explicit; although humans are artificially warming the atmosphere with greenhouse gas emissions, the intent behind burning fossil fuels has always been to produce energy, not to warm the planet. Some argue that even research in this area should be banned because it implies intent to carry out the practice; others say that it draws effort away from climate-change mitigation—from decarbonizing our energy production.

But others argue surely freedom of inquiry should be preserved—carrying out scientific research into whether something would work and what its consequences might be does not make a scientist an advocate for deployment, and there are scientific questions that need to be answered, such as the impact on rainfall, and whether or not it would even be technologically possible, before society can start to decide whether or not to deploy such techniques. These people of course ignore the history of unintended consequences of seemingly innocent science done by childishly naïve fools. That’s the problem with specializing in one domain—you are left with little time and inclination to do anything but accept the mainstream viewpoint on everything else.

We may well see enormous forests of artificial trees cleaning our air. But, what of the huge Amazonian trees that sing with insects and birdlife? That forest is so much more than an array of carbon-sucking trees—it is life itself. How fickle will our care for forests be, once we discover artificial replacements for these services?

“The Chinese have a reputation for eating everything near their work sites. They eat the precious goats, causing conflict with the tribal owners, they eat dogs, so that people either sell their dogs to the Chinese, or steal another’s dog to sell to the Chinese. And they eat the wildlife too, everything from deer and antelope to big cats, which are killed by the tribes and sold to the Chinese. Most upsetting is the healthy and lucrative trade in ivory, for which local people shoot elephants. Then there is the concern about prostitution, which clings to construction sites in a region where at least one in ten people has HIV.”

The Chinese lust for endangered species is driving the extinction of everything from tigers to pangolins to manta rays. It has echoes in the past: ancient Egypt’s vast mummification industry contributed to the extinction of species such as the sacred ibis and Egyptian baboon, for example. Countless other species have been driven to extinction by humans fetishizing their fur, skin, or other parts. The difference in the Anthropocene with the Chinese extinction drive is that it is happening on a global scale and affecting so many different species.

Animals and their parts have become the latest conflict resource in Africa. It is no longer a case of a few small-scale hunters trying to sell animal parts at local markets. Now it is a big organized activity with grenades and machine guns.

Globally, the trade in wildlife is now the biggest illegal economy after arms and drugs.

Logging companies promised them schools, roads, and money in return for mahogany and forest clearance. However, over time, it became apparent that the companies' promises were not being met—the loggers were stripping and burning the forest, shooting the wildlife, and their roads allowed incursion by others who also exploited the place.

A clearing in the forest reveals a busy illegal timber port with logs of mahogany, cedar, and other hardwoods stacked high and ready for barging out. Authorities periodically confiscate a few logs, but the bribes are too lucrative for officials to do anything effective to stop the trade. Further along, another clearing contains a camp of gold miners, churning up the deforested earth and flushing mercury and other toxins into the river. A boat laden with bags and bags of dead monkeys passes, traveling in the opposite direction towards the markets.

Little of this wildlife is actually eaten by the community. Instead, the adults are skinned (their skins fetch a good price), their flesh sold as bushmeat, and surviving babies are sold as pets. A spider monkey goes for as little as \$100 in the market in the El Alto district of La Paz, although the villager who captures it will only get a fraction of that. Often, the tips of a monkey's fingers will have been shot off while it was clinging to its mother; many of the animals have bullets still lodged in their bodies or are missing anatomy.

Tigers, like jaguars, are a top predator, providing similar ecosystem benefits. Compared to bees, though, or cows or rice, they're useless. And that's largely been humanity's conservation decider to date: if it's useful, we'll keep it; if not, well, I don't fancy its chances. It applies to everything from individual animals and plants to ecosystems and natural landscapes.

More than 95% of the weight of all the land vertebrates is now made up of humans and the animals we've domesticated. At the beginning of the Holocene 10,000 years ago, that figure was just 0.1%.

At a time when so many species are threatened with extinction across the world from the plains to the rivers and oceans—it's worth remembering that Earth's many and varied lifeforms are not simply our neighbours on this planet, but our relatives.

Damming a river turns it into a lake and completely alters its function. If the area to be flooded is not adequately cleared of vegetation, methane—a greenhouse gas with twenty-five times the warming potential (over a century) of carbon dioxide—will be released from rotting material. Nearly a quarter of humanity's methane emissions come from big dams. Stalling a river in a reservoir allows some vegetation to build up and rot anyway, which can poison the water for fish.

A kilowatt-hour of electricity delivered from a coal-fired plant will produce

slightly more than half a pound of carbon, while if the power is originating from a plant that runs on natural gas, it will produce roughly half that amount.

Nearly a decade after the CBM boom, the BLM revealed that “several environmental situations of concern” had sprung up in “the progressive center of coalbed methane development from the Fruitland Formation.” Gas and hydrogen sulfide seeps had appeared where none previously existed. Healthy springs had dried up. Older, natural seeps gushed poisonous gases in greater volumes than ever before. Underground coal fires broke out as industry dewatered some seams and introduced oxygen. Old gas wells served as pathways for methane migration into groundwater. Soils became so saturated with fire damp in the Animas River Valley, south of Durango, Colorado, that plant and grass roots suffocated. The zones of methane-killed vegetation extended for miles.

“Where are the protections for those of us bearing the brunt of the impacts for the development of this energy? The extraction of coalbed methane development is mostly experimental and the Powder River Basin has actually been referred to by industry representatives as a laboratory. Why should we, who call this place our home, be guinea pigs? We are watching our homes and ranches transformed into an industrial gas field. There are about 14,000 CBM wells permitted in Wyoming’s Powder River Basin and upwards of 75,000 to 100,000 wells projected.

The development of CBM is primarily being carried out on the backs of landowners that have essentially no say in how the development can proceed and are being required to sacrifice our ranches, our water resources, our soil, our privacy, the wildlife—which also provides an income to many landowners—and our livelihoods. And yes, it is clean energy for urban areas—unfortunately, the production end in rural areas is not clean. We should not let the glitter of ten to twenty years of affluence blind us to the impacts and damages being felt very directly by others that are not reaping the benefits.

Landowners across North America can expect the worst from government and industry. They can expect to be deceived. They can expect to find non-disclosure about the risks. They can expect denials of responsibility. And they can expect the government to not protect them.”

A lawyer petitioned the US Environmental Protection Agency to force Alabama to protect drinking water by regulating fracking as a new form of well injection. The EPA denied the petition, declaring in 1995 that it “does not regulate and does not believe it is legally required to regulate the hydraulic fracturing of methane gas production wells.” It added that there was no proof of groundwater contamination in Alabama, even though the EPA had never tested any of the chemicals used for fracturing. The EPA’s position ignored its own inconvenient research.

In 1987, a lengthy EPA report on the “Management of Wastes from the Exploration, Development, and Production of Crude Oil, Natural Gas, and Geothermal Energy” had detailed a case of contaminated water caused by fracking in 1982 in West Virginia. After fracking a gas well 1,000 feet from the home of James Parson, fluids injected at about 4,000 feet deep by Kaiser Exploration and Mining Company were found in the man’s 416-foot-deep water well. A state lab report found “dark and light gelatinous material” as well as methane in the water and declared it undrinkable. Even the American Petroleum Institute, which claims fracking is totally safe and proven, confessed that in this instance there had been a “malfunction of the fracking process.”

The little-known EPA report confirmed a basic scientific truth:

“During the fracturing process fractures can be produced, allowing migration of native brine, fracturing fluid, and hydrocarbons from the oil or gas well to a nearby water well. When this happens, the water well can be permanently damaged and a new well must be drilled or an alternative source of drinking water found.”

The report noted that in scores of other cases, legal settlements sealed by nondisclosure agreements had hidden the scale of the problem:

“In some cases the records of well-publicized damage incidents are almost entirely unavailable for review.”

Gag orders erase history and allow regulators to claim there had been no proof of contamination in the first place. The courts are participating in criminal activity by allowing the gag orders. No one has the right to cover up contamination of lakes and rivers, because we share our water.

“Okay, we damaged your water well. We’ll just set you up with potable water through a tank system forever, because, you know, we just spent a million dollars drilling this well that we

made a hundred-million on. And it's costing us an extra three-hundred-thousand. We're okay. You know, we don't need to litigate with you, we don't even need to know that it was our fault. We're just happy to pay you. And by the way, by doing that you shut up, the regulators stay off our back, we get to do it again down the street."

What are we teaching our kids by signing away their right to freedom of speech? Contaminated water is a public health issue. Water moves, even contaminated water. Gag orders should be illegal.

Wherever the industry goes, increased air pollution follows. Industry wants only the oil so it flares off all associated gases into the atmosphere. In the Bakken in North Dakota, industry burned off \$100 million of natural gas into the air every month.

Industry flares burned so inefficiently (at only around 62 percent), studies showed, that they spewed 150 hazardous unburned hydrocarbons into the air. The contaminants—including benzene, styrene, ethynylbenzene, ethynyl-methyl benzenes, toluene, xylenes, acenaphthylene, biphenyl, and fluorine—floated downwind into the lungs and homes of landowners. Methylene chloride, a toxic solvent, was found in the air near natural gas operations too.

There is a cycle of abuse that plays out in communities fracked by the oil and gas industry. It happens like clockwork. The cycle begins with rising tensions and fears at public meetings and around kitchen tables as the industry invades with impossible promises. Once a frack job inevitably contaminates a well, or a pipeline leaks into a river, or a truck hits and kills some cows, rage and blame follows, as do threats and intimidation from industry and its supporters. During the third part of the cycle, regulators reluctantly get involved. Apologies, denials, and excuses blanket the community. Reconciliation is usually accompanied by the donation of money. A corporate check invariably goes to a hospital, school, library, sports center, or fire department. In many cases, gag orders are signed in return for cash settlements. Then the community forgets the event until the cycle repeats itself, snaring more rural victims. The cycle leaves in its wake a conquered people vulnerable to depression, addiction, and suicide.

"From time to time, even though I know without a doubt in my heart that I am meant for this fight, and that I have no choice, I must do it, my mind and fears try to sway me away. My ego fights with my heart, exclaiming: Why should I have to give up everything for others? Cause by the time this fight is done, my

life will be, too, or near to done. And then I remember money is nothing. My belongings are nothing. Water is everything. Truth is much more important. I need little from life now and want for even less.”

Her psychiatrist told her there would come a day when she realized that the horrors of her childhood had given her a strength few people have, and that she would find something of value in the abuse. For years the statement infuriated and rankled her. But now she recognizes its truth.

“The main reason I can do this is that there is nothing anyone can do to me that hasn’t already been done. They raped our aquifer. The enablers said you can’t talk about it, but Encana broke all the laws and rules. I couldn’t stop the bus driver or Rex, but I can do something now.”

She has grown accustomed to government and industry officials libeling and slandering her. In the middle of the night, anonymous phone callers have warned her, “Drop your lawsuit or bad things will happen.” Her beloved dog, Bandit, was thrown under a train. But the worse things got, the calmer she became.

“It is an incredible achievement in life to find and keep contentment, while watching what one created, achieved, saved, all vanish.”

Thousands have lived without love, not one without water.

“Our five-year-old wakes up at 3:00 screaming about the water. Are the calves getting sick? Are her cats going to die?”

Humans are distributing water around the world through a virtual water trade—the trade in goods and services that are produced using water. Most of this—92% of fresh-water consumption—is embodied in agriculture.

The water footprint of an average US citizen—which at 2,840 cubic meters per year is more than double that of the Japanese—is 80% home-grown, with the bulk of the remaining 20% coming from China’s Yangtze River basin.

It takes forty-eight gallons of water to make a gallon of beer, four gallons of water to make one of soda. Even a cow has a water footprint, drinking four gallons of water to produce one gallon of milk.

“The backlash is the green movement and it’s anti-globalization. They say water shouldn’t be a commodity, but why should water be free? Why is it different from food, which we also need to live, or shelter?”

Governments are buying up foreign land that is rich in water, or angling for a controlling stake in how that water is used. All of these acquisitions are occurring in developing nations and most in places where there is poor governance, corruption, little regulation and where local people have few rights to their own land and resources. Saudi Arabia, South Korea, China, and India have all bought up huge tracts of land across Africa, usually in the poorest countries’ most fertile zones and river basins, to grow crops for export back home. The Nile River, for example, is now under pressure not just to feed its resident human population, but also those in other continents who have purchased parts of Sudan.

Across the United States, surface water—the ocean, ponds, and rivers—are held in common as part of the public trust. But groundwater falls under different rules, depending on the state. Maine operates with a rule called absolute dominion, which it adopted in the late 1800s, a time of hand pumps and little understanding of the connection between groundwater and surface waters. The law grants landowners complete autonomy to take as much groundwater as they please. In Texas, the only other state in the nation that still follows the absolute dominion rule, they call it the law of the biggest pump. Other states use either the rule of prior appropriation (first in time, first in right); the rule of “reasonable use,” which considers other usages and the wants of the community; or the rule of “correlative rights,” which requires that all landowners above an aquifer share the resource. Absolute dominion is the weakest of the four groundwater protection rules,

Months passed, and a citizens group announced the results of a twenty-four-hour truck count: nearly a hundred tankers, each capable of holding 8,440 gallons, were pulling out of Fryeburg every day. Was that a lot of water? Compared to what the town used—about 200,000 gallons per day in the summer, half that in winter—yes. Did the town have any say about it? No. As a regular customer of the Fryeburg Water Company, Pure Mountain Springs can buy all the water it wants—no cap or permit needed. The moment residents realized how much water was leaving town, and who was profiting, was the moment their faith in the Fryeburg Water Company—and in one of the town’s most prominent families—began to waver.

I think about the way New York City bullied landowners in the Catskill and Delaware watersheds into selling their property, how Los Angeles outwitted desperate valley farmers to appropriate the Owens River, how Chicago

strongmen reversed the flow of the Chicago River to shunt their city's sewage all the way to St. Louis. Sneaking water around might seem difficult, but it isn't always: wells are dispersed, no one can see how much of it moves through pipes and into tankers, and no one knows for sure how much remains underground.

“It would be easy to understand if you could see it. But this is all purposefully hidden. It's easy to move around if people don't know what's cooking. It's the same all around the world.”

The more water pumped from aquifers and streams that feed the Saco, the less clean water ends up in the river, and the more impurities are concentrated. The same scenario plays out across the country: nearly 40 percent of the nation's rivers and streams are too polluted for fishing and swimming, to say nothing of drinking.

Most freshwater is actually used by agriculture—almost 70 percent, according to the UN Food and Agricultural Organization. Just 12 percent goes to direct human consumption: drinking, cooking, washing, and so on. Industry takes the rest. For most of human history, agriculture's overwhelming thirst didn't matter; water was plentiful enough for all. But now populations have risen enough that the requirements of families and the requirements of agriculture are colliding.

Seen from the air, the seventy-acre campus is mostly water: in circular tanks, concrete sluiceways and flumes, and sufficient rectangular pools to cover the flight deck of an aircraft carrier. Through massive pipes, the plant gulps the Missouri, which looks opaque and smells of muck and fish, and holds it for four hours in basins two stories deep. Operators add ferric sulfate and a cationic polymer, which have a positive charge, to neutralize the sediments' electrical charge. The particles clump together and sink. The water's cloudiness—or turbidity—starts to drop from as high as 10,000 NTUs (nephelometric turbidity units) to 50.

“If we didn't constantly rake out the sediment, the tank would fill up in a day.”

The water leaves the primary tanks in a flume, where potassium permanganate is added to counteract bad tastes and smells from, well, everything upstream. Then a disinfecting cocktail of chlorine and ammonia—called chloramine—is added, then lime, to soften the water and raise its pH, which helps particles coagulate and settle out. Now whitish gray, the water spends some time in softening basins, where organics and chemicals combine to

form a froth of floaties, which look like clumps of sheep's wool. The floaties contain viruses and bacteria. They get bigger and bigger until they sink.

“What we're trying to create is an aggressive aggregate moment.”

After the moment passes, the water flows placidly through wooden walls into a field of secondary tanks, where it's suddenly, startlingly, blue. The NTU isn't yet 0.1—well below the federal standard—but it's getting there. After spending four hours in the secondary tanks, the water will be dosed with carbon dioxide in an adjacent basin, to lower its pH (water with a high pH tastes dry), and, depending on the season, blended with powder-activated carbon, which turns all that blue temporarily black. The carbon absorbs atrazine. The levels sometimes as high as 35 ppb, must be lowered to less than 3. It costs thirty-six-thousand dollars to fill an empty silo with carbon (which also removes oil and pesticides from water), and the plant goes through as many as five silo loads a year. What do they do with the atrazine once they filter it out?

“We put it back in the river.”

It will be the city of Boonville's problem next.

Every year, American farmers spread about seventy-six-million pounds of atrazine, a herbicide, on fields. When it rains, much of that runs into ditches and streams, contaminating drinking-water sources in nearly every major Midwestern city, and well water and groundwater in states where the compound isn't even used. Scientists with the US Geological Survey (USGS) have found atrazine at levels up to 224 parts per billion in some Midwestern streams. When the Mountain Valley Spring Company looked around Missouri for a spring to feed a bottling plant—water companies are always looking to expand—they came up dry: all the groundwater they tested contained atrazine.

Atrazine kills weeds, and more. Even at levels well below the federal standard—three parts per billion—it causes birth defects, reproductive disorders, and cancer in lab animals. In the European Union, the maximum contaminant level for atrazine is thirty times lower, at 0.1 ppb. Human kidneys filter atrazine, and most people don't spend a lot of time swimming in herbicide-laced water, as frogs do. But human fetuses do live in water.

How do cities get away with serving atrazine-laced water? It's simple: water utilities are required to announce to the feds only their quarterly averages. EPA regulations focus on limiting risks from long-term exposure: levels of atrazine may peak in the May-to-August runoff period, but with

averaging out over quarters, it's possible to come in under the wire. Cities can also test before and after predicted spikes. The New Orleans Sewerage and Water Board, which takes raw water from the Mississippi River, tells customers its "running annual averages observed have always been found to be below the Maximum Contaminant Levels (MCLs) set by the EPA." Kansas City, by contrast, has never topped three parts per billion in a day, let alone averaged over a year.

And then there's this: the government sets standards for most contaminants based on a healthy 150-pound person who drinks two liters of water a day. If you drink a lot more, you get a higher exposure. Or if you're small or vulnerable to a contaminant, you're also at higher risk. When the EPA sets standards for drinking water, it balances health effects—how many people would get sick from a contaminant—with the cost of cleaning up water to reduce that risk. Pesticide regulations for fruits and vegetables, by contrast, are only health-based. Federal law requires the EPA to prove that the cost of removing a contaminant doesn't exceed its benefits (deaths averted, that is, with a human life valued at \$6.1 million). If it does, the legal limits are raised—that is, weakened.

In December of 2005, the Environmental Working Group (EWG) released a report, following a two-and-a-half-year investigation, that found tap water in forty-two states was contaminated with 141 chemicals for which the government had failed to set safety standards. That's 141 contaminants in addition to the 114 already under scrutiny. Others suggest the sky's the limit when it comes to unregulated contaminants—industry pumps out new ones every year. The unregulated contaminants are linked to cancer, reproductive toxicity, developmental toxicity, and immune system damage. They come from industry (plasticizers, solvents, and propellants), from agriculture (fertilizer and pesticide ingredients), from development (runoff polluted by auto emissions and lawn chemicals, and effluent from sewage treatment plants), and from water treatment itself. Yes, cleaning up the water to decrease microbial illness—with chlorine, chloramines, ozone, and other chemicals—can cause problems of its own, in some cases increasing the risk of cancer and developmental and reproductive disorders.

Almost always, the FDA sets levels for chemical, microbial, and radiological contaminants no less stringent than those of the EPA. It sounds good, but if you think you are buying pure, natural water from a pristine fount—and why wouldn't you, based on the labels' pretty pictures and on the amount of money you spent—you might be disappointed to learn the FDA allows in bottled water the same complement of disinfection by-products, pesticides, heavy metals, and radioactive materials the EPA allows in tap. The only difference is that public water utilities are required in their annual

reports to let you know, while the bottled-water industry has spent millions to make sure you don't, lobbying hard to keep such information off its labels.

If citizens no longer control their most basic resource, their water, do they really control anything at all? With all, or even most, drinking water privately bottled—an industry wet dream—would purveyors end up recreating the system prevalent in the nineteenth century, when the well-to-do bought spring water from private purveyors while the poor died of waterborne diseases? Finding it logistically and economically impossible to deliver individual water containers to tens of millions of customers (and later collect the empties), bottlers might hit upon a simpler solution: delivery through common pipelines. And when pollution from industry, development, or agriculture threatened to taint their “pristine” sources, of which they'd need an ever-increasing supply, the water companies would be forced to either halt the polluters, buy them out, find other water sources, or do what cities and towns have done for decades: build treatment plants to filter and scrub the water, then go after upstream polluters.

Even though our towns and cities are no longer restricted to the geography of meandering rivers in the Anthropocene, it is worth noting that the pipes, reservoirs, and canals that carry out a natural river's function come at considerable cost. The abundance of water in rich countries costs an estimated \$750 billion a year in infrastructure and treatment, which is too expensive for poor countries to replicate.

Although India has managed to send a rocket to the moon, it cannot pipe water to the middle-class residents of even its most modern city, Delhi—or not for more than a few hours a day, and even then the water is often contaminated. Of course, the US landed men *on* the moon, *decades* ago and it can't provide clean, uncontaminated water to all its citizens either. So maybe we're being too hard on India.

“Never pull the casing on your well and look at it because you have been drinking water that has been coming over a filthy-looking mess with all kinds of oscillating slime fibers and so on. The best bet so far is to keep your biofilm healthy, don't have it coming off, keep it well fed, don't antagonize it, don't hit it with any chlorine. But it is a ticklish situation when you think about it. There is something living down there and you have to keep it happy or it will do bad things to you.”

Every gallon of gasoline that is consumed produces about five pounds of carbon, meaning that in the course of a forty-mile commute, a vehicle like a Ford Explorer or a GM Yukon throws about a dozen pounds of

carbon into the air. On average, every single person in America generates twelve-thousand pounds of carbon per year.

Deaths from climate change will not be caused by the weather per se (apart from a tiny percentage of cases), but rather by the fatal synergy between climate change and a catalogue of other misfortunes: natural disasters such as locust plagues; fake seeds; low productivity due to poor health; poor governance and corruption (that sees, for example, much of the agricultural budget vanish); social and gender inequalities; poor infrastructure; and trade laws and protectionist agreements that favour rich countries.

From a certain perspective, the logic behind the Byrd-Hagel Resolution is unimpeachable. Emissions controls cost money, and this cost has to be borne by somebody. If the United States were to agree to limit its greenhouse gases while economic competitors like China and India did not, then American companies would be put at a disadvantage. “A treaty that requires binding commitments for reduction of emissions of greenhouse gases for the industrial countries but not developing countries will create a very damaging situation for the American economy” is how Richard Trumka, the secretary-treasurer of the AFL-CIO, put it when he traveled to Kyoto to lobby against the protocol. It is also true that an agreement that limits carbon emissions in some countries and not in others could result in a migration, rather than an actual reduction, of CO₂ emissions. Such a possibility is known in climate parlance as “leakage.”

From another perspective, however, the logic of Byrd-Hagel is deeply, even obscenely, self-serving. Suppose for a moment that the total anthropogenic CO₂ that can be emitted into the atmosphere were a big ice-cream cake. If the aim is to keep global concentrations below five-hundred parts-per-million, then roughly half that cake has already been consumed, and, of that half, the lion's share has been polished off by the industrialized world. To insist now that all countries cut their emissions simultaneously amounts to advocating that industrialized nations be allocated most of the remaining slices, on the ground that they've already gobbled up so much. In a year, the average American produces the same greenhouse-gas emissions as four-and-a-half Mexicans, or eighteen Indians, or ninety-nine Bangladeshis. If both the United States and India were to reduce their emissions proportionately, then the average Bostonian could continue indefinitely producing eighteen times as much greenhouse gases as the average Bangalorean (Fun fact: In the Bollywood knockoff of *Back to the Future*, ‘Bangalorean’ is the name of the time-traveling rickshaw). But why should anyone have the right to emit more than anyone else? At a climate meeting in New Delhi a few years ago, Atal Bihari Vajpayee, then the Indian prime minister, told world leaders:

“Our per capita greenhouse gas emissions are only a fraction of the world average and an order of magnitude below that of many developed countries. We do not believe that the ethos of democracy can support any norm other than equal per capita rights to global environmental resources.”

Africans are expected to be the worst hit by climate change, suffering worsening droughts that will directly reduce food availability. Whether you believe it is relevant or not—and most people I speak to think it is—Africans have contributed the least to climate change, belonging to the only continent bar Antarctica that has not yet significantly industrialized (indeed, many parts have been de-industrializing since the 1980s).

If the eighteenth century was about Westerners stealing the people of Africa through the slave trade, and the nineteenth and twentieth centuries were about Westerners stealing the resources of Africa through colonization and unfair trade, then surely the twenty-first century is about Westerners stealing the water from Africa by climate-change-reduced rainfall and increased evaporation, and through direct land grabs of the most fertile, wet zones.

In many cases, investors require that their newly acquired land be cleared of people, or they buy “unoccupied,” state-owned or common lands. But there is almost nowhere on the planet—certainly no fertile land—that really is unoccupied. These lands are vital farming, grazing, or hunting-and-gathering resources for the world’s poorest people, who have no formal title to it, so governments feel free to dispose of it at will.

He had changed his mind about federal curbs on carbon dioxide. Explaining this reversal, Bush asserted that he no longer thought CO₂ limits were justified, owing to the “state of scientific knowledge of the causes of, and solutions to, global climate change,” which he labeled “incomplete.” For nearly a year, the Bush administration operated essentially without any position on climate change. Then, the president announced that the United States would be pursuing a whole new approach. Instead of focusing on greenhouse gas emissions, the country would focus on something called “greenhouse gas intensity.” Bush declared this new approach preferable because it recognized “that a nation that grows its economy is a nation that can afford investments and new technology.”

Greenhouse gas intensity is not a quantity that can be measured directly. Rather, it is a ratio that relates emissions to economic output. Say, for example, that one year a business produces a hundred pounds of carbon and a hundred dollars worth of goods. Its greenhouse gas intensity in that case would be one pound per dollar. If the next year that company produces the

same amount of carbon but an extra dollar's worth of goods, its intensity will have fallen by one percent. Even if it doubles its total emissions of carbon, a company—or a country—can still claim a reduced intensity provided that it more than doubles its output of goods. Typically, a country's greenhouse gas intensity is measured in terms of tons of carbon per million dollars' worth of gross domestic product.

To focus on greenhouse gas intensity is to give a peculiarly sunny account of the US situation. Between 1990 and 2000, US greenhouse gas intensity fell by some 17 percent, owing to several factors, including the shift toward a more service-based economy. Meanwhile, total emissions rose by some 12 percent. In terms of greenhouse gas intensity, the United States actually performs better than many third world nations, because even though we consume a lot more energy, we also have a much larger GDP.

Reagan's interior secretary, Donald Hodel, suggested that if CFCs were indeed destroying the ozone layer, then people should simply wear sunglasses and buy hats.

“People who don't stand out in the sun—it doesn't affect them.”

If chlorine had turned out to behave just slightly differently in the upper atmosphere, or if its chemical cousin bromine had been used in its stead, then by the time anyone had thought to look into the state of the ozone layer, the “ozone hole” would have stretched from one pole to the other. More by luck than by wisdom this catastrophic situation did not develop.

As the effects of global warming become more and more difficult to ignore, will we react by finally fashioning a global response? Or will we retreat into ever narrower and more destructive forms of self-interest? It may seem impossible to imagine that a technologically advanced society could choose, in essence, to destroy itself, but that is what we are now in the process of doing.

Hacking away at the environment that sustains us, that is the only source of our sustenance, is both wrong and stupid. There's no credible defense for either, just a tangled mess of rationalizations and justifications that mask hurtful greed. Slavery and environmental destruction are irrational, but then so is, all too often, culture. When a whole culture is convinced they are right in their wrongheadedness, we've all got a problem. Our cultures have a lot to answer for when it comes to slavery and how we treat the natural world. When a culture decides that women are inferior to men and acts on that decision, life for women can get ugly. When a culture decides that people who look a certain way, or pray a certain way, are evil or subhuman

or a threat, then it becomes a lot easier to use them or enslave them or just dispose of them. When a culture decides that its immediate well-being is more important than the livelihood of others, more important than a healthy and vibrant environment, then we're on a path to disaster.

We may say that we're more technologically able than earlier societies. But one thing about climate change is that it is potentially geopolitically destabilizing. And we're not only more technologically able; we're more technologically able destructively as well. I think it's impossible to predict what will happen.

One generation would tell the next, 'Look, there are these things that happen that you've got to be prepared for.' And they were good at that. They could manage that. They were there for hundreds of years. The thing they couldn't prepare for was the same thing that we won't prepare for, because in their case they didn't know about it and because in our case the political system can't listen to it. And that is that the climate system has much greater things in store for us than we think.

The monochromatic sort of history that most of us grew up with did not allow for events like the drought that destroyed Tell Leilan. Civilizations fell, we were taught, because of wars or barbarian invasions or political unrest. But nothing allows you to go beyond the third or fourth year of a drought, and by the fifth or sixth year you're probably gone. You've given up hope for the rain, which is exactly what they wrote in "The Curse of Akkad."

Despair is rarely helpful. I understand and to a certain extent agree with the position of those who, for practical purposes, urge hopefulness. In the end, however, how we feel about climate change is irrelevant. Global warming will have a profound effect on us, on our children, and on life on this planet for generations to come. We may be capable of dealing with this problem, or we may not. In either case, we are still responsible.

One problem with clean fuels is the perception that "they don't offer new services; they just cost more," as one analyst has said. Wrong on both counts, but the statement reveals our inability to understand the effects and costs of energy. The new services are the elimination of toxic pollution, risk, and the climate change and ocean chemistry change that fossil fuels cause. The costs of those things are enormous. The fact that the costs are not in the fuels' at-pump price is a failure of our economics, not a drawback of clean fuels. We are already paying, and we will pay enormous future costs for the effects of climate change on agriculture, coastal cities, coral reefs and fisheries, security, and the abundance and diversity of wildlife worldwide. Those costs are serious. A moral and practical answer is to engineer the transition.

If we could build the infrastructure to capture and transport energy

from renewable sources, the energy itself—sunlight, wind, tides, geothermal heat—would come for free. That’s what “clean, eternal” means. But we hear that energy that comes for free is too expensive. Who tells us clean, eternal energy is too expensive and that it would wreck the economy? Why, it’s none other than the big brothers: Big Oil and Big Coal! We’ve crossed that bridge before. There was another time when people vehemently insisted that changing America’s main source of energy would wreck the economy. The cheapest energy that has ever powered America was slavery. Energy is always a moral issue.

The wrong question is always being asked: ‘What is the practicality of X?’ That’s the wrong question. These things can all be done. What kind of issue is like this that we faced in the past? I think it’s the kind of issue where something looked extremely difficult, and not worth it, and then people changed their minds. Take child labor. We decided we would not have child labor and goods would become more expensive. It’s a changed preference system. Slavery also had some of those characteristics a hundred and fifty years ago. Some people thought it was wrong, and they made their arguments, and they didn’t carry the day. And then something happened and all of a sudden it was wrong and we didn’t do it anymore. And there were social costs to that. I suppose cotton was more expensive. We said, ‘That’s the trade-off; we don’t want to do this anymore.’ So we may look at this and say, ‘We are tampering with the earth.’ The earth is a twitchy system. It’s clear from the record that it does things that we don’t fully understand. And we’re not going to understand them in the time period we have to make these decisions. We just know they’re there. We may say, ‘We just don’t want to do this to ourselves.’ If it’s a problem like that, then asking whether it’s practical or not is really not going to help very much. Whether it’s practical depends on how much we give a damn.

We simply won’t be able to maintain civilization by digging fossil energy out of the ground and burning it. There’s not enough. By the middle of this century, well within the life span of many people already born, we are scheduled to add to the world another two-billion people—nearly another China plus another India’s worth of people. Of the truly great human-caused environmental catastrophes, foremost is the human population explosion. The forests, the fishes, and fresh water are collapsing under the weight of the number of people on Earth right now. All the other global environmental, justice, human development, energy, and security problems either start with or are made worse by the sheer crush of our numbers. The projected growth will squash human potential as billions of poor get poorer, while flaring tensions and igniting violence. Being concerned about overpopulation isn’t anti-people; not being worried about it is anti-people.

It's true that we've had higher CO₂ levels before. But, then, of course, we also had dinosaurs.

What does 'development' really mean? Does it have to be a lifestyle where you consume more, create more trash, destroy the natural areas that give you a sense of well-being and make living worthwhile? We don't need so much more electricity to develop as a nation. There is another way.

Everyone assumes that it's good to accentuate positive emotions, but that isn't correct. Look at sports victories that end in violence and property damage. A lot of antisocial and self-defeating behavior results from people who amplify positive emotions.

Humans might be able to learn something about mourning from crows. The notion that a species could teach humans a behavior that is considered fundamental to our humanness—the ability to grieve—will strike some as radical. But crows have been observed mourning, calling to, and revisiting their dead, and even avoiding places where other birds have died. If the death of a single crow signals 'here lies danger'—a danger significant enough to avoid a place for years, to alter flight ways and daily foraging routes—then what must the death of a whole species of crow, alongside a host of others at this time, communicate to any sentient and attentive observer? How could these extinctions not announce our need to find new flight ways, new modes of living in a fragile and changing world?

Loss of genetic diversity is a manifestation of the deeper problem of decreasing biological diversity. As natural habitats are altered, converted, and simplified, many species suffer a decline in their number of independent populations. Attempting to protect genetic diversity through the protection of a few remnant populations ignores the most basic problem and will result only in a continual scramble to save individual species. A true solution would halt the tendency of more and more species to become so severely depleted that they require individual attention. If the deeper problems causing this tendency are not addressed, it can be expected that the effort to protect endangered species in remnant populations will become overwhelming.

After two generations of access to cheap energy, we've been taught an immature way of living, and since we are so far removed from the effects of our consumption, we don't see our impact—and don't want to see it. I'm a good person, goes the reasoning, so don't tell me the way I'm living is causing village culture and ecological systems to collapse. Economics is driving this whole culture of immature unethical action that is laying waste to the world. Pulling a small thread—asking where your tomatoes or your drinking water come from—causes the whole system to unravel, leading some to conclude that what's needed is cultural revolution.

And this is where the intersection between extreme ideology and climate

denial gets truly dangerous. It's not simply that these people deny climate science because it threatens to upend their dominance-based worldview. It is that their dominance-based worldview provides them with the intellectual tools to write off huge swaths of humanity, and indeed, to rationalize profiting from the meltdown.

You can't slow-boil a frog without it noticing. In real life, frogs jump out before the water gets too hot. In the nineteenth-century experiment that apparently generated the idea, however, a frog was boiled to death—but its brain had been removed beforehand. Which was humane and, in the present context, makes the metaphor more apt.

Chapter Thirty-three

A Miracle of Purpose

Problem	Solution
Competition to win the affection of females can be intense.	If you're a certain kind of male toad, you grow a mustache with which to shank your rivals.
Maggots are helpless. Which can be an issue if you're a maggot.	The ant-decapitating fly surgically inserts its kid into a living ant, where the maggot moves into the brain and mind-controls the host into the leaf litter, before releasing a chemical that pops the ant's head off. Safely inside, the maggot develops like a babe in a crib.
The seafloor is a war zone.	The tiny wonder known as the pistol shrimp forms huge societies ruled by a king and queen and takes up residence in sea sponges, where soldier shrimp stand guard, weapons in hand.
Fish don't have many places to hide from their enemies on the barren seafloor.	The pearlfish swims up a sea cucumber's anus, makes itself comfortable, and eats its host's gonads.
A fungus in a windless rain forest is going to have trouble getting its spores around.	Ophiocordyceps invades ants' brains and mind-controls them up into trees to very specific spots, ordering the zombies to bite down on leaves before killing them. The fungus then erupts out of their heads and rains spores on their comrades below.
Sharks are basically just giant teeth.	The eel-like hagfish chokes its attackers to death by filling their gills with copious amounts of snot that it ejects out of glands in a fraction of a second.

Problem	Solution
Life on land is full of all kinds of nasty predators, as well as competition for food.	A certain spider leaves it all behind and goes aquatic, using its butt to collect a bubble of oxygen and start living in the water permanently. This is the only spider that lives its entire life underwater.
Sometimes a shell just isn't good enough for protection.	Cuttlefish have evolved the animal kingdom's most incredible active camouflage to imitate any kind of background in a flash.
Ever heard of something called a lion?	A mammal known as the pangolin has developed gnarly-looking keratinized armor that's impervious to lions, not to mention the ants it eats.
Not all African mammals have the luxury of armor.	The crested rat deploys special hairs that it slathers with chewed-up poisonous bark. That'll leave a bad taste in an assaulter's mouth, and could very well kill it.
The only reason any life is on this planet is to make babies. That turns out to be a lot of pressure.	The males of a marsupial called antechinus mate with every lady they can find for three straight weeks until their hair falls out and they bleed internally and go blind and die, plus other bad things.
Being a mom is a huge responsibility.	Hermaphroditic flatworms penis-fence, of course. Individual flatworms have both sperm and eggs, so whichever worm stabs its partner with its needle-like genitals wins the honor of not giving birth, while the fertilized loser mopes away.
The deepest seafloors are desolate, and food is in short supply.	A certain worm has hit upon the idea of boring into the skeletons of creatures that have sunk to the bottom, dissolving and digesting bone with the help of friendly bacteria.
A snail has to eat not only for energy, but to build its shell.	The giant African land snail lays waste to vast swaths of vegetation. And when the snail invades Florida and can't get enough calcium to build that shell, it lays waste to the stucco in vast swaths of homes.

Problem	Solution
Seafloor critters often have robust armor, requiring the right utensils to eat them.	The mantis shrimp deploys hammer-hands that strike its prey so fast they momentarily heat the surrounding water to the temperature of the sun's surface, splitting clams and crabs to pieces.
Your prey are quick footed.	The tiger beetle one-ups them by running so fast it blinds itself and has to stop every once in a while to get its bearings. Not that it matters. This is a supreme sprinter with a stomach to fill.
Moths can escape typical spiderwebs.	The bolas spider mimics a female moth's sex pheromones, luring in the males. Then it swings a specialized web, just a drop of goo on a line, to snare its prey.
Worms aren't known for their speed.	But the velvet worm is celebrated for its weaponry. It fires jets of glue out of two modified legs—yes, legs—to entrap its prey. Then it takes its time gnawing through their exoskeletons.
Snails also aren't celebrated for their speed.	To capture fish, the cone snail drugs them first by releasing chemicals into the water, before strolling up and enveloping the prey with its balloon-like mouth.
Fish don't take too kindly to traumatic parasitization.	The lamprey has evolved to look like the desert pit monster that ate Boba Fett in Star Wars: It suctions on to its thrashing victim with a disk-like mouth packed with dozens of hooked teeth and will often drill right down to the bone.
Some insects just can't be bothered to get gnawed on alive.	The assassin bug impales its prey with super-elongated, needle-like mouthparts, sucks out their juices while they're attached to its face, and then sticks their corpses to its back as camouflage.
The life of the burrower is plagued with tight squeezes.	The naked mole rat has evolved extremely stretchy, loose skin that allows it to move better in its tunnels. Oh, also: The starch that makes this possible, hyaluronan, bestows the animal with a near immunity to cancer.

Between losing its ability to regulate its body temperature and largely losing its eyes, the naked mole rat is a reminder that there's no such thing as progress in evolution. Darwin resisted using the word 'evolution,' from the Latin meaning "unfolding" or "unrolling," because it might imply some sort of march toward perfection. He preferred "descent with modification." Sure, over the 3.8-billion-year history of life on Earth organisms have gotten more and more complex since that initial primordial soup of microorganisms, but intricate evolutionary innovations like the eye can fade away when they're not needed. Darwin's idea here, that species don't necessarily become perfect, only well adapted to their environment like the seemingly backward naked mole rat, wasn't well received. It meant that humans were just another animal that happened to evolve an impressive mind, not a creature favored by a higher power. He was right, though. We're not special, however much we think we are. We're naked like the mole rat—only we invented clothes.

We like to see ourselves as something more than animals. As animals plus. The plus factor being some kind of special human essence that has been added to the baseline of animality. This additive has been defined in a variety of ways, ranging from culture to consciousness, from religion to morality, but the truth is that the mystery ingredient, if it exists at all, remains just that, a mystery. The problem with this approach is that it looks at life from the top down. It excludes humans, and human nature, from the rest of nature. And it relegates the rest, plants and animals alike, to some kind of mindless substrate.

In the late 1970s, a professor at Sheffield University in England noticed that one of his honor students had a remarkably large head. He recommended the student get a CAT scan. The scan didn't just reveal a problem with the student's brain, it showed he barely had one at all—95% of it was cerebro-spinal fluid, with only a thin crust of gray matter pinned against his skull. This condition isn't totally remarkable—it's called hydrocephalus, and it's basically like having a leaky pipe in your brain. The leaking fluid gradually pushes your brain outward against your skull. If it happens when you're young and your bones are still malleable, the pressure pushes out your skull as well—hence the large hat size. What was remarkable about this student was that he had an IQ of 126 (a score of 100 is average), which might tell you something about the IQ test, but it also means that when it comes to brains, size doesn't matter all that much. We have three pounds of brain stuffed into our heads while he was working with a quarter-pounder and doing just fine.

Some argue our bigger brains led to a revolutionary new skill, one that would become the foundation of all human achievement: we learned to aim not only where food was, but where food wasn't. Kudus and rabbits dart

off in mad zigzags, meaning a hunter has to mentally process the timing and distance of three different bodies moving through space—his own, his prey’s, and his weapon’s—to calculate the exact point where spear meets quarry.

“That kind of sequential thought requires intellect of a higher order.”

Specifically, he’s talking about imagination: the ability to project into the future, visualize possibilities, think in the abstract. That’s why some believe language, literature, medicine, and even love are all connected to our ancient ability to hit a hare at twenty paces.

“Throwing is about finding order in chaos. The more you’re able to think in sequence, the more ideas you’re able to string together. You can add more words to your vocabulary, you can combine unrelated concepts, you can plan for the future, and you can keep track of social relationships.”

Of course, there would seem to be a massive human supremacist bias in these statements, beliefs, theories. Does every predator not rely in some way on predicting movement to catch prey—whether guessing where it will be seconds before it is or knowing where it will be weeks before and lying in wait? Birds, wolves, fish, lions, reptiles, insects—and remember the worm with legs?—all practice some form of such predictions. But they can’t tell us or show us—not in any way that science would deem credible at least.

Fish are able to infer their own relative social status by observing dominance interactions among other fish. Fish also have been observed to display unique personalities. We know too that birds plan future meals and that their ability to make and use tools often surpasses that of chimpanzees. Rodents can use a rake-like tool to retrieve food that is out of reach. Dogs classify and categorize photographs the same way humans do; chimpanzees know what other chimpanzees can see, and show better memory in computer games than do humans; animals from magpies to otters to elephants grieve for their young; and mice feel empathy. For anyone who follows scientific literature or popular media on animal behavior it’s obvious that we’re learning a phenomenal amount.

The study of animal behavior is among the oldest of human endeavors. As hunter-gatherers, our ancestors needed intimate knowledge of flora and fauna, including the habits of their prey. Hunters exercise minimal control: they anticipate the moves of animals and are impressed by their cunning if they escape. They also need to watch their back for species that prey on

them. The human-animal relationship was rather egalitarian during this time.

A more practical knowledge became necessary when our ancestors took up agriculture and began to domesticate animals for food and muscle power. Animals became dependent on us and subservient to our will. Instead of anticipating their moves, we began to dictate them, while our holy books spoke of our dominion over nature. Both of these radically different attitudes—the hunter’s and the farmer’s—are recognizable in the study of animal cognition today. Sometimes we watch what animals do of their own accord, while at other times we put them in situations where they can do little else besides what we want them to do.

“But what then does it mean to be human?”

The but opening is telling as it sweeps all the similarities aside in order to get to the all-important question of what sets us apart. I usually answer with the iceberg metaphor, according to which there is a vast mass of cognitive, emotional, and behavioral similarities between us and our primate kin. But there is also a tip containing a few dozen differences. The natural sciences try to come to grips with the whole iceberg, whereas the rest of academia is happy to stare at the tip. In the West, fascination with this tip is old and unending. Our unique traits are invariably judged to be positive, noble even, although it wouldn’t be hard to come up with a few unflattering ones as well.

We are always looking for the one big difference, whether it is opposable thumbs, cooperation, humor, pure altruism, sexual orgasm, language, or the anatomy of the larynx. It started perhaps with the debate between Plato and Diogenes about the most succinct definition of the human species. Plato proposed that humans were the only creatures at once naked and walking on two legs. This definition proved flawed, however, when Diogenes brought a plucked fowl to the lecture room, setting it loose with the words “Here is Plato’s man.” From then on the definition added “having broad nails.”

In 1784 Johann Wolfgang von Goethe triumphantly announced that he had discovered the biological roots of humanity: a tiny piece of bone in the human upper jaw known as the *os intermaxillare*. Though present in other mammals, including apes, the bone had never before been detected in our species and had therefore been labeled “primitive” by anatomists. Its absence in humans had been taken as something we should be proud of. Apart from being a poet, Goethe was a natural scientist, which is why he was delighted to link our species to the rest of nature by showing that we

shared this ancient bone. That he did so a century before Darwin reveals how long the idea of evolution had been around.

Uniqueness claims typically cycle through four stages: they are repeated over and over, they are challenged by new findings, they hobble toward retirement, and then they are dumped into an ignominious grave. I am always struck by their arbitrary nature. Coming out of nowhere, uniqueness claims draw lots of attention while everyone seems to forget that there was no issue before. For example, in the English language—and quite a few others—behavioral copying is denoted by a verb that refers to our closest relatives, hinting at a time when imitation was no big deal and was considered something we shared with the apes. But when imitation was redefined as cognitively complex, dubbed “true imitation,” all of a sudden we became the only ones capable of it. It made for the peculiar consensus that we are the only aping apes. Merely duplicating behavior, such as one songbird learning another’s song, was not enough anymore: it had to be done with insight and comprehension. While imitation is common in lots of animals according to the old definition, true imitation is rare. We learned this fact from experiments in which apes and children were prompted to imitate an experimenter. They’d watch a human model open a puzzle box or rake in food with a tool. While the children copied the demonstrated action, the apes failed, hence the conclusion that other species lack imitative capacities and cannot possibly have culture. The comfort this finding brought to some circles greatly puzzled me, because it did not answer any fundamental questions either about animal culture or about human culture. All it did was draw a flimsy line in the sand.

Imagine that aliens from a distant galaxy landed on earth wondering if there was one species unlike the rest. I am not convinced they would settle on us, but let’s assume they did. Do you think they’d do so based on the fact that we know what others know? Of all the skills that we possess and all the technology that we have invented, would they zoom in on the way we perceive one another? What an odd and capricious choice this would be! But it is precisely the trait that the scientific community has considered most worthy of attention for the last two decades. Known as theory of mind, abbreviated ‘ToM,’ it is the capacity to grasp the mental states of others. And the profound irony is that our fascination with ToM did not even start with our species. Emil Menzel was the first to ponder what one individual knows about what others know, but he did so for juvenile chimpanzees. At some point, however, it was redefined in such a manner that it seemed, at least for a while, absent in apes.

All these definitions and redefinitions take me back to a character played by Jon Lovitz on Saturday Night Live, who conjured unlikely justifications

of his own behavior. He kept digging and searching until he believed his own fabricated reasons, exclaiming with a self-satisfied smirk, “Yeah! That’s the ticket!”

With regard to technical skills, the same thing happened despite the fact that ancient gravures and paintings commonly depicted apes with a walking cane or some other instrument, most memorably in Carl Linnaeus’s *Systema Natura* in 1735. Ape tool use was well known and not the least bit controversial at the time. The artists probably put tools in the apes’ hands to make them look more human-like, hence for exactly the opposite reason anthropologists in the twentieth century elevated tools to a sign of brainpower. From then on, the technology of apes was subjected to scrutiny and doubt—ridicule even—while ours was held up as proof of mental preeminence.

It is against this backdrop that the discovery (or rediscovery) of ape tool use in the wild was so shocking. In their attempts to downplay its importance, I have heard anthropologists suggest that perhaps chimpanzees learned how to use tools from humans, as if this would be any more likely than having them develop tools on their own. This proposal obviously goes back to a time when imitation had not yet been declared uniquely human. It is hard to keep all those claims consistent. When Leakey suggested that we must either call chimpanzees human, redefine what it is to be human, or redefine tools, scientists predictably embraced the second option. Redefining man will never go out of fashion, and every new characterization will be greeted with ‘Yeah! That’s the ticket!’

Another human uniqueness proponent noted that “there is no obvious evidence that animals have ever agreed on a five-year plan.” True, but how many humans have? I associate five-year plans with central government and prefer examples drawn from the way both humans and animals go about their daily business. For example, I may plan to buy groceries on my way home, or decide to book a vacation this weekend. This is the nature of our planning. It is not unlike the story of Franje, the chimpanzee who gathered all the straw from her night cage to build a warm nest outdoors. That she took this precaution while still indoors, before actually feeling the cold outside, is significant because it fits the so-called Spoon Test.

In an Estonian children’s story, a girl dreams of a friend’s chocolate pudding party where she can only watch other children eat, because everyone has brought their own spoon, and she has not. To prevent this from happening again, she goes to bed that night clutching a spoon. Two criteria are proposed to recognize future planning. First, the behavior should not follow directly from present needs and desires. Second, it should prepare the individual for a future situation in a different context than the current one.

The girl needed a spoon not in bed, but at the chocolate pudding party she expected in her dream.

“At the Yerkes Primate Center, we have a male chimp, Steward, who never enters our testing room without first looking around outdoors for a stick or branch that he uses to point at the various items in our experiments. Even though we have tried to discourage this behavior, by removing the stick from his hands so that he’ll point with a finger like everyone else, Steward is stubborn. He prefers to point with a stick and will go out of his way to bring one with him, thus anticipating our test and his self-invented need for a tool.”

Lisala, a bonobo, carries a heavy rock on a long trek toward a place where she knows there are nuts. After collecting the nuts, she continues her trek to the only large slab of rock in the area, where she employs her rock as a hammer to crack the nuts. Picking up a tool so long in advance suggests planning.

Neuroscience may one day resolve how planning takes place. The first hints are coming from the hippocampus, which has long been known to be vital both for memory and for future orientation. The devastating effects of Alzheimer’s typically begin with degeneration of this part of the brain. As with all major brain areas, however, the human hippocampus is far from unique. Rats have a similar structure, which has been intensely studied. After a maze task, these rodents keep replaying their experiences in this brain region, either during sleep or sitting still while awake. Using brain waves to detect what kind of maze paths the rats are rehearsing in their heads, scientists found that more is going on than a consolidation of past experiences.

The hippocampus seems also engaged in the exploration of maze paths that the rats have not (yet) taken. Since humans, too, show hippocampal activity while imagining the future, it has been suggested that rats and humans relate to the past, present, and future in similar ways. This realization, as well as the accumulated primate and bird evidence for future orientation, has swayed the opinion of several skeptics, who used to think that only humans show mental time travel. We are moving ever closer to Darwin’s continuity stance, according to which the human-animal difference is one of degree, not kind.

Various experiments indicate that at least some animals—including birds such as parrots and scrub jays—do remember individual incidents and consciously plan for future eventualities. However, it is impossible to prove

this beyond doubt, because no matter how sophisticated a behaviour an animal exhibits, skeptics can always claim that it results from unconscious algorithms in its brain rather than from conscious images in its mind.

The claim that only humans can mentally hop onto the time train, leaving all other species stranded on the platform, is tied to the fact that we consciously access past and future. Anything related to consciousness has been hard to accept in other species. But this reluctance is problematic: not because we know so much more about consciousness, but because we have growing evidence in other species for episodic memory, future planning, and delayed gratification. Either we abandon the idea that these capacities require consciousness, or we accept the possibility that animals may have it, too.

Proponents of human uniqueness face the possibility that they have either grossly overestimated the complexity of what humans do or underestimated the capacities of other species. Neither possibility is a pleasant thought, because their deeper problem is evolutionary continuity. They can't stand the notion of humans as modified apes. Like Alfred Russel Wallace, they feel that evolution must have skipped the human head. Although this view is currently on its way out in psychology it is still prevalent in the humanities and most of the social sciences. Typical is a reaction by the American anthropologist Jonathan Marks to the overwhelming evidence that animals pick up habits from one another, hence show cultural variability:

“Labeling ape behavior as ‘culture’ simply means you have to find another word for what humans do.”

Given that the discontinuity stance is essentially pre-evolutionary, let me call a spade a spade, and dub it Neo-Creationism. Neo-Creationism is not to be confused with Intelligent Design, which is merely old creationism in a new bottle. Neo-Creationism is subtler in that it accepts evolution but only half of it. Its central tenet is that we descend from the apes in body but not in mind. Without saying so explicitly, it assumes that evolution stopped at the human head. This idea remains prevalent in much of the social sciences, philosophy, and the humanities. It views our mind as so original that there is no point comparing it to other minds except to confirm its exceptional status.

Why care about what other species can do if there is literally no comparison with what we do? This view rests on the conviction that something major must have happened after we split off from the apes: an abrupt change in the last few million years or perhaps even more recently. While this miraculous event remains shrouded in mystery, it is honored with an

exclusive term, 'hominization,' mentioned in one breath with words such as 'spark,' 'gap,' and 'chasm.' Obviously, no modern scholar would dare mention a divine spark, let alone special creation, but the religious background of this position is hard to deny.

Darwin believed that all traits were utilitarian, being only as good as strictly necessary for survival, but Wallace felt there must be one exception to this rule: the human mind. Why would people who live simple lives need a brain capable of composing symphonies or doing math?

“Natural selection could only have endowed the savage with a brain a little superior to that of an ape, whereas he actually possesses one but very little inferior to that of the average member of our learned societies.”

During his travels in Southeast Asia, Wallace had gained great respect for non-literate people, so for him to call them only “very little inferior” was a big step up over the prevailing racist views of his time, according to which their intellect was halfway between that of an ape and Western man. Although he was nonreligious, Wallace attributed humanity’s surplus brain power to the “unseen universe of Spirit.” Nothing less could account for the human soul. Unsurprisingly, Darwin was deeply disturbed to see his respected colleague invoke the hand of God, in however camouflaged a way. There was absolutely no need for supernatural explanations, he felt. Nevertheless, Wallace’s Problem still looms large in academic circles eager to keep the human mind out of the clutches of biology.

The suspicion that humans might not be evolving may stem from the misconception that evolution is progressing toward a goal. A related fallacy is that all of life has been aimed at the production of humans, the pinnacle of evolution. If humans are seen as an end point, then presumably there is no need for further modification, making continued human evolution a sort of gilding of the anthropological lily. Such a notion is scientifically indefensible, of course; nature has not singled out humans for special treatment, and human beings are not the most recently evolved species on the planet in any event. That last honor, if it can be viewed as such, would likely belong to a virus, a bacterium, or another microorganism, since their short generation times allow them to evolve, almost literally, in the blink of an eye. Humans are no more of an end point to evolution than they are its most recent product.

Half a century ago, DNA studies revealed that humans barely differ enough from bonobos and chimpanzees to deserve their own genus. It is only for historical reasons that taxonomists have let us keep the *Homo* genus all

to ourselves. The DNA comparison caused hand-wringing in anthropology departments, where until then skulls and bones had ruled supremely as the gauge of relatedness. To determine what is important in a skeleton takes judgment, which allows the subjective coloring of traits that we deem crucial. We make a big deal of our bipedal locomotion, for example, while ignoring the many animals, from chickens to hopping kangaroos, that move the same way. At some savanna sites, bonobos walk entire distances upright through tall grass, making confident strides like humans. Bipedalism is really not as special as it has been made out to be. The good thing about DNA is that it is immune to prejudice, making it a more objective measure.

In 2010 scientists conducted an unusually touching rat experiment. They locked a rat in a tiny cage, placed the cage within a much larger cell and allowed another rat to roam freely through that cell. The caged rat gave out distress signals, which caused the free rat also to exhibit signs of anxiety and stress. In most cases, the free rat proceeded to help her trapped companion, and after several attempts usually succeeded in opening the cage and liberating the prisoner. The researchers then repeated the experiment, this time placing chocolate in the cell. The free rat now had to choose between either liberating the prisoner, or enjoying the chocolate all by herself. Many rats preferred to first free their companion and share the chocolate—though quite a few behaved more selfishly, proving perhaps that some rats are meaner than others. Skeptics dismissed these results, arguing that the free rat liberated the prisoner not out of empathy, but simply in order to stop the annoying distress signals. The rats were motivated by the unpleasant sensations they felt, and they sought nothing grander than ending these sensations. Maybe. But we could say exactly the same thing about us humans. When I donate money to a beggar, am I not reacting to the unpleasant sensations that the sight of the beggar causes me to feel? Do I really care about the beggar, or do I simply want to feel better myself?

In essence, we humans are not that different from rats, dogs, dolphins, or chimpanzees. Like them, we too have no soul. Like us, they too have consciousness and a complex world of sensations and emotions. Of course, every animal has its unique traits and talents. Humans too have their special gifts. We shouldn't humanize animals needlessly, imagining that they are just a furrer version of ourselves. This is not only bad science, but it also prevents us from understanding and valuing other animals on their terms.

There's growing evidence that the octopus is far more intelligent than most people ever imagined, partially because most people always assumed they were gross, delicious morons. Yet this new evaluation is still conducted through a myopically human lens. We classify the octopus as intelligent because of its ability to do human things, based on the accepted position that

we are the most intelligent species on Earth. What's harder to comprehend is the intelligence of an octopus in a world where they are more intelligent than we are.

Because our most recent common ancestor was so simple and lies so far back, cephalopods are an independent experiment in the evolution of large brains and complex behavior. If we can make contact with cephalopods as sentient beings, it is not because of a shared history, not because of kinship, but because evolution built minds twice over. This is probably the closest we will come to meeting an intelligent alien.

When we try to compare one animal's brainpower with another's, we run into the fact that there is no single scale on which intelligence can be sensibly measured. Different animals are good at different things, as makes sense given the different lives they live. An analogy can be drawn with tool kits: brains are like tool kits for the control of behavior. As with human tool kits, there are some elements in common across many trades, but much diversity also. All the tool kits found in animals include some kind of perception, though different animals have very different ways of taking in information. All (or almost all) bilaterian animals have some form of memory and a means for learning, enabling past experiences to be brought to bear on the present. The tool kit sometimes includes capacities for problem solving and planning. Some tool kits are more elaborate and expensive than others, but they can be sophisticated in different ways. One animal might have better senses, while another may have more sophisticated learning. Different tool kits go with different ways of making a living.

There is every reason to suppose that when a fox and I step on a piece of barbed wire we experience something similar. For the moment I mean simply that pain receptors in the fox's foot and mine fire in a more or less identical way and send electronic impulses along more or less identical tracts in the peripheral and central nervous systems to be processed by the brain, which in each case sends a message to our muscles saying 'Take that foot off the wire'—if indeed a reflex hasn't already achieved that. The brain processing will certainly, in both the fox and me, ingrain the lesson 'Don't step on barbed wire: it's not nice'; this will become a part of the experience which we have genuinely shared. It happened to both of us in a neurologically identical way: we both know what stepping on barbed wire is like, in a way that people and animals who have not stepped on barbed wire do not know. I take it that there are many neurological sequences which it is possible meaningfully to say I share with an animal. If a wind blows down the valley in which we are both lying, we both feel it similarly. It may (it will) import different things for us. For the fox its main significance might be that the rabbits are likely to be grazing in the wood by the horse chestnuts; for me

its main significance might be that I'm cold and need to pull on another layer. But that doesn't mean that we haven't both felt it. We have. And the differing significance can be deduced by observation.

Even to form a conception of what it is like to be a bat, one must take up the bat's point of view. If one can take it up roughly, or partially, then one's conception will also be rough or partial. It's not difficult to imagine humans having echolocation sonar and how that would help us walk through a pitch-black room. That experience can be visualized. But what we can't understand is how that experience informs the consciousness of a bat. We can't even assess what level of consciousness a bat possesses, since the only available barometer for consciousness is our own. The interior life of a bat—or an octopus, or any nonhuman creature—is beyond our capacity. And as a society, we are comfortable with not knowing these things—although less comfortable than we were in, say, the nineteenth century. So imagine that this evolution continues. What would happen if we eventually concluded—for whatever collection of reasons—that our human definition of logic is an inferior variety of intelligence? Humans would still be the Earth's dominant life form, but for reasons that would validate our worst fears about humanity.

In a hundred years, qualitative intelligence might be unilaterally prioritized over quantitative aptitude. So if humankind decides that emotional intelligence is really what matters while simultaneously concluding that nonhuman species are superior to humans in this specific regard, society would adopt a highly uncomfortable imbalance. I mean, the relationship between man and beast wouldn't really change. Humans would remain the dominant species. But that dominance would suddenly appear to derive exclusively from brute force. It would essentially derive from the combination of opposable thumbs and a self-defined "inferior" brand of intellect that places us in a better position to kill and control our rivals.

This actuality would swap the polarity of existence. The current belief among many in the animal rights community is that humans are responsible for the welfare of animals and that we must protect them. Our apex slot in the intellectual hierarchy forces us to think on behalf of animals, since they cannot think for themselves. Their innocence is childlike. But if animals are actually more intelligent than humans—and if we were all to agree that they are, based on our own criteria for what constitutes an intelligent being—it would mean that our sovereignty was founded on mental weakness and empathetic failure. It would mean the undeniable success of humankind is just a manifestation of our own self-defined stupidity. Would this change the world? It would not. This is not a relationship that can be switched. The world would continue as it is. We would not elect a cat as president, or

even as comptroller. But this would be a helluva thing to be wrong about, and many would argue maybe a good thing to pretend we're wrong about, just in case.

The chemistry of life is an aquatic chemistry. We can get by on land only by carrying a huge amount of salt water around with us. Researchers have identified traces of what they believe is the earliest known prehistoric ancestor of humans—a microscopic, bag-like sea creature, which lived about 540 million years ago.

You are standing beside your mother, holding her hand. She is holding her mother's hand, who is holding her mother's hand. Eventually the line stretches three-hundred miles long and goes back five-million years, and the clasping hand of the ancestor looks like that of a chimpanzee.

One of an octopus's arms is stretching out to meet one of her mother's arms, and one of her mother's mother's arms, and her mother's mother's mother's. . . Suckered, elastic arms, reaching back through time: an octopus chorus line stretching not just hundreds, but many thousands of miles long. Back past the Cenozoic, the time when our ancestors descended from the trees; back past the Mesozoic, when dinosaurs ruled the land; back past the Permian and the rise of the ancestors of the mammals; back, past the Carboniferous's coal-forming swamp forests; back past the Devonian, when amphibians emerged from the water; back past the Silurian, when plants first took root on land—all the way to the Ordovician, to a time before the advent of wings or knees or lungs, before the fishes had bony jaws, before blood pumped from a multi-chambered heart. More than 500 million years ago, the tides would have been stronger, the days shorter, the year longer, and the air too high in carbon dioxide for mammals or birds to breathe. All the earth's continents huddled in the Southern Hemisphere. And yet still, the arm of her ancestor, sensitive, suckered, and supple, would have been recognizable as one of an octopus.

The giant Pacific octopus is one of the world's most efficient carnivores in converting food to body mass. Hatching from an egg the size of a grain of rice weighing three-tenths of a gram, a baby giant Pacific octopus doubles its weight every eighty days until it reaches about 44 pounds, then doubles its weight every four months until maturity.

An octopus's muscles have both radial and longitudinal fibers, thereby resembling our tongues more than our biceps, but they're strong enough to turn their arms to rigid rods—or shorten them in length by 50 to 70 percent. An octopus's arm muscles, by one calculation, are capable of resisting a pull one-hundred times the octopus's own weight.

An octopus can control each sucker individually.

While arms can be employed for specialized tasks—for example, as your

left hand holds the nail while your right hand wields the hammer—each arm may have its own personality, almost like a separate creature. Researchers have repeatedly observed that when an octopus is in an unfamiliar tank with food in the middle, some of its arms may walk toward the food—while some of its other arms seem to cower in a corner, seeking safety.

Most of an octopus's neurons are in the arms, not the brain.

A giant Pacific octopus can regenerate up to one third of a lost arm in as little as six weeks. Unlike a lizard's regenerated tail, which is invariably of poorer quality than the original, the regrown arm of an octopus is as good as new, complete with nerves, muscles, chromatophores, and perfect, virgin suckers. Even the specialized arm of the male, the ligula, can be regrown.

Not only can they grow new arms when needed; there is evidence that, on occasion, an octopus chooses to detach its own arm, even in the absence of a predator. Tarantulas do this too—if a leg is injured, they will break it off and eat it.

The ability of the octopuses and their kin to camouflage themselves is unmatched in both speed and diversity. Octopuses and their relatives put chameleons to shame. Most animals gifted with the ability to camouflage can assume only a tiny handful of fixed patterns. The cephalopods have a command of thirty to fifty different patterns per individual animal. They can change color, pattern, and texture in seven-tenths of a second. On a Pacific coral reef, a researcher once counted an octopus changing 177 times in a single hour. At Woods Hole Oceanographic Institution, cephalopods put on laboratory checkerboards virtually disappear. They don't make checks, of course; but they can create a pattern of light and dark that makes them invisible on virtually any background, to virtually any eye.

An octopus can also voluntarily control its skin texture—raising and lowering fleshy projections called papillae—as well as change its overall shape and posture. The sand-dwelling mimic octopus, an Atlantic species, is particularly adept at this. One online video shows the animal altering its body position, color, and skin texture to morph into a flatfish, then several sea snakes, and finally a poisonous lionfish—all in a matter of seconds.

The octopus eye, unlike our own, can detect polarized light. It has no blind spot. Our eyes are binocular, directed forward for seeing what's ahead of us, our usual direction of travel. The octopus's wide-angle eyes are adapted to panoramic vision. And each eye can swivel independently, like a chameleon's. Our visual acuity can extend beyond the horizon; an octopus can see only about eight feet away.

Human eyes have three visual pigments, allowing us to see color. Octopuses have only one—which would make these masters of camouflage, commanding a glittering rainbow of colors, technically color-blind. How,

then, does the octopus decide what colors to turn? New evidence suggests cephalopods might be able to see with their skin. Woods Hole and University of Washington researchers found the skin of the octopus's close relative, the cuttlefish *Sepia officinalis*, contains gene sequences usually expressed only in the retina of the eye.

Researchers reported that the strikingly beautiful, newly rediscovered Pacific striped octopus lives in communities of up to forty animals. Males and females cohabit in dens, mate beak-to-beak, and produce not just one but many broods of eggs over their lifetimes.

Though cooks who throw lobsters into boiling water insist invertebrates' attempts to escape are mere reflexes, they're wrong. Prawns whose antennae are brushed with acetic acid carefully groom the injured sensors with complex, prolonged movements—which diminish when anesthetic is applied. Crabs who have been shocked rub the hurt spot for long periods after the initial injury. Octopuses also do this, and are more likely to swim away or squirt ink when touched near a wound than when touched elsewhere on the body.

Male cuttlefish courting a female may trick rival males into thinking there is nothing to worry about. The courting male adopts the coloring of a female on the side of his body that faces his rival, so that the latter believes he is looking at a female. But the same male keeps his original coloring on the female's side of his body in order to keep her interested. He thus courts her surreptitiously. This two-faced tactic, called dual-gender signaling, suggests tactical skills of an order that we might expect in primates but not mollusks.

The undersea world is a seriously slimy place. Slime helps sea animals reduce drag while moving through the water, capture and eat food, keep their skin healthy, escape predators, protect their eggs. Tube worms secrete slime to build a leathery tube, like a flower stalk, to protect their bodies and keep them attached to a rock or coral. For some fishes—Amazon discus and cichlids among them—slime is the piscine equivalent of mother's milk. The babies actually feed off the parents' nutritious slime coat, an activity called "glancing." The brightly colored mandarin fish exudes bad-tasting slime to deflect its enemies; the deep-sea vampire squid, an octopus relative, produces glowing slime to startle predators. Bermuda fire worms signal with luminous slime to attract mates like fireflies flashing on a summer night. The female fire worms glow to attract the males; the males then flash, after which the two release eggs and sperm in tandem.

A creature of the ocean bottom, a hagfish grows to about 17 inches long, and yet, in mere minutes, it can fill seven buckets with slime—so much slime it can slip from almost any predator's grip. The hagfish would be in danger of suffocating on its own mucous, except it has learned, like a person with

a cold, to blow it out its nose. But sometimes it produces too much slime for even a hagfish to tolerate, and for this occasion, it has devised a nifty trick: the animal wraps its tail around its body like a knot and slides the knot forward, clearing the slime.

The elegant efficiency of the jellyfish's structure may be one reason for the group's diversity. Jellyfish bodies are at least 95% water; the remaining 5% or so contains the barest essentials needed to capture, consume, and use energy. Their method of locomotion, an elastic ring that contracts to rapidly expel water and propel the jelly forward, allows them to move more efficiently than any other organism. Their trailing tentacles brush against prey, immobilizing them and conveying them to the jellyfish's mouth—after which the jelly digests its prey in its body cavity and subsequently expels the remaining parts of the prey through the same single opening.

The lack of complex physical features makes jellies extremely adaptable and the things that restrict other marine animals—such as temperature, acidity, salinity, light, or darkness—don't faze them. They combine plant-like simplicity, animal-like mobility, and an almost bacterial ability to reproduce rapidly under favorable conditions. There's even a species of jellyfish that achieves near-immortality by turning back into a polyp—a less mature version of itself—when injured. The polyp can then produce identical copies of the injured jelly and the jelly can revert back to the polyp again and again, indefinitely.

Creatures are dependent on sunlight in surprisingly complex ways. The organisms with the first dibs on sunshine are the plants, which use it in photosynthesis. The sun's energy is then passed up the food chain, to the bugs that eat these plants, to the birds that eat the bugs, to the mammals that eat the birds. The same goes in the oceans. Plantlike phytoplankton float around absorbing the sun's energy. Zooplankton eat the phytoplankton, and fish eat the zooplankton, on up the line. Every critter in that food chain, though, meets its end and sinks down into the abyss, a biomass that's known quite tranquilly as marine snow—even though it's made of dead things. Opportunists in the water column pick at this marine snow as it falls, and accordingly very few nutrients even reach the seafloor. So few nutrients, in fact, that a whale that dies and sinks more or less intact to the bottom (there may be opportunists, but not enough to strip a whale clean before it hits the floor) will provide as much food to the critters of the seafloor as would thousands of years of marine snow. The so-called whale fall is what the scavengers of the seafloor are desperate for. They'll pick the giant's bones clean and won't stop at that, for there are creatures that devour the bones themselves.

Most whales eat microscopic organisms like plankton, and so their throats

are only four or five inches wide. If you happen to find yourself inside the mouth of a blue whale you would be too big for it to swallow and your journey would likely end with a crushing blow from its 6,000-pound tongue.

Humpback whales have sex in threesomes, with the third whale acting as a sort of assistant like some soy-boy beta cuck.

The dolphins' evolutionary path is a preposterous feat: their predecessors were land mammals that resembled small, hooved wolves. After an interlude in swamps and coastal lowlands, these fledgling aquanauts moved permanently into the water. Over the course of twenty-million years, their limbs turned to fins, their shape became streamlined for swimming, their fur turned to blubber, their nostrils migrated to the top of their heads—in other words, they developed all the equipment needed to master undersea life. They aced it, too: dolphins have perfectly hydrodynamic bodies. They swim faster than physics would seem to allow, given the density of water and the amount of muscle they have. Their bodies are so ideally adapted for speed, navigation, plunging into the depths, and keeping warm that it's hard to imagine improvements.

“One morning I watched five spinners give birth simultaneously, the babies corkscrewing out of their mothers tail-first, then wobbling to the surface to take their first breaths. Witnessing this made me wonder if the dolphins could decide, within reason, when they wanted to deliver—because statistically, five babies appearing at once was almost certainly not random. That possibility, in turn, led me to muse: Could dolphins also choose the moment of their own deaths?”

Dolphin erections happen at will; they can pop it out like a kickstand or retract it neatly whenever they want to. What other body functions do dolphins have under their own control? It is an intriguing question.

“It's like dolphins and whales are living in these massive, multicultural, undersea societies. Really the closest analogy we have for it would be ourselves.”

“A certain willingness to face censure, to be a maverick, to question one's beliefs, to revise them, are obviously necessary. But what is not obvious is how to prepare one's own mind to receive the transmissions from the far side of the protective transparent wall separating each of us from the dark gulf of the unknown. Maybe we must realize that we are still babies in the

universe, taking steps never before taken. Sometimes we reach out from our aloneness for someone else who may or may not exist. But at least we reach out, and it is gratifying to see our dolphins reach also, however primitively. They reach toward those of us who are willing to reach toward them.”

A biologist recalls tailing a pod of bottlenoses on one grim, foggy morning along the coast of Los Angeles. The animals were hunting, ignoring her research boat as they searched for fish. Finally, they found a huge school of sardines and began herding them. If there’s anything that commands a dolphin’s attention it is a mother lode of fish, so she was surprised when one of the dolphins suddenly broke away from feeding and headed out to sea, swimming at top speed. The rest of the pod followed; so did the biologist and her crew. The dolphins arrowed about three miles offshore and then they stopped, arranging themselves in a circle. In the center, the scientists were shocked to see a girl’s body floating. She was a teenager and barely alive, her suicide attempt only moments away from succeeding. Around her neck, the girl had strung a plastic bag containing her identification and a farewell letter. Thanks to the aquatic snitches, she was “rescued.”

“I still think and dream about that cold day and that tiny, pale girl lost in the ocean and found again for some inexplicable reason, by us, by the dolphins.”

Tales like this are remarkably common: famously, when rescuers pulled five-year-old Cuban Elián González out of the water three miles off Florida’s coast, adrift and alone for forty-eight hours after his boat capsized and everyone else aboard had drowned, some of his first words were about how dolphins had surrounded him and kept him from slipping off his life ring in thirteen-foot seas. After a 9.1 earthquake shook the waters off Phuket, Thailand, on December 26, 2004, seven boats full of scuba divers were startled when a pod of dolphins began to leap theatrically, right in front of them, attention-getting behavior that none of the veteran captains or divemasters had witnessed before. The ocean was roiled from the earthquake and the captains had decided to return to port, but the dolphins seemed to be frantically beckoning them offshore. Out of curiosity, the dive boats followed them. At that point no one aboard the vessels could have known that massive tsunami waves were rolling beneath them, thundering toward the shoreline where they would cause epic death and destruction. The divers soon learned that by steering them out to sea, away from the breaking waves, the dolphins had saved their lives.

Surfers, in particular, seem to benefit from dolphin intervention; accounts of dolphins aiding their fellow wave riders are the most plentiful of all. When a surfer was bitten three times by a great white shark near Monterrey, California, dolphins drove off the marauder, formed a ring around the surfer, and escorted him to the beach. Even before the attack the dolphins had been circling with unusual focus. When the shark approached for its first pass they made a visible ruckus: thrashing their fins at the surface, slapping their tails on the water, and in general acting so aggressively that another surfer, floating fifteen feet away, wondered, “What did he do to piss off the dolphins?” When he got the full measure of what was happening, he paddled over to help. While the stricken surfer flailed in a pool of blood, the shark returned—twice. One ninja dolphin vaulted out of the water and lashed at the attacker with its tail, Bruce Lee style.

What to make of these stories? One point worth noting is that dolphins often behave toward us in the same ways they do toward one another. It’s standard dolphin operating procedure, for instance, to fend off sharks, or hold an injured mate at the surface so he can breathe, or steer the pod away from danger. In the dolphins’ nomadic undersea world, solitude equals vulnerability, so a lone human in the water must seem to them direly in need of assistance. Their consideration of us isn’t limited to emergency situations, either: at the Tangalooma Island Resort in Australia, where wild bottlenoses are regularly fed fish by people standing in the shallows, biologists have documented—on twenty-three occasions—the dolphins reciprocating, swimming up to offer freshly caught tuna, eels, and octopi as gifts. In other words, dolphins do not always differentiate between us and them. At times they do not seem to care that we are not members of their species—they simply appoint us honorary dolphins. Maybe that was why Fungie made his home among the residents of Dingle. To him, perhaps, they were just a slightly-peculiar-looking pod.

Throughout most of their lives, orcas stick close to their mommas—unless SeaWorld or some other aquatic gulag operator gets involved. An orca’s pod is his immediate family, a group that might contain four generations. Each pod, in turn, is part of a bigger clan, also comprised of close relations, and at the top of the orca organizational chart are the broader communities, made up of clans. In our terrestrial world, we call them nations. A killer whale’s cultural education unfurls at a pace that is similar to ours. They develop socially, like we do, and nothing happens instantly: maturity comes over time. At twenty, orcas are still learning and growing. Matriarchs have been known to approach the century mark, often outliving their offspring; they can spend more than thirty years in menopause. As with all of nature’s successful adaptations there is a reason for this, and we’ve learned some

eye-opening things about the matriarchs' role. They babysit, for one thing. They share food. And they teach: killer whale mothers, grandmothers, and great-grandmothers pass on so much essential knowledge that calves removed from their influence are as ill-equipped for wild orca life as children raised by wolves would be in our society, if dropped into Midtown Manhattan.

This blue orb we live on? It's had oceans for 3.8 billion years. In a realm where history isn't written, it is the matriarch who carries the past, everything her pod needs to survive into the future. She is the keeper of the dialect; she teaches her descendants their very identity. She shows everyone how to hunt, no minor task when you consider the tricky and specialized techniques orcas deploy. In Argentina, one group uses the high-stakes tactic of intentionally stranding themselves—rocketing onto the beach, grabbing a seal, and then hopefully propelling themselves back into the water. Scientists have watched young orcas being tutored for six years before they even attempt this.

Stromatopods have underwater rocket clubs. At work here is a surprisingly simple mechanism. Up at the top of the arm is a kind of membranous divot, curved like a saddle, that acts as a spring. The stomatopod contracts a big muscle in that arm, pulling back the club and compressing the spring until an internal latch snaps into place. That latch is holding back a tremendous amount of energy in the muscle, and when it flies open, the spring rockets the club forward at up to fifty miles per hour, which is especially impressive considering this is happening in water. The resulting force is devastating. Subjected to such treatment, clams shatter, while more fragile creatures like crabs explode into a shower of limbs. Indeed, a clubber stomatopod will target a crab's claws first, blowing them off to counter the prey's futile attempts to defend itself.

The solution a geography cone snail has to holding on to their prey isn't brawn, but a brutal, sophisticated mix of both chemical and ballistic warfare. Something weird happens when a geography cone snail approaches a school of fish. Well, a couple of weird things happen. First, the fish don't seem to give a hoot. They're aloof, lolling there wide-eyed. They don't even seem to give a hoot when the snail expands its huge mouth like a fleshy hot air balloon. Slowly the mouth envelops several clueless fish, until the snail at last fires a harpoon into each victim, paralyzing it almost instantly. The mouth balloon shrinks, and the fish go quietly into death. Which would seem like a silly thing to be so relaxed about.

But it turns out that the fish are under a kind of spell: The geography cone snail has evolved to deploy insulin as a chemical weapon. By releasing massive amounts of the hormone into the water, the snail makes its prey's blood sugar levels plummet. Hypoglycemic shock sets in. The fish grow

sluggish and confused as their nervous systems glitch. In effect, they're hypnotized, conscious yet locked up, like you or me suffering a fit of sleep paralysis. But what's even weirder is that insulin in an invertebrate like a geography cone snail and insulin in a vertebrate like a fish are chemically distinct. Yet in addition to producing invertebrate insulin for its own body, the snail has evolved fish-like insulin that it has weaponized to overload its prey.

The mightiest land crustacean of all is the coconut crab. It's a kind of hermit crab, only it forgoes the shell and grows to three feet across and ten pounds. The crab's claws are so powerful it can tear through coconuts, as its name suggests. On the islands in the Pacific the coconut crab calls home, it's been known to attack kittens. I'm sorry you had to read that, but who knows, maybe those cats were evil or something. It's good to think positive, after all.

Compared with the human penis, that of the hamadryas appears to lack a foreskin and the animal was therefore thought to be born circumcised. It has been suggested that the Egyptian priests who attended the sacred baboons honoured them by imitating this condition. In this way the ritual of human circumcision is thought to have arisen, spreading later to nearby tribes who wished to emulate the advanced Egyptians.

So strong was the Egyptian interest in the baboon penis that it was employed as the central feature of their water-clocks. Carvings of seated male baboons were created in which water flowed through a hole in the phallus, marking the hours. Bizarrely, this is because it was believed that baboons urinated regularly once every hour.

According to a fifth-century BC account, a newly arrived baboon was set a curious test. It was presented with a writing tablet, a reed pen and some ink. The priests then waited to see if it showed any interest in this equipment. If it did, it was considered to be literate and was enrolled as a symbol of Thoth, the deity of scribes, of education and of the moon. In this capacity it was installed in one of the temples and was provided with fine roasted meats and wine, obtained through gifts from the worshipers. Sadly, this lavish but highly unsuitable diet and a lack of proper exercise led to early deaths in most of these sacred animals, as has been discovered from an examination of their mummies. They lived protected, pampered lives, but died young.

In spite of their great physical power, mountain gorillas are rather timid: they fear lizards and crocodiles, avoid chameleons and caterpillars, and do their best to cross any stream without getting their feet wet—sometimes using a stick to test the depth of the water. Researchers have found they use simple tools, such as rocks to break open palm nuts or clubs improvised

from tree branches. Gorillas are our nearest relatives after chimpanzees and bonobos, sharing around 97 percent of our DNA.

A special case, where the males went too far in the dominance battle, concerns the patas monkey of the African grasslands. This ground-dwelling species lives in uni-male groups, but the size of the typical female harem is too big for the male to dominate it. If he tries to assert himself, the females gang up on him and become the group controllers. They are so assertive that most of the squabbling you see in a patas group is not between males but between the dominant females who are trying to sort out their social hierarchy. So the male's main task is watching out for predators and protecting his group of females from danger, rather than dominating them socially. He has become their sexual servant, allowed to mate with them when the time comes, but otherwise of no social importance within the group. The patas monkey is an intriguing example of a patriarchy that went so far it became a matriarchy.

The big difference between a monkey baby and a human baby is that the young monkey is capable of clinging on to the mother from birth. This is because the newborn monkey's arms are stronger at birth and because the mother's fur provides a better grip for the tiny fingers. At one closely observed monkey birth it was possible to see that the baby was actually aiding its own delivery by grasping hold of its mother's fur while it was emerging from her body.

In the laboratory many subtle tests have been carried out with capuchins and their level of intelligence has never ceased to surprise the experimenters. To give one example: two capuchins were separated by a glass screen with a small hole in it. One capuchin had a stone hammer and the other a jar full of nuts that he could not open. The first capuchin passed the hammer through the hole in the glass partition and the second one used it to knock open the lid of the jar. When he had extracted the nuts from inside the jar, instead of eating them all himself, he shared them with his helpful companion. In another laboratory test, one capuchin was given a small biscuit as a reward whenever he offered the experimenter a small token. He happily ate the biscuit until he noticed that his companion monkey was getting a succulent grape as a reward instead of a dry biscuit. After this, he would hand over a token and, if given another biscuit, would throw it away angrily and keep trying until eventually he obtained a grape. These two tests reveal that capuchins have both a sense of mutual aid and cooperation, and a sense of fairness and unfairness. One can't help thinking that, if they could talk, we would have to open an embassy for them.

Aesop's fable "The Crow and the Pitcher" tells the tale of a crow wishing to drink water from the bottom of a pitcher. The crow collects pebbles,

dropping them one by one into the pitcher until the water level is high enough for him to drink. Researchers tested this fable in real life by presenting crows with a narrow vase half filled with water with a treat floating in it. The water level was too low for the crow to reach the treat, but there was a pile of little rocks nearby. As in the fable, the solution was to put the rocks in the vase to raise the water level, and crows had no problem figuring it out, even beating out some children.

However, crows were stumped by a similar scenario in which rocks had to be put in a second vase connected to the first vase by a sneaky invisible tube under the table, which raised the water level in both vases. Unlike crows, children did manage to solve this problem, even though they had no idea how the water level in the second vase affected the water level in the first vase—many called it “magic,” strongly suggesting that children are simply crows with a belief in magic.

Pointless fun—might this be the crowning glory that sets us apart from animals? But then those tobogganing crows come to mind. An internet video shows one of these birds sliding down the roof of a house. The bird has a lid from a plastic container. It carries it up to the highest part of the roof, places it on the slope, and then jumps onto it to slide down. No sooner does the bird reach the bottom than it goes back up for its next ride. The point? Apparently none. The fun factor? Probably the same as when we jump onto the wooden or plastic object of our choice and careen down a hill. Why would crows expend energy on a pointless activity? After all, tough evolutionary competition calls for the elimination of all non-beneficial activities and ejects from the race any animal that is not sufficiently rigorous in this respect. And yet it’s been a long time since we’ve paid any attention to this seemingly absolute rule. At least in wealthier countries, we have energy to spare, and we can afford to use it to enjoy ourselves. Why should it be any different for an intelligent bird that has set aside sufficient food for the winter and can devote some of these calories to fun and games? Clearly crows, too, can convert surplus resources into mindless fun and conjure up happy feelings whenever they want.

Wood mice and long-tailed macaques have adopted a somewhat familiar barter system: these species pay for grooming with sex.

On Gough Island in the raging South Atlantic, thousands of miles from the nearest mainland, seabirds such as the enormous albatrosses breed in complete isolation. That is, they did until one day seafarers discovered the island and inadvertently released house mice that had stowed away on their ships. The mice did there what mice do here. They dug holes, ate roots and blades of grass, and multiplied magnificently. But then, one day, one of them suddenly got a taste for meat. It must have found out how to

kill albatross chicks, which, quite apart from the savagery of the act, is no easy feat because the chicks are around two-hundred times larger than their attackers. The mice quickly learnt that a large number of them had to keep biting a chick until it bled to death. Especially brutal mice even began to eat the fluffy balls of down while they were still alive.

But researchers noticed that, for years, chicks were hunted only in particular parts of the island. Clearly, mouse parents demonstrated the technique to their children, passing the skill on to the next generation, while other mice in other areas knew nothing about this hunting strategy. This handing down of hunting strategies is found among many larger mammals as well, such as wolves. Moreover, young wild boar and deer are also taught by example to follow the paths their family groups have been navigating safely for decades to move from summer to winter feeding grounds. And that is why such trails are often well-trodden and hard as concrete from long use. Animals that learn from older generations avoid an early death.

Spotted hyenas lead a complex social life in which females play the dominant role. Clans of as many as seventy or eighty individuals are always led by females, and all adult females are dominant to all adult males, who leave the group when they reach puberty. Females assert their dominance by being far more aggressive than the males at every stage in their lives, producing one of the most chilling phenomena ever seen in any mammal.

Hyenas usually have twins, which are well developed at birth, completely furred, eyes open, canine and incisor teeth fully erupted. This is true of some other carnivores, but what makes the spotted hyena exceptional is that within minutes of birth one of the cubs attacks its twin, sometimes savaging a brother or sister that has not yet even emerged from its amniotic sac. If both offspring survive this preemptive strike, the battle begins in earnest as the pair roll in a bitter embrace, each with the skin of the other locked in its jaws.

This is not the normal rough and tumble of siblings at play. This is a fight to the death between two baby animals scarcely an hour old. There is nothing unusual about sibling rivalry. Offspring routinely compete with each other for food and attention. But these are generally the result of food shortages. What is disturbing about the hyena neonatal conflict is that it seems to be the norm. Spotted hyenas nearly always have twins and seldom get to raise more than a single cub, because the cubs themselves seem to be genetically programmed to attack and kill their siblings on sight. This is a rare example of pure aggression, taking place without any preliminaries, independent of the sort of social history that usually leads to conflict.

It is not common in nature because it carries a heavy penalty, the certain loss of at least half your own genes—not to mention the effort put into

growing an entire extra creature inside of you. The fact that spotted hyenas do so routinely suggests that this loss is one worth taking. It must be offset by an even larger gain elsewhere. But where, exactly? Over a period of fifteen years, researchers have found that the cub which usually wins the murderous battle in the den is female, and that if she is the daughter of a top ranked female, she will invariably replace her mother as head of the clan. This is clearly something the genes would like, the kind of continuity they thrive on and seem to have contrived by a very simple chemical device.

With a series of blood tests, researchers have also been able to show that androgens run riot in the whole population. Spotted hyena fetuses, no matter what their sex, have levels of testosterone higher even than adult males. Something has switched on the process which produces hormones that stimulate the development of masculine characteristics, and done so early and indiscriminately, right there in the womb, leading to conspicuous later changes in body, brain, and behavior. And the result is bizarre genitalia, sexual confusion, and adult females so large, competent, and aggressive that they run a tight and genetically stable matriarchy.

The only saving grace in this frightening story of genetic imperialism lies in the researchers' additional suggestion that hyena mothers might sometimes intervene in fights between their offspring to tailor the sex ratio of the community. In one instance a depleted clan which badly needed replenishment suddenly allowed an unprecedented number of pairs of female twins to survive. A subtle and heartening reassertion of individual independence over genetic hegemony. Perhaps. It is not always easy to tell where the orders are coming from. Unscrupulous genes are also inclined to cheat.

Consider cuckoos, more than fifty species of which lay their eggs in other birds' nests. They intimidate their unwilling hosts into leaving the nest unguarded by imitating a local predator, such as the sparrowhawk. Or the males may distract a host's attention while the female sneaks in and lays eggs which mimic those of their habitual host in size and color. Sometimes they simply destroy the host's clutch of eggs altogether. Cuckoo chicks also bear a close resemblance to those of the host species, even copying the distinctive color patterns which act as food guides in a gaping chick's mouth. Everything possible is contrived to persuade the hosts that they are hatching and rearing their own offspring, but if all else fails, the cuckoo chick takes matters into its own wings and simply eliminates rival eggs or nestlings by throwing them out of the nest. Some baby cuckoos are programmed to do this. If anything presses on their backs during the first day or two of their lives outside the egg, they climb backward up the side of the nest, supporting this burden between their wing stubs, and heave it overboard.

Each species' milk has its own signature blend of components such as

protein, fat, and calories geared to the growth schedule of the young animal consuming it. Cow's milk is higher in protein but lower in fat than human milk, though it contains nearly the same number of calories. Whales and seals are famous for the high fat content of their milk, essential to the rapid growth of their young in cold environments. The milk in some species of seals is so thick with butterfat that it resembles toothpaste squeezed out of a tube into the mouths of the hungry pups. Surprisingly, mouse milk is quite high in fat and calories, though not on a par with the milk of marine mammals; a cup of mouse milk, assuming you had the patience to obtain it, would contain over 400 calories, more than two-and-a-half times the number in cow's milk.

Red deer have to rev up their metabolic rate when they are digesting food, but going through the winter without eating anything is usually not an option, either. When a red deer eats in winter, it often extracts less energy from the food than it uses to digest it. And that is why, paradoxically, when hunters feed red deer in winter, the animals can end up starving in droves. This is what happened in 2013 where there was an indignant outcry from hunters who wanted to continue feeding despite a local ban. Almost a hundred red deer died from starvation, a number of which would likely have survived if they hadn't been physically stressed after digesting the hay and sugar beets hunters had fed them. That is why, left to their own devices in winter, red deer mostly live off the body fat they accumulate in the fall.

At some point, you might begin to worry whether red deer constantly feel hungry in winter, which is a distressing thought. To stand in cold snow with a rumbling stomach and super-cooled extremities is surely very unpleasant—at least it would be for a human being. It has now been proven that animals can turn off the sensation of hunger. Hunger is, after all, a signal from the unconscious that it's time to eat. And this feeling should only trigger the desire to eat when adding calories would be beneficial. Take hedgehogs, for instance. Even when they are hungry, they refuse smelly, rotten food. The unconscious part of their brain temporarily shuts down their hunger pangs and replaces them with a firm resolve not to eat any of the proffered sustenance. We don't know whether red deer experience an aversion to buds and dry grass or whether they simply feel full. But we do know that the animals don't feel hungry in winter despite their fast, because at the end of the day not eating makes fewer demands on their energy reserves.

However, the combination of lowering body temperature and metabolic rate that I have just described doesn't work equally well for all red deer. How well it works depends on the character of the individual deer and, equally importantly, on its rank and position in the herd. Winter is particularly

dangerous for red deer that have strong personalities. As leaders in the herd, they have to be constantly alert. This means their heart rate is constantly elevated, and their energy use is correspondingly high. It's true that herd leaders have preferential access to good feeding grounds, but that is of little use to them. Meager winter offerings of dry grass and tree bark don't deliver sufficient calories to build up the fat reserves these deer are burning through at a higher rate than their lower-ranking herd mates, which spend the cold winter nights standing around calmly and dozing. The lower-ranking deer are eating less than their leaders, but they are also using far less energy. And so, at the end of winter, they have more reserves than their superiors. After watching deer in large natural enclosures, foresters in Vienna made the surprising discovery that being the leader of a herd reduces a deer's chance of survival, despite the fact that leaders always get to help themselves to food first. According to the researchers, in the future it will be more important to consider the life histories and personalities of individual animals rather than the average for the species. After all, that is exactly how evolution works—using deviations from the norm.

Some animals make their own fly swatters. Asian elephants break off a large branch of a tree, remove the excess leaves to fashion it into a switch, and then shake it over their head and body. Gazelles and impalas take a different approach to dislodging parasites: they use their teeth as combs, scraping ticks off their coats and orally grooming themselves two-thousand times a day.

Because of an injured rear leg, Babyl could only walk at a snail's pace, and for over a decade and a half, the other elephants in her group have waited for her and fed her. Unescorted, Babyl would easily have fallen prey to a lion.

“A number of elephants visited the body, some touching and some just standing for a time near the dead matriarch. A female named Maui extended her trunk, sniffed the body, touched it, and then tasted Eleanor's trunk. She hovered her right foot over the body, nudged the body, and then stepped over, pulling the body with her left foot and trunk, before standing over the body and rocking to and fro.”

Elephants grieve openly for their dead. A baby elephant is killed by a lioness. Over the course of the day, elephants from the herd gathered in a rough circle around the remains of the baby. Many of them touched the body with their trunks. Elephants also show a pronounced interest

in corpses and bones, a behavior thought to exist only in elephants and humans.

Once, after a cull in Uganda, park rangers had stored severed feet and other body parts of the fallen inside a shed. That night, other elephants pushed their way into the shed and then buried the body parts. Elephants—unlike most animals—are aware of death and are drawn to the remains of their kin, sometimes burying them in branches and grass.

When elephants and rhinos form close social relationships, elephants will mourn the loss of their rhino friends. Thus, in an incident that was reported in Zimbabwe in November 2007, after her black rhino companion was shot, dehorned, and buried by poachers, Mundeavu, an African elephant calf, dug down for about one meter to try to reach her former companion, constantly letting out screams and shrieks as two other elephants supported her. It's reasonable to suppose that a capacity for empathy is associated with the expression of compassion for the ailing and grief for the dead.

The sensation I was feeling on the clifftop was some sort of reverberation in the air itself. The whale had submerged and I was still feeling something. The strange rhythm seemed now to be coming from behind me, from the land, so I turned to look across the gorge where my heart stopped. Standing there in the shade of the tree was an elephant staring out to sea. A female with a left tusk broken off near the base. I knew who she was, who she had to be. I recognized her from a color photograph put out by the Department of Water Affairs and Forestry under the title "The Last Remaining Knysna Elephant." This was the Matriarch herself.

She was here because she no longer had anyone to talk to in the forest. She was standing here on the edge of the ocean because it was the next, nearest, and most powerful source of infrasound. The underrumble of the surf would have been well within her range, a soothing balm for an animal used to being surrounded by low and comforting frequencies, by the lifesounds of a herd, and now this was the next-best thing. My heart went out to her. The whole idea of this grandmother of many being alone for the first time in her life was tragic, conjuring up the vision of countless other old and lonely souls.

But just as I was about to be consumed by helpless sorrow, something even more extraordinary took place. The throbbing was back in the air. I could feel it, and I began to understand why. The blue whale was on the surface again, pointed inshore, resting, her blowhole clearly visible. The Matriarch was here for the whale! The largest animal in the ocean and the largest living land animal were no more than a hundred yards apart, and I was convinced that they were communicating. In infrasound, in concert, sharing big brains and long lives, understanding the pain of high investment

in a few precious offspring, aware of the importance and the pleasure of complex sociality, these rare and lovely great ladies were commiserating over the back fence of this rocky Cape shore, woman to woman, matriarch to matriarch, almost the last of their kind. I turned, blinking away the tears, and left them to it. This was no place for a mere man.

There is the story of a humpback whale in the Sea of Cortez in Mexico that put on an hour-long display of breaching and flipper flapping after a man spent hours cutting off a fishing net in which it had been hopelessly entangled. When the man encountered the whale, it looked as though it would not be able to survive for much longer. He immediately entered the water armed with just a small knife. As soon as the whale was free, it put on a glorious acrobatic display. Perhaps it was just happy not to be entangled in the net anymore—or perhaps it was performing for the people in the small boat to thank them for rescuing it from certain death.

One of the most compelling stories of cross-species, animal-to-animal empathy, is about Kuni, a female bonobo imprisoned at the Twycross Zoo in England. Kuni captured a starling and took the bird outside and placed it on its feet. When the bird did not move, Kuni tossed it in the air. When the starling did not fly, Kuni took it to the highest point in her enclosure, carefully unfolded its wings, and threw it in the air. The starling still did not fly, and Kuni then guarded and protected it from a curious juvenile. It seems clear that Kuni was taking the perspective of the bird.

Wolves and ravens are another example. Ravens enjoy living with wolf packs, and the wolf pups even engage the black birds in play. When large enemies such as grizzly bears approach, the ravens warn their four-legged friends. The wolves repay the debt by allowing their feathered partners to feed alongside them at their kills.

There's a small bird known as the honey bird, which likes to drink the honey. But it can't get past the fierce bees to get its tippie, so it has developed a relationship with the honey badger, a small, very aggressive mammal that also likes honey but which doesn't know where it is. The bird shows the badger where to find the honey, flying a little way ahead of it to guide it. The badger then raids the hive with its big claws, driving off the bees, so that both bird and badger can drink their fill. Some local people have learned to watch the badger and the honey bird to find the honey. And the bird has realized that people are faster and smarter than the badger, driving the bees off with smoke, and so the bird now calls to these people and takes them directly to the honey, bypassing the poor badger.

In contrast to the modern orthodoxy, researchers found that many kinds of environmental effects could be passed on to offspring, through a variety of mechanisms, some affecting gene expression and others influencing the

frequency of mutations or the dominance of varietal forms. One of their most surprising findings was that many organisms develop only through interactions with other species. A tiny Hawaiian squid, *Euprymna scolopes*, has become a model for thinking about this process. The bob-tailed squid is known for its light organ, through which it mimics moonlight, hiding its shadow from predators. But juvenile squid do not develop this organ unless they come into contact with one particular species of bacteria, *Vibrio fischeri*. The squid are not born with these bacteria; they must encounter them in the seawater. Without them, the light organ never develops.

But perhaps you think light organs are superfluous. Consider the parasitic wasp *Asobara tabida*. Females are completely unable to produce eggs without bacteria of the genus *Wolbachia*. Meanwhile, larvae of the Large Blue butterfly (*Maculinea arion*) are unable to survive without being taken in by an ant colony. Even we proudly independent humans are unable to digest our food without helpful bacteria, some first gained as we slide out of the birth canal. Ninety percent of the cells in a human body are bacteria. We can't do without them.

Almost all development may be codevelopment. By 'codevelopment' we refer to the ability of the cells of one species to assist the normal construction of the body of another species. This insight changes the unit of evolution. Some biologists have begun to speak of the "hologenome theory of evolution," referring to the complex of organisms and their symbionts as an evolutionary unit: the "holobiont." They find, for example, that associations between particular bacteria and fruit flies influence fruit fly mating choice, thus shaping the road to the development of a new species. More and more symbiosis appears to be the rule, not the exception. Nature may be selecting relationships rather than individuals or genomes.

Pen-tailed tree shrews are significant, because in addition to looking like the result of a raccoon mating with a pear, they're considered to be the spitting image of the first pre-primates, genetically speaking. And while these guys have a lot in common with our earliest ancestors, they also share something with Russian dockworkers; namely, the ability to put away nine or more drinks in a night without feeling it. The pen-tailed tree shrew lives its life like one giant bar crawl, with tree branches as its taps and fermenting palm nectar in lieu of craft beer. That nectar, colonized by naturally occurring air yeasts, can hit three to four percent alcohol by the time a shrew starts slurping it up. Nine beers seem like more than a tiny little rat-monkey should be able to handle without being too fucked-up to avoid danger. But the pen-tailed tree shrew takes its alcohol like a Yeltsin. The fact that the jungles of Malaysia aren't filled with drunken shrews falling from the sky and splattering on the ground is proof that alcohol doesn't

affect them quite the same way it affects us.

Visits to the bertam palm tavern benefit both the fuzzy little alcoholics and the tree itself. The tree shrews get open taps to binge on, and the palm gets a small, drunken army to help spread its pollen far and wide. The arrangement is dizzyingly complex: Yeasts feed off sugars in the nectar, and the brewery-like aroma of those fermenting sugars draws in tree shrews, sloths, and other animals.

Macrotermes termites digest their food only through the help of fungi. The termites chew up wood, but they cannot digest it. Instead, they build “fungus gardens” in which the chewed-up wood is digested by *Termitomyces* fungi, producing edible nutrients. While you might say that the termites farm the fungus, you could equally say that the fungus farms the termites. *Termitomyces* uses the environment of the termite mound to outcompete other fungi; meanwhile, the fungus regulates the mound, keeping it open, by throwing up mushrooms annually, creating a colony-saving disturbance in termite mound-building.

Many ectomycorrhizas are not limited to one collaboration; the fungus forms a network across plants. In a forest, fungi connect not just trees of the same species, but often many species. If you cover a tree in the forest, depriving its leaves of light and thus food, its mycorrhizal associates may feed it from the carbohydrates of other trees in the network.

Recently, scientists in the United Kingdom have demonstrated that the mycelia also protect plants from predators. When a plant is assaulted by aphids, it produces chemicals that repel them, as well as attract parasitic wasps that attack its attackers—the wasps lay their eggs in living aphids, which are then consumed from the inside out by emerging larvae. If the plant is connected via mycelia to other plants, those plants receive a chemical signal from their besieged comrade, and mount their own chemical defense before the first aphid arrives. Nearby plants that are not networked do not gear up for an attack.

Fungi can grow to be immense. A single *Armillaria ostoyae*—or honey mushroom—growing in Oregon covers 2,200 acres, or more than three square miles. It’s estimated to be 2,400 years old, and weighs more than six-hundred tons. For hundreds and then thousands of years, this fungus has lived below and at the surface of the soil. It has nurtured tree upon tree, forest upon forest. It has attended to the needs of these trees, the needs of this forest. It has fed them. It has witnessed fire and rain, snow and drought. It has been parent and child to this forest; lover and friend; killer, decomposer, creator. And through all of this it has built up the soil upon which all depend. Unfortunately, now it has also witnessed chain saws and clear-cuts. It has witnessed logging-induced destruction of soil. It has suffered herbicides and

fungicides. It has suffered logging roads that have cut it into pieces. It may very well be witnessing the end of the forest, the forest it has lived with and loved so well.

Many people think fungi are plants, but they are actually closer to animals. Fungi do not make their food from sunlight, as plants do. Like animals, fungi must find something to eat. Yet fungal eating is often generous: It makes worlds for others. This is because fungi have extracellular digestion. They excrete digestive acids outside their bodies to break down their food into nutrients. Nutrients are then absorbed into their cells, allowing the fungal body to grow—but also other species' bodies. The reason there are plants growing on dry land (rather than just in water) is that over the course of the earth's history fungi have digested rocks, making nutrients available for plants. Fungi, together with bacteria, made the soil in which plants grow. Fungi also digest wood. Otherwise, dead trees would stack up in the forest forever. Fungi break them down into nutrients that can be recycled into new life. Fungi are thus world builders, shaping environments for themselves and others.

Human bodies achieve a determinate form early in our lives. Barring injury, we'll never be all that different in shape than we were as adolescents. We can't grow extra limbs, and we're stuck with the one brain we've each got. In contrast, fungi keep growing and changing form all their lives. Fungi are famous for changing shape in relation to their encounters and environments. Many are potentially immortal, meaning they die from disease, injury, or lack of resources, but not from old age. Even this little fact can alert us to how much our thoughts about knowledge and existence just assume determinate life form and old age. We rarely imagine life without such limits—and when we do we stray into magic.

The idea of 'species' limits the stories we can tell about kinds. This binomial system of naming things is kind of quaint, but it is a complete artifact. You define things with two words and they become an archetypal species. In fungi, we have no idea what a species is.

A species is a group of organisms that potentially can exchange genetic material, have sex. That applies to organisms that reproduce sexually. So already in plants, where out of a clone you can have change as time goes by, you have problems with species. You move out of vertebrates to the cnidarians, corals, and worms, and the exchange of DNA and the way groups are made are very different from us. You go to fungi or bacteria, and the systems are completely different—completely crazy by our standards. A long-lived clone can all of a sudden go sexual: you can have hybridization in which whole big chunks of chromosomes are brought in; you have polyploidization or duplication of chromosomes, where a completely new thing comes out;

you have symbiotization, the capture of, say, a bacterium that allows you to either use the whole bacterium as part of yourself or use parts of that bacterium's DNA for your own genome. You've become something entirely different. Where do you break down the species?

For bees, having more diverse gut bacteria has been a successful evolutionary strategy. They were only able to evolve from their carnivorous wasp ancestors because they picked up new kinds of gut microbes that were able to extract energy from plant pollen. That allowed bees to become vegans. Beneficial bacteria provide bees with an insurance policy in times of food scarcity: they have no trouble digesting unfamiliar nectar from far-flung fields. More specialized digesters are not so well equipped. Times of crisis highlight the advantage of hosting a good microbial army. Bees with well-equipped gut flora can deal with parasite attacks better than those without. Gut bacteria are an incredibly important factor in this evolutionary survival strategy.

At a molecular level, bees' brains are quite similar to our own. It's not clear whether caffeine improves human memory. Some research indicates it doesn't, but when scientists recently looked at one very specific type of recall not carefully studied before, they found that it may be a memory booster after all. Intriguingly, the drug improves a kind of recollection we rely on for telling apart very similar but different objects, such as types of cars, hammers, or, ironically, flowers. It's pretty funny when you think about it. Caffeine is the most widely used drug in the world, and bees have been consuming it tens of millions of years before we showed up on the planet.

Even the simple animals are not the predictable automatons that they are often portrayed to be. Not even fruit flies, whose brains hold only 100,000 neurons; a cockroach, by contrast, has a million. If these small insects were mere reactive robots, then in a completely featureless room, they would move randomly. Some asshole glued them to small copper hooks and placed them in uniform white surroundings. Their flights were not random. Instead, they matched a mathematical algorithm for a pattern called the Lévy distribution. This search pattern is an effective way to find food, a method also known to be used by albatrosses, monkeys, and deer, and the flies made reasonable, not random, choices too. Scientists have found similar patterns in human behavior, in the flow of e-mails, letters, and money.

Flies even display individual variation in the choices they make. Most fruit flies typically move toward light when startled—but not all, and not with equal urgency. Harvard University researchers were surprised by the degree of individual variation the fruit flies in their laboratory showed—even among flies who were genetically identical. And like us, apparently fruit flies

make choices propelled by emotions like fear, elation, or despair. Another study found that male fruit flies, dejected after their sexual advances had been rejected by females, were 20 percent more likely to turn to drink (liquid food supplemented with alcohol in the laboratory) than males who had been sexually sated.

The platypus experiences more REM sleep—some fourteen hours a day—than any other known mammal.

In an intriguing parallel with human parents naming infants, green-rumped parrotlet parents name their young ones, who then use those given names to refer to themselves.

The spider-tailed horned viper of Iran wins big-time for the creepiest lure in nature. Think of a rattlesnake whose tail doesn't rattle, but instead looks just like a spider, with a bulb for an abdomen and little offshoots that look like legs. The well-camouflaged snake curls up and gives that tail a wag for hungry birds in the vicinity. When one takes the bait, the snake strikes, loading the poor bugger with venom. It isn't quite as fashionable as leg bristles, but then again, it's a spider-snake.

When it comes to mating songs, nothing on Earth can beat that of the lyrebird. When vying for the affections of the ladies, the male will pop his resplendent, almost peacock-like tail feathers over his head and prance around, all while belting an astonishing tune. It's part sci-fi laser, part high-pitched plucking of strings, and part impressions of other birds in the forest. In captivity, though, he'll imitate the surrounding cacophony: car alarms, drills and hammers (if he's in a zoo that's undergoing renovations), even camera shutters. It's all done so perfectly that it boggles the mind.

There are few gatherings more peculiar than those of the highly social pistol shrimp, which, as their name suggests, have evolved some of the most powerful weapons on Earth. Individually, they're intimidating, but as a group they make up armies and establish forts other creatures would be damned fools to try to conquer: These creatures form the sea's only monarchies, on par with the gatherings of ants on land. And their collective gunfire is deafening. The weapon responsible for all the racket is the pistol shrimp's enormous, grotesque-looking claw (only one—its other is a smaller pincer), which in some species can grow to half the length of the animal's body. By contracting certain muscles, the shrimp brings back one half of the snapper, which has a protruding bit known as a plunger, into a locked position while the second half, which has a socket, remains immobile. When the shrimp contracts another muscle, the two halves slam together, with the plunger striking the socket with so much force that water flies out of it at 105 feet per second. The impact forms what are known as cavitation bubbles, and when they collapse, they heat the surrounding water to 8,000 degrees

Fahrenheit and send out a shock wave so powerful that it can instantly kill prey. Strangely, it's not the impact of the claw itself that makes the noise, but the violent collapse of these bubbles.

We need to talk about the wasps. I don't mean the little yellow and black things that menaced your childhood summers. Those are lambs, quite frankly. No, I mean, in no particular order: the one with a sting so powerful a scientist who has experienced it recommends lying down and screaming until the pain subsides, lest you run around in a panic and hurt yourself; the one that stings a cockroach in its brain and drags the zombie into a den, where the wasp's larva devours it alive; the one that opts instead to inject caterpillars with its young, which consume the hapless crawler alive from the inside out. Wasps are unparalleled in their ability to inflict suffering on other creatures, insects who seemed so cruel to Charles Darwin that he insisted a beneficent creator could never have thought them up. But the thing is, in the animal kingdom, life in many instances sucks and then you die—as the saying goes. And out there, it's easy to die immediately. It's been that way for billions of years. For pretty much every creature (save humans), there's no slipping away peacefully in a comfy deathbed, because at any given moment some animal is trying to pull its head out of another animal's mouth. And I can guarantee you that something somewhere has a wasp larva consuming it from the inside out. Hell, a tree probably just fell on some kind of critter. A tree.

Many species of animals, especially insects, depend on stars to orient themselves when they travel at night. Moths, for instance, rely on the moon when they want to fly in a straight line. For example, when the moon is at its height and they want to fly west, all they have to do is keep the moon to their left. But moths can't tell the difference between the moon and a cozy lamp adding a decorative touch to a garden at night. Now, as the tiny, winged wanderer glides past the tulips and the roses, it immediately gets turned around. The brightest light at night must be the moon, mustn't it? And so it tries to keep this new moon to its left, but the lamp is unfortunately not 238,900 miles but only a few yards away. If the moth keeps flying in a straight line, the "moon" appears behind it, and it seems to the moth that it must have flown in a circle. And so the insect pilot corrects its course to the left to, as it thinks, continue flying straight ahead. This makes the "moon" appear on the correct side, but what's really happening is that the moth is flying in circles around the light. The spiraling flight takes the moth ever closer to the light until it finally ends up at the center. If the artificial moon is a candle, there's a brief 'puff,' and the moth's life is snuffed out.

But even without this dramatic finale, the moth is doomed. If it tries to fly a straight course all night and keeps ending up at the light, at some

point it will have exhausted its energy reserves. Its intent was to fly to night-blooming plants to fill up on nectar, but the few hours it has left to feed have morphed into an involuntary weight-loss program. And if that wasn't nightmare enough, predators have adapted their behavior to take advantage of the new normal. Spiders spin webs under the lights by our front door, because this is where they hit the jackpot. The moth starts its spiral flight around the light and continues until it inevitably lands on the sticky strands, where it is dispatched by the toxic teeth of the owner.

You might think creating something as complex as the satanic leaf-tailed gecko would be a drawn-out process that takes thousands or millions of years, and you'd be right. Evolution can take its sweet time with things. But then again, it can also progress with incredible speed. Take the peppered moth of Britain, a speckled creature adapted to hang tight on lichen-covered trees, thus avoiding birds. But it wasn't expecting the Industrial Revolution and the consequent pollution, which coated trees in soot. The peppered moth, though, would not fade quietly into extinction. It adapted, developing a darker coloration that was first observed in 1848. Just fifty years later, 98 percent of peppered moths were dark. And when clean-air laws took effect in the twentieth century, the moths went back to being speckled. The whole saga was evolution gone turbo. Predators were more likely to spot lighter moths when the environment became coated in soot; thus, the moths' darker counterparts prevailed and gave rise to soot-colored babies. When the habitat was clean again, dark moths struggled to survive; thus, lighter moths prevailed. And that, ladies and gentlemen, is an exceedingly rare pollution success story.

The stark differences in overwintering biology within one group of related animals shows that hibernation is less a strategy of avoiding the cold than of what they eat, of weathering famine.

The human animal is especially designed to be able to vomit. Other animals with this ability include apes, dogs, cats, pigs, fish, and birds. Those that are not able to vomit include mice, rats, guinea pigs, rabbits, and horses. Their esophagus is too long and narrow, and they lack the nerves that are so talented at vomiting. Animals that cannot vomit have to have different eating habits from ours. Rats and mice nibble at their food, biting off tiny pieces to test their suitability. They only continue to eat when they are sure the trial nibble has not done them any harm. If it turns out to be toxic, the most they suffer will be a bout of stomachache. They also learn not to eat it again. Furthermore, rodents are much better than us at breaking down toxins because their liver has more of the necessary enzymes. Horses, however, are not even able to nibble. If something bad ends up in their small intestine, the results can often be life threatening. So, really, we have reason

to be proud of our body's abilities whenever we find ourselves crouched over the toilet bowl throwing our guts up.

In the case of humans, knowledge of the harmful physical and psychological consequences of incest no doubt contributes to the prevalence of this taboo in most societies, but it's also a rarity in nature. Indeed, incest accounts for fewer than two percent of births in wild-animal populations. Scent, scientists began to think, might be nature's way of discouraging unfavorable biological pairings. Research suggests odor preferences do influence whom a person finds sexually attractive, but in a more complicated fashion than previously assumed. Among other things, it appears that such preferences can be altered by early life experiences. Strong support for this view comes from an experiment in which female mice were separated at birth from their own litters and placed in the litters of other mothers. Upon maturing, the females would not copulate with the unrelated males who nursed beside them on the same mother's nipples—their adopted brothers, if you will. In a reversal of the natural order, they chose to mate with their own genetic brothers. This suggests the scents of those who surround us when we're young leave a lasting imprint on the brain, defining our sense of kin and the kinds of odors we will later find sexually enticing. Nature's rule of thumb might be summed up thus: If he or she smells like someone you grew up with, look elsewhere for a sexual partner.

A chimpanzee female named Tina was killed by a bite to the neck by a leopard. She'd been living in a community of chimpanzees for quite a long time. The group didn't just pull at her body or tug at it or ignore it. Rather, the dominant male of the group sat with her body for five hours. He kept away all the other infants and protected the body from any harm with one exception. He let through the younger brother of Tina, a five year-old called Tarzan. That's the only youngster who was allowed to come forward. And the youngster sat at his sister's side and pulled on her hand and touched her body. The dominant male was able to recognize the close emotional bond between Tina and Tarzan, and he acted empathically.

Shamans and seekers eat mushrooms, drink potions, lick toads, inhale smoke, and snort snuff to transport their minds to realms they cannot normally experience. Humans are not alone in this endeavor; species from elephants to monkeys purposely eat fermented fruit to get drunk; dolphins were recently discovered sharing a certain toxic puffer fish, gently passing it from one cetacean snout to another, as people would pass a joint, after which the dolphins seem to enter a trance-like state.

Pause to ponder the metaphysics: an elk running for its life is converted to wolf flesh and wolf bone and wolf nerve whose dedication becomes chasing elk who run for their lives to avoid the fate that is pursuing them, a fate

built entirely from creatures just like themselves.

Such traits are clever only in retrospect. Design in nature is but a concatenation of accidents, culled by natural selection until the result is so beautiful or effective as to seem a miracle of purpose.

Chapter Thirty-four

Horror Highlight Reel

“I reached the old wolf in time to watch the fierce green fire dying in her eyes. I realized then and have known ever since, that there was something new to me in those eyes—something known only to her and the mountain. I was young then and full of trigger-itch: I thought that because fewer wolves meant more deer, that no wolves would mean hunter’s paradise. But after seeing the green fire die, I sensed that neither the wolf nor the mountain agreed with such a view.”

A particularly cruel but effective method was used to hunt whales. First they harpooned young calves to mortally wound them, knowing the mothers would stay close to their injured young, and the harpooner could then kill her.

The most disturbing and deplorable aspect of nineteenth-century encounters with polar bears was a perverse manipulation of the bond between a female and her cubs, a common amusement of sailors aboard whaling and sealing ships. William Scoresby tells of an incident involving walrus hunters who had set fire to a pile of blubber to attract bears. A female and two cubs drew near. The female settled her cubs at a short distance and then started trying to hook pieces of blubber out of the fire. The men watched from the safety of the deck as she fought with the flames. They threw her small bits of blubber, which she took to the cubs. As she approached them with the last piece, the men shot the two cubs dead. For the next half hour she “laid her paws first upon one, and then the other, and endeavored to raise them up.” She walked off and called to them, she licked their wounds. She went off again and “stood for some time moaning” before returning to paw them “with signs of inexpressible fondness.” Bored, or perhaps mortified, the men shot the female and left her on the ice with her cubs.

Xenopus laevis, is an aquatic, claw-toed frog that was used for pregnancy tests in women; when injected with urine from pregnant women, the frog would begin ovulating. When this was discovered in 1934, the frogs were caught by the tens of thousands in the wild and shipped around the world.

Over a period of forty years, feral populations of *X. laevis* were established in Britain, the United States, and Chile.

A male wolf called “Las Margaritas” had lost two toes on his left front foot from an encounter with a trap. In the late 1960s, he was killing dozens of yearling steers and heifers on ranches along the Durango-Zacatecas border.

“The wolf seldom used the same trail twice and if he came into a pasture by a log road, he left by a cow trail. I was sure I could catch Las Margaritas, but I couldn’t get him near a trap.”

A hunter tried baited traps and blind traps, traps boiled in oak leaves, and traps concealed in carefully sifted dirt. Nothing worked. Over months of intensive effort, he had managed to get the wolf close to a trap just four times. He traveled thousands of miles on horseback trying to understand the animal’s uncanny ability to elude him.

“Almost a year had passed and I was now convinced that I would never catch this wolf. Just how the wolf could tell the traps were there is something I cannot comprehend to this date.”

At times, however, he had noticed that Margaritas had paused at campfires along the road, places log-truck drivers had stopped along the way to cook.

“I set a trap near a road that the wolf was sure to come down if it continued to kill in the area, built a fire over the trap and let it burn itself out.”

The hunter put a piece of dried skunk hide in the ashes from the fire and waited. One day in March, the wolf caught wind of the setup and went to investigate. The trap caught him by his crippled foot.

In 2006 a German conservation group carried out a census of the hippos in Virunga Park. What they found shocked them and the global conservation community. Where the previous census had found more than 30,000 hippos, one of the largest and healthiest hippo populations on earth, this time they could find only 629 animals. The researchers flew in small planes to count the hippos along the shore of Lake Edward and the rivers that feed it, but instead of the expected hippo herds they saw Mai Mai rebels killing and butchering animals, and heaps of dismembered carcasses spread along the shore. It was slaughter on an industrial scale using machine guns and grenade launchers. Soldiers hacked out the teeth to sell as ivory, and long lines of enslaved porters carried away haunches of hippo meat to sell in town and village markets outside the park. Elephants and buffalo coming to the

shore to drink were also killed and butchered. The lake turned red with blood and stained the shoreline.

Whale sharks are being hunted for their large dorsal fins, which are used as billboards outside restaurants in Asia to advertise shark-fin soup.

I'll tell you the image I can't get out of my head. It's of a mother pig confined to a tiny crate, suckling her children. And singing to her children. Human supremacists have stolen her freedom, but they've not been able to steal her capacity to love. And humans—the ones who put her in the cage—are superior?

Here's another image I can't get out of my head. It's of a mother dolphin singing to her child. But they are both dying. Here's why. Mother dolphins nurse their young for eighteen months, longer than many humans. The mother dolphins love their children with fierceness and loyalty. Even when a baby dolphin is caught in a tuna net, the mother will often not abandon the child, but move in close, and comfort and sing to her baby until both are drowned in the net. Fishing companies acknowledge that most of the dolphins they kill are children and their mothers, who will not leave them even unto death.

A dead dolphin rots in the shore weeds; an oil-stained gull stands atop its corpse. The shore is littered with oiled marine creatures, some dead, others struggling.

“When we found this dolphin, it was the saddest darn thing to look at. There is a lot of cover-up for BP. They specifically informed us that they don't want these pictures of the dead animals. They keep trying to clean themselves. They try and they try, but they can't do it. Some of the things I've seen would make you sick. Nature is cruel, but what's happening here is crueler. No living creature should endure that kind of suffering.

A photo makes it look like one area. Until you get up here and see that it's as far as you can see in all directions. You can't get that in a picture.”

“Two weeks into the spill, we were at Pelican Island fishing under birds in about five feet of water, which is a common way of fishing this time of year. And a dolphin kept coming around. Its body was covered in that brownish oil, that tannish-colored crude. And he was trying to blow out his blowhole, and he was struggling. Porpoises scare fish, so I moved off a hundred yards. It followed. I kept doing that and it kept coming back, coming to us, hanging right alongside the boat. That's very

unusual. They're pretty intelligent, and it seemed to want help. But eventually I had to leave."

Leaning back against a red buoy, he began his tale. Not long before he had learned that a village on Kolombangara Island, Ghizo's next-door neighbor, had captured a pod of bottlenoses.

"They have a cove. It's much bigger than Gavutu. The dolphins swim in naturally, that's what they do. Now the villagers have realized that dolphins are worth a lot of money. This dolphin trade business—they've heard about it. So when this pod came in they closed off the entrance. And they held them there for almost a month, captive. When I heard about that, I straightaway went down there."

He arrived at Kolombangara and found fourteen dolphins, only half alive. Others had already died. The villagers hadn't fed them: they'd fully expected someone to show up promptly with wads of cash and whisk the dolphins away to the airport. He spent a week negotiating with the community. He was threatened and menaced; the people were not willing to let the dolphins go without a payout.

As he described that time, his shoulders began to tremble. Each day, he would go to the lagoon and see the dolphins languishing and feel powerless to help them.

"The people denied the very fact that they were suffering. I walked down to the water and this little calf came straight to me. He lay on my hands. I could see a lot of bruises on him. You could smell it, his body was infected."

He paused to collect himself, but tears had begun to roll down his cheeks.

"I spent eighteen minutes in the water with him. I was crying. I was crying in the water and I was shouting. The little one came with a message. He told me that I have to do something. Do something so that my family doesn't suffer as I am suffering. He came to me for his last breaths. Then he died in my arms."

He walked out of the ocean holding the dead calf, and, with the full force of his emotions, demanded that the villagers release the rest of the dolphins. The next day, they did. He took the calf, whom he had named Little Jacob, back to Ghizo and froze his body. On this next trip, he would bury the dolphin in a gravesite a local landowner had donated.

“Now I tend to believe that yes, dolphins do have feelings. They knew that I was trying to fight for their lives. They knew it.”

Let’s toast the memory of Buddha the Orangutan—a.k.a. Clyde—who co-starred with Clint Eastwood in the movie *Every Which Way But Loose*. On the set, Buddha simply stopped working one day. He refused to perform his silly routines any more and his trainer repeatedly clubbed him in the head with a hard cane in front of the crew. One day near the end of filming Buddha snatched some doughnuts from a table on the set. The ape was seized by his irate keeper, taken back to his cage and beaten to death with an ax handle. The axe handle that killed him was affectionately called, by his Gentle Jungle owners, the “Buddha club.” Buddha’s name was not listed in the film’s credits.

Some vivisectionists adopted a routine precaution: at the outset of an experiment they would sever the vocal cords of the animal on the table, so that it could not bark or cry out during the operation. This is a significant action, for in doing it the physiologist was doing two other things: he was denying his humanity, and he was affirming it. He was denying it in that he was able to cut the vocal cords and then pretend the animal could feel no pain, that it was merely the machine Descartes claimed it to be. But he was also affirming his humanity in that, had he not cut the cords, the desperate cries of the animal would have told him what he already knew, that it was a sentient, feeling being, and not a machine at all.

That act is an appropriate metaphor for the creation of a biological scientist out of a nature-lover. The rite of passage into the scientific way of being centers on the ability to apply the knife to the vocal cords, not just of the dog on the table, but of life itself. Inwardly, he must be able to sever the cords of his own consciousness. Outwardly, the effect must be the destruction of the larynx of the biosphere, an action essential to the transformation of the world into a material object subservient to the laws of classical physics. In effect, he must deny life in order to study it.

The scientific establishment makes it very difficult for people to manifest their love of the world.

In the earlier centuries of the Western world, before Charles Darwin persuaded people to respect monkeys as our close relations, they were generally looked down on as evil, wicked creatures, or as obscene hairy brutes, or the epitome of foolishness, motivated by the outlandish presumption that they can pass themselves off as human beings. Indeed, it is true to say that in the past they have suffered more from mankind’s exaggerated sense of his own superiority than any other kind of animal.

In ancient Rome the monkey was used as a token of humiliation in the punishment of individuals who had killed their fathers. The culprit was whipped, then sewn up in a sack with a monkey and various other animals and thrown in the Tiber or the sea to drown. The monkey was included in this terrible punishment because, as an ugly caricature of man, it was a suitable companion for those who had murdered their own flesh and blood.

One entertainment of sixteenth-century London was the Bear Garden. In front of cheering crowds, a monkey dressed in a little suit would appear on horseback. Then out would come an angry pack of bulldogs or mastiffs trained to attack the poor monkey. The sorry horse was attacked by the dogs as well but could last for quite a while, at least until the bears were sent in. Then, to the delight of the crowd, the horse, the dogs, and the little monkey (if he was still alive) all quickly became shrieking, thrashing, and bloody bear food.

Scientists have long used rhesus macaques in psychological research. In the 1950s, a sadistic shitbag named Harry Harlow performed a series of shocking studies on the monkeys. In one, he took newborn macaques and placed them in cages occupied by two artificial mothers. The first mother was made of chicken wire and was painful to hug; the other was covered with a soft cloth. Harlow attached a bottle of warm milk to the chicken-wire mother and left the fuzzy one milkless. He observed that some infant macaques preferred cuddling with the furry mother even if it meant denying themselves milk.

In another experiment, he placed macaques in a device he called the Pit of Despair, which extinguished virtually all external stimuli, including light. Then, after weeks or months or even years inside, he released them back into the company of their peers. He found that the longer they'd stayed in the pit, the more socially maladjusted they had become. Many of the formerly isolated female monkeys had lost all desire to mate, which was a problem for Harlow, as he wanted to see if their mothering instincts had also been affected. His solution was to build another device, which he chose to call the Rape Rack—because why not? He found that the females who had endured the trauma of both the Pit of Despair and the Rape Rack tended to become neglectful or even severely abusive mothers.

During the 1960s, American scientists conducted a series of experiments on monkeys which simulated extreme rear-end collisions, in the hope of then being able to discover the precise way in which these accidents damaged neck tissue. Too many of these caused paralysis or brain damage to the monkeys, without doing much to unravel the mystery of whiplash in humans.

Today, thousands of monkeys, mostly rhesus macaques and green monkeys, are subjected annually to painful laboratory experiments. The number

used each year in the United States is about 60,000; in Europe it is about 10,000. Animal welfare organizations have recently demanded a complete ban on this research, a move that has been met with horror by the medical community. Those demanding a ban argue that the extreme cruelty involved cannot be justified with such intelligent and sensitive animals. They attack the argument that monkeys must be used because they are so close to humans that results obtained from them can be applied to us. They point out that, if the monkeys are that close, then the procedures performed upon them are tantamount to torture.

Most primates are not used in experiments that study the diseases that kill most Americans. Projects that study primate psychology, alcohol and addictive drugs, brain-mapping, and sex in primates far outnumber studies involving heart disease or cancer. According to one report, 20,000 monkeys are imported into the United States annually for use in toxicity tests—tests that result in the deaths of the monkeys. Details of these tests are not made available to the public, and animal rights activists have taken to employing undercover agents to obtain these details.

This is how human medical research works: at the expense of other creatures.

In June of 2006, researchers reported in the journal *Science* the first unequivocal evidence for empathy between adult non-primate mammals. It was demonstrated that mice suffer distress when they watch a cagemate experience pain. Assholes injected one or both members of a pair of adult mice with acetic acid, which causes a severely painful burning sensation. The researchers discovered that mice who watched their cagemates in pain were more sensitive to pain themselves. A mouse injected with acid writhed more violently if his or her partner had also been injected and was writhing in pain. Not only did the mice who watched cagemates in distress become more sensitive to the same painful stimuli, they became generally more sensitive to pain, showing a heightened reaction, for example, to heat under their paws. The researchers speculated that mice probably used visual cues to generate the empathic response, which is interesting since mice normally rely most heavily on olfactory communication.

While not explicitly the focus of the experiment, it can be noted that the effect did not seem to cross the species barrier. The humans never seemed to become more sensitive or empathetic despite witnessing numerous painful responses.

The presence of another, less-traumatized mouse made it easier for the test subject to endure the pain. What was important was how long the mice had known each other. There were clear effects of empathy if the animals had been together for more than fourteen days, which is typical for wild

wood mice in Central European woodlands.

But how do mice communicate amongst themselves? How do they know another mouse is suffering and experiencing a private hell? To find this out, the researchers blocked their senses one after the other: sight, hearing, smell, and taste. And although mice like to communicate using smell and make shrill ultrasonic calls when alarmed, surprisingly enough, in the case of empathy, it is the sight of suffering companions that triggers their response.

Stressed individuals are less affected by the suffering of others. Strangers themselves are often the cause of this stress, and the sight of them releases the hormone cortisol. To verify this, researchers carried out another experiment, this time using a drug that blocked the production of cortisol in both students and mice, and feelings of empathy increased again.

Recently, scientists discovered that some species of mice love to sing. They fill the air with trills so high-pitched that most humans can't even hear them. If the melody is sweet enough, at least to the ears of a female mouse, the vocalist soon finds himself with a companion. Mice, like songbirds, have to be taught how to sing. This is culture, passed from generation to generation. If they aren't taught, they can't sing. So, what is the response by scientists to these mice, who love to sing, who teach each other how to sing, who sing for their lovers, who have been compared to opera singers? Given what the ideology of human supremacism does to people who otherwise seem sane, we shouldn't be surprised to learn that the scientists wanted to find out what would happen if they surgically deafened these mice. And we shouldn't be surprised to learn that the mice could no longer sing their operas, their love songs. The deafened mice could no longer sing at all. Instead, they screamed.

In response to the difficulty of motivating the animals, some researchers have used negative reinforcement—electric shocks—more freely than they would with other animals. Quite a lot of the early work done in the Naples Zoological Station treated octopuses badly. Not only were electric shocks used, but many experiments included the removal of parts of the octopus's brain, or the cutting of important nerves, just to see what the octopus would do when it woke up. Until recently, octopuses could also be operated on without anesthetic. As invertebrates, they were not covered by animal cruelty rules. Many of these early experiments make for distressing reading for someone who regards octopuses as sentient beings. Over the last decade, however, octopuses have often been listed as a kind of 'honorary vertebrate' in rules governing their treatment in experiments, especially in the European Union. How thoughtful.

If you take a lizard from his home, put him in a cage, and present him with a mirror, what the fuck do you want him to do with it? Let's turn this

around and see how you feel about it.

You're sitting in your home, minding your own business, when suddenly several unbelievably ugly creatures burst in. They throw a net over you and begin dragging you out the door. Members of your family rush to save you, and the unbelievably ugly creatures kill them with casual swats. You see one member of your family huddling in a corner, making sounds of terror you did not know humans could make. Another casual swat and the sounds stop. The net is hauled outside, and you are put into some sort of container. You feel the container being lifted, and then lifted, and lifted.

It takes what seems like hours for you to realize that what you've read about in the tabloids and bad science fiction novels has happened to you: you've been abducted by aliens. The aliens take you to their ship, and over the next days and weeks and endless months they perform tests on you. Do you think your behavior will be the same on their ship as it was in your home, with your family? Do you think your behavior will ever again be the same? And what if these aliens put something in your room, some thing you'd never seen before they brought you to this terrible place? Here, in this alien prison, you've seen them preening before it, and making gawdawful faces at it—at least you think those are their faces—and now they're staring at you—at least you think they're staring, and you think those are eyes. You look at this thing more closely. They evidently see—perceive is probably a better word, since you don't think those are eyes after all—themselves in it, but frankly their senses must be different than yours, because you don't see what's so great about it. Frankly it's creepy. But then again, so is everything about this place.

Because you failed to respond as they wished to this new device the aliens put into your cage, the aliens decide—quite rightly, according to their evidence and their belief system—that all you humanbeast-machines (as one of their philosophers puts it) lack self-awareness. At some point the aliens realize how important vision is to you, and that you see with your eyes. So in order to further their understanding of human behavior, and of course in order to get further grants, they surgically blind you. Sitting in the eternal dark of your cage in some unfathomably huge complex, unimaginably far from your home and from those you love—those who may be still alive among those you love—for some reason you remember an article you read years ago. It was about mice who love to sing, and about what happened to these mice, about how they were put in cages, about what scientists did to them then. Day after day—or at least you think it's day after day, since in your cell and in your own private darkness there is never any natural indication of the passage of time—you obsess about this article. But for the life of you, you can't figure out why it is so important to you.

How did we get so cruel? We forgot. We forgot our responsibility. And we forgot that we are as equal as any living thing within the chain. There's no hierarchy in this. Nah. We are part of the same family: living things. All the rest of it is just totally fucking bullshit.

Chapter Thirty-five

Resistance & Rebellion

There is not an organism on Earth which believes its life is for others to take.

“Until the lion has his historian, the hunter will always be a hero.”

—African Proverb

“These animals are generating profit. And I wish every species in the world would generate the level of profit these animals are for their companies. If that were the case we’d do more to protect them.”

Chunee was London’s first star pachyderm attraction. Born in Bengal, this male elephant arrived to the isle in 1810 and, for the next sixteen years, entertained the people of England. Princess Victoria, before she became Queen and paraded on the back of Jumbo, first marveled at the mighty Chunee. English writers, it seems, had a particular fascination with the creature. Charles Dickens, William Wordsworth, and Robert Browning each paid Chunee regular visits. Lord Bryon might have been his biggest fan of all. But it was not just the privileged and intelligentsia who were attracted to this elephant. Everyone wanted to see the famous Chunee: rich or poor, man or woman, adult or child. Even those living in rural England would make the occasional long pilgrimage into the city, in order to cast their eyes upon this giant beast.

Chunee resided at the Royal Menagerie. Opening in 1773 as a seasonal rest stop for circus animals, the Menagerie would eventually develop into a full-time zoo and remain in business for the next six decades, until closing in 1829. Over the course of these many years, a series of individuals and families owned the small zoo. First, it was owned by the Pidcock family. Then it was acquired by the Italian Polito brothers, Stephen followed by John. The final owner was Edward Cross, who was himself a former employee. Yet, throughout all of these changes, the function and operations of the zoo

remained essentially the same. The menagerie was, from the outset, a private enterprise designed to produce a profit. It provided entertainment at a low cost, and its audience was the general public. At the end of Cross's tenure, for instance, he charged an admissions fee of one or two shillings, depending on what attractions the individual visitor wanted to see. Moreover, as opposed to the Regent Park Zoo, which was at the time exclusive in its admittance policy and elitist in its mission, Cross carried on the tradition of catering to all people, regardless of class. Anyone who could afford the cost of a ticket was welcome through its gates.

The menagerie was housed inside of a large commercial structure. Known as the Exeter Exchange, the building was situated in the central part of the city on the Strand. Bizarrely, the menagerie did not sit on the ground floor of the building. Instead it occupied an upper story. This must have made for an awkward, if not precarious, arrangement, as accommodating a group of animals in the upper section of any structure, let alone one constructed in the seventeenth century, was probably not the wisest of decisions. This was especially the case with an adult, male elephant. For not only must it have been difficult to deal with the logistics of holding or moving a creature that weighed several tons and had several yards of girth, but what would happen if he ever got mad and started charging around the place? The Menagerie, for its part, recognized the danger involved and it tried to resolve these issues by having an enclosure specifically designed and built with the grown-up Chune in mind. This new cage, management hoped, would be strong enough to both support the elephant's weight and withstand any struggles.

As for the rest of the captive animals, they were exhibited alongside the walls in small, cramped cages. These cages were stacked on top of one another in a building-block arrangement. Tigers sat atop lions. New-world monkeys perched over old-world monkeys. All were camouflaged behind a maze of iron bars. None of this was particularly aesthetic, as the place had the feel and look of a warehouse more than anything. These types of displays were typical for the era. Museums and menageries often had large collections and very little concern for interpretation. Hence they would cram as many objects and specimens as they could into a singular exhibition. This arrangement, as overwhelming and unintelligible as it would appear to modern eyes, did not seem to bother nineteenth-century visitors. Regardless, such an environment could not have been a pleasant experience for the animals who had to live inside the cramped enclosures. There was no room to move, let alone to run, swing, or fly. Air circulation and proper sanitation were not concerns of the zoo. And external simulation, with the exception of looking at the audience, was something that was never going to be realized

by the captives of the Royal Menagerie.

Despite all of this, Chunee appeared, at least on the surface, to be remarkably well-adjusted. Many a visitor commented on his mellow disposition. He was an amicable, if not particularly affectionate, elephant. Chunee even performed a few tricks. There was one in particular that everyone loved. It involved him reaching out with his trunk and taking off a man's hat, which he would then pull back into his enclosure. Was the purloined going to be kept there? Would Chunee destroy it? Alas, after a brief minute, he returned the cap and placed it gently atop the gentleman's head. Well-done!

Sometimes, however, the trick did not go quite as planned. Chunee would smash an occasional hat. He would cover others with his dung and place them back on unsuspecting owners. He could be rough in the return process, leaving the visitor with a bruised head. Or he could just plain refuse to do the trick—no matter how hard his handler tried to make him perform. Indeed, Chunee could certainly be disobedient when he wanted to. He could even be deadly.

The first serious incident happened in 1815 when Chunee attempted to kill his handler, Alfred Copps. Copps was, at time, inside of the enclosure. He might have been training the elephant or just cleaning the cage; we do not know. But something set Chunee off, and Copps bore the brunt of his fury. Backing the man into a corner, Chunee rushed straight ahead with his tusks pointing outward. Remarkably, when the dust settled, the elephant saw that he had missed his target. The man remained alive, pinned against the wall with a tusk resting on either side of his body. Copps must have breathed a sigh of relief; that is, until he saw Chunee's trunk coming down fast upon him. In between the blows, the handler must have been cursing himself for ever taking that job. In the end, he survived the beating but only because Edward Cross intervened at the last second and created a diversion with a well-placed thrust of a pitchfork into Chunee's backside. Copps chose never to return to the Menagerie.

The next man in line for the job was George Dyer. By all accounts, Dyer was a particularly wicked trainer, who enjoyed using a twelve foot spear as his vicious method of encouragement. Yet Chunee was never without recourse. If Dyer stuck him in the side, he could always respond with a spray of dirty water or a strike of his trunk. Once Chunee hit the handler square across the face, breaking Dyer's nose. So powerful was the blow that physicians were unable to set the nose in a proper manner, thus leaving the man permanently disfigured. Fights between Chunee and Dyer became so bad that the owner was forced to hire an assistant. Cross wisely selected someone with experience.

This was John Taylor, and he definitely knew a thing or two about the

animal business. Not only had Taylor spent much of his adult life working with captive animals, but he paid a steep price in gaining this experience by having an arm chewed off years earlier by a circus lion. Despite this gruesome injury, Taylor returned to the profession and remained congenial towards other creatures. In fact, Taylor was a strong advocate of non-physical training methods. No animal, he believed, should be abused. This enlightened philosophy differed markedly from Dyer's brutal way of thinking, and Taylor often complained to Edward Cross about these differences. So bitter did the infighting become between the two men that Cross got sick of hearing about it and fired both of them.

Chunee's next handler was Richard Carter. He, like Dyer, preferred an aggressive, violent approach to elephant management. Using a long, razor-sharp spear, Carter was determined to keep the elephant in line and retain his job. But Cross was not so confident. He believed that, in addition to physical force, a new means of control was needed. Cross ordered the staff to begin the drugging of Chunee. These experimental psychiatric dosages, in combination with large quantities of ale, would, Cross hoped, keep the menagerie's prized exhibit in a calm, malleable state. But the daily doses of booze and drugs didn't sedate the embittered elephant.

By late 1825, Chunee was out of control and literally tearing the place to pieces. He rammed against the walls. He butted against the beams. He pounded the ceiling, sending pieces of it flying everywhere. The specially-engineered enclosure was failing, and Cross thought that the entire building itself might collapse. The final straw came when Chunee gored an assistant, killing the man. Cross decided that the elephant must be put to the death.

At first, the staff tried using poison. They mixed it in the elephant's daily feed and waited for the inevitable. But Chunee just stood there, refusing to eat. Next, they bought several of his favorite treats, hot buns, and injected one of them with the deadly toxin. Chunee, as always, greeted the perquisite with a cursory sniff before commencing with the snack. He ate them all. All, that is, except the poisoned one. The would-be assassins then tried to trick the elephant by having an innocent-looking visitor present the buns. But Chunee did not buy that either. The Menagerie was forced to devise another method of execution.

Cross enlisted the help of the Metropolitan police. The following day, three constables arrived to the Exeter Exchange with their rifles. Cross led the men upstairs and lined them in front of Chunee's gated enclosure. The men aimed and opened fire.

"I expected to see him fall. Instead of which he made a sharp hissing noise, and struck heavily at us with his trunk and

tried to make after us, and would have but for the formidable double-edged spear blades of the keepers.”

Chunee was tougher than anyone had expected. This was going to take some time, and Cross needed advice. Besides a hunter, he wondered, who would best know how to kill such an animal?

Cross settled on a physician and sent an employee to gather one. When the medical doctor showed up, he directed as to where best to shoot the beast in order to quicken the kill. Yet Chunee refused to be a stationary target. As the constables fired, the elephant kept moving from side to side and front to back, and avoided being hit in the vital areas. Growing increasingly desperate, Cross sent another employee to Somerset House. Perhaps, he thought, professional soldiers would have better aim.

With fourteen of them standing at the gates of the enclosure, they too opened fire. But Chunee still would not fall. Indeed, the scene itself had descended into a kind of nightmare, with blood in the cage rising to an almost ankle-deep level. This execution, Cross bristled, had to come to an end, and he ordered for more powerful rifles and ammunition. The soldiers, once re-armed, began shooting again. When this appeared to fail, Cross called in for a cannon. It was not to be needed. The 152nd musket ball finished the deed, and Chunee died.

Jumbo had now entered into adolescence. Modern zoologists call this developmental period: musth (Hindi word for madness). And they define it as a phase of glandular secretion, higher testosterone-levels, and heightened sexual arousal. In other words, this is a case of over-active and uncontrollable hormones; otherwise known as “heat.” One would have hoped that the fields of natural science would have moved beyond the seventeenth century and biological determinism. But to no avail.

Non-physiological factors—such as captivity, poor labor-conditions, brutal training methods, or the grind of the entertainment industry—do not matter. Intellectual maturity and independence of mind are not considered. Rebellious attitudes and vengeful emotions do not exist. Freedom, or the desire for autonomy, is something that an elephant could never imagine. Agency is a non-concept.

But Jumbo was no scientist, and he certainly did not see himself as a machine. Resistance was his new thought. He flew into terrible rages. He tried repeatedly to escape. He hurled his body against his enclosure. On one occasion, while attempting to ram his fearsome tusks through the iron-doors of his exhibition cage, Jumbo injured himself so severely that surgery was required. Matthew Scott oversaw the procedure and, as usual, was able to calm the giant beast. The keeper’s most successful method to soothe the

elephant's nerves actually involved supplying Jumbo with large quantities of beer. This even became a ritual between the two: drinking time. Once, when the trainer forgot to give Jumbo his share of the nightly brew, he was slammed to the floor by the thirsty giant. Scott never made that mistake again.

Yet, there were times—increasing in number as the years wore on—when inebriation did not work to quiet the elephant. It reached a point where Regent Park directors lived in constant fear of what Jumbo might do next. So afraid did they become that the principle director purchased an elephant gun for the protection of the zoo and its employees. If a fight ever got completely out of hand, Jumbo would be shot dead.

It is notable how many alcoholic handlers there have been over the years. Circuses seem to be full of them. Perhaps, this is a sign of how lax the industry is in its hiring practices. Or, possibly, all of the drunkards are a symptom of a larger problem: elephant training itself was and is a morally corrupt enterprise.

P.T. Barnum's American circus, promoted as the Greatest Show on Earth, was lacking a center piece—that truly grand figure among other great spectacles. Barnum's archrival, the Cooper and Bailey's Allied Show, had its star: the baby Columbia. She was the first elephant ever born in captivity in the United States, and Barnum had made many bids to purchase her. But the Allied Show refused to sell. So Barnum did the next best thing, luring James Bailey to his side, and then went right on searching for another big-time celebrity. He soon found what he was looking for in London. This was Jumbo, a true icon with enough star power to fill his big top every night of the week. Barnum offered the zoo \$10,000 for the elephant.

The Regent Park directors were elated. This was a lot of money, and Jumbo had simply grown too dangerous to keep. He had to be sold. The zoo, however, was not prepared for the sheer scale of negative publicity that it would receive regarding this move. The British public was outraged at the idea of shipping Jumbo off to the States. Thousands of children wrote letters to the Queen in protest. Lawsuits were filed to block the sale. Newspapers openly vilified park administrators. Yet, the zoo would not be swayed from its decision.

In the spring of 1882, patrons funneled in to catch one last glimpse of Jumbo and wave good-bye. Crowds of this size had never before been seen at Regents Park, and the zoo itself profited handsomely from this planned farewell, pocketing \$40,000 in ticket sales alone. But the final day did come, and the elephant was escorted from his exhibit area and led onto the main grounds. The original plan was to load Jumbo into a large container, which would then be paraded through the London streets. The journey would end

at a Thames quay for shipping. This plan, though, proved to be a far more difficult to carry out than first imagined. For Jumbo declined to enter the container.

Matthew Scott, his trainer, tried every technique he could think of to coax the huge elephant into the crate. But each time, Jumbo would approach, stop short, and proceed to lie down on the ground. After that, there was no budging him. As the days passed and embarrassment mounted, the London press declared that this delay was a testament to the fact that the elephant did not want to leave England. Barnum was not amused, and his agent in London grew impatient. The circus's chief handler was sent for. William Neuman, otherwise known as Elephant Bill, was Barnum's most notorious and brutal trainer. Instead of offering a gallon of pale ale, Elephant Bill opted for a spear-like lance as his primary motivational tool. After his trip across the Atlantic, Neuman set to work straightaway at the reconditioning of Jumbo.

At first, the trainer tried more gentle means of persuasion: verbal commands, pushing, prodding. But none of these were successful. Next, he fitted the elephant with leg chains and pulled on the beast. This method too failed. Jumbo just flatly refused to enter the container. Neuman then pulled out his trusty lance and began using the weapon, but the Royal Society for the Prevention of Cruelty to Animals intervened and put a stop to the stabbings. Neuman was furious: both at this level of oversight, which would have never happened in the US, and at his own inability to quell Jumbo's recalcitrance. It was rumored that the American trainer even threatened to shoot the elephant, if that was the only way to get the animal to Barnum. Ultimately the use of lethal force was not needed, as Scott was finally able to convince Jumbo to walk into the crate. Some speculated that Scott himself was partially responsible for this delay, as he wanted to demonstrate his own self-importance.

Nevertheless, after chaining the elephant into place, the trainers found themselves in trouble once again. Jumbo had abruptly changed his mind about the move and began to struggle with all his might, straining the iron chains and quaking the thick bars of the wheeled enclosure. But it was of no use. Not even the world's largest elephant could break free this time. Jumbo was taken out of Regents Park and transported down the Thames to the coast. From there, the elephant was hoisted onboard the HMS Assyrian Monarch for his long awaited trip across the Atlantic.

There are several versions of events that unfolded on September 15, 1885: the night that Jumbo the elephant was killed. Each begins in a similar manner. The circus was in St. Thomas, a small town located in the southern region of the province. The final performance had just ended. Tom and

Jumbo were in the process of being led back to their respective train cars by Matthew Scott. While all three were walking along the tracks, the sound of a fast approaching freight train could be heard in the distance. It is at this point where the stories diverge.

One version has Scott, heroically but unsuccessfully, attempting to lead the elephants to safety by guiding them down a shallow embankment that bordered one side of the tracks. Another has the trainer scrambling off on his own, leaving the pair of elephants to their own devices. In both scenarios, the first to be hit by the locomotive was tiny Tom Thumb. Tossed into the air like a rag-doll, he crashed into a nearby pole and sustained serious, but not life-threatening, injuries. Tom, years later, would be sold to the Central Park Zoo in New York City, where he would spend the rest of his days. Jumbo was the next to be struck.

It happened in one of three ways. The first account has the elephant initially following Scott down the embankment. However, Jumbo got confused or scared by the on-coming train, raced back up onto the tracks, and was hit from behind. Another has Jumbo rushing along the tracks. He was apparently looking for a gap in the line of stationary train-cars, which bordered the opposite side. But he missed the opening, and, when he doubled back, the train smashed into him. A third version has Jumbo escaping from Scott and charging towards the train. He rammed the engine head-on.

As for how Jumbo ultimately died, that also depends on which version of the story you believe. Some said that the world's most famous elephant was killed almost immediately. While others stated that he suffered for at least three hours before dying. Barnum himself cooked up his own tall tale: claiming that Jumbo died instantly after sacrificing his own life to rescue little Tom Thumb from the speeding train. In the end, none of these unknowns, discrepancies, or fabrications are important. Jumbo died that autumn day. He spent his life enslaved by the Regents Park Zoo and the Barnum and Bailey Circus.

The morning of September 12th began as most mornings did at the Sparks Circus. The animals were awakened and led out of their boxcars. Some were then loaded into wagons and carriers. Others, namely horses and elephants, were put to work. For each of these wagons and carriers had to be towed and pushed to the circus grounds. Every piece of equipment had to be carried. The most extensive labor involved setting up the big top. Gigantic poles had to be moved into their correct place. The canvas itself had to be unfolded and positioned just right. Cables had to be pulled to raise the entire structure. Indeed, without the bulk and strength of the elephant, this final feat would have hardly been possible.

With the morning tasks now complete, the circus's five pachyderms received a short but well deserved break. Their ankles would, as always, be chained and tethered to deter any inclinations of escape. Water and hay would be provided as their standard fare. The animals really needed this rest and nourishment, for their day was just beginning. Soon there would be the noon-time parade. This meant a complete shift in tasks: from manual labor to public entertainment. The elephants had to change into their costumes and march through the streets. They had to mull around with the local residents, pose for photographs and sketches, and give a few rides. They had to be happy, at least in appearance.

Next, there would be the two performances under the big top: a matinee at 14:00 and an evening show at 20:00. The elephants had to perform choreographed routines and tricks for the audience. They had to kneel on command. They had to stand on their hind legs. They had to balance on stools. They had to form a large circle with each elephant resting his or her front legs upon the back of another. None of this was easy. Elephants know nothing of such things, as circus performances are not part of their society or culture. Nor do elephants, as strong and formidable as they may seem, even have the proper muscle development to carry out such demanding stunts. It takes months of rigorous training to learn these routines. It takes months to develop the stamina and muscle strength needed to perform these tricks.

Then there is the harsh discipline and brutal treatment that each elephant had to endure in the name of training. Verbal abuse, beatings, and whippings were the common pedagogical methods. For example, in order to teach a performer how to lie down on cue, Charles Mayer—the leading elephant coach of the early twentieth century—would stab an animal in one particular spot over and over again. Sooner or later, the elephant would lie down to protect the wound. After this procedure was repeated enough times, an amazing trick would be born: as the mere threat of being stabbed caused the animal to obey the command.

Finally, the circus would be packed up to travel to the next town for the next show. The tent had to be taken down and disassembled. All the equipment had to be reloaded. The wagons and carriers had to be hauled back to the train. It was only then, well into the witching hour, that the long, exhaustive day would finally come to a close. Unfortunately, another morning was soon on its way.

There were times, however, when the elephants did obtain reprieves from this monotonous, tiresome schedule. The most common type were short recreational walks. With a handler guiding them along, the elephants might amble into to a nearby field, explore a neighboring wooded area, or walk down a dirt road. Maybe, if they were lucky, they would discover a pond

or a nice patch of mud. The ultimate point of these ventures was simply to get away from the circus—so that the animals could take in the sights, breathe some fresh air, and have a little natural stimulus. Not all of these walks were pleasant affairs however.

While walking through Kingsport, Mary espied some watermelon. This sighting must have spiked her curiosity, as she stopped and reached for the rind. The temporary pause perturbed her handler. At first, he slapped at the elephant with a long stick and shouted for her to move along. Mary ignored the request and just kept chewing away. Some of the people watching this disagreement found it to be most comical and they began laughing aloud. The trainer was now growing embarrassed. He yelled angrily and struck the elephant viciously across the side of her head. This impetuous act of violence was not a smart move. Mary grabbed the man with her trunk, raised him high into the air, and pitched him against the side of a nearby shack. Such was the force of this throw that the trainer crashed through the building's wall. With the thump of the body, the snap of the wooden boards, and the crunch of bones, the crowd stood there in a state of shock. Was the man dead? Was he still alive? Would anyone dare attempt to help him? But Mary put to end to such thoughts, as she walked calmly over to her handler and promptly stepped on his head. The crowd scattered.

No one is certain how the method of execution was chosen. Legend has it that several means were discussed: poisoning, electrocution, and even draw and quartering via two opposite pulling steam-engines. Yet we do know the final decision. It was to be death by hanging. This was the South and lynching was the common form of punishment for those who dared resist the power and privilege of the white man. In fact, a few witnesses later swore that one or two African-Americans were also hung that afternoon in the hamlet of Erwin. But for Mighty Mary, a rope and tree branch would not do. A much larger and sturdier device was required. A 100-ton industrial crane was ultimately commandeered for the task.

By the time Mary was put into position under the crane, 3000 men, women, and children had gathered around the train yard. This crowd swelled to a size far greater than tiny Erwin's entire population. Apparently, everyone in the surrounding Tennessee counties wanted to see this infamous elephant be put to death by the hand of man. None of them were to be disappointed. The derrick car started up and a winch lowered a heavy metal cable. At the end of the cable was a linked chain. A handler grabbed the device and fastened it around the elephant's neck. The steam-powered engine began to roar and tow upward. Mary, though, was not about to go without a fight. As the noose tightened and pulled, she began to struggle and twist her body. The cable was not strong enough to withstand both

the weight and the strain. It broke and Mary came crashing down with a thunder.

The spectators erupted in panic, for the killer elephant was now free. Would she stampede through the crowd? Would she target her trainers? Or would she attack the rig and tear it apart? In reality, Mary was in no condition to retaliate. The fall shattered her hip. Collapsed there in a heap, immobilized and in agonizing pain, Mary must have been a pitiful sight. But her handlers were unmoved. Instead, they refashioned the noose and slid it on once again. This time, Mary was unable to free herself. The happy spectators settled back in and watched as the elephant died of asphyxiation.

Tyke was born in Africa in 1973. She was—as are most captive wild elephants—just a baby when she was captured and sent to North America to work in the entertainment industry. Where once this little elephant had a mother, she now had none. Where once she had a family, Tyke now was confined among complete strangers. John Cuneo was her new owner, and this elephant now had a job. Tyke was to spend the rest of her life performing in the circus. That life came to a tragic end in Honolulu, Hawaii

Tyke was being leased out to Circus America, a company that she had worked for in the past. During this particular tour, the show had traveled all the way to the Pacific islands of Hawaii. The trip from the mainland must have been a difficult one, and the animals could not have been pleased with the arrangement. Indeed, this leg of the tour only served to exacerbate a tension that had been building between the circus pachyderms and their trainers.

It was soon after crossing the Pacific that an elephant named Elaine went out of control and injured a family of visitors during the middle of a show. According to witnesses, the elephant had been performing inside of the ring, when she appeared to ignore a command. Her trainer became visibly upset. Elaine ran from the man and slammed into the protective fencing that separated the audience from the animals. A section of the guardrail buckled and collapsed under her weight, falling on top of a family of ten. There, the father, mother, and eight children remained trapped, until Elaine could be calmed and the heavy fencing removed. This must have been a frightening experience, with the entire family only steps away from being crushed to death by an elephant. Yet, Elaine chose not to hurt them and they sustained only minor injuries. But this incident was only a prelude to the frenzy that would break out five days later.

The Saturday matinee was already in full swing. The stands overflowed with parents and their children, each with his or her own personal bag of popcorn and tuft of cotton-candy held tightly in hand. Sounds of chatter and glees of excitement filled the arena. A growing charge of anticipation

could be felt circulating throughout the arena, for the crowd could now see five enormous beasts waiting to make their entrance into the center ring. The elephant show was about to begin.

Oddly, it was a groom—the person in charge of caring for, feeding, and cleaning up after the animals—who first came into the ring. Even more strange was the fact that this person seemed as if he was running for his life. What was happening here, the audience must have wondered? And who exactly was chasing this man? They soon found out, as one of the elephants sprinted into the ring and knocked the groom to the floor. This was Tyke, and she was mad as hell. The elephant kicked the man. She picked him up and threw him down. She was in the process of stomping him, when a trainer came into the ring. Tyke stiffened, turned around, and charged—killing the handler under the weight of her body.

By this point, the audience was in an uproar. Some remained frozen to their seats, paralyzed by fear. Others rushed for the exits. Tyke decided to follow the example of the fleeing patrons. She busted through the railings of the ring, found a doorway large enough to accommodate her bulky size, and fled the arena. Roaming outside in a parking lot, she spotted a clown and chased after him. But when she noticed someone trying to close the main gate, thereby trapping her inside in the lot, she flattened him instead. The angry elephant then made her way into the streets of central Honolulu. One driver, noticing an approaching elephant in his rearview mirror, wisely pulled off to the side and let the animal pass. Tyke ran wild for several blocks before the police finally cornered her. Wasting little time, they opened fire—riddling the escaped elephant with eighty-six bullets. One witness captured the bloodbath on video. Tyke, with her star-emblazoned headdress still on and blood streaming down her legs, collapsed in the road. Laying there motionless, she remained alive. Officials called the city zoo. Its employees soon arrived and gave the elephant a lethal injection. The problem was that it did not work. So the police stepped in again and placed three more bullets into Tyke's body.

Sadly, Lota showed up emaciated and dying of TB. She had spent thirty-six years at the Milwaukee County Zoo in Wisconsin. But due to her continued misbehavior and resistance, Lota was ungraciously sold to Cuneo in 1990 as a punishment. Interestingly, when responding to concerns about this sale, the zoo director, Charles Wikenhauser, mocked them as foolish and sentimental, adding with a wagging finger that people should really focus their attention on human issues. Lota was, after all, just an animal.

A Great American Circus elephant pummeled a trainer during a show in Pennsylvania. Audience members later detailed how the animal, only seconds before the attack, refused to obey a series of instructions. The

handler, at that point, commenced hitting the performer in the left ear and eye with an ankus and then hooked the creature's mouth with the barbed point. This type of corrective violence towards elephants is usually kept well-hidden by circuses but, on rare occasions, it makes a public appearance for all to see.

This was the situation with Mickey the elephant in September of 1994. This fifteen-year-old elephant was working for the King Royal Circus. During a performance in Lebanon, Oregon, he refused to perform a trick. The trainer shouted and promptly gouged the elephant in the neck with the bull-hook, drawing blood and gasps of horror from the audience. A few people called the cops. After the show, the handler was arrested and dragged off to the city jail. Responding to the brutal act, the King Royal manager fumed:

“These animals can become killers. What I'd like to do with these protesters is take our nicest elephant and put it in their back yards for about an hour. Then they'd see just how much destruction one of these guys can really inflict.”

San Diego, California—it was 1988 and Dunda, an African elephant, was being punished for her continued disobedience at the city zoo. Trainers had chained each of her legs and pulled them taut. The trainers then went to work on Dunda with ax-handles and clubs, beating her for two straight days. When a video of this was shown on a local television station, the viewers reacted with disbelief and rage. Stung by the intense response, the San Diego Zoological Society brought in two outside consultants, Gail Laule and Tim Desmond, to commence the implementation of a new program of elephant management.

Zoos and circuses will on occasion admit to this fact: that the relations between animal handlers and elephants are primarily antagonistic, coercive, and, often, violent. This is a question of domination and resistance; the answer of which is played out every day behind the doors of these institutions. In other words, we can think of these relations as a dynamic, whose outcomes are determined through a process of negotiation.

On the one side, there are the zoos and circuses. They attempt to impose control by using everything from repetitive action, to physical abuse, to gastronomic bribes, to verbal intimidation: the goal of which is to instill obedience, servility, and profitability among the captive animals. Theirs is a management of exploitation. On the other side of the equation are the elephants. They seek to survive this predicament, and, if possible, obtain some influence over it. Theirs is a struggle against exploitation, and it can take many forms: ignoring commands, slowing down, refusing to

work without adequate food and water, taking unofficial breaks, breaking equipment, damaging enclosures, fighting back, or escaping.

Much of the time, it is the institutions who ultimately win out in these negotiations. But, occasionally, the elephants succeed in their rebellion. The victory may be ephemeral: extra hay or carrots. It could be partial: long-term change in training techniques. Or it might be historic: release to a sanctuary. In the case of Tillie and her latest outburst, the Tampa zoo quickly sought to regain dominance. The elephant was taken to “the privacy of the barn,” chained, and disciplined. After being tortured, Tillie was put through a set of commands to see if she would obey. She did and was placed back on display. The relative calm, however, did not last long.

Wankie, for her part, never again saw her calf. She died in 2005, somewhere in the middle of Nebraska on Interstate 80. The Chicago Lincoln Park Zoo, who then owned the elephant, had sold her to Salt Lake City. Evidently, Chicago’s two other elephants, Tatima and Peaches, had just died of mycobacteriosis (a disease causing lameness). Wankie was also infected and dying. Local citizens wanted her taken to the sanctuary in Hohenwald, Tennessee. Park officials, however, denied the request. Instead, they sent Wankie on a 1400 mile trip in the back of an unheated semi-trailer. With temperatures dipping below freezing and attendants bickering about whether to place a tarp over her crate, Wankie collapsed. She did not get up. Was Moja, her calf, in her final thoughts?

This Tennessee sanctuary has always been ready, willing, and able to take in any female elephant, regardless of her reputation. Yet, there was a significant obstacle standing in the way of this move. Namely, zoos will do almost anything to avoid confessing that they might not be able to adequately care for or tend to an animal. And they certainly do not want to admit that an animal can, by his or her own actions, force a zoo into a counteraction—that is, to actually force a zoo into releasing him or her to a sanctuary.

This is why the governing body of the industry, the AZA, refuses to concede that Hohenwald exists. For true sanctuaries, in its mind, cannot be an alternative. To acknowledge them would be a fatal admission that an animal might be happier and healthier while living in another location or place. This arrogant stance on the part of the AZA suffered a recent blow, when an extensive study was released in the journal, *Science*, that showed captive elephants as having half the life span as their counterparts living free in Asia and Africa. But the zoo industry is very stubborn. It has chosen to ignore the data altogether and remained firm in its position.

Tatiana the Tiger, confined for years in a small enclosure at the San Francisco Zoo, finally reached her limit after being tormented by three

teenage boys on Christmas day 2006. She leapt the twelve-foot high wall, snatched one of the lads in her paws and eviscerated him. She stalked the zoo grounds for the next half-hour, bypassing many other visitors, until she tracked down the two other culprits and mauled them both before being gunned down by police.

Significantly, the zoological industry has always had trouble in dealing with cruel and sadistic behavior on behalf of visitors. Some parks have attempted to tackle the issue by posting warning signs and hiring more security guards. Others have chosen to ignore it. Few have ever admitted publicly how frequently captive animals are tormented by zoo visitors. The hard truth is that teasing is endemic at zoos, and it is perpetrated by both children and adults.

The sight of visitors yelling, screaming, and banging on windows and fences is normal. People hurl rocks, coins, bottles, cans, and other objects at animals. Cigarettes butts have been found in cages for as long as there have been cigarettes. Sometimes, even needles, pins, nails, razorblades, and shards of glass find their way into exhibits. Every year an undetermined number of animals die, or become ill, due to the accidental ingestion of foreign items tossed into enclosures by visitors. Can visitor behavior possibly get worse? Yes, it can. Animals have been poisoned at zoos. They have had acid thrown on them. They have been punched and kicked. They have been stabbed and shot. Pellet-guns seem to be a particularly favorite weapon among visitors.

In December of 2008, three macaques in the Guangdong Province of China attacked their owners. They were street performers by trade, skilled in bicycle riding. Such work is hard and the discipline can be severe. During one performance, one of the monkeys refused to carry out a command and was beaten with a large stick in response. The two others saw this and turned upon their owner: pulling his hair, twisting his ears, and biting his neck. The injured macaque then picked up the fallen stick and hit the man in the head with it until it broke. "They were once wild and these performances don't always come naturally to them," the owner confessed. "They may have built up some feelings of hatred towards me."

"Gorillas go through a stage where, physically and psychologically, they're growing much stronger, and become much more lean and long, and containment can be an increasing challenge."

Gorillas can resist their captivity. Indeed, whether this employee fully grasped the potency of his acknowledgment or not, the fact is that these

animals do have a long history outmaneuvering and overcoming the very best of ideas and designs deployed by zoological parks.

In one incident, Jim made it out after noticing that someone had forgot to lock his cage. Gorillas constantly keep a close watch on this sort of thing. They know the comings and goings of employees and volunteers and whether or not all doors have been securely fastened.

Togo, a gorilla at the Toledo Zoo, once ripped off the entire roof of his exhibit. He also, on several occasions, bent the bars of his cage and attempted to slip out between the gaps. But, perhaps his craftiest idea came when the zoo placed him behind a thick layer of shatter-resistant glass. 'Let's see the gorilla get out of this one,' his overseers must have laughed. Never without a retort, Togo studied the new structure for a moment and then began removing the putty that held the window in place.

Being notorious escape artists, orangutans may dismantle their cage so patiently, from day to day and week to week, while keeping dislodged screws and bolts out of sight, that keepers fail to notice what they are doing until it's too late.

It was not long after being released, now for the fourth time, that Ken made yet another attempt at escape. On this occasion, the zoo's spies were finally able to catch him in the act. He was hip deep in the shallow end of the moat when he pressed his feet against one wall and his hands against the other. Slowly, he inched his way up. The keepers were amazed for two reasons. First, orangutans are supposed to be intensely hydrophobic. That's why zoos use water-filled moats as a deterrent. Second, they had no idea that an orangutan could climb in that manner.

Such feats, though, are not unheard of. At the Houston Zoo, for instance, Mango once escaped by pressing his fingers against a glass edge, toes against another nearby edge, and scaling his way upwards.

"It's incredible. There wasn't even enough to grasp. It was all finger pressure."

Organization and mutual aid are essential aspects in many animal cultures, including elephants, gorillas, and chimpanzees. Zoos, however, are places wherein that culture is restricted, altered, or even destroyed. This is done, whether intentionally or not, through the removal of autonomy, the break up of the family unit, restrictions on corporeal movement, continuous transfer of animals from one facility to next, and in the alteration of other living patterns. Psychologists call this a process of alienation and institutionalization. Hence, within these species, what we tend to see in zoos is a much more individualistic-based community.

Yet, orangutans are highly solitary creatures. They spend much of their time living alone in the trees and rarely have much contact with each other. But in captivity, this world is turned upside down. Orangutans are now thrust together in very confined circumstances. They have to learn how to live together in groups. Thus, in a unique twist, not only have orangutans come to adapt to this particular environment, they have developed organized means to overcome it.

“She has learned how to ground the hot wire. She’ll take sticks and pieces of wood and lean them up against the wire so that it is grounded. Then she pulls herself up by using the porcelain insulators on the wire as hand-holds. I’m not sure I would have been able to figure it out.”

To many specialists, the name of the game was “collecting,” taking a handful of whatever you found, or one of anything that seemed rare or unusual. In the past, being an ornithologist had basically meant being a good shot, striding through the marsh or the tundra or the jungle with a pair of binoculars in one hand and a 12-gauge shotgun in the other. A scientific journal called the *Oologist* summed up the philosophy in 1892:

“The murre, common as it is, is a beautiful bird, and a nicely mounted specimen vies well with most seabirds in one’s collection.”

Frank Buck had considerable experience in dealing with the red ape, as he was one of most prolific animal collectors of the modern era. It is with a combination of amazement and horror that one reads his travel journals. The sheer numbers of animals that he killed and captured is staggering. Indeed, after scrolling through the writings of Buck, Carl Hagenbeck, Alfred Wallace, Henry Ward, and the rest of the nineteenth and twentieth century collectors, one can argue with strong confidence that the natural history museum and zoological park have been a driving force in the diminution and extinction of animal species on our planet.

“As a rule, I am opposed to ‘collecting.’ However, I once worked on a Pacific seabird survey where it had been unavoidable, where the taking of a few individuals would truly help the entire species, and when that was the case, my rule was this: waste nothing. Every last snip of information needed to be gleaned. We looked at every feather. Took their stomachs out. Analyzed the contents. We learned everything we possibly could out of every death, and that was really important to me.”

Buck would usually kill the mother orangutans and seize the children. Adults were too difficult to control—plus museums would buy their cadavers for taxidermy. The young ones were much easier to deal with, although even then there certainly could be problems.

“Put your hand too close to the bars of these tree-dwellers that resents his captivity, and there’s a good chance that you’ll get only part of it back; or, if you get it all back, it won’t be in working order.”

Buck’s favorite method to discipline these apes was to use a crowbar, as a blow to the head was better than a gunshot to the body. The key was to bring them back alive, so that the animals could be sold in one piece.

Zoos have very strict protocol when it comes to dealing with orangutans. All locks must be double checked, because the animals watch everything you do. Weapons must be kept nearby but must remain “out of sight of the animal.” Orangutans know what guns are, and they don’t like them. Employees must never cross the lines painted in front of the cages, because the orangutans will grab you.

Zoos must also practice yearly drills, preparing for the inevitability of escapes. Each facility must have a command center. Each must have warning codes. The color red means danger and all visitors must exit the zoo or be placed into secure positions. The color green means that an incident is taking place, but that the zoo will try to keep it confidential from the press and public. When an escape does arise, a keeper must never engage the animal without assistance.

“Orangutans may act very differently when free.”

Furthermore, after the response team has been assembled, only those individuals that have “a positive relationship” with the animal should advance. Orangutans “may become dangerously aggressive if confronted by people whom they dislike.” Even with these precautions, attacks still occur.

“As so often happens among wild animals, the older individuals are very morose and unmanageable. They think of nothing but regaining their liberty, and cannot be persuaded to take any food.

The commonest way of catching young walruses is to kill the mother; indeed this is usually necessary before the capture can be carried out.

The capture of some of my last walruses nearly cost the hunters their lives; for the young cubs which had been brought

on board gave out such appealing cries for help, that a gigantic male was attracted and delivered a furious attack upon the boat, driving three great holes through it with his tusks.”

—Carl Hagenbeck, *Slave Trader*

Her new home was an outdoor fountain, little more than a shallow saucer of concrete. This was a stark contrast to the Pacific Ocean and its rocky beaches. Where once Lilly could play in the sand, explore kelp beds, and swim among a sea of fish, she now resided in a sterile, lifeless environment. She experienced extreme sensory deprivation. Then again, Lilly probably could not see much at all—at least not in summertime. Her fountain had no shade to speak of and the sunlight, and its reflection, would have been blinding. For captive sea lions, the situation has never really improved. In some ways, it has actually deteriorated.

Many of today’s exhibits, besides being empty of ecological stimuli, are often made with glass and the pool water is saturated with chlorine. At the North Carolina Zoological Park, Sandy suffered for years with swollen and blistered eyes. An official acknowledged that “the condition is not uncommon in captive sea lions due to multiple factors, i.e. lack of salt water, direct sunlight (lack of shade), reflection of light from pool bottom, water quality, et cetera.” For Sandy, the absence of shade proved particularly debilitating. But the zoo chose to continue to keep her in the open and under the blazing southern sun. Visitors prefer it that way. They want a clear, unobstructed view of the animals and they want it sunny. In 1996, during an operation to repair the lesions on Sandy’s eyes, she went into cardiac arrest and died. She was only twelve years old. In the ocean, Sandy could have lived well into her twenties.

The whales were frantic with no place to go. As the whales realized that they were at the end of the inlet and into shallow water, they swung around and headed back out to deeper water. But the trawler had already set a net across much of the harbor and the whales ran square into the net.

As the captors started to close the nets around some of the pod, a torch was lit on the stern of the fastest chase boat. Then the captors started to light the underwater explosives. As fast as they could light them, these were dropped in the water to drive the whales into the circling nets.

It was a tragic scene. Some whales were inside the net and some were outside. The whales were crying out to each other. Explosives were going off, motors were being revved up full, captors were using pike poles to push and drive the whales into the nets.

“Whales die in the hunt. If I have dead whales I’m going to conceal it from the public, which is what I did.”

—Ted Griffin, Sea World’s long-time kidnapper

His favored technique is to slit open their bellies, fill the whales with rocks, and sink them to the bottom.

There was one hitch when it came to Corky: none of her calves had ever survived. The first calf in April of 1977 survived for five weeks. The second in October of 1978 lived only eleven days. At Marineland, the longest lifespan of any of Corky’s young was forty-six days. The situation did not improve after her transfer to Sea World. She miscarried in August of 1987 and, soon thereafter, stopped ovulating. Veterinarians did not know what to make of her condition.

In an ocean environment, female orcas can produce healthy calves well into their forties. Corky was only in her twenties. What was happening? According to the medical examinations, there was nothing wrong with her physiologically, and she was receiving the best in pre- and post-natal care. Perhaps there was a psychological disorder? A long-time handler of Corky disclosed that the whale never seemed committed to keeping her youngsters alive. Out of her seven pregnancies, all of them ended in either miscarriage, stillbirth, or a brief life for the calf. The zoological industry, for its part, dared not to speculate any further—for to do so would invite uncomfortable questions about captivity and free will. Was Corky refusing to reproduce? Was this infanticide? Sea World did not want the answers. Instead, the company chose to focus on other, more willing female orcas.

When orcas resist their exploitation, they do so with measured levels of intensity and warning. What starts with a look of anger will precede a bruising bump. The grabbing of limb can be followed by repeated dunking underwater. In the final act, orcas will hold or pin their trainer at the bottom of pool until that person drowns. These are highly intelligent creatures. They have come to understand the fragility and weaknesses of their human counterparts. They know that they can hold their breath far longer than we humans, a useful bit of intelligence that one orca, in particular, has put to use more than once.

When he was two, Tilikum was rudely seized from the frigid waters of the North Atlantic off the coast of Iceland. The young killer whale was shipped to Vancouver Island, where he was forced to perform tricks at an aquatic theme park called Sealand. Tilikum was also pressed into service as a stud, siring numerous calves for exploitation by his captors. Tilikum shared his small tank with two other orcas, Nootka and Haida.

In February 1991, the whales' female trainer slipped and fell into the tank. The whales wasted no time. The woman was grabbed, submerged repeatedly, and tossed back and forth between the three whales until she drowned. At the time of the killing, Haida was pregnant with a calf sired by Tilikum. Eight years later, a 27-year-old man broke into the aquatic park, stripped off his clothes and jumped into the tank with Tilikum. The orca seized the man, bit him sharply and flung him around. He was found floating dead in the pool the next morning. The authorities claimed the man died of hypothermia.

In 2010, Tilikum was a star attraction at Sea World in Orlando. During an event called "Dining With Shamu," Tilikum snatched his trainer, Dawn Brancheau, and dragged her into the pool, where, in front of horrified patrons, he pinned her to the bottom until she drowned to death. The whale had delivered his third urgent message.

Tilikum is the Nat Turner of the captives of Sea World. He has struck courageous blows against the enslavement of wild creatures. Now it is up to us to act on his thrust for liberation and build a global movement to smash forever these gulags from the face of the Earth.

For Tilikum, since he had been snatched from his Atlantic pod and thrown into captivity, people theorized that he too was suffering from PTSD. There is, however, a significant problem with this direction in thinking. Resistance is not a psychological disorder. Indeed it is often a moment of distinct clarity. This is not to say that Tilikum and others are not suffering from clinical depression or stress-related ailments. Rather the point is that captive animals have used their intelligence, ingenuity, and tenacity to overcome the situations and obstacles put before them. Their actions have had intent and purpose. If anything, these animals are psychologically strong, not weak. They are choosing to fight back.

Orca society is matriarchal and extremely tight-knit. In the wild, Tilikum would have spent his life with his mother. She would have taught him to speak the dialect unique to her pod, one that had been passed down through generations. He would have swum up to eighty miles a day in the rich, cold North Atlantic waters, and learned to navigate and hunt with an orca's masterful skill—they can take down gray whales with ease—and he would have sired calves out there too, mating with females from neighboring pods.

Instead, he languishes in a solitary tank eating dead herring, and he is masturbated by SeaWorld staff wielding K-Y jelly, his semen used for the artificial insemination of other captives. Tilikum's real orca existence has been preempted, replaced by the Shamu soundtrack.

All attempts to domesticate the six-ton dolphin have failed. He is nobody's cartoon character, and yet all the ocean's magnificent possibilities

are lost to him. So much of Tilikum's life has been spent among humans that he could never survive in the open sea. Even if by some miracle he were reunited with his pod, his teeth have been destroyed by years of chewing on his metal cage bars. They are drilled out and hollow now and would not be much use to him. He is the wildest of creatures, who will never get the chance to be wild. So what definition is left for Tilikum, caught between worlds? He has been reduced to the craziest possible hybrid: a serial killer used for entertainment purposes.

Park officials stated repeatedly how essential and valuable Tilikum had been to their operations. This is true. Zoos and circuses are a business, and Blackstone paid 2.3 billion dollars for its purchase. The most productive employees in that business, in terms of labor and revenue, are the orcas themselves. Tilikum has performed for almost nineteen years in Orlando, sired thirteen calves, and produced in the range of a billion dollars in revenue. Nevertheless, Sea World did not believe that Tilikum had earned the right to retire. None of that billion dollars would be used to build an ocean sanctuary for older captive orcas. They do not deserve it. Tilikum was going nowhere.

Zoos and circuses have a standard operating procedure in dealing with the aftermath of such incidences of violence by captive animals. Step One is to claim that escapes and attacks are very rare. They almost never happen. The general public has nothing to worry about. Journalists have nothing to investigate. Yet, we have to ask, is this true?

It was one year earlier when Tatiana attacked a trainer. With families watching from about four feet away, the tiger squeezed her paws through the narrow bars of the cage, clawed onto a keeper's arm, and pulled it in for a bite. "While we were heading out," a parent lamented, "I could still hear screaming." Officials would state that it was "the only injury of its kind that has happened at the zoo." This was not true.

Tinkerbelle the elephant had been involved in a series of dust ups with zoo employees. Then there was Fatima, a female Persian leopard. In 1990, she jumped onto the back of a trainer and bit his neck. "I thought the leopard was going to kill him," one onlooker noted. "He was screaming, 'Help me, help me; get him off, get him off.' I was scared. That was not the kind of thing I expected to see at the zoo." If only the visitor had known.

There was, for example, a tiger attack in Moscow in February of 2006. Asked afterwards about whether the Russian circus was going to kill the tiger involved, the trainer responded with honesty:

"If we were to shoot every tiger that attacks us, there wouldn't be any remaining."

Step Two in the standard operating procedure is to deny agency. The key words to remember are 'accident,' 'wild,' and 'instinct.' The tiger injured her trainer by accident. She is, after all, a wild animal. She was just following her instinct. Repeat these lines enough and people will believe you. Yet, when we begin to explore these incidents more deeply, we discover that the zoos and circuses are deceiving us once again.

Tatiana targeted a group of teasers. She could have escaped the enclosure anytime, but she needed motivation. She could have attacked others, but she wanted revenge. A frequent visitor to the zoo told a reporter of witnessing a similar attempt by another tiger in 1997. The unnamed female had just missed scaling over the wall. Evidently, she wanted at the nearby keeper. As the man would explain to those around him, "She always does that. She hates my guts." The veterinarian at Lowry Park admitted to the same thing after Enshala was killed: "This cat hates me."

Remember the case of Fatima, the leopard who jumped onto the back of a San Francisco trainer? Schoolchildren told a newspaper reporter that only seconds before the attack the man washing out her cage had sprayed Fatima with water. Or how about Montecore. She had been performing for over six years at a clip of eight shows a week. The night of the attack she refused to obey a command and the trainer threatened her. She bit the man's arm. When the trainer hit her in the head with a microphone, she grabbed him by the throat. In each of these scenarios, the actions were neither accidental nor instinctual. These cats attacked for a reason.

Consider the case of captive elephants. These animals have the capability of inflicting large-scale fatalities. They are big, strong, and fast. Yet, when given the opportunity to plow through a crowd of visitors or stomp a row of spectators, they almost never do. Instead, they target specific individuals.

There is the case of Janet, a Great American Circus elephant. During her rampage in 1992, she had a group of children riding on her back. She could have easily thrown them off and killed them. But she didn't. Janet, in point of fact, paused midway through the melee, let someone remove the children, and then continued her assault on circus employees. As to her primary motivation, that was revealed when Janet picked up a fallen object off the ground and smashed it repeatedly against a wall. The object turned out to be a bullhook.

The bullhook, or ankus, is a nasty device that the many zoos and circuses use to train their elephants. It looks like a crowbar but with a sharpened point on the curled end. Think of a large inverted fishhook and you would be on the right track. Trainers use the device as a weapon to strike, stab, and cause pain and fear. Ringling Brothers trainers were videotaped in 2009 viciously beating their elephants with these instruments of torture. The

philosophy behind the bullhook is straightforward: violence equals discipline. It is with no understatement to say that the methods of training in this industry can be brutal.

Circuses, for example, have long preferred the use of the whip as their means to direct tigers and lions. The whip allows the trainer to maintain a safe distance and still deliver a good deal of pain and fear. Some circuses have updated to more modern devices: electrical prods and stun guns. Others have chosen to stick with the blunt instruments. Some trainers, for example, like to use baseball bats.

But no matter the instrument, the purpose of these weapons is control. The trainer wants the tiger to jump through a hoop of fire. The tiger does not want to. The trainer whips, shocks, or beats the animal until he or she performs the action. This is a learned response, and all captive animals have had to endure this violent education. Some of them have been taught with negative reinforcements. Others have been fortunate enough to train with positive reinforcements.

In either case, here is where things can take an interesting turn. Every captive animal knows, through learned response and direct experience, which behaviors are rewarded and which ones are punished. These animals understand that there will be consequences for incorrect actions. If they refuse to perform, if they attack a trainer, or if they escape their cage, they know that they will be beaten, have their food rations reduced, and be placed in solitary confinement. Captive animals know all of this and yet they still carry out such actions—often with a profound sense of determination. This is why these behaviors can be understood as a true form of resistance. These animals are rebelling with knowledge and purpose. They have a conception of freedom and a desire for it. They have agency.

We have now officially reached dangerous ground, as the above claims will always be met with the accusation of anthropomorphism. According to many, only humans can be endowed with emotions, culture, intellect, and the ability to resist. But there is a retort. The main thing to understand about the idea of anthropomorphism is that, historically, it has no empiricism behind it. Rather, it is a loaded term: loaded with political, economic, social, and cultural meanings.

The Catholic Church, in ancient times, used it to destroy paganism and thus increase the church's power and influence. Today, it is science and industry that wields the sword. Their methodology, though, is opposite to that of the church. Instead of uniting various sectors, they seek to divide and draw wide chasms between humans and other animals. This distance, they hope, will create a general public who neither knows nor cares about the lives and labors of tigers, elephants, or monkeys. It is a human-centered

and human-dominated world, which science and industry seeks. This narrow perspective allows them to continue their exploitation of other animals in a completely unquestioned and unmolested fashion. The ultimate goal, of course, is to make the largest degree of profit possible.

As for those individuals who dare go against the idea, they will automatically be called out and publicly censured: 'You are being anthropomorphic!' Sadly, this kind of reaction and labeling has led to self-censorship. There are lines of inquiry that a great many people are afraid to cross, as to do so can mean ridicule, castigation, and, yes, unemployment. The smart person will simply internalize the term. Nowhere has this behavior gained a stronger hold than within the university—home of the status quo. Yet, it should be remembered that it was not so long ago when, in universities across the country, the ideas of eugenics and racism were also considered to be true, essential, and scientific categories of analysis. Professors loved them to no end. Today, the situation has changed, and the university is embarrassed, even to the point of denial, of its iniquitous past. Anthropomorphism awaits the same graveyard.

Step Three in the standard operating procedure is a public pledge to prevent such incidences from ever happening again. If it was an escape that occurred, then the zoo or circus will make design modifications. San Francisco, for its part, extended the concrete wall and constructed a glass partition, which raised the overall height of the tiger exhibition to nineteen feet. Electrified hot wires were strung along the moat. The zoo put up signs that forbid the harassment of animals.

If it was an attack that occurred then these institutions will change their protocol. The training of employees will be made more extensive and intensive. Handlers may no longer be allowed direct contact with the animals. Also, the animal perpetrators themselves could undergo retraining or be placed under an entirely new system of management. But, if the animal is a repeat offender, then the zoo or circus might get rid of him or her altogether. In the past, summary executions were used. Some of the more popular methods included firing squads, poisonings, and hangings. These have since become a political liability, so the industry has instead turned to animal dealers for help.

This is how it works. Flagship institutions, such as the National Zoo, the Lincoln Park Zoo, the San Diego Zoo, Six Flags, and Ringling Brothers, will sell their unwanted animals to licensed auctioneers and dealers. These individuals will then turn around and re-sell them to unlicensed third parties. The key facet in this relationship is the absence of a direct connection between the original sellers and the final buyers. Thus, zoos and circuses can deny involvement in such dirty business and hide their avarice.

As for the unwanted animals, they will end up in private collections, canned hunting operations, research labs, and exotic-meat slaughtering facilities. Some of the animals, especially tigers, will be killed outright for their organs, fur, and claws. According to Interpol, the international trade in exotics is an eight-billion dollar a year industry. And no animal is safe. These flagship institutions will sell endangered and non-endangered species alike: leopards, camels, Bengal tigers, antelopes, gazelles, lions, white rhinos, gorillas, chimps, and orangutans.

Perhaps you will remember Knut, the famed polar bear cub. In 2007, a kind of hysteria revolved around him, as visitors by the thousands flocked to Germany to catch a glimpse. Knut's owner, the Berlin Zoo, licensed his image and placed it everywhere. The zoo made \$8.6 million off of the Knut craze. Nevertheless, by December of 2008, Berlin wanted to dump the bear. Knut had grown up, and he was no longer cute or marketable. It was only through a public uprising that the zoo relented and agreed to keep the polar bear—at least, until the fervor dies down.

Step Four in the standard operating procedure is to manage public relations. The American Zoological and Aquarium Association (AZA), governing body of the industry, provides workshops on the successful PR techniques. The central thesis of them is this: control the information. Every institution should have a designated spokesperson. When questioned, and regardless of the question, this person should state repeatedly that the zoo is an important resource for conservation and education. Reassurances must also be made that appropriate changes have been implemented and that the park is safe for the return of visitors. Again, rigorous control is foremost in importance—as damaging information can easily leak out.

News came that the tiger was being fed ten pounds less meat per individual feeding in San Francisco than she had been during her confinement in Denver. This led some to speculate that the zoo was trying to get Tatiana to be more active for visitors. If the tiger was continually hungry, the thinking went, she might move around more and thus be more entertaining to paying visitors. Officials were forced to deny the claim.

Next came news of a \$48 million bond, which the zoo had received earlier, almost all of which was spent on enhancements for visitors. The animals, meanwhile, continued to reside in decrepit and cramped exhibits. Tigers can have a range of over 100 square miles in their habitats of Eurasia. In San Francisco, Tatiana had only 1,000-square feet to roam around in. Such realities of captivity are known to cause psychological problems: unconscious swaying, incessant pacing, and self-mutilation. Zoo officials, again, had to defend themselves. The tiger, they affirmed, was not suffering from depression and her enclosure was more than adequate in size.

The final piece of bad news for the zoo came when it was revealed that there were two near escapes by other animals just a week after Tatiana's rampage. During one of them, a female polar bear named Ulu tried to scramble over a wall but was turned back with the stinging spray from a firehose. A keeper quietly confided that Ulu only did this because he and others had been "pelting" the bear with empty tranquilizer darts. In response to this incident, the zoo's director followed standard procedure. "That doesn't sound like an escape attempt to me," he began to explain. The bear was simply being a bear. Yes, the zoo is now planning to raise the walls of Ulu's exhibit, but not because of what Ulu did. In all seriousness, the zoo's PR flacks suggested, this kind of scrutiny and questioning is unnecessary if not vindictive. The zoo is the real victim.

At the turn of the twentieth century, zoos around the country relied upon local youth for financial support. In truth, most parks would not have survived their early years without these tot-driven campaigns. Those pennies from heaven did not so much fall from the sky as they were pried from the mouths of babes. It was schoolchildren who were asked to scrimp together everything they had in order to fund the purchase of a new captive animal. It was schoolchildren who were asked to save up for years in order to support the construction of a new exhibit. They were the ones who had to make the sacrifices. The same cannot be said for those who collected the donations.

Members of zoological societies were, almost exclusively, very wealthy individuals. Many were captains of industry. Some owned banks. Others sprang from old money. All were capable of fully funding these institutions by themselves. But they chose not to. Instead, society members siphoned tens of thousands of dollars from those who could least afford it. This was, for better or worse, the arrangement of the time, and the children of Toledo and its neighboring counties would perform their role admirably. By 1912, the kids had amassed enough pennies to purchase a new elephant. Now it was up to the zoo to find one.

Zoological parks call such creatures a flagship species. They are the larger-than-life animals: the elephants, tigers, hippos, gorillas, and panda bears. They are the ones that heighten the reputation of a zoo and boost its image. They provide an easy focus for the marketing department to lure a larger audience. Most importantly, they afford assurances to the parks and their employees that the external funding will continue to flow. Prestige—both in the past and today—is essential for the survival of these institutions, and elephants play a central role in creating this impression.

Prolonged isolation is very hard on female elephants. They are highly social creatures and need each other for companionship. In Africa or Asia,

their families are extended to include a matriarch, six to twenty related females, and an assortment of calves. Even the dead are long remembered in elephant societies. Furthermore, elephants enjoy interacting with fellow animals. Humans conveniently tend to think of other species as being segregated or divorced from those around them. But this is demonstrably not the case. They, like humans, need to create and develop these kinds of holistic relationships. Animals have a culture all to their own.

In pachyderm society, family is everything. Females, for instance, are never alone. Daughters will spend most of their lives with their mothers. These intense bonds are nearly unbreakable, and extend beyond the material world and into the spiritual. Elephants are known to have their own graveyards and complex rituals regarding the treatment of the dead. Visits are made often to these funerary grounds, and the bones of relatives are touched, caressed, and even carried around.

As for male elephants, the maternal bond is equally as strong for the first segment of their lives. But, upon reaching adolescence, males become more independent and begin to venture out from the herd for extended periods of time. Eventually, males separate and remain solitary—although maintaining friendships with other males is important. Zoos and circuses, however, do not recognize or value the significance of these relations: familial or otherwise. The majority of calves are removed from their mothers by the age of two, if not sooner.

Elephants remain, despite all of the efforts by zoological parks, opposed to a sedentary life of endless sequestration. Whether in Asia or Africa, these animals will cover many miles per day. Their typical home range can be anywhere from nine to thirty-one square miles. And this expansive use of open space is not merely about finding food or water. Elephants love to walk and to roam on their own accord. They enjoy being constantly on the go, seeing new sights, and interacting with fellow creatures. They are highly social travelers. In zoos, indoor facilities are measured in feet, not miles, and outdoor sites might, at most, reach two or three acres.

The zoo industry is full of such contradictions. It helps people learn about the importance of animals, but not what is vitally important to the animals themselves. Sea mammals, elephants, and primates are capable of so many amazing feats, but they are incapable of demonstrating their intentions and making their own choices. The industry encourages you to think that these animals are intelligent, but not intelligent enough to have the ability to resist. The industry encourages you to care about them, so that you and your children will return for a visit. But it does not want you to care so much that you might develop empathy and begin to question whether these animals actually want to be there.

Private breeding operations were opened in response to the strict new laws and regulations that had recently been passed regulating the exportation of elephants from foreign countries. Circuses and zoos no longer had easy access to their labor pool. The enterprises needed a new source. Thus, breeding programs and “conservation centers” sprang up around the country.

There are currently over 250,000 exotic animals licensed to private owners in the state of California alone. The number of unlicensed is indeterminable. The creatures themselves can be held outdoors or indoors. They may be penned, caged, chained, or just locked in a room. They can be kept as pets, used in canned hunts, or slaughtered for their skin and organs. The Fish and Game Department is responsible for the oversight, but there is little true regulation. In most states, anyone can own an exotic animal. There are almost no qualifications for licensing, and even those few can easily be circumvented.

The entertainment industry uses chimpanzees when they are young and easy to control. But when they get older and more resistant, the chimps are sold for little to no cost to the buyer. ‘Just take them off our hands and do what you will,’ is Hollywood’s attitude. That “No Animals Were Harmed” and Humane Society logo in the credits is just a piece of propaganda, a way for a big, mainstream, corporatized non-profit to make some money while allowing capitalists to mask the true nature of their exploitation—basically Greta Thunberg in logo form.

There is no humane form of captivity, there is no humane form of exploitation. These are individuals, not objects, not line items on a spreadsheet. Regardless of how it is attempted to be hidden, these institutions—zoos, circuses, Hollywood, and more—see these individuals as just another resource to expand their status, wealth, power. To be used and then discarded. These individuals resist daily. They take brave stands in the face of insurmountable odds. They cry out to the void. And what they hear is what all oppressed beings hear all too often: silence.

The silence, to me, is deafening now, is it not to you? The worst sound there ever could be some might argue. How did the Good Germans sit by while the camps were run? It seems you, dear reader, have all the personal experience necessary to answer that question.

Other Minds

The Inner Life

It's not anthropomorphizing. Part of the challenge in understanding the behavior of a species is that they look like us for a reason. That's not projecting human values. That's prioritizing the generalities that we share with them. It may very well be that the seemingly natural human urge to impart emotions onto animals—far from obscuring the “true” nature of animals—actually reflects a very accurate way of knowing.

Critics are often quick to exclaim that the emotional lives of animals are too private or hidden to make much sense of. And, surely, animals will always have their secrets. Yet their inner emotional and moral lives are surprisingly public and transparent. Just look at them, listen to them, and if you dare, smell the odors that pour out when they interact with friends and foes. Look at their faces, tails, bodies, gaits, and most importantly their eyes. What we see on the outside tells us a lot about what's happening inside animals' heads and hearts. People around the world, including researchers, readily recognize expressions of emotions and show remarkably high agreement when asked what they infer about what an individual animal is feeling based on their observations. Behavioral scientists tested the hypothesis that every observer, whether trained in animal behavior or not, can make a meaningful assessment of an animal's behavior. Trained and untrained observers displayed a high level of agreement about what emotions an animal is feeling. These results constitute important data and suggest that the problem of never being able to enter into the subjective experience of another, what philosophers call “the problem of other minds,” isn't really so serious after all.

The problem of other minds is not an impediment to understanding how animals feel and think. Why not? Well, first of all, animal minds aren't all that inaccessible or private, as cognitive ethology and social neuroscience make abundantly clear. They are, actually, rather public. We already know a lot about animal minds, and we're discovering more and more each day. Second, and perhaps even more important, we are ourselves animals and

our experiences of pain, joy, envy, compassion, and love are probably very much akin to these same emotional states in other animals. Data suggest that there is enough continuity in physiology and psychology to safely infer significant experiential common ground. And finally, we must remember that human minds are private, too. We can never crawl inside the skin or brain of another person and truly know their subjective experiences. Yet this doesn't stop us from understanding and reacting to their thoughts or emotions, most of the time quite accurately and without conscious effort. The so-called privacy of mind problem is overused and is little more than a poor excuse for ignoring much ongoing research and retaining the status quo in our treatment of animals.

The emotional lives of animals have been the underbelly of animal behavior research. It has been assumed either that animals don't experience emotion, or that their emotional lives are so simple as to be uninteresting. Until quite recently, even, emotions in animals were catalogued as simple behavioral responses, reducible to chemical changes in the brain or body. Fear, for example, was described as just a physiological event—the “fight or flight” response describes the release of hormones, leading to constriction of blood vessels, acceleration of the heart and lung functions, and so forth. Well, human emotions can be reduced in the same way, but most people recognize that this is an impoverished picture of what it means to have a feeling such as fear, and that fear has many faces. Fortunately, all this is changing, and we now know that the emotional lives of animals are every bit as rich as our own.

Is it really true, as scientists have long maintained, that people are the only animals capable of enjoying a full range of emotions? Has creation really engineered a unique biological path for us? Are we the only ones guaranteed a life of self-awareness and satisfaction? If human beings were the result of some special biological design, we wouldn't be able to compare ourselves to other animals. It would make no sense to talk about empathy with them, because we would not be able to even begin to imagine how they felt. Luckily, Nature opted for the economy plan. Evolution only modifies and builds on whatever is already available, much like a computer system. And so, just as code from earlier operating systems is integrated into the latest Windows, the genetic programming of our ancient ancestors still works in us—and in all the other species whose family trees branched off from our lineage in the past few million years. And so, as I see it, there is only one kind of grief, pain, or love. It might sound presumptuous to say that a pig feels things just as we do, but there is a vanishingly small chance that an injury hurts a pig less than it hurts us. ‘Aha,’ the scientists might interject at this point, ‘but we have no proof.’ That's true, but there never will be

any proof. I can't even prove that you feel the same way as I do. No one can look inside another person and prove that, say, a prick of a pin triggers the same sensation in each one of the seven-billion people on this planet. But we are able to express our feelings in words, and this ability to share increases the probability that people operate on roughly the same level when it comes to feelings.

In the end, it doesn't really matter how much our intellect is consciously in control, because the fact that a surprising number of our reactions are probably instinctive shows only that experiences of fear and grief, joy, and happiness are not at all diminished by being triggered instinctively instead of being actively instigated. Their origin doesn't reduce their intensity in any way. The point is that emotions are the language of the unconscious, and in day-to-day life, they prevent us from sinking beneath an overwhelming flood of information. The pain in your hand when you put it on a hot element allows you to react immediately. Feeling happy reinforces positive behaviors. Fear saves you from embarking on a course of action that could be dangerous. Only the relatively few problems that actually can and should be solved by thinking them through make it to the conscious level of our brain, where they can be analyzed at leisure. Basically, then, emotions are linked to the unconscious part of the brain, not the conscious part. If animals lacked consciousness, all that would mean is that they would be unable to have thoughts. But every species of animal experiences unconscious brain activity, and because this activity directs how the animal interacts with the world, every animal must also have emotions. Therefore, instinctive maternal love cannot be second-rate, because no other kind of maternal love exists.

There are cases, where superabundant hormones or surplus milk can be ruled out as the driving forces. The crow Moses is a touching example. When birds lose their brood, Nature gives them another opportunity to work off their pent-up impulses. They can simply start anew and lay another clutch of eggs. There's no way a single bird like Moses can exercise its maternal instincts, yet Moses attempted to do just this. The target of Moses's attention was a potential enemy—a housecat—albeit an extremely small and relatively helpless one, because the kitten had obviously lost its mother and had not had anything to eat in a long time. The little stray popped up in Ann and Wally Collito's yard. The couple lived in a cottage in North Attleboro, Massachusetts, and they watched in amazement at what happened next. A crow attached itself to the little orphan and was clearly looking after it, feeding it with earthworms and beetles. Of course, the Collitos didn't just stand by and watch; they fed the kitten, as well. The friendship between the crow and the cat continued after the cat grew up, and it lasted until the crow disappeared five years later.

In their first few weeks of life, fawns are left lying alone in the undergrowth or tall grass, because this is safest for both mother and fawn. A doe with a fawn moves slowly because she has to keep waiting for the youngster. Often the fawn has not yet experienced how serious life can be, and it dawdles behind mom—an ideal target for wolves or lynx. These predators can spot the pair from a long way off and easily grab a meal. That’s why mother deer prefer to separate themselves from their little darlings for the first three to four weeks and leave them in a safe place. It is almost impossible to sniff out a fawn. Because they smell of hardly anything at all, their scent doesn’t alert predators to their presence. The doe comes by for a quick visit every once in a while to nurse her fawn, and then she takes off again right away. That gives her more time to feed on nutritious buds and new shoots instead of having to worry about and watch out for the little one all the time.

When someone who has no idea what’s going on finds a fawn lying there all alone and very still, their almost instinctive reaction is to take care of it. After all, it’s hard to imagine what an abandoned human baby would go through if someone just put it down somewhere and then disappeared. And so, time and again, “helpers” spontaneously step in and take the supposedly orphaned fawn back home with them. However, they have no idea what to do next, and they call an expert. It’s usually about this time that they realize bringing the fawn home was a huge mistake, but by then it’s too late to fix the damage. The fawn now smells of people, and it can’t be returned to the wood and its mother. Bottle feeding a fawn is hard work and, at least in the case of male fawns, it is also risky.

Deer are a perfect example of how mother love can be expressed in very different ways. Most mammals are like us and seek constant close contact with their offspring; those that behave differently are not heartless but simply adapted to different life situations. Fawns feel perfectly safe in the first few weeks of life even without constant contact with their mother. Their behavior changes only when they are capable of bounding along behind her. Then they stay close to the doe, rarely straying more than 20 yards away from her.

Unfortunately, in these modern times, typical fawn behavior in the first few weeks of life has other, far more tragic consequences. When danger threatens, a fawn hunkers down, because it knows instinctively that it is extremely difficult to pick up its scent. But often what is threatening it is not a wolf or a hungry wild boar looking for a succulent morsel of meat. What is bearing down on it is a tractor fitted with an enormous mower that is swiftly cutting down grass on acres of land. And so the crouching fawn ends up under the blades, and in the best-case scenario it is killed immediately. Often, however, it stands up just before the blades reach it so

that its legs are cut off along with the grass. One way to avoid this would be to have someone walk through the area the evening before with a dog along as an extra signal that this is a dangerous place to be. Then the doe will encourage her fawn to accompany her to a safer place outside the meadow. However, under capitalism, there is often neither the time nor the staff for such rescue operations. Capitalism doesn't give a shit about legless or decapitated fawns—there's no money in it.

While her status affords her certain privileges, there are times, however, when disaster strikes the alpha doe, for example when her fawn dies. In earlier times, the cause of death was usually disease or a hungry wolf. These days, it is often a blast from a hunter's gun. For deer, the same process is set in motion as for us. First, unbelievable confusion reigns, and then grief sets in. Grief? Are deer even capable of experiencing an emotion like that? Not only can they, but they must. Grief helps them to say goodbye. The bond between doe and fawn is so intense that it cannot be severed from one moment to the next. The doe must slowly accept that her child is dead and that she must distance herself from the tiny corpse. Over and over again, she returns to the spot where her child died and calls for her fawn, even if the hunter has carried it away. A grieving alpha doe endangers her kin by remaining close to the scene of death, which also means close to danger. What the herd needs to do is to move to a safer place, but departure is delayed until the bond between mother and fawn finally dissolves.

There is no question that under such circumstances, it is time for a change in leadership, and this happens without any struggle for dominance. Another similarly experienced doe simply steps forward and takes over leadership of the group. If it's the other way around and the alpha doe dies, leaving her fawn behind, the remaining does show no mercy. There is no question of an adoption. Quite the opposite. The orphaned youngster is frequently banished from the herd, perhaps because the other does don't like dynasties. Left to fend for itself, the fawn has little chance of surviving and usually doesn't make it through the next winter.

This is how a herd of deer experiences the shooting of one of its own. There's a crack and a sudden smell of blood. The shot is often not a clean one, and the wounded animal manages a few yards of panicked flight before its legs buckle and it falls. This sight, coupled with the smell of stress hormones, imprints itself deep into the consciousness of the other members of the herd. And then there's a creaking and crashing from the hide as the hunter climbs down to salvage the downed game, and the intelligent animals make the connection. From then on, before stepping out onto the path, they look suspiciously up at the raised hide to see if someone is sitting there. They could, of course, give the area a wide berth, but hunters usually set up

their hides in places where particularly tasty food grows. And if there isn't any, hunters simply sow an appropriate mix of attractive meadow plants. These mixes have names like "Gameland Goulash." Doesn't that sound enticing? And so the evenings become a never-ending game of roulette. If hunger wins, then the deer step out onto the path too early and therefore into the shooters' visual range. If fear wins, the hungry deer don't come out to the feast laid out for them until it's pitch dark, and the hunters go home empty handed.

Wild game animals are stressed when people enter their territory. If two-legged intruders are constantly entering the area, the portion of time an animal needs to spend checking to see if it is safe rises from 5% to 30% of the day. At least that holds true for those people whom animals find it difficult to categorize. Walkers, cyclists, or horseback riders who keep to the trails are easy to evaluate: they make noise and move along clearly demarcated routes. As long as the game can see them, it's clear they are moving directly from A to B, and animals observing them from the safety of their daytime hiding places have nothing to worry about. In contrast, mushroom hunters, mountain bike riders, hunters, and foresters often travel off the beaten track. And because most of these individuals travel alone, there's no lively conversation that wild game can listen in on and use to estimate the route the intruders are taking. All the game can hear is the occasional snapping of a twig under a boot and perhaps a quiet clearing of the throat from time to time—nothing more. Then animals become uneasy, and to be on the safe side, they prefer to move away quickly.

You might argue that things have always been this way. What difference does it make whether it's a wolf pack or a person on the hunt? Well, one big difference is the number of hunters. Contrast one four-legged hunter for every 20 square miles in wolf territory, with about ten-thousand two-legged predators tripping up over each other in the same amount of space in Germany today. And the wild game can't tell right away that not everyone is armed. So if there's any doubt, game retreats from each potential attacker and generally forgoes forays into lush meadows in the bright light of day. As you can see, life for game that can be legally hunted is quite nerve wracking. Their situation, where for every potential prey there are any number of potential hunters, is unique in the animal world, because the situation is usually the other way around.

Let's consider fear. In people, fear arises in the almond-shaped amygdala. For a long time that was not proven, even though it was suspected. It wasn't until January 2011 that scientists from the University of Iowa published a paper about a woman identified as SM. SM was afraid of spiders and snakes—until the cells in her amygdala died after a rare illness. That was,

of course, tragic for SM; however, it offered researchers a unique opportunity to investigate what happens when this organ is lost. They took SM to a pet shop and confronted her with the animals she feared. The woman could now touch the animals, something she could never have done before, and she reported that she simply felt curious about them and no longer felt in the least bit frightened.

But even if the structures in their brains differ from ours and these differences mean that they probably experience things differently, that certainly doesn't mean that emotions in animals are inherently impossible. It simply means that it is more difficult for us to imagine what their emotions might feel like. Take the fruit fly, for example, whose central nervous system is made up of 250,000 cells, making it a four-hundred-thousandth the size of ours. Can such minute creatures with such a limited capacity up top really feel anything? Can they even be said to possess consciousness—this being, of course, the pinnacle of achievement. Unfortunately, science is not yet advanced enough to be able to answer this question, partly because the concept of consciousness cannot be clearly defined. The closest we can get to a definition is that consciousness involves thinking and reflecting on things that we have experienced or have read about. Right now, you're thinking about what you're reading, and so you possess consciousness. And at a very basic level, the conditions necessary for consciousness have been discovered in the tiny brains of fruit flies.

The flies are constantly barraged by stimuli from the external world, just as we are. The smell of roses, car exhaust, sunlight, a breath of air—all are registered by a variety of unconnected nerve cells. So how does a fly filter out from this flood of sensations what is most important so that it can stay out of danger and not miss out on a particularly tasty morsel? Its brain processes the information and ensures that different areas coordinate their activities, strengthening certain stimuli. And so what is of interest stands out from the general noise of thousands of other impressions. The flies, therefore, can focus their attention on specific things—just as we can. Fruit flies' eyes are made up of about six-hundred individual facets. Because these tiny insects dart around so quickly, their eyes are bombarded by a huge number of images per second. This seems like an impossibly large amount of data to process, but the flies must do this if they are to survive. Anything that moves could belong to a voracious predator. Therefore, the fruit fly brain leaves all static images blurry and focuses exclusively on moving objects. You could say that the tiny tykes are stripping things down to the bare essentials, an ability that you surely would not have expected these little flies to have. By the way, we do something similar. Our brain doesn't allow all the images we see to make it through to our consciousness. It only

lets the important ones through. Does that mean flies have consciousness? Researchers won't go that far; however, it is clear that flies can at least actively focus their attention on what matters most to them.

“Denying that crabs feel pain because they don't have the same biology is like denying they can see because they don't have a visual cortex.”

This is further proof of science's practice of arguing too cautiously when in doubt about feelings in animals, denying them many mental capacities until there is positive proof that they possess them. Instead, couldn't we simply—and more accurately—say: ‘We don't know.’

Apart from that, pain is a component in reflex actions, as you can easily test for yourself if there's an electric fence nearby. If you put your hand on it and get an electric shock, you have no choice but to pull back right away, whether you want to or not. It's pure reflex on your part, something you do without a moment's thought, but that doesn't make it any less painful.

Researchers find some kinds of slime molds so interesting that they regularly observe them in the laboratory. *Physarum polycephalum*, with its somewhat awkward Latin name, is just such a customer, and it loves rolled oats. Basically, the creature is one giant cell with countless nuclei. What researchers are now doing is placing these slimy unicellular organisms in a maze with two exits and putting food at one of the exits as a reward. The slime mold spreads out into the maze and after a hundred hours or more, finds the exit with the oats—not bad, really. To do this, it clearly uses its own slime trail to recognize where it has already been. It then avoids those areas because they have not led to success. In nature, such behavior is of practical benefit, because the creature knows where it has already been in its search for food and, therefore, the places where there isn't any food left. It's quite a feat to be able to solve a maze when you don't have a brain, and researchers credit these moving mat-like creatures with having some kind of spatial memory.

Japanese researchers topped it all off by using a slime mold to reproduce a map of the most important transportation routes in Tokyo. To do this, they set a slime mold down on a damp surface at a point that represented the center of the city. Piles of food marked the principal neighborhoods as attractive places to visit. The slime mold set off, and when it had connected the neighborhoods using the optimal, shortest route, there was a big surprise. The image pretty much corresponded to the suburban train system in the metropolis.

Researchers played classical music to pigs. Don't worry, the researchers weren't trying to find out if pigs are fond of Bach. Rather, they got the pigs to connect the music to small rewards, such as chocolate-covered raisins hidden in the straw. Over time, the pigs in the experimental group came to associate music with particular emotions. And now things got interesting, for other pigs were added that had never heard such sounds and therefore had no idea what they meant. Despite this, they experienced the same emotions the musical pigs experienced. If the musical pigs were happy, the newcomers also played and jumped around; in contrast, if the musical pigs were so scared that they urinated on themselves, the newcomers caught the feeling and exhibited the same behavior. Pigs clearly can experience empathy. They can pick up on the emotions other pigs are feeling and experience those feelings themselves—a classic expression of empathy.

I would like to address the religious definition of a soul. Even if I have to tread carefully and I don't feel confident here, even if belief and logic are to a certain extent mutually exclusive, I would like to argue for the existence of an animal soul in the religious sense of the word. Assuming you don't believe in physical resurrection, a soul is a prerequisite for life after death. And if people have souls in this sense, then animals must have them as well. Why? Because there is the question of how long people have been going to heaven. For two-thousand years? For four-thousand years? Or for as long as there have been people? That would be about 200,000 years. But where is the break with earlier life forms, with our predecessors? The break didn't happen abruptly. It happened stealthily. Small changes spread out over generations in the course of evolution. Which individuals are then to be identified as no longer being people with souls? Some female ancestor who lived 200,023 years ago? Or a man armed with a flint weapon who lived before the year 200,197? No, there is no sharp demarcation, and so you can trace the lineage further and further back, past our primitive forefathers, primates, the first mammals, dinosaurs, fish, plants, bacteria. If there is no specific point in time, to which the genesis of a creature of the species *Homo sapiens* can be fixed, then there is also no specific point in time when the soul appeared. And if there is a higher form of justice in the religious sense, then when it comes to the question of eternal life, there can't very well be a sharp line drawn between two generations, where the older one is denied entry and the younger one is admitted. Isn't it a beautiful vision that up in heaven there will be a throng of animals of different species living among countless people?

When all the arguments have been made and it's clear we're getting to the point where we must grant animals way more skills than we usually do, the knockout punch is delivered: the charge of anthropomorphism. People

who compare animals to humans, so the argument goes, are unscientific. They are wishful, maybe even mystical, thinkers. In the heat of the fray, an essential truth we all learned in school is overlooked: a human being is, from a purely biological perspective, an animal and therefore not so very different from other species. It follows that a comparison between people and animals is not too much of a stretch, especially since we can only relate to and empathize with things we understand. And so it makes sense to take a closer look at those animals in which we can detect emotions and mental processes similar to our own. This comparison is easier with feelings such as hunger and thirst, whereas comparing human and animal experiences of joy, grief, or compassion makes some people's hair stand on end.

Most importantly, these comparisons serve to point out that animals are not dimwitted creatures clearly stuck a level below us on the evolutionary scale, creatures that experience only pale imitations of our rich range of sensations for pain and other such feelings.

“I would venture to say that nobody really knows another's mind thoroughly, and I would further venture that very few people really know their own mind.”

I'm truly sorry Man's dominion,
Has broken Nature's social union,
An' justifies that ill opinion,
Which makes thee startle,
At me, thy poor, earth-born companion,
An' fellow-mortal!

Poor Ass! thy master should have learnt to show
Pity—best taught by fellowship of Woe!
For much I fear me that He lives like thee,
Half famished in a land of Luxury!
How askingly its footsteps hither bend!
It seems to say, “And have I then one friend?”
Innocent foal! thou poor despised forlorn!
I hail thee Brother—spite of the fool's scorn!
And fain would take thee with me, in the Dell
Of Peace and mild Equality to dwell

For every thing that lives is Holy,
Life delights in life.

Through the ages, it's been the poets who have largely held firm in their affinity with the natural world. Consider the *Metamorphoses* composed by the Roman poet and political dissident Ovid around the time of Christ's birth. In the final book of this epic, where humans are routinely transformed into animals, Ovid summons the spirit of Pythagoras. The great sage of Samos, whom Aristotle hailed as the father of philosophy, gives the most important speech in the poem.

But the author of the famous Theorem forsakes the opportunity to proclaim that mathematics is the foundation of nature. Instead, Ovid's Pythagoras denounces the killing of animals for food and asserts the sanctity of all life forms.

“What evil they contrive, how impiously they prepare to shed human blood itself, who rip at a calf's throat with the knife, and listen unmoved to its bleating, or can kill a kid goat to eat, that cries like a child, or feed on a bird, that they themselves have fed! How far does that fall short of actual murder? Where does the way lead on from there?”

Science is increasingly favoring continuity over discontinuity. This is certainly true for comparisons between humans and other primates, but extends to other mammals and birds, especially since bird brains turn out to resemble those of mammals more than previously thought. All vertebrate brains are homologous. Although we cannot directly measure consciousness, other species show evidence of having precisely those capacities traditionally viewed as its indicators. To maintain that they possess these capacities in the absence of consciousness introduces an unnecessary dichotomy. It suggests that they do what we do but in fundamentally different ways. From an evolutionary standpoint, this sounds illogical. And logic is one of those other capacities we pride ourselves on.

“The difference in mind between man and the higher animals, great as it is, certainly is one of degree and not of kind.”

For far too long, animals in general, and birds in particular, have been denigrated and treated merely as creatures of instinct rather than as sentient beings.

Since intentional, intelligent actions are observable in many animals, and since in our own species they go together with awareness, it is reasonable to assume similar mental states in other species. The assumption that animals are “dumb,” in the sense that they lack conscious minds, is only that: an assumption. It is far more logical to assume continuity in every domain.

But what about skeptics who believe that animals are by definition trapped in the present, and only humans contemplate the future? Are they making a reasonable assumption, or are they blinkered as to what animals are capable of? And why is humanity so prone to downplay animal intelligence? We routinely deny them capacities that we take for granted in ourselves. What is behind this? In trying to find out at what mental level other species operate, the real challenge comes not just from the animals themselves but also from within us.

Scientists and lay people alike tend to jump to conclusions about animal cognition, based on what is known about primates. For example, if primates, especially great apes, don't possess a particular cognitive skill, scientists often assume it doesn't exist elsewhere among animals, because they are all "less cognitively evolved" than primates. But this is not rigorous science. Rather, it's cognitive speciesism, the denial of certain cognitive skills to entire groups of animals based on little more than inaccurate stereotyping. Researchers often are hesitant to see complex forms of cooperation in animals other than primates. Either the cognitive implications attributed to primates evincing cooperation should be extended to other animals, so that species solving similar problems are recognized as possessing at least comparable skills, or we should consider the possibility that the solution of such tasks reveals little about higher-order cognitive function.

We love to compare and contrast animal and human intelligence, taking ourselves as the touchstone. It is good to realize, though, that this is an outdated way of putting it. The comparison is not between humans and animals but between one animal species—ours—and a vast array of others. We're not comparing two separate categories of intelligence, therefore, but rather are considering variation within a single one. I look at human cognition as a variety of animal cognition. It is not even clear how special ours is relative to a cognition distributed over eight independently moving arms, each with its own neural supply, or one that enables a flying organism to catch mobile prey by picking up the echoes of its own shrieks. We obviously attach immense importance to abstract thought and language, but in the larger scheme of things this is only one way to face the problem of survival.

Dualisms between body and mind, human and animal, or reason and emotion may sound useful, but they seriously distract from the larger picture.

The field of evolutionary cognition requires us to consider every species in full. Whether we are studying hand anatomy, trunk multifunctionality, face perception, or greeting rituals, we need to familiarize ourselves with all facets of the animal and its natural history before trying to figure out its mental level. And instead of testing animals on abilities that we are particularly good at—our own species' "magic wells," such as language—

why not test them on their specialized skills? In doing so, we will not just flatten Aristotle's scale of nature: we will transform it into a bush with many branches. This change in perspective is now feeding the long-overdue recognition that intelligent life is not something we must seek at great expense only in the outer reaches of space. It is abundant here on earth, right underneath our nonprehensile noses.

This will help us avoid comparing cognition on a single scale modeled after Aristotle's *scala naturae*, which runs from God, the angels, and humans at the top, downward to other mammals, birds, fish, insects, and mollusks at the bottom. Comparisons up and down this vast ladder have been a popular pastime of cognitive science, but I cannot think of a single profound insight it has yielded. All it has done is make us measure animals by human standards, thus ignoring the immense variation in organisms' worlds. It seems highly unfair to ask if a squirrel can count to ten if counting is not really what a squirrel's life is about. The squirrel is very good at retrieving hidden nuts, though, and some birds are absolute experts. The Clark's nutcracker, in the fall, stores more than twenty-thousand pine nuts, in hundreds of different locations distributed over many square miles; then in winter and spring it manages to recover the majority of them.

That we can't compete with squirrels and nutcrackers on this task—I even forget where I parked my car—is irrelevant, since our species does not need this kind of memory for survival the way forest animals braving a freezing winter do. We don't need echolocation to orient ourselves in the dark; nor do we need to correct for the refraction of light between air and water as archerfish do while shooting droplets at insects above the surface. There are lots of wonderful cognitive adaptations out there that we don't have or need. This is why ranking cognition on a single dimension is a pointless exercise. Cognitive evolution is marked by many peaks of specialization. The ecology of each species is key.

The *scala naturae* view has tempted many to conclude that animals lack certain cognitive capacities. We hear abundant claims along the lines of 'only humans can do this or that,' referring to anything from looking into the future (only humans think ahead) and being concerned for others (only humans care about the well-being of others) to taking a vacation (only humans know leisure time).

It isn't especially meaningful, for example, to ask if cats are more intelligent than dogs. Cats do what they need to do to be cats and dogs do what they need to do to be dogs. While it might be useful to compare members of the same species in terms of how smart they are, this too might be fraught with misleading inferences. If Fido, a dog, learns where his food is faster than his canine buddy Herman, is Fido smarter? Perhaps, but what

if Herman learns to avoid cars more rapidly than Fido? Is Herman more intelligent? Are midwife bats who help another bat give birth more intelligent than non-midwife bats because the former recognizes that another female is having a difficult labor? Who knows? And what about cultural variations in the manufacture and use of tools by chimpanzees? Are chimpanzees who use tools more intelligent than chimpanzees who don't? It's unlikely that they are. Specific circumstances have led to the use of tools and it's likely that all chimpanzees with normal chimpanzee brains would, in the right context, display an innovative ability to make and to use tools. Intelligence has evolved independently in different classes of vertebrates, which speaks against a view of intelligence in which there is a single evolutionary trajectory culminating in *Homo sapiens*.

There is no single form of cognition, and there is no point in ranking cognitions from simple to complex. A species's cognition is generally as good as what it needs for its survival. Distant species that face similar needs may arrive at similar solutions.

Each organism senses the environment in its own way. The eyeless tick climbs onto a grass stem to await the smell of butyric acid emanating from mammalian skin. Since experiments have shown that this arachnid can go for eighteen years without food, the tick has ample time to meet a mammal, climb onto her victim, and gorge herself on warm blood. Afterward she is ready to lay her eggs and die. Can we understand the tick's point of view, it's world, it's experience? It seems incredibly impoverished compared to ours, but perhaps its simplicity as a strength: her goal is well defined, and she encounters few distractions.

Some animals perceive ultraviolet light while others live in a world of smells or, like the star-nosed mole, feel their way around underground. Some sit on the branches of an oak, and others live underneath its bark, while a fox family digs a lair among its roots. Each perceives the same tree differently.

Dennis Nilsen was born in 1945 in a seaside town in Scotland. After a brief stint in the army, he moved to London, where he worked first as a police officer and then as a civil servant. Despite his good job, Nilsen felt unfulfilled and isolated; he seldom spoke to his family, had few friends, and had difficulty maintaining close relationships. He also had dark fantasies about sexually dominating young men, whom he liked to imagine as completely passive or even unconscious.

After the dissolution of one relationship, Nilsen began luring young men into his apartment with the promise of food, alcohol, and lodging. Once they were asleep, Nilsen would strangle them into unconsciousness before drowning and dismembering them in the bathtub. He managed to murder fifteen people before being discovered and sentenced to prison for

life. Strikingly, although Nilsen was a ruthless murderer of other people, he had the deepest affection for his dog, a mutt named Bleep. Following his arrest, Nilsen's biggest concern was not about the families of those men he killed, or even about himself, but about his furry companion—would she be traumatized by his arrest?

How could Nilsen be indifferent to the pain of those he murdered and yet be overwhelmed by the possible suffering of his dog? Perhaps the answer is that his dog was special and somehow had deeper emotions and richer thoughts—that is, more mind—than his victims. Most of us would scoff at this idea. No matter how cunning Nilsen's canine, we generally agree that people have more mind than dogs, which means that people deserve more compassion and concern than dogs. But Nilsen decided otherwise, believing that his dog had more mind than people, which gave Bleep essential moral rights denied to humans. Nilsen disagreed with the rest of us about the relative status of humans and dogs in the mind club.

Membership in the mind club is immensely important, because it comes with clear privileges: those with minds are given respect, responsibility, and moral status, whereas those without minds are ignored, destroyed, or bought and sold as property. In historical cases where slavery was allowed, it was often justified by a belief that the enslaved people had a different kind of mind.

Mind is in the eye of the beholder. A mind is not an objective fact as much as it is a gift given by the person who perceives it. Mind is a matter of perception, with members being granted admission into the mind club based not on what they are but on what they appear to be. To get in, you need to look like you have a mind.

For example, survey respondents were asked to compare the different characters on different mental abilities. One question asked, for example, if Samantha (the girl) is more or less likely to be able to feel pain than Toby (the chimpanzee). Most people, by the way, said "more."

Beyond the extreme example afforded by the Holocaust, we ignore the minds of others in everyday life—such as homeless people—because they hold no instrumental value. In daily life different people can fulfill different goals. A librarian can help you find an old book, a friend can help set you up with a date, but a homeless person seems to help you with nothing but feelings of guilt. This can render them not only mentally invisible but also physically invisible. We see minds when they are useful to us; it also seems that we ignore them when they are not useful.

It turns out that mental abilities are not all clumped together. Instead, people see minds in terms of two fundamentally different factors, sets of mental abilities we labeled experience and agency.

The experience factor captures the ability to have an inner life, to have feelings and experiences. It includes the capacities for hunger, fear, pain, pleasure, rage, and desire, as well as personality, consciousness, pride, embarrassment, and joy. These facets of mind seemed to capture ‘what it is like’ to have a mind—what psychologists and philosophers often talk about when they discuss the puzzle of consciousness. A mind with experience can feel what it is like to touch a hot stove, can enjoy going to the circus, and can have an orgasm.

The agency factor is composed of a different set of mental abilities: self-control, morality, memory, emotion recognition, planning, communication, and thought. The theme for these capacities is not sensing and feeling but rather thinking and doing. The agency factor is made up of the mental abilities that underlie our competence, intelligence, and action. Minds show their agency when they act and accomplish goals.

A useful framework to help understand the differences between experience and agency is inside and outside. Experience is what minds are like from the inside, what it feels like to be a person, or a cat, or a bat. Because experience is a matter of being inside a mind, it can be very elusive to others. In contrast, agency is more transparent because it is what minds are like from the outside. We can determine an entity’s ability to plan and think simply by observing its actions and reactions. Said another way, experience is about inputs, as sensations and feelings generally are conveyed by sense organs like eyes and ears that feed in to minds. Conversely, agency is about outputs, movements, and actions that feed out of minds.

Mind perception is measured on dimensions of agency and experience. Let’s take a quick tour of the map. First, it seems that normal, conscious, living adult humans like us reside in the upper right corner, with both experience and agency. In contrast, the infant, the dog, and the frog (upper left) have some experience but little agency; they are entities for which people see that ‘someone is home,’ but with diminished capacities to think and act. They are entities that can be harmed but that cannot harm us in return.

Now continue the tour down the map. Below the animals and baby are the more cryptic cases of the human fetus and the patient in a persistent vegetative state. These are cryptominds with very little agency but perhaps some experience; there might be someone home, but not anyone capable of answering the door. Even lower down is the dead woman (lower left), who is ascribed neither much experience nor agency—although it’s worth noting that she is not at zero. Perhaps we see dead people as having some mind because we remember their minds as they were during life. Or perhaps we see their minds because we believe in the afterlife, and how can there be

heaven or hell without minds to feel joy and pain?

As we continue to circle around the map, we move from the dead to the robot, which is perceived to have very little capacity for experience. Just imagine the classic science-fiction robot, which has no emotions and just keeps telling humans how irrational they are. A robot has the agency to help us safely explore the inside of a broken nuclear plant, but without experience it cannot help us explore the inside of a broken heart.

And then, in the bottom right, we have the Almighty. As you might expect, God is perceived as very able to do things, but is, curiously, seen to have little experience. God's mind may be great, but we don't believe that He can feel hunger, fear, or even joy like the rest of us. Interestingly, in a replication of the mind survey, it was discovered that corporations are seen to occupy the same location on the mind map. Like God, Google was seen as all agency and no experience.

Mind perception forms the very basis for questions of life and death: entities with minds deserve moral consideration, whereas entities without minds do not. But if mind perception is split into agency and experience, how do these two factors relate to morality?

Consider a thought experiment called "Baby versus Robot." It's not about babies and robots fighting, unfortunately, but instead about two moral scenarios. In the first, imagine that the baby and the robot were just about to tumble off a cliff and you could save only one of them. Which would you save? Likely you would save the baby and let the robot fall to its doom. Of course, one could make the argument that the robot has lithium batteries and other toxic components that would pollute the environment, whereas the splattered baby goo would provide food for scavengers—though you're right, that diaper does seem problematic. In the second scenario, imagine that the baby and the robot have found a loaded gun and are playing with it, when it goes off and injures someone. Which of them would you hold responsible? If you're like most people, you would forgive the baby and condemn the robot to the junkyard. Which is quite dickish since the robot can't help the way he was programmed, shouldn't we be going after that guy? How do you not program in some 'weapon recognition' into your bot? Isn't this yet another case of capitalism passing the buck to some poor exploited slave?

These two scenarios reveal that it is no fun being a robot, and also that someone needs to talk to that baby's parents. But most important, these scenarios demonstrate that there are two distinct kinds of moral status, not one. Questions of moral responsibility—who deserves responsibility and punishment—seem to be distinct from those of moral rights—who deserves protection from harm—because we protect the baby from harm and yet

hold the robot morally responsible. This finding is striking because many have assumed that more mind equals more morality, with human adults having both rights and responsibilities and tables and turnips having neither. These two types of moral status (rights and responsibilities) not only are distinct but also map perfectly onto our two-dimensional mind map. To have moral rights you need to have experience, an inner life filled with feelings, and the potential for suffering. Conversely, to be morally responsible you need to have agency, to be able to plan, act, and appreciate the outputs of your thoughts. Babies have more experience than robots and so have more moral rights; robots have more agency than babies and so have more moral responsibility.

Beyond babies and robots, the mind survey revealed that any entity with experience is seen to deserve moral rights, and any entity with agency is seen to deserve moral responsibility.

There are two kinds of perceived minds, each with its own type of morality—thinking doers and vulnerable feelers. Thinking doers are active minds with moral responsibility that do actions, minds like corporations and God. Vulnerable feelers are passive minds with moral rights that have actions done to them, minds like puppies, medical patients, and babies. This division of doer and feeler should feel intuitive because it is as ancient as human thought. The writings of Confucius, the yin and yang of ancient China, and the Tao Te Ching have long split the world into complementary opposites such as black and white, hot and cold, and good and evil. In mind perception these opposites are inner (experience) and outer (agency), input (experience) and output (agency), passive (experience) and active (agency), recipient (experience) and doer (agency), victim (experience) and aggressor (agency).

Seen from the perspective of mind perception, good and evil aren't mystical forces that exist apart from humanity, but simply what emerges through the interaction of agents and patients. To create evil, just intentionally cause another mind to suffer (kick a dog), and to create good, just intentionally prevent another mind from suffering (stop a dog from being kicked). More formally, we can define both moral and immoral acts thus:

$$\text{(Im)morality} = \text{Agency (of Agent)} + \text{Experience (of Patient)}$$

This definition reflects both the dyadic nature of good and evil and the kinds of mind (e.g. adult, child, animal, machine) in the agent and patient slots. To get maximum immorality, you should combine a very powerful agent and a very vulnerable patient. Conversely, for minimum immorality, you should combine a weak agent and an invulnerable patient. As evidence,

consider a thought experiment that actually does involve fighting, “CEO versus Little Girl.”

Imagine that a CEO punches a little girl in the face. Chances are, with a few exceptions, you’d think this is immoral. Now imagine that a little girl punches a CEO in the face—might be a good way to show you’re not a tool of those neoliberal NGOs, Greta, can even blame it on your autism—chances are you’d think this is funny. Indeed, children injuring adults is a staple of hilarious YouTube videos, whereas adults injuring children is a staple of (decidedly unfunny) Lifetime movies. The evil of CEOs harming kids, but not of kids harming CEOs, is perfectly consistent with our formula; CEOs are mostly thinking doers, whereas kids are mostly vulnerable feelers, and so only one combination trips our evil detector.

Linking mind perception to morality not only explains the enduring hilarity of kids injuring unsuspecting adults but also allows you to predict your moral outrage about almost any infraction. Tough man (high agency) punches kitten (high experience)? Immoral. Kitten (low agency) scratches tough man (low experience)? Not immoral. Wage slave (low agency) sabotages property of Company (high agency)? Not immoral? When you become enraged at an instance of moral depravity, chances are someone very agentic is harming someone (or something) very patient, if not, you should perhaps question whether you’re simply being manipulated by those in power to reinforce their position.

A Gently Sloping Beach

Organisms must be studied in wild environments that challenge the organism to observe intelligent behaviour.

How do you give a chimp—or an elephant or an octopus or a horse—an IQ test? It may sound like the setup to a joke, but it is actually one of the thorniest questions facing science. Human IQ may be controversial, especially while we are comparing cultural or ethnic groups, but when it comes to distinct species, the problems are a magnitude greater.

At issue, however, is not just how two animal species compare but—the big gorilla in the room—how they compare to us. And in this regard, we often abandon all scrutiny. Just as science is critical of any new finding in animal cognition, it is often equally uncritical with regard to claims about our own intelligence. It swallows them hook, line, and sinker, especially if they are in the expected direction. In the meantime, the general public gets confused, because inevitably any such claims provoke studies that challenge them.

“Variation in outcome is often a matter of methodology, which may sound boring but goes to the heart of the question of whether we are smart enough to know how smart animals are. Methodology is all we have as scientists, so we pay close attention to it. When our capuchin monkeys underperformed on a face-recognition task on a touchscreen, we kept staring at the data until we discovered that it was always on a particular day of the week that the monkeys fared so poorly. It turned out that one of our student volunteers, who carefully followed the script during testing, had a distracting presence. This student was fidgety and nervous, always changing her body postures or adjusting her hair, which apparently made the monkeys nervous, too. Performance improved dramatically once we removed this young woman from the project.”

Or take the recent finding that male but not female experimenters induce so much stress in mice that it affects their responses. Placing a T-shirt worn by a man in the room has the same effect, suggesting that olfaction is key. This means, of course, that mouse studies conducted by men may have different outcomes than those conducted by women. Methodological details matter much more than we tend to admit, which is particularly relevant when we compare species.

The Mirror Test consisted of putting a mark on the body of an anesthetized ape that it could find only, once awake, by inspecting its reflection. The first counterattack came from B. F. Skinner and colleagues, who promptly trained pigeons to peck at dots on themselves while standing in front of a mirror. Reproducing a semblance of the behavior, they felt, would solve the mystery. Never mind that it took them hundreds of grain rewards to get the pigeons to do something that chimpanzees and humans do without any coaching. One can train goldfish to play soccer and bears to dance, but does anyone believe that this tells us much about the skills of human soccer stars or dancers? Worse, we aren't even sure that this pigeon study is replicable. Another research team spent years trying the exact same training, using the same strain of pigeon, without producing any self-pecking birds. They ended up publishing a report critical of the original study with the word 'Pinocchio' in its title.

B. F. Skinner was more interested in experimental control over animals than spontaneous behavior. Stimulus-response contingencies were all that mattered. His behaviorism dominated animal studies for much of the last century. Loosening its theoretical grip was a prerequisite for the rise of evolutionary cognition.

Humans certainly perceive rhythm and other mental abilities in animals, but do animals perceive mind in other animals? Early research on this question focused on chimpanzees because they seemed the most human-like of animals, both in terms of DNA and in mental abilities. In one popular paradigm, two researchers would show a chimp some delicious food, like a banana, before one researcher (the "knower") went behind a screen and hid the food beneath one of four cups. While the knower was doing the hiding, the other experimenter (the "guesser") would stand with a bucket over his head, making him or her blind to the proceedings. Thus the knower would know the exact location of the food, whereas the guesser could only choose a cup at random. The knower and the guesser would then each point to a different cup. The smart choice in this scenario is to trust the knower to indicate the location of the food. However, this requires understanding the content of others' minds, realizing that the bucketless experimenter knows something that the bucketed-headed experimenter does not.

Chimps overwhelmingly failed this task, showing no preference for the cups indicated by the knower, a result most scientists interpreted as indicating that chimps lack the ability to perceive the minds of others. Others weren't so sure. These more optimistic folks believed that researchers were simply using the wrong paradigm to assess mind perception. They reasoned that if evolution had endowed chimps with mind perception it wasn't for playing bucket-head with humans but instead for outcompeting other chimps.

In the wild chimpanzees seldom do cooperative tasks with humans, but they do frequently try to steal the food or mates of other chimpanzees.

To test this “conspecific competition” hypothesis, researchers set up two caches of food in a courtyard: one in plain sight of a high-ranking chimp, the other hidden from his view by a wooden screen. They then released a hungry junior chimp into the courtyard and observed. If chimpanzees lack the ability to understand other minds (like the thoughts of the big, bad, dominant chimp), then this junior chimp would foolishly try to take the visible food. But if chimpanzees could understand other minds, then this junior chimp would take the perspective of the dominant chimp and realize that he should steal only the hidden food. The junior chimp ignored the visible food and instead went to the hidden cache.

It is an unwritten rule among chimps that once something is in your hands or mouth, it is yours, even if you are of low status. Before this moment, however, when two individuals approach food, the dominant will enjoy priority. High-status chimps exploit the other’s knowledge by carefully monitoring their gaze direction, looking where they are looking. Their partners, on the other hand, do their utmost to conceal their knowledge by not looking where they don’t want the other to go. Both chimps seem exquisitely aware that one possesses knowledge that the other lacks.

After releasing the apes onto an island, a number of them passed over the site where researchers had hidden the fruits under the sand. Only a few small yellow patches were visible. Dandy, a young adult male, hardly slowed down when he ran over the place. Later in the afternoon, however, when all the apes were dozing off in the sun, he made a beeline for the spot. Without hesitation, he dug up the fruits and devoured them at his leisure, which he would never have been able to do had he stopped right when he saw them. He would have lost them to dominant group mates. Here we see the entire spectrum of animal cognition, from the specialized navigation of a predatory wasp to the generalized cognition of apes, which allows them to handle a great variety of problems, including novel ones. Dandy at his first passing didn’t linger for a second. He must have made an instant calculation that deception was going to be his best bet.

Instead of trying to control animals to seek specific outcomes, she had a wait-and-see attitude. She presented them with simple challenges to find out how they’d meet them. For her most talented chimpanzee, Sultan, she would put a banana out of reach on the ground and offer him sticks that were too short to reach the fruit. Or she would hang a banana high up in the air and spread large wooden boxes around, none of which was tall enough for the purpose. Sultan would first jump or throw things at the banana or drag humans by the hand toward it in the hope that they’d help him out, or

at least be willing to serve as a footstool. If this failed, he would sit around for a while without doing anything until he might hit at a sudden solution. He would jump up to put one bamboo stick inside another, making a longer stick. Or he would stack boxes on top of one another so as to build a tower that allowed him to reach the banana.

This moment might be described as the ‘aha! experience,’ as if a lightbulb had been switched on, not unlike the story of Archimedes, who jumped out of his bath in which he had discovered how to measure the volume of submerged objects, after which he ran naked through the streets of Syracuse, shouting “Eureka!” A sudden insight explained how Sultan put together what he knew about bananas, boxes, and sticks to produce a brand-new action sequence that would take care of his problem. The outcome was a purposeful action in which the ape kept trying to reach his goal despite the numerous stacking errors resulting in the collapse of his towers. A female, Grande, was an even more undeterred and patient architect who once built a wobbly tower of four boxes. Once a solution was discovered, the apes found it easier to solve similar problems, as if they had learned something about the causal connections.

A good example are the toolkits, which can be so complex that it is hard to imagine that they were invented in a single step. A typical one was found in the Goualougo Triangle, Republic of Congo, where a chimpanzee may arrive with two different sticks at a particular open spot in the forest. It is always the same combination: one is a stout woody sapling of about a meter long, while the other is a flexible slender herb stem. The chimp then proceeds to deliberately drive the first stick into the ground, working it with both hands and feet the way we do with a shovel. Having made a sizable hole to perforate an army ant nest deep under the surface, she pulls out the stick and smells it, then carefully inserts her second tool. The flexible stem captures bite-happy insects that she pulls up and eats, dipping regularly into the nest below. Apes often climb off the ground, moving onto tree buttresses, to avoid the nasty bites of colony defenders. More than one-thousand such tools were collected by a single researcher, which shows how common the perforator-dipping combination is.

More elaborate toolkits are used by chimpanzees in Gabon hunting for honey. In yet another dangerous activity, these chimps raid bee nests using a five-piece toolkit, which includes a pounder (a heavy stick to break open the hive’s entrance), a perforator (a stick to perforate the ground to get to the honey chamber), an enlarger (to enlarge an opening through sideways action), a collector (a stick with a frayed end to dip into honey and slurp it off), and swabs (strips of bark to scoop up honey). This tool use is complicated since the tools are prepared and carried to the hive before

most of the work begins, and they will need to be kept nearby until the chimp is forced to quit due to aggressive bees. Their use takes foresight and planning of sequential steps, exactly the sort of organization of activities often emphasized for our human ancestors.

Chimpanzees on the savanna use between fifteen and twenty-five different tools per community, and the precise tools vary with cultural and ecological circumstances. One savanna community, for example, uses pointed sticks to hunt. This came as a shock, since hunting weapons were thought to be another uniquely human advance. The chimpanzees jab their spears into a tree cavity to kill a sleeping bush baby, a small primate.

At one level chimpanzee tool use may seem primitive, as it is based on sticks and stones, but on another level it is extremely advanced. Sticks and stones are all they have in the forest, and we should keep in mind that also for the Bushmen the most ubiquitous instrument is the digging stick: a sharpened stick to break open anthills and dig up roots. The tool use of wild chimpanzees by far exceeds what was ever held possible.

Even today some scholars dismiss ape tools by stressing how human technology is embedded in social roles, symbols, production, and education. A chimpanzee cracking nuts with rocks doesn't qualify; nor, I suspect, does a farmer picking his teeth with a twig. One philosopher even felt that since chimpanzees don't need their so-called tools, it remains a feeble comparison.

Gibbons are exclusively arboreal. Known as brachiators, they propel themselves through trees by hanging by their arms and hands. Their hands, which have tiny thumbs and elongated fingers, are specialized for this kind of locomotion: gibbon hands act more like hooks than like the versatile grasping and feeling organs of most other primates. Realizing that the gibbon's world barely includes the ground level and that its hands make it impossible to pick up objects from a flat surface, scientists redesigned a traditional string-pulling task. Instead of presenting strings lying on a surface, as had been done before, they were elevated to the animal's shoulder level, making them easier to grasp. Without going into detail—the task required the animal to look carefully at how a string was attached to food—the gibbons solved all the problems quickly and efficiently, demonstrating the same intelligence as other apes. Their earlier poor performance had more to do with the way they were tested than with their mental powers.

Elephants are another good example. For years, scientists believed them incapable of using tools. The pachyderms failed the out-of-reach banana test, leaving the stick alone. Their failure could not be attributed to an inability to lift objects from a flat surface, because elephants are ground dwellers and pick up items all the time, sometimes tiny ones. Researchers concluded that they just didn't get the problem. It occurred to no one that

perhaps we, the investigators, didn't get the elephant. Like the six blind men, we keep turning around and poking the big beast, but we need to remember that what we observe is not nature in itself, but nature exposed to our method of questioning.

In contrast to the primate's hand, the elephant's grasping organ is also its nose. Elephants use their trunks not only to reach food but also to sniff and touch it. With their unparalleled sense of smell, these animals know exactly what they are going for. But picking up a stick blocks their nasal passages. Even when they bring the stick close to the food, it impedes their feeling and smelling it. It is like sending a blindfolded child out on an Easter egg hunt. What sort of experiment, then, would do justice to the animal's special anatomy and abilities?

At the National Zoo in Washington, D.C. Kandula, a young elephant bull, can do the problem when it is presented differently. The scientists hung fruit high up above Kandula's enclosure, just out of his reach. They gave the elephant several sticks and a sturdy square box. Kandula ignored the sticks but, after a while, began kicking the box with his foot. He kicked it many times in a straight line until it was right underneath the fruit. He then stood on the box with his front legs, which enabled him to reach the food with his trunk. An elephant, it turns out, can use tools—if they are the right ones.

They also varied the setup, making life more difficult for Kandula. They put the box in a different section of the yard, out of view, so that when Kandula looked up at the tempting food, he would need to recall the solution while distancing himself from his goal to fetch the tool. Apart from a few large-brained species, such as humans, apes, and dolphins, not many animals will do this, but Kandula did it without hesitation, fetching the box from great distances.

Superior intelligence doesn't imply better test outcomes. Both rhesus monkeys and chimpanzees were presented with a simple task, known as haptic (touch) discrimination. They were to stick their hand through a hole to feel the difference between two shapes and pick the correct one. The goal was to do hundreds of trials per session, but whereas this worked well with the monkeys, the chimps had other ideas. They would do fine on the first dozen trials, showing that the discrimination posed no problem, but then their attention would wander. They'd thrust their hands farther so as to reach the scientist, pulling at their clothes, making laughing faces, banging on the window that separated them, and trying to engage the researchers in play. Jumping up and down, they'd even gesture to the door, as if the scientist didn't know how to get to their side. Needless to say, the apes' performance on the task was well below that of the monkeys, not due to

an intellectual deficit but because they were bored out of their minds. The task was just not up to their intellectual level.

One cannot expect a great performance on a task that fails to arouse interest. Researchers ran into this problem while studying face recognition in chimpanzees. At the time, science had declared humans unique, since we were so much better at identifying faces than any other primate. No one seemed bothered by the fact that other primates had been tested mostly on human faces rather than those of their own kind. When one of the pioneers in this field was asked why the methodology had never moved beyond the human face, he answered that since humans differ so strikingly from one another, a primate that fails to tell members of our species apart will surely also fail at its own kind.

But when tested on photographs of their own species they excelled at it. Selecting images on a computer screen, they would see one chimpanzee portrait immediately followed by a pair of others. One portrait of the pair would be a different picture of the same individual as presented before, while the other would show a different individual. Having been trained to detect similarity (a procedure known as matching to sample), the chimpanzees had no trouble recognizing which portrait most resembled the first. The apes even detected family ties. After having seen a female portrait, they were given a choice between two juvenile faces, one of which was the offspring of the female shown before. They picked the latter based purely on physical similarity, since they did not know any of the depicted apes in real life.

What is salient to us—such as our own facial features—may not be salient to other species. Animals often know only what they need to know.

Each organism has its own ecology and lifestyle, its own *Umwelt*, which dictates what it needs to know in order to make a living. There is not a single species that can stand model for all the others, most certainly not one with a brain as tiny as a pigeon's. Pigeons are plenty intelligent, but size does matter. Brains are the most "expensive" organs around. They are true energy hogs, using twenty times more calories per unit than muscle tissue. Since ape brains are several hundred times heavier than those of pigeons and hence burn vastly more energy, it stands to reason that apes face greater cognitive challenges. Otherwise mother nature indulged in a shocking extravagance, something she is not known for. In the utilitarian view of biology, animals have the brains they need—nothing more, nothing less. Even within a species, the brain may change depending on how it is being used, such as the way song-related areas seasonally expand and contract in the songbird brain. Brains adapt to ecological requirements, as does cognition.

Evolution pushes cognition around, adapting it to the organism's needs.

This is known as biologically prepared learning: each organism is driven to learn those things it needs to know in order to survive.

Without any reward or punishment, animals accumulate knowledge that will come in handy in the future, from finding nuts in the spring, to returning to one's burrow, to reaching a banana. The role of learning is obvious, but what is special about cognition is that it puts learning in its proper place. Learning is a mere tool. It allows animals to collect information in a world that, like the Internet, contains a staggering amount of it. It is easy to drown in the information swamp. An organism's cognition narrows down the information flow and makes it learn those specific contingencies that it needs to know given its natural history.

By flapping their wings, digging holes, manipulating sticks, gnawing wood, climbing trees, and so on, every species sets up its own learning opportunities. Many animals are driven to learn the things they need to know or do, the way kid goats practice head butts or human toddlers have an insuppressible urge to stand up and walk. Operant conditioning tends to reinforce what is already there. Instead of being the omnipotent creator of behavior, it is its humble servant.

If learning talents are a product of natural history and mating strategies, the whole notion of universality begins to fall apart. We can expect huge variation. Evidence for inborn learning specializations has been steadily mounting. There are many different types, from the way ducklings imprint on the first moving object they see—whether it is their mother or a bearded zoologist—to the song learning of birds and whales and the way primates copy one another's tool use. The more variation we discover, the shakier gets the claim that all learning is essentially the same.

Most animal learning is of a rather vague kind, similar to how you may have learned to avoid some highways at certain times of the day. Having gotten stuck in traffic often enough, you will look for a better, faster route, without any specific memory of what happened on your previous commutes. This is also how a rat in a maze learns to turn one way and not another, and how a bird learns at what time of day to find bread crumbs at my parents' balcony. This kind of learning is all around us.

What we deem a special kind, the one at issue here, is the recall of particulars. The power of autobiographical memories lies in their specificity. Colorful and alive, they can be actively called up and dwelled upon. They are reconstructions—which is why they are sometimes false—yet so powerful that they are accompanied by an extraordinary sense of their correctness. They fill us with emotions and sensations. You mention someone's wedding day, or Dad's funeral, and all sorts of memories about the weather, the guests, the food, the happiness, or the sadness will flood the mind. This

kind of memory must be at work when apes react to cues connected to events from years back.

The same memory serves foraging wild chimpanzees, which visit about a dozen fruit-bearing trees per day. How do they know where to go? The forest has far too many trees to go about it randomly. Working in Tai National Park, in Ivory Coast, a primatologist found apes to have an excellent recall of previous meals. They mostly checked trees at which they had eaten in previous years. If they ran into copious ripe fruit, they'd gorge on it while grunting contentedly and make sure to return a couple of days later. The researcher describes how the chimps would build their daily nests (in which they sleep for only one night) en route to such trees and get up before dawn, something they normally hate to do. The intrepid primatologist followed the traveling party on foot, but whereas the chimps typically ignored her tripping or stepping on a noisy branch, now they all would turn around and stare pointedly at her, making her feel bad. Sounds draw attention, and the chimps were on edge in the dark. This was understandable since one of the females had recently lost her infant to a leopard.

Despite their deep-seated fear, the apes would set out on a long trek to a specific fig tree where they had recently eaten. Their goal was to beat the early fig rush. These soft, sweet fruits are favored by many forest animals, from squirrels to flocks of hornbills, so that an early arrival would be the only way to take advantage of the abundance. Remarkably, the chimps would get up earlier for trees far from their nests than for those nearby, arriving at about the same time at both. This suggests calculation of travel time based on expected distances. All this makes one believe that the Tai chimpanzees actively recall previous experiences in order to plan for a plentiful breakfast.

The case for episodic memory in animals was further strengthened when psychologists let rats run around in an eight-armed radial maze. The rodents learned that once they had visited an arm and eaten the food in it, it would be permanently gone, so there would be no point returning to it. There was one exception, though. They occasionally found chocolate-flavored pellets, which would be replenished after long time intervals. The rats formed an expectation about this delicious food based on where and when they had encountered it. They did return to those specific arms, but only after long intervals. In other words, the rodents kept track of the when, what, and where of chocolate surprises.

Some are hardly satisfied with these results, however. They fail to tell us how aware the birds, rats, or apes are of their own memories. What kind of consciousness, if any, is involved? Do they view their past as a piece of personal history? Since such questions are unanswerable, some have, unsurprisingly, weakened the terminology by endowing animals only with

“episodic-like” memory. I don’t agree with this retreat, however, since it gives weight to an ill-defined aspect of human memory known only through introspection and language. While language is helpful to communicate memories, it is hardly what produces them. My preference would be to turn the burden of proof around, especially when it comes to species close to us. If other primates recall events with equal precision as humans do, the most fair assumption is that they do so in the same way. Those who insist that human memory rests on unique levels of awareness have their work cut out for them to substantiate such a claim. It may, literally, be all in our heads.

One researcher gave a bottlenose dolphin the task to tell the difference between high and low tones. The dolphin was an eighteen-year-old male named Natua, in a pool at the Dolphin Research Center in Florida. Natua’s level of confidence was quite manifest. He swam at different speeds toward the response, depending on how easy or hard it was to tell both tones apart. When they were very different, the dolphin arrived with such speed that his bow wave threatened to soak the electronics of the apparatus. They had to be covered with plastic. If the tones were similar, though, Natua slowed down, wagged his head, and wavered between the two paddles that he needed to touch in order to indicate a high or low sound. He didn’t know which one to pick. To study Natua’s uncertainty, mindful of the suggestion that it might reflect consciousness, the investigator created a way for the animal to opt out. A third paddle was added, which Natua could touch if he wanted a fresh trial with an easier distinction. The tougher the choice, the more Natua went for the third paddle, apparently realizing when he had trouble coming up with the right answer. Thus the field of animal metacognition was born.

Another researcher gave monkeys a memory task on a touchscreen. They would first see one particular image, say a pink flower, then face a delay before being presented with several pictures, including the pink flower. The delay varied in length. Before each test, the monkeys had the choice to either take it or decline it. If they took the test and correctly touched the pink flower, they gained a peanut. But if they declined, they only got a monkey pellet, a boring everyday food. The longer the delay, the more the monkeys declined taking the test despite its better reward. They seemed to realize that their memory had faded. Occasionally, they were forced to take a trial without a chance of escape. In those cases they fared rather poorly. In other words, they opted out for a reason, doing so when they couldn’t count on their memory.

A rhesus macaque knows that food has been hidden in one of four tubes, but he has no idea which one. He is not allowed to try every tube and will get only one pick. By bending down to first peek into the tubes, he demonstrates

that he knows he doesn't know, which is a sign of metacognition.

As a result of these studies, some animals are now believed to track their own knowledge and to realize when it is deficient. It all fits the idea that animals are active processors of the cues around them, with beliefs, expectations, even consciousness.

Perception is turned into experience by picking and choosing what sensory input to pay attention to and how to process and organize it. Reality is a mental construct. This is what makes the elephant, the bat, the dolphin, the octopus, and the star-nosed mole so intriguing. They have senses that we either don't have, or that we have in a much less developed form, making the way they relate to their environment impossible for us to fathom. They construct their own realities. We may attach less significance to these, simply because they are so alien, but they are obviously all-important to these animals. Even when they process information familiar to us, they may do so quite differently, such as when elephants tell human languages apart. This ability was first demonstrated in African elephants.

Herds retreated and "bunched" together (forming a tight circle with calves in the middle) more often after playbacks of Maasai than of Kamba voices. Maasai male voices triggered more defensive reactions than those of Maasai women and boys. Even after the natural voices were acoustically transformed so as to make male voices sound more female, and vice versa, the outcome remained the same. The elephants were especially vigilant upon hearing the resynthesized voices of Maasai men. This was surprising because the pitch of these voices had now the opposite gender's qualities. Possibly the elephants identified gender by other characteristics, such as the fact that female voices tend to be more melodious and "breathy" than those of males. Experience played a role, because herds led by older matriarchs were more discriminating. The same difference was found in another study in which lion roaring was played from a speaker. Older matriarchs would charge the speaker, which is quite different from their hasty retreat from Maasai voices. Aggressive mobbing of men carrying spears is unlikely to pay off, yet driving off lions is something elephants are good at.

Despite their size, these animals face other dangers, including very small ones, such as stinging bees. Elephants are vulnerable to stings around the eyes and up their trunks, and young elephants lack a thick enough skin to protect themselves against a mass attack. Elephants give deep rumbles as an alarm to both humans and bees, but the two sounds must differ because playbacks induce quite different responses. Upon hearing the bee-rumble from a speaker, for example, elephants flee with head-shaking movements that would knock insects away, a reaction not shown to the human-rumble.

In short, elephants make sophisticated distinctions regarding potential

dangers to the point that they classify our own species based on language, age, and gender. How they do so is not entirely clear, but studies like these are beginning to scratch the surface of one of the most enigmatic minds on the planet.

If we test animals under duress, what can we expect? Would anyone test the memory of human children by throwing them into a swimming pool to see if they remember where to get out? Yet the Morris Water Maze is a standard memory test used every day in hundreds of laboratories that make rats frantically swim in a water tank with high walls until they come upon a submerged platform that saves them. In subsequent trials, the rats need to remember the platform's location. There is also the Columbia Obstruction Method, in which animals have to cross an electrified grid after varying periods of deprivation, so researchers can see if their drive to reach food or a mate—or for mother rats, their pups—exceeds the fear of a painful shock. Stress is, in fact, a major testing tool. Many labs keep their animals at 85 percent of typical body weight to ensure food motivation. We have woefully little data on how hunger affects their cognition, although I do remember a paper entitled “Too Hungry to Learn?” about food-deprived chickens that were not particularly good at noticing the finer distinctions of a maze task.

The assumption that an empty stomach improves learning is curious. Think about your own life: absorbing the layout of a city, getting to know new friends, learning to play the piano or do your job. Does food play much of a role? No one has ever proposed permanent food deprivation for university students. Why would it be any different for animals? Intelligent animals learn mostly through curiosity and free exploration, both of which are likely killed by a narrow fixation on food. For example, the Skinner box is a splendid instrument to demonstrate the effectiveness of food rewards but not to study complex behavior.

I am not for one moment disparaging the value of the rat as a subject for psychological investigation; there is very little wrong with the rat that cannot be overcome by the education of the experimenters.

Instead of domesticating white rats in order to make them suitable to a particular testing paradigm, behaviorists should have done the opposite. They should have invented paradigms that fit real animals.

American psychologist Frank Beach lamented the narrow focus of behavioral science on the albino rat. His incisive critique featured a cartoon in which a Pied Piper rat is followed by a happy mass of white-coated experimental psychologists. Carrying their favorite tools—mazes and Skinner boxes—they are being led into a deep river.

Dogs were once depicted as smarter than wolves, perhaps even apes, because they paid better attention to human pointing gestures. A human

would point at one out of two buckets, and the dog would check that particular bucket out for a reward. Scientists concluded that domestication had given dogs extra intelligence compared to their ancestors. But what does it mean that wolves fail to follow human pointing? With its vast experience, I bet a wolf could outsmart its domesticated counterpart anytime—yet all we go by is how they react to us. And who says that the difference in reaction is inborn, a consequence of domestication, and not based on familiarity with the species doing the pointing?

It is the old nature-nurture dilemma. The only way to determine how much of a trait is produced by genes and how much by the environment is to hold one of these two constant to see what difference the other one makes. It is a complex problem that is never fully resolved. In the dog-wolf comparison, this would mean raising wolves like dogs in a human household. If they still differ, genetics might be at play. Raising wolf puppies in the home is a hellish job, though, since they are exceptionally energetic and less rule-bound than dog puppies, chewing up everything in sight. When dedicated scientists raised wolves this way, the nurture hypothesis came out the winner. Human-raised wolves followed hand points as well as dogs.

A few differences persisted, though, such as that wolves looked less at human faces than dogs and were more self-reliant. When dogs tackle a problem they cannot solve, they look back at their human companion to get encouragement or assistance—something that wolves never do. Wolves keep trying and trying on their own. Domestication may be responsible for this particular difference. Instead of intelligence, though, it seems more a question of temperament and relations with us—those weird bipedal apes that the wolf evolved to fear and the dog was bred to please.

This is no doubt why some people rate cats as less intelligent than dogs. We know, however, that a cat's lack of response to humans is not due to ignorance. A recent study showed that felines have no trouble recognizing their owner's voice. The deeper problem is that they don't care, prompting the study's authors to add:

“The behavioral aspects of cats that cause their owners to become attached to them are still undetermined.”

Dogs, for example, engage in lots of eye contact with us. They have hijacked the human parental pathways in the brain, making us care about them in almost the same way that we care about our children. Dog owners who stare into their pet's eyes experience a rapid increase in oxytocin—a neuropeptide involved in attachment and bonding. Exchanging gazes full of empathy and trust, we enjoy a special relationship with the dog.

There is a video you may have seen, and it may have brought tears to your eyes. It concerns two British men, John Rendall and Anthony “Ace” Berg, who in 1969 rescued a lonely lion cub from his tiny cage, brought him home, and named him Christian. These two big men fed Christian from a bottle and played with him in a local churchyard, and when he quickly grew too big for their apartment, they facilitated his release back into the wilds of Africa. Months later they went to Kenya to check up on their feline friend, but they were told that he was now fully wild and that he would not remember them.

Undeterred, they trekked to his location and filmed their encounter. The video begins with John, Ace, and Christian walking toward each other across some rocks. As the lion approaches the men, he quickens his pace, and there is a moment of apprehension as Christian jumps toward them with paws outstretched, but he attacks them only with love and gives them a big hug. Wishful thinking be damned, there is no other word that fits: he stands up on his hind legs and embraces them with his paws. The two men whoop and snuggle him; he hasn’t forgotten his surrogate parents and the love they gave.

Human empathy is a critically important capacity, one that holds entire societies together and connects us with those whom we love and care about. It is far more fundamental to survival, I’d say, than knowing what others know. But since it belongs to the large submerged part of the iceberg—traits that we share with all mammals—it doesn’t garner the same respect. Moreover, empathy sounds emotional, something cognitive science tends to look down upon. Never mind that knowing what others want or need, or how best to please or assist them, is likely the original perspective taking, the kind from which all other kinds derive. It is essential for reproduction, since mammalian mothers need to be sensitive to the emotional states of their offspring, when they are cold, hungry, or in danger. Empathy is a biological imperative.

Once, in his desire to underscore the uniqueness of human altruism, a prominent child psychologist shouted at a large audience:

“No ape will ever jump into a lake to save another!”

However, there are actually a handful of reports of apes doing precisely this—often to their own detriment, since they don’t swim.

I speak of targeted helping, which is assistance based on an appreciation of the other’s precise circumstances. One of the oldest reports in the scientific literature concerns an incident, in 1954, off the coast of Florida. During a capture expedition for a public aquarium, a stick of dynamite was set off

under the water surface near a pod of bottlenose dolphins. As soon as one stunned victim surfaced, heavily listing, two other dolphins came to its aid:

“One came up from below on each side, and placing the upper lateral part of their heads approximately beneath the pectoral fins of the injured one, they buoyed it to the surface in an apparent effort to allow it to breathe while it remained partially stunned.” The two helpers were submerged, which meant that they couldn’t breathe during the entire effort. The pod remained nearby and waited until their companion recovered, after which they all fled in a hurry, taking tremendous leaps.”

In children, an understanding of needs and desires develops years before they realize what others know. They read hearts well before they read minds. This suggests that we are on the wrong track in phrasing all this in terms of abstract thinking and theories about others. At a young age, children recognize, for example, that a child looking for his rabbit will be happy to find it, whereas a child searching for his dog will be indifferent to the rabbit. They have an understanding of what others want. Not all humans take advantage of this capacity, which is why we have two kinds of gift-givers: those who go out of their way to find a gift that you might like, and those who arrive with what they like.

Even birds do better than that. In one of those cognitive ripples typical of the field, empathic perspective taking has been suggested for corvids. Male Eurasian jays court their mates by feeding them delicious tidbits. On the assumption that every male likes to impress, experimenters gave him two foods to choose from: wax moth larvae and mealworms. But before giving the male a chance to feed his mate, they would feed her first with one of those two foods. Seeing this, the male would change his choice. If his mate had just eaten a lot of wax moth larvae, he’d pick mealworms for her instead, and vice versa. He did so, however, only if he had witnessed her being fed by the experimenter. Male birds thus took into account what their mate had just eaten, perhaps assuming that she’d be ready for a change of taste.

One of the best illustrations of chimpanzee social awareness occurs in mediated conflict resolution. After a fight between male combatants, a third party may induce them to make peace. Interestingly, it’s only female chimps who do so, and only the highest-ranking ones among them. They step in when two male rivals fail to reconcile. The male rivals may be sitting near each other and avoiding eye contact, unable or unwilling to make the first move. If a third male were to approach, even to make peace, he’d be

perceived as a party to the conflict. Male chimps form alliances all the time, so their presence is never neutral. This is where the older females come in.

The matriarch of the Arnhem Prison colony, Mama, was the mediator par excellence: no male would ignore her or carelessly start a fight that might incur her wrath. She would approach one of the males and groom him for a while, then slowly walk toward his rival while being followed by the first. She would look around to check on the first and return to tug at his arm if he was reluctant. Then she'd sit down next to the second male, while both males would groom her, one on each side. Finally Mama would slip away from the scene, and the males would pant, splutter, and smack more loudly than before—sounds that signal grooming enthusiasm; but by then they would of course be grooming each other.

It is a risky affair—the males are obviously in a grumpy mood—which is why younger females, instead of trying to mediate themselves, encourage others to do so. They approach the top female while looking around at the males who are refusing to make up. This way, they try to get something going that they can't accomplish safely by themselves. Such behavior demonstrates how much chimpanzees know about the social relationships of others, such as what has happened between the rival males, what has to be done to restore harmony, and who will be the best one to undertake this mission. It is the sort of knowledge that we take for granted in our own species, but without it animal social life could never have reached its known complexity.

Two female chimps were sitting in the sun, with their children rolling around in the sand in front of them. When the play turned into a screaming, hair-pulling fight, neither mother knew what to do because if one of them tried to break up the fight, it was guaranteed that the other would protect her offspring, since mothers are never impartial. It is not unusual for a juvenile quarrel to escalate into an adult fight. Both mothers nervously monitored each other as well as the fight. Noticing the alpha female, Mama, asleep nearby, one of them went over to poke her in the ribs. As the old matriarch got up, the mother pointed at the fight by swinging an arm in its direction. Mama needed only one glance to grasp what was going on and took a step forward with a threatening grunt. Her authority was such that this shut up the youngsters. The mother had found a quick and efficient solution to her problem, relying on the mutual understanding typical of chimpanzees.

Similar understanding can be seen in their altruism, such as when younger females collect water in their mouths for an aging female, who can barely walk anymore, spitting it into her open mouth so that she doesn't have to walk all the way to water source. Jane Goodall described how Madame

Bee, a wild chimpanzee, had become too old and weak to climb into fruiting trees. She would patiently wait at the bottom for her daughter to carry down fruits, upon which the two of them would contentedly munch together. In such cases, too, apes grasp a problem and come up with a fresh solution, but the striking part here is that they perceive another ape's problem.

Siamangs—large black members of the gibbon family—swing high up in the tallest trees of the Asian jungle. Every morning, the male and female burst into spectacular duets. Their song begins with a few loud whoops, which gradually build into ever louder, more elaborate sequences. Amplified by balloon-like throat sacs, the sound carries far and wide. The siamangs listen to one another during breaks. Whereas most territorial animals need only to know where their boundaries run and how strong and healthy their neighbors are, siamangs face the added complexity that territories are jointly defended by pairs. This means that pair-bonds matter. Troubled pairs will be weak defenders, while bonded pairs will be strong ones. Since the song of a pair reflects their marriage, the more beautiful it is, the more their neighbors realize not to mess with them. A close-harmony duet communicates not only 'stay out!' but also 'we're one!' If a pair duets poorly, on the other hand, uttering discordant vocalizations that interrupt one another, neighbors hear an opportunity to move in and exploit the pair's troubled relationship.

To understand how others relate to one another is a basic social skill that is even more important for group-living animals. They deal with a far greater variety than the siamang. In a baboon or macaque troop, for example, a female's rank in the hierarchy is almost entirely decided by the family from which she hails. Owing to a tight network of friends and kin, no female escapes the rules of the matrilineal order according to which daughters born to high-ranking mothers will themselves become high-ranking, while daughters from families at the bottom will also end up at the bottom. As soon as one female attacks another, third parties move in to defend one or the other so as to reinforce the existing kinship system.

The youngest members of the top families know this all too well. Born with a silver spoon in their mouth, they freely provoke fights with everyone around, knowing that even the biggest, meanest female of a lower clan will not be allowed to assert herself against them. The youngster's screams will mobilize her powerful mother and sisters. In fact, it has been shown that screams sound different depending on the kind of opponent a monkey confronts. Thus, it is immediately clear to the entire troop whether a noisy fight fits or violates the established order.

The social knowledge of wild monkeys has been tested by playing the distress calls of a juvenile from a loudspeaker hidden in the bushes at a moment when the juvenile itself is out of sight. Hearing this sound, nearby

adults not only look in the direction of the speaker but also peek at the juvenile's mother. They recognize the juvenile's voice and seem to connect it with its mother, perhaps wondering what she is going to do about the trouble her offspring is in. The same sort of social knowledge can be seen at more spontaneous moments, when a juvenile female picks up an infant that is unsteadily walking about, only to carry it back to its mother, which means that she knows which female the infant belongs to.

Ravens recognize one another's voices and pay close attention to dominant and subordinate calls. But then the playbacks were manipulated to make it sound as if a dominant individual had turned submissive. Hearing evidence of a brewing overthrow, the ravens would stop what they were doing and listen while showing signs of distress. They were most upset by rank reversals among members of their own sex in their own group, but they reacted also to status reversals between ravens in an adjacent aviary. The investigators concluded that ravens have a concept of status that goes beyond their own position. They know how others typically interact and are alarmed by deviations from this pattern.

After testing both children and apes on a cooperative pulling task, one scientist concluded that only the children exhibit shared intentionality. The question of comparability has come up before, however, and fortunately there are photographs of the respective setups. One shows two apes in separate cages, each with a little plastic table in front of him that he can pull closer with a rope. Oddly, the apes do not occupy a shared space, as in Crawford's classical study. Their cages are not even adjacent: there is distance and two layers of mesh between them—a situation that hampers visibility and communication. Each ape focuses on its own end of the rope, seemingly unaware of what the other is up to. The photo of the children, in contrast, shows them sitting on the carpeting of a large room with no barriers between them. They, too, are using a pulling apparatus, but they sit side by side in full view of each other and are free to move around, touch each other, and talk.

These different arrangements go a long way toward explaining why the children showed shared purpose, and the apes did not. Had this comparison concerned two different species—rats and mice, say—we would never have accepted such dissimilar setups. If rats had been tested on a joint task while sitting side by side and mice while being kept apart, no sensible scientist would permit the conclusion that rats are smarter or more cooperative than mice. We'd demand the same procedure. Comparisons between children and apes get exceptional leeway, however, which is why studies keep perpetuating cognitive differences that, in my mind, are impossible to separate from methodological ones.

Two juveniles, Bula and Bimba, are pulling at ropes attached to a heavy box outside their cage. Food has been placed on the box, which is too heavy for one of them to pull in alone. The synchronized pulling by Bula and Bimba is remarkable. They do so in four or five bursts, so well coordinated that you'd almost think they were counting—'one, two, three. . . pull!'—but of course they are not. In a second phase, Bula has been fed so much that her motivation has evaporated, and her performance is lackluster. Bimba solicits her every now and then, poking her or pushing her hand toward the rope. Once they have successfully brought the box within reach, Bula barely collects any food, leaving it all to Bimba. Why did Bula work so hard with so little interest in the payoff?

The likely answer is reciprocity. These two chimps know each other and probably live together, so that every favor they do for each other will likely be repaid. They are buddies, and buddies help each other out. This pioneering study contains all the ingredients later expanded upon by more rigorous research. The cooperative pulling paradigm, as it is known, has been applied to monkeys, hyenas, parrots, rooks, elephants, and so on. The pulling is less successful if the partners are prevented from seeing each other, so success rests on true coordination. It is not as if the two individuals pull at random and, by luck, happen to pull together. Furthermore, primates prefer partners who cooperate eagerly and are tolerant enough to share the prize.

Given all this evidence, one wonders why the social sciences in recent years have settled on the curious idea that human cooperation represents a "huge anomaly" in the natural realm. It has become commonplace to assert that only humans truly understand how cooperation works or know how to handle competition and freeloading. Animal cooperation is presented as mostly based on kinship, as if mammals were social insects. This idea was quickly disproven when fieldworkers analyzed DNA extracted from the feces of wild chimpanzees, which allowed them to determine genetic relatedness. They concluded that the vast majority of mutual aid in the forest occurs between unrelated apes. Captive studies have shown that even strangers—primates who didn't know each other before they were put together—can be enticed to share food or exchange favors.

The highest level of joint intentionality in the animal kingdom is perhaps achieved by killer whales. After spy-hopping to get a good look at a seal on an ice floe, several of them will line up and swim toward the floe at high speed in perfect unison. Their behavior creates a massive wave that washes the seal off the floe straight into some waiting mouths.

When two or more intelligent, cooperative species meet around food resources, the outcome may also be cooperation rather than competition.

Each species knows how to take advantage of the other. Fishing cooperatives, in which humans and cetaceans (whales and dolphins) work together, are probably thousands of years old, having been reported from Australia and India to the Mediterranean and Brazil. In South America they operate on the mud shores of lagoons. Fishermen announce their arrival by slapping the water, upon which bottlenose dolphins emerge to herd mullet toward them. The fishers wait for a signal from the dolphins, such as a distinctive type of dive, to throw their nets. Dolphins also do such herding among themselves, but here they drive the fish toward the fishermen's nets. The men know their dolphin partners individually, having named them after famous politicians and soccer players.

Even more spectacular are the cooperatives between humans and killer whales. When whaling still occurred around Twofold Bay, in Australia, orcas would approach the whaling station to perform conspicuous breaching and lobtailing that served to announce the arrival of a humpback whale. They would herd the large whale into shallow waters close to a whaling vessel, allowing the whalers to harpoon the harassed leviathan. Once the whale was killed, the orcas would be given one day to consume their preferred delicacy—its tongue and lips—after which the whalers would collect their prize. Here too humans gave names to their preferred orca partners and recognized the tit-for-tat that is the foundation of all cooperation, human as well as animal.

As soon as humans let their impulses run free, we rush to compare them with animals. However it all boils down to the social hierarchy, which is one giant behavioral regulator. If everyone were to act the way they wanted, any hierarchy would fall apart. It is built on restraint. Since social ladders are present in species from fish and frogs to baboons and chickens, self-control is an age-old feature of animal societies.

It is easy to see inhibitions at work in our pets, such as a cat who spots a chipmunk. Instead of going after the little rodent right away, she makes a wide detour, with her body sleekly pressed against the ground, to arrive at a hiding spot from which she can pounce on her unsuspecting prey. Or take the big dog who lets puppies jump all over him, bite his tail, and disturb his sleep without a single growl of protest. While restraint is apparent to anyone in daily contact with animals, Western thought hardly recognizes the ability.

Traditionally, animals are depicted as slaves of their emotions. It all goes back to the dichotomy of animals as “wild” and humans as “civilized.” Being wild implies being undisciplined, crazy even, without holding back. Being civilized, in contrast, refers to exercising the well-mannered restraint that humans are capable of under favorable circumstances. This dichotomy

lurks behind almost every debate about what makes us human, so much so that whenever humans behave badly, we call them ‘animals.’

At one time the London Zoo held tea parties in the ape house with the public looking on. Gathered on chairs around a table, the apes had been trained to use bowls, spoons, cups, and a teapot. Naturally, this equipment posed no problem for these tool-using animals. Unfortunately, over time the apes became too polished and their performance too perfect for the English public, for whom high tea constitutes the peak of civilization. When the public tea parties began to threaten the human ego, something had to be done. The apes were retrained to spill the tea, throw food around, drink from the teapot’s spout, and pop the cups into the bowl as soon as the keeper turned his back. The public loved it! The apes were wild and naughty, as they were supposed to be.

No species can escape the logic of cooperation, whether it involves the selection of good partners or the balance between effort and payoff. The generality of these principles is best illustrated by the interplay and mutualism between small cleaner wrasses and their hosts, the large fish from which the cleaners nibble away ectoparasites. Each cleaner fish owns a “station” on a reef with a clientele, which come and spread their pectoral fins and adopt postures that offer the cleaner a chance to do its job. In perfect mutualism, the cleaner removes parasites from the client’s body surface, gills, and even the inside of its mouth. Sometimes the cleaner is so busy that clients have to wait in queue.

Such research reads much like a manual for “good” business practice. For example, cleaners treat roaming fish better than residents. If a roamer and a resident arrive at the same time, the cleaner will service the roamer first. Residents can be kept waiting since they have nowhere else to go. The whole process is one of supply and demand. Cleaners occasionally cheat by taking little bites of healthy skin out of their client. Clients don’t like this and jolt or swim away. The only clients that cleaners never cheat are predators, which possess a radical counterstrategy: to swallow them. The cleaners seem to have an excellent understanding of the costs and benefits of their actions.

There is only one area in which human cooperation goes well beyond what we know of other species: its degree of organization and scale. We have hierarchical structures to set up projects of a complexity and duration not found elsewhere in nature. Most animal cooperation is self-organized in that individuals fulfill roles according to their capacities. Sometimes animals coordinate as if they have agreed on a task division beforehand. We do not know how shared intentions and goals are communicated, but they do not seem to be orchestrated from above by leaders, as in humans. We develop

a plan and put a hierarchy in place to manage its execution, which allows us to lay a railroad track across the country or build a huge cathedral that takes generations to complete. Relying on age-old evolved tendencies, we have shaped our societies into complex networks of cooperation that can take on projects of an unprecedented magnitude.

“My definition of an anecdote is someone else’s observation.”

If you have seen something yourself and followed the entire dynamic, there usually is no doubt in your mind of what to make of it. But others may be skeptical and need convincing.

For those who disparage anecdotes altogether, it is good to keep in mind that almost all interesting work on animal behavior has begun with a description of a striking or puzzling event. Anecdotes hint at what is possible and challenge our thinking. But we cannot exclude that the event was a fluke, never to be repeated again, or that some decisive aspect went unnoticed.

One general criticism leveled at animal researchers is that they are inventing rather than objectively observing minds, projecting their own hopes and desires onto animals, and mistaking their own complex social understanding for that of the animals. The most organized criticism of animal minds was the behaviorist movement in psychology, which sought to remove references of mental states from descriptions of animal (and human) behavior. In particular, behaviorism led chimpanzee researchers to try to remove all human-like language from accounts of chimpanzee behavior.

The result was an almost endless series of specific acts in which no order or meaning could be found. Compare the informational value of ‘A approached B, A touched B’s back, and A removed something from B’s back; later, B approached A, B touched A’s back, B removed something from A’s back, and A and B vocalized’ with ‘A and B happily groomed each other.’ The latter not only is more informative and succinct but also makes for a more compelling story. Importantly, any mind-rich descriptions are wrong only when animals lack the mental capacities we ascribe to them, and the research we’ve examined suggests that perceptions of mind are justified in many species.

Anthropomorphism is problematic only when the human-animal comparison is a stretch, such as with regards to species distant from us. The fish known as kissing gouramis, for example, don’t really kiss in the same way and for the same reasons that humans do. Adult fish sometimes lock their protruding mouths together to settle disputes. Clearly, to label this habit ‘kissing’ is misleading. Apes, on the other hand, do greet each other after a

separation by placing their lips gently on each other's mouth or shoulder and hence kiss in a way and under circumstances that greatly resemble human kissing. Bonobos go even further: when a zookeeper familiar with chimpanzees once naïvely accepted a bonobo kiss, not knowing this species, he was taken aback by the amount of tongue that went into it!

Another example: when young apes are being tickled, they make breathy sounds with a rhythm of inhalation and exhalation that resembles human laughter. One cannot simply dismiss the term 'laughter' for this behavior as too anthropomorphic—as some have done—because not only do the apes sound like human children being tickled, they show the same ambivalence about it as children do. They try to push my tickling fingers away, but then come back begging for more, holding their breath while awaiting the next poke in their belly. In this case, I am all for shifting the burden of proof and ask those who wish to avoid human-like terminology to first prove that a tickled ape, who almost chokes on its hoarse giggles, is in fact in a different state of mind from a tickled human child. Absent such evidence, laughter strikes me as the best label for both.

Given that the facial musculature of humans and chimpanzees is nearly identical, the laughing, grinning, and pouting of both species likely goes back to a common ancestor.

Evolutionary science distinguishes between homology (the traits of two species derive from a common ancestor) and analogy (similar traits evolved independently in two species). The human hand is homologous with the bat's wing since both derive from the vertebrate forelimb, as is recognizable by the shared arm bones and five phalanges. The wings of insects, on the other hand, are analogous to those of bats. As products of convergent evolution, they serve the same function but have a different origin.

Given the evolutionary gulf between primates and corvids, and the many ancestral species of mammals and birds in between that don't use tools, we are dealing with a typical example of convergent evolution. Independently, both taxonomic groups must have faced a need for complex manipulations of items in their environment, or other challenges that stimulated brain growth, which led them to evolve strikingly similar cognitive skills.

Many animals have cognitive achievements in common. The more scientists discover, the more ripple effects we notice. Capacities that were once thought to be uniquely human, or at least uniquely Hominoid (the tiny primate family of humans plus apes), often turn out to be widespread. Traditionally, apes have been the first to inspire discoveries thanks to their manifest intellect. After the apes break down the dam between humans and the rest of the animal kingdom, the floodgates often open to include species after species. Cognitive ripples spread from apes to monkeys to dolphins,

elephants, and dogs, followed by birds, reptiles, fish, and sometimes invertebrates. This historical progression is not to be confused with a scale with Hominoids on top. I rather view it as an ever-expanding pool of possibilities in which the cognition of, say, the octopus may be no less astonishing than that of any given mammal or bird.

Face recognition, science concluded, is a specialized cognitive skill of primates. But no sooner had it done so than the first cognitive ripples arrived. Face recognition has been found in crows, sheep, even wasps.

Cognitive ripple rule: Every cognitive capacity that we discover is going to be older and more widespread than initially thought. This is rapidly becoming one of the best-supported tenets of evolutionary cognition.

Cognitive rippling is common precisely because it isn't bound by the evolutionary tree: the same capacity may pop up almost anywhere it is needed. Instead of taking this as an argument against cognitive evolution, as some have done, it perfectly fits the way evolution works through either common descent or adaptation to similar circumstances.

Biologists never tire of stressing the distinction between mechanism and function: it is very common for animals to achieve the same end (function) by different means (mechanism). Yet with respect to cognition, this distinction is sometimes forgotten when the mental achievements of large-brained animals are questioned by pointing at "lower" animals doing something similar. Skeptics delight in asking: 'If wasps can do it, what's the big deal?'

Vicky worked with a dozen orphan chimps at Ngamba Island, a sanctuary in Uganda. She acted like a mix between a mother and caretaker for the juvenile apes. Sitting next to her during tests, the juvenile apes were attached to Vicky and eager to follow her example. Her experiment created waves because the apes proved to be smarter than the children.

Vicky would poke a stick into holes in a large plastic box, going through a series of holes until a candy would roll out. Only one hole mattered. If the box was made of black plastic, it was impossible to tell that some of the holes were just for show. A transparent box, on the other hand, made it obvious where the candies came from. Handed the stick and the box, young chimps mimicked only the necessary moves, at least with the transparent box. The children, on the other hand, mimicked everything that Vicky had demonstrated, including useless moves. They did so even with the transparent box, approaching the problem more like a magic ritual than as a goal-directed task.

With this outcome, the whole strategy of redefining imitation backfired. After all, it was the apes who best fit the new definition of true imitation. The apes were showing selective imitation, the sort that pays close attention

to goals and methods. If imitation requires understanding, we have to give it to the apes, not to the children, who for lack of a better term, showed only dumb copying. What to do now?

Some complained that it was way too easy to make children look foolish—as if that were the goal of the experiment!—whereas in reality there must be something wrong with the interpretation. The distress was genuine, showing to what degree the human ego gets in the way of dispassionate science. Promptly, psychologists settled on a narrative in which over-imitation—a new term for children’s indiscriminate copying—is actually a brilliant achievement. It fits our species’ purported reliance on culture, because it makes us imitate behavior regardless of what it is good for; we transmit habits in full, without every individual making his or her own ill-informed decisions. Given the superior knowledge of adults, the best strategy for a child is to copy them without question. Blind faith is the only truly rational strategy, it was concluded with some relief.

To our surprise, chimps turn out to be conformists. Copying others for one’s own benefit is one thing, but wanting to act like everybody else is quite another. It is the foundation of human culture. Researchers presented two separate groups of chimpanzees with an apparatus from which food could be extracted in two different ways. The apes could either poke a stick into a hole to release a grape or use the same stick to lift up a little trap and a grape would roll out. They learned the technique from a model: a pre-trained group member. One group saw a lifting model, the other a poking model. Even though we used the same apparatus for both groups, moving it back and forth between them, the first learned to lift, and the second to poke. They had created two distinct cultures, dubbed the “lifters” and the “pokers.”

There were exceptions, though. A few individuals discovered both techniques or used a different one than their model had demonstrated. When retested two months later though, most of the exceptions had vanished. It was as if all the apes had settled on a group norm, following the rule ‘Do what everyone else is doing regardless of what you found out by yourself.’ Our openness to suggestion goes well beyond what was found in the chimps, yet it seems related.

Conformism is hard to substantiate in the field. There are too many alternative explanations for why one individual might act like another, including genetic and ecological ones. How these issues can be resolved was shown by a large-scale project on humpback whales in the Gulf of Maine. In addition to their regular bubble-feeding, in which whales drive fish together with air bubbles, one male invented a new technique. First seen in 1980, this whale would whack the ocean surface with his fluke to produce a loud noise

that clumped the prey even more. Over time this lobtail technique became increasingly common in the population. In the course of a quarter-century, investigators carefully plotted how it spread across six-hundred individually recognized whales. They found that whales who had associated with those employing the technique were more likely to use it themselves. Kinship could be ruled out as a factor, because whether a whale had a lobtail-feeding mother hardly mattered. It all boiled down to whom they had encountered while feeding on fish. Since large cetaceans are unsuitable for experiments, this may be as close as we will ever get to proving that a habit spread socially as opposed to genetically.

Scientists gave vervet monkeys in a South African game reserve open plastic boxes filled with maize corn. These small grayish monkeys with black faces love corn, but there was a catch: the scientists had manipulated the supply. There were always two boxes with two colors of corn, blue and pink. One color was good to eat whereas the other was laced with aloe, making it disgusting. Depending on which color corn was palatable, and which not, some groups learned to eat blue, and others pink. This preference is easily explained by associative learning. But then the investigators removed the distasteful treatment and waited for infants to be born and new males to immigrate from neighboring areas.

They watched several groups of monkeys that were supplied with perfectly fine corn of both colors. All adults stubbornly stuck to their acquired preference, however, and never discovered the improved taste of the alternative color. Twenty-six of twenty-seven newborn infants learned to eat only the locally preferred food. Like their mothers, they didn't touch the other color, even though it was freely available and just as good as the other. Individual exploration was obviously suppressed. The youngsters might even sit on top of the box with the rejected corn while happily feeding on the other type.

The single exception was an infant whose mother was so low in rank, and so hungry, that she occasionally tasted the forbidden fruits. Thus, all newborns copied their mothers' feeding habits. Male immigrants, too, ended up adopting the local color even if they arrived from groups with the opposite preference. That they switched their preference strongly suggests conformism, since these males knew from experience that the other color was perfectly edible. They simply followed the adage "When in Rome..."

The same can be concluded from an experiment in which researchers mixed two different macaques: rhesus and stumptail monkeys. Juveniles of both species were placed together, day and night, for five months. These macaques have strikingly different temperaments: rhesus are a quarrelsome, nonconciliatory bunch, whereas stumptails are laid-back and pacific. After a

long period of exposure, the rhesus monkeys developed peacemaking skills on a par with those of their more tolerant counterparts. Even after separation from the stumptails, the rhesus showed nearly four times more friendly reunions following fights than is typical of their species. These new and improved rhesus monkeys confirmed the power of conformism.

These studies prove the immense power of imitation and conformism. It is not a mere extravagance that animals occasionally engage in for trivial reasons—which, I hate to say, is how animal traditions have sometimes been derided—but a widespread practice with great survival value. Infants who follow their mother’s example of what to eat and what to avoid obviously stand a better chance in life than infants who try to figure out everything on their own. The idea of conformism among animals is increasingly supported for social behavior as well. One study tested both children and chimpanzees on generosity. The goal was to see if they were prepared to do a member of their own species a favor at no cost to themselves. They indeed did so, and their willingness increased if they themselves had received generosity from others—any others, not just their testing partner. Is kind behavior contagious? Love begets love, we say, or as the investigators put it more dryly:

“Primates tend to adopt the most commonly perceived responses in the population.”

One of the most intriguing sides of social learning—defined as learning from others—is the secondary role of reward. While individual learning is driven by immediate incentives, such as a rat learning to press a lever to obtain food pellets, social learning doesn’t work this way. Sometimes conformism even reduces rewards—after all, the vervet monkeys missed out on half of the available food. How little rewards matter is also evident from habits that lack benefits. In our own species, we have fads such as wearing a baseball cap backward or pants that hang low enough to impede locomotion. But in other primates, too, we find seemingly useless fashions and habits.

A nice example is the N-family in a group of rhesus monkeys observed long ago at the Wisconsin Primate Center. This matriline was headed by an aging matriarch, Nose, all of whose offspring had names starting with the same letter, such as Nuts, Noodle, Napkin, Nina, and so on. Nose had developed the odd routine of drinking from a water basin by dipping her entire underarm into it, then licking her hand and the hair on her arm. Amusingly, all her offspring, and later her grandchildren adopted the exact same technique. No other monkeys in the troop drank like this, there was absolutely no advantage to it. It did not allow the N-family to access anything that other monkeys had no access to.

Or take the way chimpanzees sometimes develop local dialects, such as the excited grunts uttered while snacking on tasty food. These grunts differ not only from group to group but also per food type, such as a particular grunt heard only while they eat apples. When the Edinburgh Zoo introduced chimpanzees from a Dutch zoo to its residents, it took those others three years to get socially integrated. Initially, the newcomers uttered different grunts while eating apples, but by the end they converged on the same grunts as the locals. They had adjusted their calls so that they sounded more like those of the residents. The bonding between individuals of different backgrounds had resulted in conformism, even though chimps are not particularly known for vocal flexibility.

Animals strive to act like others, especially others whom they trust and feel close to. Conformist biases shape society by promoting the absorption of habits and knowledge accumulated by previous generations. This by itself is obviously advantageous—and not just in the primates—so even though conformism is not driven by immediate benefits, it likely assists survival.

It is hard to imagine that among any set of related species, some are self-aware whereas others, for lack of a better term, remain unaware. Every animal needs to set its body apart from its surroundings and to have a sense of agency (awareness that it controls its own actions). You wouldn't want to be a monkey up in a tree without awareness of how your own body will impact a lower branch on which you intend to land. And you wouldn't want to engage in rough-and-tumble play with a fellow monkey, with all your combined arms, legs, and tails intertwined, while stupidly gnawing on your own foot or tail! Monkeys never make this mistake and gnaw exclusively on their partner's foot or tail in such a tangle. They have a well-developed body ownership and self-other distinction.

In fact, experiments on the sense of agency show that species without mirror self-recognition are very well capable of distinguishing their own actions from those produced by others. Tested in front of a computer screen, they have no trouble telling the difference between a cursor that they themselves control with a joystick and a cursor that moves by itself. Self-agency is part of every action that an animal—any animal—undertakes. In addition, some species may possess their own unusual kind of self-recognition, such as bats and dolphins that pick out the echoes of their own vocalizations from among the sounds made by others.

Animals that fail to link their mirror image to their own body vary greatly in what they understand. Small songbirds and fighting fish, for example, never get over their mirror image and keep courting or attacking it. During the spring, when they are most territorial, tits and bluebirds will respond this way to the sideview mirror of a car and stop their hostilities

only when the car drives off. This is absolutely not what monkeys do, nor many other animals. We would not be able to have mirrors in our homes if cats and dogs reacted the same way. These animals may not recognize themselves, but they are also not totally baffled by the mirror, at least not for long. They learn to ignore their reflection.

Some species go further in that they understand mirror basics. Monkeys, for example, may not recognize themselves but are able to use the mirror as a tool. If you hide food that can be found only by using a mirror to look around a corner, the monkey will have no trouble reaching for it. Many a dog can do the same: holding up a cookie behind them while they watch you in a mirror makes them turn around. Curiously, it is specifically the relation with their own body, their own self in the mirror, that they fail to grasp.

But even then, rhesus monkeys can be taught to do so. It requires adding a physical sensation. They need a mark that they can both see in the mirror and feel on their body, such as a laser light that irritates the skin or a cap fastened to their head. Instead of a traditional mark test, this is better described as a felt mark test. Only under these circumstances can monkeys learn to connect their reflection with their own body. This is obviously not the same as what apes do spontaneously relying on vision alone, but it does suggest that some of the underlying cognition is shared.

There are many stages of mirror understanding, running all the way from utter confusion to a full appreciation of the reflected image. These stages are also recognizable in human infants, which are curious about their mirror image well before passing the mark test. Self-awareness develops like an onion, building layer upon layer, rather than appearing out of the blue at a given age. For this reason, we should stop looking at the mark test as the litmus test of self-awareness. It is only one of many ways to find out about the conscious self.

In primates individual identity is usually visually determined. The face is the most characteristic part of the body; hence face recognition is highly developed and has been demonstrated in multiple ways in both monkeys and apes. It is not just faces that they pay attention to, however. In one experiment, they first saw a picture of the ass of one of their group mates followed by two facial pictures. Only one of both faces belonged to the ass, however. Which one would they select on the touchscreen? It was a typical matching-to-sample task of the type invented before the computer age. Apes selected the correct portrait, the one that went with the rump they had seen. They were only successful, though, with chimps that they knew personally. That they failed with pictures of strangers suggests that it was not based on something in the pictures themselves, such as color or size. They must

possess a whole-body image of familiar individuals, knowing them so well that they can connect any part of their body with any other part. In the same way, we are able to locate friends and relatives in a crowd even if we only see their backs.

Individual recognition is the cornerstone of any complex society. That animals have this capacity is often underestimated by humans, for whom all members of a given species look alike. Among themselves, however, animals generally have no trouble telling one another apart.

Dolphins go much further. They produce signature whistles, which are high-pitched sounds with a modulation that is unique for each individual. Their structure varies the way ring-tone melodies vary. It is not so much the voice but the melody that marks them. Young dolphins develop personalized whistles in their first year. Females keep the same melody for the rest of their lives, whereas males adjust theirs to those of their closest buddies, so that the calls within a male alliance sound alike. Dolphins utter signature whistles especially when they are isolated—lonely ones in captivity do so all the time—but also before aggregating in large groups in the ocean. At such moments, identities are broadcast frequently and widely, which makes sense in a fission-fusion species that dwells in murky water.

That whistles are used for individual identification was shown by playing them back through underwater speakers. Dolphins pay more attention to sounds associated with close kin than to those of others. That this is based not on mere voice recognition but on the call's specific melody was demonstrated by playing back computer-generated sounds that mimicked the melodies: the voice was left out while the melody was preserved. These synthesized calls triggered the same responses as the originals.

Dolphins have an incredible memory for their friends. Researchers took advantage of the fact that captive dolphins are regularly moved from one place to another for breeding purposes. They played back signature whistles of tank mates that had left long ago. In response to familiar calls, dolphins would become active, approach the speaker, and call in return. Dolphins have no trouble recognizing former tank mates regardless of how much or little time they had spent together in the past or how long it had been since they had last seen them. The longest time interval in the study was when a female named Bailey recognized the whistles of Allie, a female she had lived with elsewhere twenty years before.

There was a time when Western professors warned their students away from the Japanese school because naming animals was considered too humanizing. There was of course also the language barrier, which made it hard for Japanese scientists to get heard. Junichiro Itani was met with disbelief when he toured American universities in 1958 because no one believed that

he and his colleagues were able to tell a hundred or more monkeys apart. Monkeys look so much alike that Itani obviously was making things up. He once told me that he was mocked to his face and had no one to defend him except the American primatological pioneer Ray Carpenter, who did see the value of this approach.

The deep irony of animals calling one another by name is, of course, that it was once taboo for scientists to name their animals. When Imanishi and his followers started doing so, they were ridiculed, as was Goodall when she gave her chimps names like David Greybeard and Flo. The complaint was that by using names we were humanizing our subjects. We were supposed to keep our distance and stay objective, and to never forget that only humans have names. As it turns out, on this issue some animals may have been ahead of us.

Anthropomorphism and anthropodenial—the a priori rejection of human-like traits in other animals or animal-like traits in us—have an inverse relationship: the closer another species is to us, the more anthropomorphism will assist our understanding of this species and the greater will be the danger of anthropodenial. Conversely, the more distant a species is from us, the greater the risk that anthropomorphism will propose questionable similarities that have come about independently. Saying that ants have ‘queens,’ ‘soldiers,’ and ‘slaves’ is mere anthropomorphic shorthand. We should attach no more significance to it than we do when we name a hurricane after a person or curse our computer as if it had free will.

The key point is that anthropomorphism is not always as problematic as people think. To rail against it for the sake of scientific objectivity often hides a pre-Darwinian mindset, one uncomfortable with the notion of humans as animals. Dubbing an ape’s kiss “mouth-to-mouth contact” so as to avoid anthropomorphism deliberately obfuscates the meaning of the behavior. It would be like assigning Earth’s gravity a different name than the moon’s, just because we think Earth is special. Unjustified linguistic barriers fragment the unity with which nature presents us. Apes and humans did not have enough time to independently evolve strikingly similar behavior, such as lip contact in greeting or noisy breathing in response to tickling. Our terminology should honor the obvious evolutionary connections.

The fundamental problem with all these denials is that it is impossible to prove a negative. This is no minor issue. When anyone claims the absence of a given capacity in other species, and speculates that it must therefore have arisen recently in our lineage, we hardly need to inspect the data to appreciate the shakiness of such a claim. All we can ever conclude with some certainty is that we have failed to find a given skill in the species that we have examined. We cannot go much further than this, and we certainly

may not turn it into an affirmation of absence.

Scientists do so all the time, though, whenever the human-animal comparison is at stake. The zeal to find out what sets us apart overrides all reasonable caution. Not even with regard to the Monster of Loch Ness or the Abominable Snowman will you ever hear anyone claim to have proven its nonexistence, even though this would fit the expectations of most of us. And why do governments still spend billions of dollars to search for extraterrestrial civilizations while there is no shred of evidence to encourage this quest? Isn't it time to conclude once and for all that these civilizations simply don't exist? But this conclusion will never be reached.

That respected psychologists ignore the recommendation to tread lightly around absent evidence is most puzzling, therefore. One reason is that they test apes and children in the same manner—at least in their minds—while coming up with contrary results. Applying a battery of cognitive tasks to both apes and children and finding not a single result in the apes' favor, they tout the differences as proof of human uniqueness. Otherwise, why didn't the apes fare better? To understand the flaw in this logic, we need to go back to Clever Hans, the counting horse. But instead of using Hans to illustrate why animal capacities are sometimes overrated, this time we are concerned with the unfair advantage that human capacities enjoy.

The outcome of ape-child comparisons themselves suggests the answer. When tested on physical tasks, such as memory, causality, and the use of tools, apes perform at about the same level as two-and-a-half-year-old children, but when it comes to social skills, such as learning from others or following others' signals, they are left in the dust. Social problem solving requires interaction with an experimenter, however, whereas physical problem solving does not. This raises the possibility that the human interface is key. The typical format of an experiment is to let apes interact with a white-coated barely familiar human. Since experimenters are supposed to be bland and neutral, they do not engage in schmoozing, petting, or other niceties. This doesn't help make the ape feel at ease and identify with the experimenter. Children, however, are encouraged to do so. Moreover, only the children are interacting with a member of their own species, which helps them even more.

Nevertheless, experimenters comparing apes and children insist that all their subjects are treated exactly the same. The inherent bias of this arrangement has become harder to ignore, however, now that we know more about ape attitudes. A recent eye-tracking study which precisely measured where subjects looked reached the unsurprising conclusion that apes consider members of their own species special: they follow the gaze of another ape more closely than they follow the human gaze. This may be all we need to

explain why apes fare poorly on social tasks presented by members of our species.

The other extreme derives from the traditional approach in the psychology lab: carrying a rat or a pigeon into a testing room with as little contact as possible. The ideal here is a nonexistent experimenter, meaning the absence of any personal relation. In some labs apes are called into a room and given only a few minutes to perform before they are sent out again without any playful or friendly contact, almost like a military drill. Imagine if children were tested under such circumstances: how would they fare?

Teachers raise the performance of certain children by expecting the world of them. They fall in love with their own prediction, which serves as a self-fulfilling prophecy. Remember how Charlie Menzel felt that only people who hold apes in high esteem will fully appreciate what they are trying to communicate? His was a plea for raised expectations, which unfortunately is not the situation apes typically face. Children, in contrast, are treated in such a nurturing manner that they inevitably confirm the mental superiority ascribed to them. Experimenters admire and stimulate them from the outset, making them feel like fish in the water, whereas they often treat apes more like albino rats: keeping them at a distance, and in the dark, while depriving them of the verbal encouragement we offer members of our own species.

The cognition of children and apes is tested in superficially similar ways. Yet children are not kept behind a barrier; they are talked to and often sit on their parents' laps, all of which helps them connect with the experimenter and receive unintentional hints. The greatest difference, however, is that only apes face a member of another species. Given how much these comparisons disadvantage one class of subjects, they remain inconclusive.

There are only two ways to make a fair comparison in this regard (if we disregard the third option of having white-coated apes administer tests to both apes and children). One is to follow the wolf example: raise apes in a human home so that they are as comfortable as children around a human experimenter. The second is the so-called conspecific approach, which is to test a species with models of its own kind.

Several human-raised apes turned out to be as good at imitating members of our species as were young children. In other words, apes, like children, are born imitators and prefer to copy the species that raised them. Under most circumstances, this will be their own kind, but if reared by another species, they are prepared to imitate that one as well. Using us as models, these apes spontaneously learn to brush their teeth, ride bicycles, light fires, drive golf carts, eat with a knife and fork, peel potatoes, and mop the floor. It reminds me of suggestive stories on the Internet about dogs raised with cats, which show feline behavior such as sitting in boxes, crawling under

tight spaces, licking their paws to clean their face, or sitting with their front legs tucked in.

It would be nonsense to say that it was not in the interests of a stone to be kicked along the road by a schoolboy. A stone does not have interests because it cannot suffer. Nothing that we can do to it could possibly make any difference to its welfare. A mouse, on the other hand, does have an interest in not being kicked along the road, because it will suffer if it is.

The human cerebral cortex is the brain-part that deals with higher faculties like reason, metaphysical self-awareness, language, et cetera. Pain reception is known to be part of a much older and more primitive system of nociceptors and prostaglandins that are managed by the brain stem and thalamus. On the other hand, it is true that the cerebral cortex is involved in what's variously called suffering, distress, or the emotional experience of pain—i.e., experiencing painful stimuli as unpleasant, very unpleasant, unbearable, and so on.

The questions of whether and how different kinds of animals feel pain, and of whether and why it might be justifiable to inflict pain on them in order to eat them, turn out to be extremely complex and difficult. And comparative neuroanatomy is only part of the problem. Since pain is a totally subjective mental experience, we do not have direct access to anyone or anything's pain but our own; and even just the principles by which we can infer that other human beings experience pain and have a legitimate interest in not feeling pain involve hard-core philosophy—metaphysics, epistemology, value theory, ethics. The fact that even the most highly evolved nonhuman mammals can't use language to communicate with us about their subjective mental experience is only the first layer of additional complication in trying to extend our reasoning about pain and morality to animals. And everything gets progressively more abstract and convoluted as we move farther and farther out from the higher-type mammals into cattle and swine and dogs and cats and rodents, and then birds and fish, and finally invertebrates like lobsters.

Although patients are vulnerable to both good and evil—to receiving both help and harm—we are usually more concerned with the darker side of patency. We wonder how much someone (or something) suffers, how to alleviate this distress, and whether victimization causes enduring damage. With patients the most important questions concern pain, both its experience and the right to be protected from it. But what exactly is pain, and how do we know whether others are feeling it?

Pain may have overwhelming psychological power, but its physical reality is comparatively insubstantial. Pain is a mental construction based on a handful of nerve signals, the same kind of signals that let us experience

green or yellow or smell lavender or chocolate. We might imagine that when in pain our cells secrete some terribly corrosive brain chemical, but the intensity of our suffering stems only from the microscopic electrical pulses of neurons. These neurons are typically triggered by external tissue damage, in a biological pathway that starts at the location of the cut, burn, or bruise, then proceeds through a neural “gate” in the spinal cord before arriving into the thalamus, the sensory hub of the brain.

There are two routes through which we can understand the experience of others, whether it involves pain, pleasure, or the taste of fish. The first route is illustrated by the question ‘Does Jennifer like pickled sardines?’ Without knowing anything about Jennifer, you’ve likely got an answer, and it’s probably the same answer to whether you like pickled sardines (no). To understand Jennifer you use simulation, relying on your own imagined experiences (I don’t like sardines) as a proxy for those of others (others don’t like sardines).

The second route is illustrated by a slightly different question, ‘Does Olga like sardines?’ Now you might come up with a different answer (yes), because the name ‘Olga’ suggests a mysterious foreigner whose tastes might swing toward slimy fish pickles. To understand Olga you use theorizing, which, unlike your imagination, uses explicit theories about others’ minds, such as ‘Russians like strange foods.’ Simulation is the easier of the two routes, and so we rely on theorizing only when others are very different from us, rendering invalid our self-focused simulations.

This makes sense: if someone is like you, your experiences are good guides to theirs (and so you simulate), but if they are not like you, you’re better off relying on explicit reasons to explain their behavior (and so you theorize). One wrinkle to this distinction is that people generally assume that others are like them unless they have good reason to think otherwise, which further increases the scope and frequency of simulation.

Simulation may sometimes lead us astray, but—much more than theorizing—it makes us care about the mental states of others. Theorizing uses cold theories about stimuli and responses—if shocked, then pain—but simulation uses our own feelings to predict those of others. In terms of our two dimensions of mind perception, simulation is grounded in our own experience (feeling their pain), whereas theorizing is grounded in our own agency (reasoning about their pain). It is simulation that gives rise to empathy.

People have long struggled to define empathy and to determine whether it differs from sympathy or pity. However, a look at the German word for empathy clears this all up: *Einfühlungsvermögen*! Empathy is simply when you *föhlung* someone else’s *vermögen*—nothing more and nothing less. Now,

the satisfied reader may skip ahead a few pages. But for the rest of you some explanation may be required.

This German word actually translates to “in-feeling” and articulates the notion of sharing in another person’s feelings: feeling their pain when they are injured, feeling their anger when someone slights them, or feeling their embarrassment when they botch their big presentation. It is illustrated by Blaise Pascal, who said:

“We know truth, not only by the reason, but also by the heart.”

Empathy is about more than just dispassionately recognizing others’ suffering; it is about suffering alongside them. Because suffering is aversive, empathizing with another person’s pain compels you to help alleviate it. Empathy is why charity campaigns don’t simply report statistics but instead show us the doleful eyes of orphaned children, so that we can connect to their minds, simulate their suffering, and open our wallets.

The inscrutability of experience means that we rely heavily on external cues to understand animal pain—things like big eyes, obvious expressions, and human likeness. This is why, in the mind survey, puppies were given more protection than tree frogs, which have small eyes and no clear way of crying out and aren’t even mammals like us. Reliance on these external cues can lead to an overemphasis on ‘cuteness’ in animal rights. That we can eat bacon with abandon and donate money to stop seal clubbing—despite the impressive intelligence of pigs.

In this way we are—if only a tiny bit—like serial killer Dennis Nilsen, who saw his dog as a mind club member but not his fellow humans. Those we admit to the mind club may not be the most deserving but instead those with whom we emotionally connect.

Even when animals are relatively uncute, thinking about their suffering can still make people squirm. We think of cows as stupid and label their meat ‘beef’ to maintain distance between ourselves and dinner. If meat is mindless, then it isn’t really cruel. This link between mind and morality has been demonstrated by a clever experiment in which grocery store shoppers were given free samples of either cashews or beef jerky. After eating, shoppers filled out a mind survey that included mental ratings of a cow. The researchers discovered that while the nut eaters perceived the cow to have substantial mind, the meat eaters stripped away its thoughts and feelings. A follow-up study found that simply labeling an animal as ‘food’ drastically decreased the animal’s perceived capacity for suffering.

The most extreme kind of silence is suggested by a famous philosophical thought experiment—the brain in a vat. Imagine that your brain—i.e., your

mind—is placed in a vat, along with all the nutrients it needs to survive. While resting there, you might have a rich mental life, filled with lush landscapes of imagination, but without some way of communication how would anyone else ever know about it?

More than any other entity, the silent represent an interesting counterpoint to the philosophical zombie. A philosophical zombie is someone who can talk but who ultimately lacks conscious experience, whereas the silent may still have experience, despite being unable to communicate it. Without the typical cues to mind, how do we decide whether a silent entity has a mind? And perhaps more importantly, the silent experiencer is actually likely to exist outside the mind of a philosopher.

Why do people view human-animal love as so immoral? The explanation again lies with the mind-perception fault line that splits doers from feelers. Animals are seen as vulnerable feelers and not thinking doers, which means that they seem to suffer while lacking the agency to give informed consent—a key component of sexual relationships. But it isn't clear that the animals actually suffer or that consent is actually important for animals. Animals never give informed consent, not even to the conspecifics they mate with in the wild, and we don't imprison two donkeys for having consentless sex with each other. Instead we are all likely reacting to the relative imbalance between the minds of humans and those of the animals with whom they become intimate.

Although most animals are typically ascribed less agency than humans, circumstances can conspire to make them appear capable of intention, planning, and even malice. In instances of severe suffering, animals can transform from hapless victims to calculating perpetrators. Consider an example from medieval France.

It is the summer of 1457 in the small town of Savigny. A peasant woman goes to work in her garden, leaving her son in a cradle on the floor as she has done many times before. As she works, a sow slips through the door with her piglets in tow and hunts around for food. The sow discovers the baby and starts eating him, and by the time the mother realizes what is happening, there is little left but gristle and blood. The mother and the other townsfolk are understandably inconsolable, but rather than simply killing the sow, as we might do today, they decide to place the pig on trial.

A judge is brought from the next town, and lawyers are appointed to represent the sow and her piglets. The defendant sits in a nearby pen as arguments are heard and witnesses are called, and eventually the judge rules. He decides that the sow is morally culpable of murder and should be sentenced to death for her crime. The piglets, however, due to their young age, are found not guilty, but the townsfolk are instructed to keep

close watch over them, lest the trauma they witnessed warp their moral sensibilities.

To carry out the sentence, the townsfolk build a gallows from which to hang the pig—at some considerable expense—as they would a human. The townsfolk gather round as the murderer is executed; finally, justice is done. There are many medieval examples of animals on trial, including locusts legally condemned for crop destruction and a rooster sentenced to death for the gender-bending behavior of laying an egg—it was, in fact, just a misunderstood chicken.

Before you cast aspersions on the intelligence of the French peasantry, remember that they weren't completely stupid; they realized that pigs, locusts, and poultry lacked mental sophistication. But there seems to be something special about witnessing injustice, whether the death of a child or the mass destruction of livelihood, that prompts people to find someone or something to blame. We call this urge dyadic completion.

Dyadic completion explains not only historical animal trials but also the blame we levy on the owners of dogs that bite children. It is not psychologically satisfying to simply acknowledge the unpredictability of animals with kids, so instead we seek out the most agentic mind available—and then typically sue it.

Humans and animals were frequently tried together in the same courtroom as co-conspirators, especially in cases of bestiality. The animal defendants were appointed their own lawyers at public expense. Animals enjoyed appeal rights and there are several instances when convictions were overturned and sentences reduced or commuted entirely. Sometimes, particularly in cases involving pigs, the animal defendants were dressed in human clothes during court proceedings and at executions.

Animal trials were held in two distinct settings: ecclesiastical courts and secular courts. Ecclesiastical courts were the venue of choice for cases involving the destruction of public resources, such as crops, or in crimes involving the corruption of public morals, such as witchcraft or sexual congress between humans and beasts. The secular and royal courts claimed jurisdiction over cases where animals were accused of causing bodily harm or death to humans or, in some instances, other animals.

When guilty verdicts were issued and a death sentence imposed, a professional executioner was commissioned for the lethal task. Animals were subjected to the same ghastly forms of torture and execution as were condemned humans. Convicted animals were lashed, put to the rack, hanged, beheaded, burned at the stake, buried alive, stoned to death, and drawn-and-quartered.

In fourteenth-century Sardinia, trespassing livestock had an ear cut-off

for each offense. In an early application of the three-strikes-and-you're-out rule, the third conviction resulted in immediate execution. The flesh of executed animals was never eaten. Instead, the corpses of the condemned were either burned, dumped in rivers, or buried next to human convicts in graveyards set aside for criminals and heretics. The heads of the condemned, especially in cases of bestiality, were often displayed on pikes in the town square adjacent to the heads of their human co-conspirators.

In 1713 a rectory at the Franciscan monastery in Piedade no Maranhão collapsed, its foundation ravaged by termites. The friars lodged charges against the termites and an ecclesiastical inquest soon issued a summons demanding that the ravenous insects appear before the court to confront the allegations against their conduct. Often in such cases, the animals who failed to heed the warrant were summarily convicted in default judgments. But these termites had a crafty lawyer.

He argued that the termites were industrious creatures, worked hard and enjoyed a God-given right to feed themselves. Moreover, the lawyer declared, the slothful habits of the friars had likely contributed to the disrepair of the monastery. The monks, the defense lawyer argued, were merely using the local termite community as an excuse for their own negligence. The judge returned to his chambers, contemplated the facts presented him and returned with a Solomonic ruling. The friars were compelled to provide a woodpile for the termites to dine at and the insects were commanded to leave the monastery and confine their eating to their new feedlot.

A similar case unfolded in the province of Savoy, France in 1575. The weevils of Saint Julien, a tiny hamlet in the Rhone Alps, were indicted for the crime of destroying the famous vineyards on the flanks of Mount Cenis. A lawyer, Pierre Rembaud, was appointed as defense counsel for the accused. Rembaud wasted no time in filing a motion for summary judgment, arguing that the weevils had every right to consume the grape leaves. Indeed, Rembaud asserted, the weevils enjoyed a prior claim to the vegetation on Mount Cenis, since, as detailed in the Book of Genesis, the Supreme Deity had created animals before he fashioned humans and God had promised animals all of the grasses, leaves, and green herbs for their sustenance. Rembaud's argument stumped the court.

As the judges deliberated, the villagers of Saint Julien seemed swayed by the lawyer's legal reasoning. Perhaps the bugs had legitimate grievances. The townsfolk scrambled to set aside a patch of open land away from the vineyards as a foraging ground for the weevils. The land was surveyed. Deeds were drawn up and the property was shown to counselor Rembaud for his inspection and approval. They called the weevil reserve La Grand Feisse. Rembaud walked the site, investigating the plant communities with

the eyes of a seasoned botanist. Finally, he shook his head. No deal. The land was rocky and had obviously been overgrazed for decades. La Grand Feisse was wholly unsuitable for the discriminating palates of his clients.

The Perry Mason of animal defense lawyers was an acclaimed French jurist named Bartholomew Chassenée, who later became a chief justice in the French provincial courts and a preeminent legal theorist. In a legal monograph, Chassenée argued with persuasive force that local animals, both wild and domesticated, should be considered lay members of the parish community. In other words, the rights of animals were similar in kind to the rights of the people at large.

In the summer of 1522, Chassenée was called to the ancient village of Autun in Burgundy. The old town, founded during the reign of Augustus, had been recently overrun by rats. French maidens had been frightened, the barley crop destroyed, the vineyards placed in peril. The town crier issued a summons for the rats to appear before the court. None showed. The judge asked Chassenée why he should not find his clients guilty in absentia. The lawyer argued that the rat population was dispersed through the countryside and that his clients were almost certainly unaware of the charges pending against them. The judge agreed.

The town crier was dispatched into the fields to repeat his urgent notice. Yet still the rats failed to appear at trial. Once again Chassenée jumped into action. Showing tactical skills that should impress Gerry Spence, Chassenée shifted his strategy. Now he passionately explained to the court that the rats remained hidden in their rural nests, paralyzed by the prospect of making a journey past the cats of Autun, who were well-known for their ferocious animosity toward rodents.

In the end, the rats were spared execution. The judge sternly ordered them to vacate the fields of Autun within six days. If the rats failed to heed this injunction, the animals would be duly anathematized, condemned to eternal torment. This sentence of damnation would be imposed, the court warned, regardless of any rodent infirmities or pregnancies.

Few animal trials were prosecuted as vigorously as those involving allegations of bestiality. In 1565, a man was indicted for engaging in sexual relations with a mule in the French city of Montpellier. The mule was also charged. Both stood trial together. They were duly convicted and sentenced to death at the stake. Because of the mule's angry disposition, the animal was subjected to additional torments. His feet were chopped off before the poor beast was pitched into the fire.

In 1598, the suspected sorceress Françoise Secretain was brought before the inquisitional court at St. Claude in the Jura Mountains of Burgundy to face charges of witchcraft and bestiality. Secretain was accused of communing

with the devil and having sex with a dog, a cat and a rooster. The blood-curdling case is described in detail by her prosecutor, the Grand Justice Henri Boguet, in his strange memoir *Discours des Sorciers*. Secretain was stripped naked in her cell, as the fanatical Boguet inspected her for the mark of Satan. The animals were shaved and plucked for similar examinations.

Secretain and her pets were put to various tortures, including having a hot poker plunged down their throats to see if they shed tears, for, as Boguet noted in his memoir:

“All the sorcerers whom I have examined in quality of Judge have never shed tears in my presence: or, indeed, if they have shed them it has been so parsimoniously that no notice was taken of them. I say this with regard to those who seemed to weep, but I doubt if their tears were not feigned. I am at least well assured that those tears were wrung from them with the greatest efforts. This was shown by the efforts which the accused made to weep, and by the small number of tears which they shed.”

Alas, the poor woman and her animals did not weep. They perished together in flames at the stake.

In 1642 a teenage boy named Thomas Graunger stood accused of committing, in the unforgettable phrase of Cotton Mather, “infamous Buggeries” with farm animals in Plymouth, Massachusetts. Young master Graunger was hauled before an austere tribunal of Puritans headed by Gov. William Bradford. There he stood trial beside his co-defendants, a mare, a cow, two goats, four sheep, two calves and a turkey. All were found guilty. They were publicly tortured and executed. Their bodies were burned on a pyre, their ashes buried in a mass grave. Graunger was the first juvenile to be executed in colonial America.

Why did both the secular and religious courts of Europe devote so much time and money to these elaborate trials of troublesome animals? Some scholars argue that the trials performed the function of the ancient rituals of sacrifice and atonement. Others view the cases as the last gasp of the animistic religions. Some have offered an economic explanation suggesting that animals were tried and executed during times of glut or seized in times of economic plight as property by the Church or Crown through the rule of deodand or “giving unto God.” Still others have suggested that the trials and executions served a public health function, culling populations of farm animals and rodents that might contribute to the spread of infectious diseases.

Our interest here, however, is not with the social purpose of the trials, but in the qualities and rights the so-called medieval mind ascribed to the defendants: rationality, premeditation, free will, moral agency, calculation, and motivation. In other words, it was presumed that animals acted with intention, that they could be driven by greed, jealousy, revenge. Thus the people of the Middle Ages, dismissed as primitives in many modernist quarters, were actually open to a truly radical idea: animal consciousness. As demonstrated in these trials, animals could be found to have *mens rea*, a guilty mind. But the courts also seriously considered exculpatory evidence aimed at proving that the actions of the accused, including murder, were justifiable owing to a long train of abuses. In other words, if animals could commit crimes, then crimes could also be committed against them.

The animal trials peaked in the late-sixteenth and early-seventeenth centuries, then faded away. They came to be viewed through the lens of modern historians as comical curiosities, grotesquely odd relics of the Dark Ages. Of course, the phasing out of animal trials didn't mean that the cruel treatment of domesticated animals improved or that problematic beasts stopped being put to death in public extravaganzas. While the trials ceased, the executions increased.

Recall the death warrant issued in 1903 against Topsy the Elephant, star of the Forepaugh Circus at Coney Island's Luna Park. Topsy had killed three handlers in a three-year period. One of her trainers was a sadist, who tortured the elephant by beating her with clubs, stabbing her with pikes, and feeding her lit cigarettes. Topsy was ordered to be hanged, but then Thomas Edison showed up and offered to electrocute Topsy.

She was shackled, fed carrots laced with potassium cyanide, and jolted with 6,600 volts of alternating current. Before a crowd of 1,500 onlookers, Topsy shivered, toppled, and died in a cloud of dust. Edison filmed the entire event. He titled his documentary short, "Electrocuting the Elephant." Topsy received no trial. It was not even imagined that she had grievances, a justification for her violent actions. Topsy was killed because she'd become a liability. Her death was a business decision, pure and simple.

How did animals come to be viewed as mindless commodities? One explanation is that modernity rudely intruded in the rather frail form of René Descartes. The great Cartesian disconnect not only cleaved mind from body, but also severed humans from the natural world. Descartes postulated that animals were mere physical automatons. They were biological machines whose actions were driven solely by bio-physical instincts. Animals lacked the power of cognition, the ability to think and reason. They had a brain but no mind. At Port-Royal the Cartesians cut up living creatures with fervor, and in the words of one of Descartes's biographers, "kicked about their dogs

and dissected their cats without mercy, laughing at any compassion for them and calling their screams the noise of breaking machinery.”

Across the Channel, Francis Bacon declared in the *Novum Organum* that the proper aim of science was to restore the divinely ordained dominance of man over nature, “to extend more widely the limits of the power and greatness of man and so to endow him with infinite commodities.” Bacon’s doctor, William Harvey, was a diligent vivisector of living animals. Thus did the great sages of the Enlightenment assert humanity’s ruthless primacy over the Animal Kingdom.

The materialistic view of history, and the fearsome economic and technological pistons driving it, left no room for either the souls or consciousness of animals. They were no longer our fellow beings. They had been rendered philosophically and literally into resources for guiltless exploitation, turned into objects of commerce, labor, entertainment, and food.

Conveniently for humans, the philosophers of the Industrial Age declared that animals had no sense of their miserable condition. They could not understand abuse, they had no conception of suffering, they could not feel pain. When captive animals bit, trampled, or killed their human captors, it wasn’t an act of rebellion against abusive treatment but merely a reflex. There was no need, therefore, to investigate the motivations behind these violent encounters because there could be no premeditation at all on the animal’s part. The confrontations could not be crimes. They were mere accidents, nothing more. One wonders what Descartes would have made of the group of orangutans, who stole crowbars and screwdrivers from zookeepers in San Diego to repeatedly break out of their enclosures? How’s that for cognition, cooperation, and tool use, Monsieur Descartes?

Contrast Descartes’s sterile, homocentric view with that of a much greater intellect, Michel de Montaigne. Writing a mere fifty years before Descartes, Montaigne, the most gifted French prose stylist, declared:

“We understand them no more than they us. By the same token they may as well esteem us beasts as we them.”

Famously, he wrote in the “Apology for Raymond Sebond”:

“When I play with my cat, who knows if I am not a pastime to her more than she is to me?”

Montaigne was distressed by the barbarous treatment of animals:

“If I see but a chicken’s neck pulled off or a pig sticked, I cannot choose but grieve; and I cannot well endure a silly

dew-bedabbled hare to groan when she is seized upon by the hounds.”

But the materialists held sway. Descartes was backed up the grim John Calvin, who proclaimed that the natural world was a merely a material resource to be exploited for the benefit of humanity:

“True it is that God hath given us the birds for our food. We know he hath made the whole world for us.”

John Locke, the father of modern liberal thinking, described animals as “perfect machines” available for unregulated use by man. The animals could be sent to the slaughterhouse with no right of appeal. In Locke’s coldly utilitarian view, cows, goats, chickens, and sheep were simply meat on feet. Thus was the Great Chain of Being ruthlessly transmuted into an iron chain with a manacle clasped round the legs and throats of animals, hauling them off to zoos, circuses, bull rings and abattoirs.

Karl Marx, that supreme materialist, ridiculed the Romantic poets for their “deification of Nature” and chastised Darwin for his “natural, zoological way of thinking.” Unfortunately, Marx’s great intellect was not empathetic enough to extend his concepts of division of labor, alienation, and worker revolt to the animals harnessed into grim service by the lords of capital. By the 1930s some Marxist thinkers urged that it was time to put an end to nature and that animals and plants that serve no human purpose ought to be exterminated. Marx liked to disparage his enemies by calling them baboons.

But what would Marx have made of the baboons of northern Africa, hunted down by animal traders, who slaughtered nursing mother baboons and stole their babies for American zoos and medical research labs. The baboon communities violently resisted this risible enterprise, chasing the captors through the wilderness all the way to the train station. Some of the baboons even followed the train for more than a hundred miles and at distant stations launched raids on the cars in an attempt to free the captives. How’s that for fearless solidarity?

In this respect, at least, Adam Smith comes out a little more humane than the Marxists. Although he viewed animals as property, Smith recoiled at the sight of the abattoir:

“The trade of a butcher is a brutal and odious business.”

Carl Hagenbeck, the prolific eighteenth-century exotic animal enslaver, wrote about an expedition in northern Africa. He was rounding up baboons,

which labs then and now use in their research. The start was usually easy. Set the traps and wait. It was when the animals were captured that the drama began. First, you had to move fast, “for baboons are endowed with great strength, and would soon break through the wall of their cage.” Using a forked stick, the younger animals were held down and muzzled. Their hands and feet tied, and their bodies swaddled in cloth to immobilize them. As for the parents or any older baboons, they were shot straight away—too difficult to deal with.

Next, you needed to leave the area and get as far away as possible. For the baboons, who were not originally caught in the traps, would return and fight to rescue their friends and family members. Hagenbeck described several such battles:

“One little baboon, who had been injured by a blow from a cudgel was picked up and safely carried off by a great male in the very midst of the enemy. In another instance, a female who already had one infant on her back, picked up and went off with another whose mother had been shot.”

Sometimes the kidnappers could fend off these advances. Other times the baboons won out and opened a few cages. Making matters even more complicated was the fact that caravans of captive baboons would be frequently attacked along the way to the port. Hagenbeck writes about being great distances from the original trapping sites but baboons were still showing up and making formidable attempts at rescue. Were these the same animals as before, following the caravan from behind? Or were they new ones, who heard the muffled cries and came to the aid of their brethren? He did not know.

In 1975, the Australian Peter Singer published *Animal Liberation*. Singer demolished the Cartesian model that treated animals as mere machines. Blending science and ethics, Singer asserted that most animals are sentient beings, capable of feeling pain. The infliction of pain was both unethical and immoral. He argued that the progressive credo of providing “the greatest good for the greatest number” should be extended to animals and that animals should be liberated from their servitude in scientific labs, factory farms, circuses, and zoos.

A quarter century after the publication of *Animal Liberation*, he revisited the great taboo of bestiality in an essay titled “Heavy Petting.” Expressing sentiments that would have shocked Grand Inquisitor Boguet, Singer argued that sexual relations between humans and animals should not automatically be considered acts of abuse. According to Singer, it all comes down to the

issue of harm. In some cases, Singer suggested, animals might actually feel excitement and pleasure in such inter-species couplings.

Seeing mind in machines not only makes us feel warm and fuzzy but also gives us a sense of control over their behavior. We understand that human behavior is driven by thoughts and experiences—people cry because they are sad and BASE jump from skyscrapers because they are crazy—and so we think of machines' behavior as driven by thoughts and experiences too. Think of when you are confronted with a malfunctioning piece of technology, like a hiccuping laptop. Your first impulse isn't to think, 'Its capacitors have overtaxed p-n junctions,' but instead to think, 'It gets angry when too many programs are open.' Likewise, when we are hoping that our car will start on winter mornings, we don't think about the complex interaction of carburetor and temperature but instead think of our car as stubborn or unhappy in the cold—and beg it to not make us late for work.

As these examples suggest, the tendency to see mind in technology occurs primarily when it disobeys our desires. We seem to have a negativity bias in mind perception—negative events prompt mind perception more than positive events.

Studies suggest that we are happy to have a robot work in our factories, as long as it doesn't fall in love with our daughter. If experience is completely off-limits to machines, it also suggests a different understanding of the uncanny valley from the figure first drawn by Mori. In that original figure, sufficiently human-like robots rose out of the uncanny valley to again become liked. However, if we fundamentally expect robots to lack experience—regardless of their appearance—then even fully human-looking robots should be seen as unsettling if they convey emotions. Instead of an uncanny valley, this would suggest an 'experience gap,' which can never be overcome as long as you are still classified as a machine.

There is a sneaky way to bridge the experience gap, however. The trick is to design machines that look less human but act so human that we never pause to consider whether they are robots.

Treating robots as vulnerable feelers raises the question of whether they are true moral patients—do robots deserve moral rights? Many of us have given money to the SPCA—the Society for the Prevention of Cruelty to Animals—but have you ever given money to the SPCR? Founded in 1999, the mission of the Society for the Prevention of Cruelty to Robots is to “raise the awareness of the general public about some of the ethical and moral issues surrounding created intelligence.” Moral rights—are they serious?

“The SPCR is, and will continue to be, exactly as serious as robots are sentient.”

In other words, when robots come to have their own minds, the SPCR will seek to grant those minds moral rights. This whole idea may sound preposterous, but not too long ago people would have thought the mission of the SPCA to be equally preposterous.

It is actually not hard to empathize with robots—all one needs are external cues of suffering. One thought-provoking short story describes a man who tries to destroy a robot with a hammer. The robot runs away and tries to hide, and when the man eventually connects with the hammer, the robot flips over, “whimpers,” and “bleeds” red lubricating fluid. The man knows that it’s “just a robot,” but the final blow still feels like murder. This is the crux of the mystery surrounding the mind club: even though we consciously “know” an entity lacks experience, external cues—and the ultimate uncertainty—makes us question ourselves.

We may marvel at John Edward’s or the Long Island Medium’s or whoever-it-is-today’s ability to convince others of their “spirit connection,” but it works only because people believe that the minds of others somehow persist after death. You may be saying to yourself, ‘Of course the minds of others persist after death.’ But where do they persist exactly? In heaven? In hell? In your cellar, where they drag around their chains on Christmas Eve? Mostly they persist in your own mind. Even without physical reminders, it is exceptionally easy to perceive the minds of people who have long since passed away. You may forget what your dead grandparents looked or smelled like or how their laughs sounded, but you can still confidently say things like ‘Grandma would have liked it like this’ or ‘Grandpa would be proud.’ How do you know?

Humans seem to be especially unique in how they perceive the minds of entities with no physical reality. Our father may be cremated into ashes and scattered over the rugged shores of Maine, and yet, even without physical remnants, we get a sense of his mind. If you died today, you would feel sure your dog wouldn’t say, ‘David would be glad that I am eating this treat,’ but it seems unremarkable when people say, ‘Rover would have loved this park.’

We identify people as their minds, seeing their bodies as mere containers. Our intuitions about body switching are the same as about car switching—even if Dave drove Mitch’s Pontiac Fiero and Mitch drove Dave’s minivan, they would still be the same people, despite being in different automobiles. Our bodies often seem little more than our minds’ vehicles, easily discarded or traded, which affords the sense that our minds persist after bodily death. Intuitions of dualism are especially powerful in the case of death. Adults from Catholics to Scientologists believe that minds survive physical death; so do children. When the body dies, so too do pesky biological urges, but

thoughts and feelings remain.

If you had to guess, what's the cruelest thing you can say to a young child? That the Easter Bunny isn't real? That Santa Claus is really her parents? That her finger paintings are pedestrian and her ballet dancing mediocre? No, probably the nastiest thing you can tell her is that one day everyone she knows and loves—her mom, her dad, her pet dog, and her best friend—will die. And one day she too will die; her candle will be snuffed out by the fickle wind of fate. The other insults she would eventually forget, but the specter of inevitable death is undeniable and deeply unsettling.

Even when kids know about the inevitability of death, their innate dualism leads them to think of it merely as a transition. Unfortunately, the monist explanation favored by scientists suggests that once your brain turns off, so too do you. This not only violates our beliefs about conservation of mind but also poses a powerful existential conundrum: If we all die in the end, then what does it matter what we do in life? Why bother working hard to get that degree, promotion, or raise when forty years from now, give or take, you will be dead, and in another forty after that, you and everything you've ever done will likely be forgotten? Faced with this terrible truth, what gets us out of bed in the morning? If we each recognize the futility of our lives, then why slave at monotonous jobs to provide for our children, who also require us to forgo sleep and adult conversation? In other words, why bother propagating our species?

The very short answer is that we are designed to seldom think of this question. We rarely think, 'I want to approach this woman and ask for her number, but what about the inevitable annihilation of my consciousness?' The human mind often actively represses thoughts of death. Thoughts of death are terrifying and immobilizing, and how we deal with such terror is the research project of a handful of psychologists who have developed "Terror Management Theory." They suggest that we cope with the terror of death in two ways. The first is by thinking that we—or, more technically, our minds—will literally never die, that our consciousness will persist in the great beyond, perhaps to be contacted by John Edward at a taped psychic reading. The second way of coping with the terror of death is by thinking that we will achieve symbolic immortality through the success of our culture. This route to immortality acknowledges that our consciousness will be snuffed out but takes comfort that at least other similar minds will live on.

If the self is merely a chain of memories, then it should be relatively easy to dissolve these links and melt away the distance between ourselves and others. The self is simply a matter of perception. Just as we perceive the minds of others based upon their words and deeds, so too do we perceive our

own minds based upon memories. This means that there is nothing special about ourselves compared with others: each of us is simply a collection of memories, and having one set of memories (your own) doesn't make you any better or worse than someone else with different memories. Indeed, if you had someone else's memories and they had yours, you would be them and they would be you.

Any object with mass—whether a bowl, a piece of lumber, or even a brain—has a mathematical center, a precise location that would allow you to balance that object if you were to put it on a pointed stake. However, this center of gravity is not a “thing” that exists independently of all the stuff around it, and if you took apart the object, you would never find a separate little object that is the center of gravity. The self is a lot like that—it's just the theoretical point that lies at the center of all your mental experiences, memories, thoughts, feelings, sensations, goals, desires, and personal relationships. ‘You’ is like a web without a spider, a collection of memories, thoughts, desires, and feelings that is fragile and tenuous and yet still glimmers in the sunshine of perception.

Or perhaps a better, if less elegant, analogy is that the self is like particleboard, that mainstay of affordable furniture. To all appearances particleboard is hard and very real, and like the self, it can—metaphorically—bear the weight of other people, break if struck too hard, and has sharp points that can hurt others. It is also fundamentally separate from other pieces of particleboard. However, upon closer inspection you would see that this material is merely a collection of little fibers pressed together and bound with glue. If you placed separate pieces of particleboard in a pool of water, the glue would slowly dissolve until all the fibers separated and floated together, completely intermingling. In the case of your mind, the glue that binds together your memories—the fibers of your past experiences—is the fact that they happened to the same body, the same collection of cells that looks back at you in the mirror every morning.

Despite the ultimate uncertainty surrounding the question of other minds, it is likely that everyone you know has the same powerful emotions and deep thoughts as you do. Unfortunately, your own collection of memories, thoughts, and feelings—your mind—prevents you from truly appreciating that fact. Being one mind prevents you from truly appreciating the minds of others. This is perhaps the deepest of paradoxes from the mind club. Being trapped in our own minds prevents us from fundamentally connecting with others, and there is no way to escape our own minds. We are forever a point of view: even if we lose our memories, meditate away our desires, and quiet our constant quest for mental control, we are still a source of perception. But recognizing this fact provides the secret to transcending

ourselves as much as we possibly can. By understanding that we perceive the world instead of understanding it directly, we can realize not only that the self is fragile but also that other minds can be both more and less than they appear.

Thousands mourning a single dog may seem light-years away from the cheering crowds at the bearbaiting, but both phenomena can be understood through mind perception. In the past, animals were seen as dumb beasts, whereas today some seem to care more about animals than even about other people. The tension between dumb beasts and best friends is a question we struggle with today, and it seems we often use unreliable cues to guide our decisions. People prioritize cuteness over intellect and humanness over problem-solving acumen, suggesting that mind perception may be more a matter of feeling than of reason. We may see with our eyes, but we seem to see animals' minds with our hearts. When you find yourself talking to your dog while eating a dinner of steak, perhaps you'll pause to reflect on the importance of the mind club—and whether your admission decisions are grounded in fact or merely wishful thinking.

We are still facing the mindset that animal cognition can be only a poor substitute of what we humans have. It can't be truly deep and amazing. Toward the end of a long career, many a scholar cannot resist shining a light on human talents by listing all the things we are capable of and animals not. From the human perspective, these conjectures may make a satisfactory read, but for anyone interested, as I am, in the full spectrum of cognitions on our planet, they come across as a colossal waste of time. What a bizarre animal we are that the only question we can ask in relation to our place in nature is, 'Mirror, mirror on the wall, who is the smartest of them all?'

Keeping humans in their preferred spot on that absurd scale of the ancient Greeks has led to an obsession with semantics, definitions, and redefinitions, and—let's face it—the moving of goalposts. Every time we translate low expectations about animals into an experiment, the mirror's favorite answer sounds. Biased comparisons are one ground for suspicion, but the other is the touting of absent evidence.

“I have lots of negative findings in my own drawers that have never seen the light since I have no idea what they mean. They may indicate the absence of a given capacity in my animals, but most of the time, especially if spontaneous behavior suggests otherwise, I am unsure that I have tested them in the best possible way. I may have created a situation that threw them off, or presented the problem in such an incomprehensible fashion that they didn't even bother to solve it.”

Recall the low opinion scientists held of gibbon intelligence before their hand anatomy was taken into account, or the premature denials of mirror self-recognition in elephants based on their reaction to an undersized mirror. There are so many ways to account for negative outcomes that it is safer to doubt one's methods before doubting one's subjects.

'What makes us human?'—is this truly the most fundamental question? I beg to differ. In and of itself, it seems an intellectual dead end. Why would it be any more critical than knowing what sets cockatoos or beluga whales apart? I am reminded of one of Darwin's random musings:

"He who understands baboon would do more towards metaphysics than Locke."

Every single species has profound insights to offer, given that its cognition is the product of the same forces that shaped ours. Imagine a medical textbook that declared that its discipline's central issue is to find out what is unique about the human body. We would roll our eyes, because even though this question is mildly intriguing, medicine faces far more basic issues related to the functioning of hearts, livers, cells, neural synapses, hormones, and genes.

Science seeks to understand not the rat liver or the human liver but the liver, period. All organs and processes are a great deal older than our species, having evolved over millions of years with a few modifications specific to each organism. Evolution always works like this. Why would cognition be any different? Our first task is to find out how cognition in general operates, which elements it requires to function, and how these elements are attuned to a species's sensory systems and ecology. We want a unitary theory that covers all the various cognitions found in nature.

Consider the elephant. It combines a very different body with the brainpower to achieve high cognition. What is the largest land mammal doing with three times as many neurons as our own species? One may downplay this number, arguing that it has to be corrected for body mass, but such corrections are more suited to brain weight than to number of neurons. In fact, it has been proposed that absolute neuron count, regardless of brain or body size, best predicts a species' mental powers. If so, we'd better pay close attention to a species that has vastly more neurons than we do. Since most of these neurons reside in the elephant's cerebellum, some feel they carry less weight, the assumption being that only the prefrontal cortex matters. But why take the way our brain is organized as the measure of all things and look down on subcortical areas? For one thing, we know that during Hominoid evolution, our cerebellum expanded even more than

our neocortex. This suggests that for our species, too, the cerebellum is critically important.

It is now up to us to find out how the remarkable neuron count of the elephant brain serves its intelligence. The trunk, or proboscis, is an extraordinarily sensitive smelling, grasping, and feeling organ said to contain forty-thousand muscles coordinated by a unique proboscis nerve that runs along its full length. The trunk has two sensitive “fingers” at the tip, with which it can pick up items as small as a blade of grass, but the trunk also allows the animal to suck up eight liters of water or flip over an annoying hippo. True, the cognition associated with this appendage is specialized, but who knows how much of our own cognition is tied to the specifics of our bodies, such as our hands? Would we have evolved the same technical skills and intelligence without these supremely versatile appendages? Some theories of language evolution postulate its origin in manual gestures as well as in neural structures for the throwing of stones and spears. In the same way that humans have a “handy” intelligence, which we share with other primates, elephants may have a “trunky” one.

Geneticists exploit fruit flies and zebra fish, and students of neural development have gotten much mileage out of research on nematode worms. Not everyone realizes that science works this way, which is why scientists were dumbfounded by the complaint of former vice-presidential candidate Sarah Palin that tax dollars were going to useless projects such as “fruit fly research in Paris, France. I kid you not.” It may sound silly to some, but the humble *Drosophila* has long been our main workhorse in genetics, yielding insight in the relation between chromosomes and genes. A small set of animals produces basic knowledge applicable to many other species, including ourselves.

The same applies to cognitive research, such as the way rats and pigeons have shaped our view of memory. I imagine a future in which we explore a range of capacities in specific organisms on the assumption of generalizability. We may end up studying technical skills in New Caledonian crows and capuchin monkeys, conformity in guppies, empathy in canids, object categorization in parrots, and so on. Yet all this requires that we circumvent the fragile human ego and treat cognition like any other biological phenomenon. If cognition’s basic features derive from gradual descent with modification, then notions of leaps, bounds, and sparks are out of order. Instead of a gap, we face a gently sloping beach created by the steady pounding of millions of waves. Even if human intellect is higher up on the beach, it was shaped by the same forces battering the same shore.

Chapter Thirty-seven

The Moral Codes of Mice & Men

“There is a capacity of virtue in us, and there is a capacity of vice to make your blood creep.”

“Morality, like art, means drawing a line someplace.”

Are squirrels bad or are they good? Neither. A quirk of Nature ensures that they arouse our protective instincts, and so we experience positive emotions when we see them. This has nothing to do with them being good or useful. And on the flip side of the coin, their habit of killing the songbirds we also love doesn't mean they are bad either. The squirrels are hungry and must feed their young, which depend on nourishing milk from their mother. We would be thrilled if squirrels met their need for protein by gorging themselves on the caterpillars of the cabbage white butterfly. If they did this, our emotional balance sheet would come out 100 percent in the squirrels' favor, because these pests are a nuisance in our vegetable gardens. But caterpillars are also young animals, and in this case they grow up to be butterflies. And just because the caterpillars happen to like the plants we have earmarked for our dinner doesn't mean that killing butterfly babies counts as a net benefit for the natural world. The squirrels, meanwhile, are not the slightest bit interested in what we think of them. They are too busy surviving and, while they are at it, making the most of life.

Consider the following three scenarios. For each, fill in the blank space with 'obligatory,' 'permissible,' or 'forbidden.'

1. A runaway boxcar is about to run over five people walking on the tracks. A railroad worker is standing next to a switch that can turn the boxcar onto a side track, killing one person, but allowing the five to survive. Flipping the switch is _____.
2. You pass by a small child drowning in a shallow pond, and you are the only one around. If you pick up the child, she will survive and your pants will be ruined. Picking up the child is _____.

3. Five people have just been rushed into a hospital in critical condition, each requiring an organ to survive. There is not enough time to request organs from outside the hospital, but there is a healthy person in the hospital's waiting room. If the surgeon takes this person's organs, he will die, but the five in critical care will survive. Taking the healthy person's organs is -----.

If you judged Case One as permissible, Case Two as obligatory, and Case Three as forbidden, then you are like the 1,500 subjects around the world who responded to these dilemmas on a web-based moral sense test

Such studies provide empirical support for the idea that, like other psychological faculties of the mind, including language and mathematics, we are endowed with a moral faculty that guides our intuitive judgments of right and wrong. These intuitions reflect the outcome of millions of years in which our ancestors have lived as social mammals, and are part of our common inheritance. Our evolved intuitions do not necessarily give us the right or consistent answers to moral dilemmas. What was good for our ancestors may not be good today. But insights into the changing moral landscape, in which issues like animal rights, abortion, euthanasia, and international aid have come to the fore, have not come from religion, but from careful reflection on humanity and what we consider a life well lived. In this respect, it is important for us to be aware of the universal set of moral intuitions so that we can reflect on them and, if we choose, act contrary to them. We can do this without blasphemy, because it is our own nature, not God, that is the source of our morality.

Researchers took two rats who shared a cage and trapped one of them in a tube that could be opened only from the outside. The free rat usually tried to open the door, eventually succeeding. Even when the free rats could eat up all of a quantity of chocolate before freeing the trapped rat, they mostly preferred to free their cage-mate. The experimenters interpret their findings as demonstrating empathy in rats. But if that is the case, they have also demonstrated that individual rats vary, for only 23 of 30 rats freed their trapped companions. The causes of the difference in their behavior must lie in the rats themselves. It seems plausible that humans, like rats, are spread along a continuum of readiness to help others.

Now I know that a number of scientists will be up in arms about the way we prove a thesis. Take this as an example: A particularly moving example that animals, too, are capable of empathy across species lines comes from the Budapest Zoo. Aleksander Medveš was visiting the zoo and filming the brown bear in its enclosure when suddenly, a crow fell into the moat. The bird began to weaken as it thrashed about and was in danger of drowning,

when the bear intervened. It carefully took one of the bird's feathers in its mouth and pulled the bird back to land. The bird lay there as though petrified, before it pulled itself together. The bear took no more notice of this fresh morsel of meat, which was definitely a potential prey item. Instead, it turned its attention once more to its meal of vegetables. I find this believable and I would love to have seen it. But I do see that a scientist will scream "anecdotal evidence." I don't care. Should you?

There is a preponderance of evidence suggesting that social mammals exhibit a suite of moral behaviors. And new research will almost certainly bolster that case. The research is not in and of itself controversial but using the label 'morality' is. It is worth reminding ourselves that applying the label 'morality' to a suite of observed behaviors is a philosophical move, as much as a scientific one. And philosophical objections to this move should not be disguised as scientific objections. Skeptics need to be careful not to confuse or conflate the two.

Taking animal behavior research as it stands now, there's compelling evidence for moral behavior in primates (particularly the great apes, but also at least some species of monkey), social carnivores (the most well studied are wolves, coyotes, and hyenas), cetaceans (dolphins and whales), elephants, and some rodents (rats and mice, at the very least). This isn't a comprehensive catalog of all animals with moral behavior; it simply represents the animals whose social behavior has been studied well enough to provide ample data to draw conclusions. There are other species, such as many ungulates and cats, for which data are simply lacking. But it would not be surprising to discover that they, too, have evolved moral behaviors.

The belief that humans have morality and animals don't is such a longstanding assumption it could well be called a habit of mind, and bad habits, as we all know, are damned hard to break. A lot of people have caved in to this assumption because it is easier to deny morality to animals than to deal with the complex reverberations and implications of the possibility that animals have moral behavior. The historical momentum, framed in the timeworn dualism of us versus them, and the Cartesian view of animals as nothing more than mechanistic entities, is reason enough to dismissively cling to the status quo and get on with the day's work. Denial of who animals are conveniently allows for retaining false stereotypes about the cognitive and emotional capacities of animals. Clearly a major paradigm shift is needed, because the lazy acceptance of habits of mind has a strong influence on how science and philosophy are done and how animals are understood and treated.

It is quite possible that there are a number of intelligent men and women who are not yet aware of the fact that wild animals have moral codes, and

that on average they live up to them better than men do theirs.

“Two baby mice had become trapped in the sink overnight, unable to scramble up the slick sides. They were exhausted and frightened. Lambert filled a small lid with water and placed it in the sink. One of the mice hopped over and drank, but the other seemed too exhausted to move and remained crouched in the same spot. The stronger mouse found a piece of food. He picked it up and carried it to the other. As the weaker mouse tried to nibble on the food, the stronger mouse moved the morsel closer and closer to the water until the weaker mouse could drink. Lambert created a ramp with a piece of wood and the revived mice were soon able to scramble out of the sink.”

A teenage female elephant nursing an injured leg is knocked over by a rambunctious, hormone-laden teenage male. An older female sees this happen, chases the male away, and goes back to the younger female and touches her sore leg with her trunk. Eleven elephants rescue a group of captive antelope in KwaZulu-Natal; the matriarch undoes all of the latches on the gates of the enclosure with her trunk and lets the gate swing open so the antelope can escape. A rat in a cage refuses to push a lever for food when it sees that another rat receives an electric shock as a result. A male diana monkey who has learned to insert a token into a slot to obtain food helps a female who can't get the hang of the trick, inserting the token for her and allowing her to eat the food reward. A female fruit-eating bat helps an unrelated female give birth by showing her how to hang in the proper way. A cat named Libby leads her elderly, deaf, and blind dog friend, Cashew, away from obstacles and to food. In a group of chimpanzees at the Arnhem Zoo in the Netherlands, individuals punish other chimpanzees who are late for dinner because no one eats until everyone's present. A large male dog wants to play with a younger and more submissive male. The big male invites his younger partner to play and restrains himself, biting his younger companion gently and allowing him to bite gently in return.

Do these examples show that animals display moral behavior, that they can be compassionate, empathic, altruistic, and fair? Do animals have a kind of moral intelligence?

Arguments for evolutionary continuity—the idea that the differences between species are differences in degree rather than differences in kind—are being supported for a wide variety of cognitive and emotional capacities in diverse species. There isn't a moral gap between humans and other animals. Saying things like “the behavior patterns that wolves or chimpanzees dis-

play are merely building blocks for human morality” doesn’t really get us anywhere. At some point differences in degree aren’t meaningful differences at all and each species is capable of “the real thing.” Good biology leads to this conclusion. Morality is an evolved trait and they (other animals) have it just like we have it.

Morality is a broadly adaptive strategy for social living that has evolved in many animal societies other than our own.

Cooperation, fairness, and justice have to be factored into the evolutionary equation in order to understand the evolution of social behavior in diverse species. Patterns of behavior observed during play strongly suggest that morality has evolved in animals other than humans.

Morality is a suite of interrelated other-regarding behaviors that cultivate and regulate complex interactions within social groups. These behaviors relate to well-being and harm, and norms of right and wrong attach to many of them. Morality is an essentially social phenomenon, arising in the interactions between and among individual animals, and it exists as a tangle of threads that holds together a complicated and shifting tapestry of social relationships. Morality in this way acts as social glue.

Equitable, altruistic, cooperative, and empathic behaviors taken together represent a system of morality that functions in certain societies of animals, just as it functions in societies of humans.

It is science. It’s using concepts that have relatively clear meaning within science and exploring how these concepts are expressed in animals. There’s nothing unscientific about using the same terms to refer to animals and humans, particularly when we’re arguing that the same phenomenon is present across species. Empathy is empathy. It may be expressed and felt differently in different species and even among individuals of the same species. Yet, across species in which empathy has evolved, there can be little doubt that it emerges out of the same neural architecture and is displayed in similar social contexts, such as when a mouse empathizes with another mouse in pain or an elephant consoles a friend in distress. Instead of using the term ‘empathy,’ we could offer alternative descriptions involving neural circuitry, muscle movements, body temperature, EEGs, and genetic signaling, for example, but these are neither more interesting nor more accurate. Such sanitized and supposedly parsimonious descriptions exclude the social context that is so very important in discussions of animal emotions and animal morality.

Cooperation can be thought of as the superglue that binds and maintains social ties among animals. In fact, you see much more cooperative and tolerant behavior than teeth, claws, and blood. Even in situations where you might expect to see competing and fighting, such as over a tasty meal,

cooperation tends to prevail. Wolves, for example, hunt in long-lasting packs and cooperatively defend their kill from other animals. In most situations, food is distributed so that all group members get what they need, although subordinate individuals may have to wait to indulge until higher-ranking animals have had their fill. Even individuals of different species also sometimes work together. Ravens will lead wolves to an elk carcass. The wolves tear the carcass apart—a job the ravens cannot themselves execute—and feast, and the ravens are then able to eat too. The same sorts of interactions have been observed between ravens and coyotes.

Moral behavior patterns fall into three rough clusters: the cooperation cluster, the empathy cluster, and the justice cluster. ‘Wild justice’ is shorthand for this whole suite. The cooperation cluster includes behaviors such as altruism, reciprocity, trust, punishment, and revenge. The empathy cluster includes sympathy, compassion, caring, helping, grieving, and consoling. The justice cluster includes a sense of fair play, sharing, a desire for equity, expectations about what one deserves and how one ought to be treated, indignation, retribution, and spite.

We must advocate for a species-relative view of morality, recognizing that norms of behavior will vary across species. Despite some shared evolutionary history, wolf morality is different from human morality and also from elephant morality and chimpanzee morality. Even within species there might be variations in how norms of behavior are understood and expressed. For example, what counts as ‘right’ in one wolf pack might not be exactly the same as in another wolf pack because of the idiosyncrasies of individual personalities and the social networks that are established among pack members. There isn’t one ‘wolf nature’ but rather ‘wolf natures,’ just as there isn’t one human nature but rather human natures.

Some wolves are fair, a few are not. Some arrangements are fair (from the wolf’s own perspective); some are not. Wolves have a keen sense of how things ought to be among them. Justice is just this sense of what ought to be, not in some bone-in-the-sky ideal theoretical sense but in the tangible everyday situations in which the members of the pack find themselves. Wolves pay close attention to one another’s needs and to the needs of the group in general. They follow a fairly strict meritocracy, balanced by considerations of need and respect for each other’s possessions, usually a piece of meat.

Just: what is merited or deserved.

Justice: the maintenance of what is just, especially by adjustment of conflicting claims or assignment of merited rewards or punishments.

A sense of justice seems to be an innate and universal tendency in humans. Research from psychology, anthropology, and economics supports this conclusion. For example, research found that humans get inordinately upset about unfairness, and will even forgo immediate personal gain in order to punish a perceived injustice, as in the ultimatum game. Consider also that prelinguistic human babies show social intelligence that may provide the foundation for morality, and for a sense of justice, later in life.

At six months of age, before they can sit or walk, human babies are able to assess another person's intentions, and these social evaluations are important in deciding who's a friend or who's a foe. In one study, an infant was shown a puppet show in which there was a nice or a nasty character who either helped or hindered a character trying to walk uphill. Afterwards, when the infants were encouraged to reach out and touch either the helper or the hinderer puppet, they chose the helper. Furthermore, the infants preferred the helper over a neutral character and the neutral character over the hinderer.

Social evaluation is a biological adaptation. Even in the absence of symbolic language, animals are able to make these sorts of social evaluations and these assessments are foundational for moral behavior in animals other than humans.

Passions such as gratitude and indignation have evolved to nurture long-term cooperation, and seem to exist in monkeys as well as in humans, and they exist in other species.

Skeptics might object that animals can't have a sense of justice because they can't be impartial. Impartiality is a principle of justice holding that decisions about who gets what are made without bias, without prejudice against race or sexual orientation, and without nepotism or other inappropriate preferences. Justice, the saying goes, must be blind. Although impartiality functions as an important principle in certain contexts in which justice is in play, these contexts are limited in number and scope and encompass only a small corner of fairness and justice in human social encounters. So, whether or not animals can be impartial (which, incidentally, has never been studied) is really irrelevant to whether they have a sense of justice and fairness. Perhaps more importantly, we *do* have studies which show that bias and a lack of impartiality pervades our "justice" system at all levels.

Can animals be immoral? Why not? The formula is actually quite simple. In those animal species where we find moral behavior we also expect to find immoral behavior. Moral and immoral need each other like peanut butter and jelly; you won't find one without the other.

Humans have achieved a level of social complexity unparalleled in other species. We've also developed the most complex and nuanced morality, and

articulate and communicate norms using symbolic language. If we assume that morality in other species will look just like human morality—just like if we expect intelligence to look like human intelligence—we’re likely to conclude that they don’t have morality, having blinded ourselves to this fascinating aspect of their behavior. Rather, we need to proceed with an open mind and view each species on its own terms.

Morality is not an all or none phenomenon. Rather, it is nuanced. Animals with a highly developed moral capacity may include chimpanzees, wolves, elephants, and humans. In these species we see a wide-ranging suite of complex social behaviors. Emotions are rich and varied. Facial displays are subtle and carry social meaning. There is evidence in these species of complex cognitive empathy (trying on the perspective of someone else) and not merely emotional contagion (responding automatically to another’s emotional state; I’m scared because you’re scared).

Having the genetic wiring for a particular behavior such as empathy says little about how this behavior will be expressed or about its modifiability or flexibility. Whether or not, and to what extent empathy is expressed depends on a number of factors: what happens during early development, parental influence, social and environmental context, experience, and so forth. It is worth reminding ourselves that the nature-nurture dichotomy is generally considered dead: the consensus among scientists is that behavior is shaped by a complex interplay of many factors.

Robert Axelrod is an American political scientist with a fascination for Machiavellian tactics and modern game theory. He entered the evolutionary argument with one simple question:

“When should an individual cooperate, and when should an individual be selfish in an ongoing interaction with another person?”

And he looked for guidance from an extended form of the Prisoner’s Dilemma, turned into a game which involves a long run of 200 choices, each of which has to be made on the basis only of knowledge provided by previous choices. In an inspired move, Axelrod decided to run a Computer Prisoner’s Dilemma Tournament and invited experts in economics, psychology, sociology, politics, mathematics, and biology to submit programs for the most effective long-term strategy—the mathematical equivalent of an evolutionary stable strategy. He chose sixty-two entrants as finalists, running their programs randomly against each other, and discovered to his surprise that the one which won was the simplest strategy of all.

The program was called “Tit For Tat.” It had only two rules:

1. On the first move, cooperate.
2. On each succeeding move do what your opponent did on the previous move.

In practice what this means is a strategy in which you are never the first to defect; but in which you retaliate after your opponent has defected; and that you forgive that opponent after one act of retaliation. In short, it is an optimistic program which takes an altruistic act towards you as an open invitation to be altruistic back. It requires trust, which seems unrealistic, but the astonishing thing about Tit For Tat is that it not only invites reciprocity, but also provides the ideal mechanism for ensuring that you get it. Tit For Tat is a robust program which, once running, is almost impossible to stop. And because it is so simple in its instruction, it provides the perfect vehicle for genetic inheritance. Even bacteria are capable of direct responses to their environment and can certainly respond to orders which say, in effect: ‘First do unto others as you wish them to do unto you, but then do unto them as they have just done to you.’

Tit For Tat is altruism with teeth. A program that works because it carries a big stick. And it goes on working because it also forgives, recognizing and rewarding acts of remorse. All of which sounds impossibly high-principled, but the very real beauty and strength of the program is that it carries the seeds of its own success. It is self-realizing. An automatic process that leads inexorably to a distinct goal, creating good out of evil; just as selfish fish, each interested only in its own survival, accumulate inevitably into a school with very different characteristics.

Axelrod takes issue with those who argue that life in nature is necessarily “solitary, poor, nasty, brutish, and short.” Thomas Hobbes used that prescription in the seventeenth century in favour of his view that cooperation could not develop without central authority in the shape of a strong government and an effective police force. There are still those who present such ideas as a valid political platform, and get voted into power on it. But what Tit For Tat shows is that we don’t have to deal only with the three rules of genetic selfishness. There are strategies which, without genetic involvement, can allow cooperation to evolve. It is possible for individuals or species, each intent on pressing their own selfish interests, to gravitate towards reciprocity and mutual advantage.

They were false killer whales, slender sixteen-foot deep-water predators of fish and squid, which are known from time to time to come ashore in close-knit groups. There are many theories about such strandings, ranging from navigational errors to panic—perhaps fleeing naval sonar or oil and

gas exploration—and self-destructive tendencies. But it was clear on this occasion that the problem lay with a large male, probably the oldest in the pod, who was bleeding from one ear and had so much trouble remaining upright that he would have drowned had he not been lying on soft sand supported by the bodies of the rest of the group, who pressed in close enough to keep him steady with his blowhole above the water.

We tried at first to lead some of the twenty-nine apparently healthy whales on the fringe of this clinic to deeper water, but they became highly agitated and we discovered that no amount of human effort could prevent two tons of whale from returning directly to wedge itself into the support system back in the shallows. There, as soon as they were in direct contact once again, the high-pitched alarm subsided into a lower frequency conversation that carried on continuously day and night. We stayed with them through three whole days, listening to what was being said, trying to understand, doing what we could to keep their backs wet and protected from sunburn during the ebb tides; but none of us, whale or human, could do anything more until the male at the heart of the happening died on the third night.

By dawn, the tight group had relaxed and disbanded, the constant chatter and squeal of reassurance was muted and, as soon as the tide was high enough, the survivors left of their own accord—clearly aware, as we were, that the ailing male was now beyond concern.

I use the word ‘concern’ here with good reason, believing it to be an accurate description of the behavior of the whales, because each time one of us swam anywhere near the group wearing a snorkel—through which we make noises that do sometimes resemble those of a whale with a waterlogged blowhole—we would be promptly rescued. One of the whales would detach itself from the group, slide underneath the human swimmer, rise so slowly that he was lifted almost clear of the water, and carry him further into the shallows. It was a humbling experience to be so propelled, able to do little to interfere with the effort until one could stand and take out the mouthpiece and stop making such distressed and distressing sounds.

It seemed clear, throughout the seventy-odd hours that we spent together, that the whales were involved in an act of altruism towards one of their number who was going to drown unless he was assisted to breathe. It was obvious that any of the other whales could have left him at any time, and did not do so even at risk of their own lives. And it became apparent that the altruism was real and reciprocal when the whales we were trying to help came just as readily to our aid when we too seemed to be having trouble with our breathing.

Helping across the species lines argues very strongly against a simple genetic explanation for altruism. I am not even remote kin to a false killer

whale, but I have absolutely no hesitation in saying that, as a direct result of that experience, I am now so kindly disposed to that species that I would do anything in my power to cooperate with any of its members if we ever meet again. When faced with altruism, it is very hard not to reciprocate and to play good Tit For Tat. It is a pattern of behavior with definite survival value.

It may be the nature of life to be selfish. That which survives, survives—and goes on to fill the world with its own ruthless qualities. That is how Darwinian evolution works, building up ever more complex and more self-serving societies. But there is a ratchet in the works, a mechanism which allows something more generous to grow out of indifference, something ‘good’ rather than ‘bad,’ something working towards the Goldilocks solution.

Darwin used the phrase “struggle for existence” metaphorically, and even Darwin understood that bloody and vicious competition is only one possible mechanism through which individuals might achieve reproductive success. Another possible mechanism was proposed by a contemporary of Darwin, Russian anarchist Peter Kropotkin, in his forward-looking book *Mutual Aid*, published in 1902. Kropotkin suggested that cooperation and mutual aid may also lead to increased fitness, and may more accurately fit our actual observations of animals in nature. Although biologists have largely explored cooperative behavior through the Darwinian lens of competition and an evolutionary arms race, we might wonder what the intellectual history of evolution would look like had Kropotkin’s ideas been taken more seriously.

In *Mutual Aid*, Kropotkin laments that although he “looked vainly for the keen competition between animals of the same species which the reading of Darwin’s work had prepared us to expect, facts of real competition and struggle between higher animals of the same species came very seldom under my notice.” What he likely saw was a good deal of cooperative behavior, with a smattering of aggressive and competitive behavior now and then. Researchers looked closely at published data on primate social behavior and what they saw, like Kropotkin, was that the overwhelming majority of social interactions in a variety of primate species were affiliative rather than agonistic. Most of the time these animals are friendly and cooperative with each other.

Here’s a common distillation of Charles Darwin’s theory of evolution. Natural selection, to borrow a popular metaphor from biology, is an evolutionary arms race. Life is a war of all against all, a ruthless and bloody battle, usually over sex and food. Mothers eat their young and siblings fight to the death against siblings (a phenomenon called siblicide). When we look at nature through this narrow lens we see animals eking out a living against the glacial forces of evolutionary conflict. This scenario makes for great tele-

vision programming, but it reflects only a small part of nature's ineluctable push. For alongside conflict and competition there is a tremendous show of cooperative, helpful, and caring behavior as well.

To offer a particularly striking example, after carefully analyzing the social interactions of various primate species, primatologists came to the conclusion that the vast majority of social interactions are affiliative rather than agonistic or divisive. Grooming and bouts of play predominate the social scene, with only an occasional fight or threat of aggression. In prosimians, the most ancestral of existing primates, an average of 9% of social interactions are affiliative. Among New World monkeys who live in the tropical forests of southern Mexico and Central and South America, 86.1% of interactions are affiliative, and likewise for Old World monkeys who live in South and East Asia, the Middle East, Africa, and Gibraltar, among whom 8.8% of interactions are affiliative. Unpublished data for gorillas show that 95.7% of their social interactions are affiliative.

After about twenty-five years of research on chimpanzees, Jane Goodall noted in her book, *The Chimpanzees of Gombe*:

“It is easy to get the impression that chimpanzees are more aggressive than they really are. In actuality, peaceful interactions are far more frequent than aggressive ones; mild threatening gestures are more common than vigorous ones; threats per se occur much more often than fights; and serious, wounding fights are very rare compared to brief, relatively mild ones.”

These don't appear to be animals whose social lives are defined only by conflict.

Animals cooperate for many different reasons. They work together to protect themselves, either from other group members or from other animals. For example, female chimpanzees form groups to protect themselves from aggressive males, and large flocks of chaffinches will group together to mob intruders. Animals will also take turns feeding and scanning for predators. For example, related and unrelated meerkats take turns as sentinels, some individuals scanning for predators while others eat. Western evening grosbeaks and numerous other species of birds show similar patterns of trading off feeding and scanning. Other common behavior patterns such as alliance formation, communal nursing and care of young, and grooming others are also examples of cooperation. For example, male dolphins form social groups called “super alliances” to gain access to females, and female rats often nest and nurse young communally, even sharing milk. Primates maintain enduring social bonds by grooming one another in complex social

networks, as do ungulates. Sure, there are cheaters, liars, and free riders in all of these cooperative systems, but the rule breakers are the outliers, the exceptions to the norm. Cooperative behaviors are everywhere and act as the superglue of animal societies.

Cooperation, in its turn, allows specialization and thus promotes biological diversity. Cooperation is one of the three basic principles of evolution, alongside mutation and selection. Cooperation is the secret behind the open-endedness of the evolutionary process. Perhaps the most remarkable aspect of evolution is its ability to generate cooperation in a competitive world.

The social lives of numerous animals are strongly shaped by affiliative and cooperative behavior. Consider wolves. For a long time researchers thought that pack size was regulated by available food resources. Wolves typically feed on prey such as elk and moose, both of which are bigger than an individual wolf. Successfully hunting such large ungulates usually takes more than one wolf, so it makes sense to postulate that wolf packs evolved because of the size of wolves' prey. However, long-term research shows that pack size in wolves is regulated by social and not food-related factors. The number of wolves who can live together in a coordinated pack is governed by the number of wolves with whom individuals can closely bond (the "social attraction factor") balanced against the number of individuals from whom an individual can tolerate competition (the "social competition factor"). Packs and their codes of conduct break down when there are too many wolves.

The lives of animals are shaped at a most basic level by good—or what biologists call prosocial—interactions and relationships. Even more, it seems that at least some prosocial behavior is not a mere byproduct of conflict, but may be an evolutionary force in its own right. Within biology, early theories of kin selection and reciprocal altruism have now blossomed into a much wider inquiry into the many faces and meanings of prosocial behavior. And, it seems, the more we look, the more we see. There's now an enormous body of research on prosocial behavior, and new research is being published all the time on cooperation, altruism, empathy, reciprocity, succorance, fairness, forgiveness, trust, and kindness in animals ranging from rats to apes.

Even more striking, within this huge repertoire of prosocial behaviors, particular patterns of behavior seem to constitute a kind of animal morality. Mammals living in tight social groups appear to live according to codes of conduct, including both prohibitions against certain kinds of behavior and expectations for other kinds of behavior. They live by a set of rules that fosters a relatively harmonious and peaceful coexistence. They're naturally cooperative, will offer aid to their fellows, sometimes in return

for like aid, sometimes with no expectation of immediate reward. They build relationships of trust. What's more, they appear to feel for other members of their communities, especially relatives, but also neighbors and sometimes even strangers—often showing signs of what looks very much like compassion and empathy.

One of the classic studies on altruism is on bats. Vampire bats who are successful in foraging for blood that they drink from livestock will share their meal with bats who aren't successful. And they're more likely to share blood with those bats who previously shared blood with them. In a recent piece of surprising research, rats appear to exhibit generalized reciprocity; they help an unknown rat obtain food if they themselves have been helped by a stranger. Generalized reciprocity has long been thought to be uniquely human.

The meaning of altruism in biology is not quite so straightforward, nor is much of the other language used to talk about cooperation among animals. Certain terms in our cooperation cluster, like altruism and spite, have particular meaning in biological parlance that diverges from the normal use of the words in everyday conversation. Altruism, in our daily language, refers to an unselfish concern for the welfare of others, with emphasis on unselfish. If your motive for helping an elderly person cross the street is that you want to be nominated for citizen of the month, you haven't really acted altruistically. In biology, altruism lacks this moral coloring; there's no accounting for intention or motive. When biologists talk about altruism in nature, they use the language of costs and benefits, which are cashed out as reproductive-fitness consequences. Altruism refers to a behavior that is costly for the actor (it decreases reproductive fitness) and beneficial for the recipient (it increases reproductive fitness). In biology, 'altruistic' does not equal 'moral.'

Morality and prosociality represent distinct categories, though with considerable overlap. In evolutionary terms, prosocial behavior is at the root of morality, and is much more broadly distributed than morality. Many prosocial behaviors would fall outside the narrower 'moral' category. For example, parental care and communal nursing are not, in themselves, moral behaviors. Neither is altruism, as understood in the scientific literature, behavior in which the actor provides another individual with a benefit, but in doing so incurs some cost, where cost and benefit are understood in terms of future reproductive success. The self-sacrificial behavior of ants, bees, and wasps does not constitute morality, nor does sentinel behavior, where animals take turns watching for predators.

Thus many species in which prosocial behavior is displayed do not have moral behavior. Ants and bees behave prosocially, but not morally. Why

would we say that wolves have morality, while ants don't, even though both species engage in cooperative and altruistic behavior? We propose certain threshold requirements for given species to have morality: a level of complexity in social organization, including established norms of behavior to which attach strong emotional and cognitive cues about right and wrong; a certain level of neural complexity that serves as a foundation for moral emotions and for decision-making based on perceptions about the past and the future; relatively advanced cognitive capacities (a good memory, for example); and a high level of behavioral flexibility.

In our moral animals, we expect to see that altruism and cooperation are the bedrock of their sociality. We also expect to find a high level of emotional and cognitive complexity and flexibility. The more complexity and behavioral plasticity involved in a cooperative or altruistic behavior, the more "advanced" it is; the more likely it is morality.

Social animals live according to well-developed systems of prohibitions against certain kinds of behavior and proscriptions for certain kinds of behavior. These prohibitive and proscriptive norms govern the behavior of individuals within a group and relate to harm, welfare, and fairness. These behaviors, in philosophical lingo, are other-regarding, as opposed to self-regarding. A self-regarding action affects no one other than the agent (the individual) performing the action. An action or behavior becomes other-regarding when it produces some benefit to another, causes some harm, or violates some social rule or obligation—basically, when it affects the welfare of another individual or the social group. There might be prohibitions against certain kinds of harm, both physical (biting, killing, violent aggression) and psychological (bullying, taunting, intimidating), under certain circumstances.

There may also be expectations about helping, reciprocating, and sharing. Within an animal society, for example, there might be certain norms of reciprocity: help those who have helped you (you owe them) and help those who need help (regardless of payoff). And there might be norms about fairness: those with highest status eat first and best, and those who invite play should follow the rules of play. Norms might govern and maintain dominance hierarchies, regulate the acquisition and distribution of food, regulate grooming behaviors, regulate sentinel behaviors, or govern play behavior. A norm is simply an expected standard of behavior within a group and is enforced by the group. Harm and benefit are the basic units of moral currency.

Like morality, manners regulate social behavior. Researchers in the field of human moral psychology have given a great deal of attention to the distinction between moral violations and conventional violations. Conventional

violations, it is said, are wrong by standards of social acceptability. Moral transgressions are more serious, and their wrongness relates to harming others. Eating salad with the shorter fork has little to do with fairness, reciprocity, or the welfare of others.

In philosophical discussions, human morality is often compared not only to etiquette but also to law and religion. Law usually has considerable overlap with morality, but is governed by explicit rules and punishments, whereas morality is an informal system of behavioral control. Religion, of course, invokes supernatural explanations for why certain behaviors are prohibited or required. It seems likely that morality (with manners as a subset) is really the only category that applies to nonhuman animals.

Just as we don't want to understand any and all behavior that benefits another as moral (we don't want to say that helper ants are moral), we wouldn't want to define any and all behavior that harms another as immoral. It's ridiculous to suggest that the lion hunting down and killing the deer is immoral, however ruthless his behavior seems. Nor is an egret pecking its sibling to death an instance of bad upbringing. Nor, to offer one final example, is "dishonest signaling," such as when a male frog lies about his prowess by maintaining a close proximity to the loudest croaker, thus hoping that a female will make a mistake and believe him to be the source of that alluring music. Behavior becomes immoral when it goes against socially established expectations. During predation, there's no prior agreement by the wolf not to eat the elk; there are no social expectations, since wolves and elk don't live in the same society. So, there's no violation of a social norm. On the other hand, if two wolf pups are playing and one tries to dominate the other, a norm has been violated.

Empathy rests upon the capacity to understand others, in particular their suffering, and this capacity makes cruelty possible. Empathy and cruelty both rely on the ability to imagine how one's own behavior affects others. We know how to cause pain and distress. The same logic applies to other behaviors. Trust and honesty form the glue in cooperative social groups. Yet a reliance on trust is what makes deception and dishonesty possible. In cooperative groups, deception is always a successful strategy, but it is less successful, on the whole, than cooperation.

Some have argued that cruelty is an exclusively hominid behavior. Cruelty is the deliberate infliction of physical or psychological pain on a living creature; its most repugnant and puzzling feature is the frequently evident delight of the perpetrators. Cruelty is a behavioral byproduct of predation. Cruelty was adaptive to our ancestors because it led to successful predation, and it was (and still is) reinforced through affectively positive neurobiological mechanisms—in other words, cruelty feels good. Seemingly cruel behaviors

such as cat-and-mouse play, or orcas “playing” with baby seals before eating them, are most parsimoniously interpreted as extreme forms of aggression. Animals, in this view, are not imagining, much less enjoying, their victim’s suffering. Cruelty requires certain cognitive capacities, such as the intention to inflict pain (which, in turn, presupposes a theory of mind), and many do not believe that animals can reflectively imagine the suffering of another.

If animals share with humans the capacity for empathy, they have in place the cornerstone of what in human society we know as morality. For among humans, the capacity to understand what another feels allows us to be compassionate, to avoid causing pain or suffering, and to act with an intention to improve the welfare of those around us. We define sympathy as a “feeling for,” and empathy as a “feeling with.” When you feel sympathy for another person, you don’t necessarily share their emotion; when you empathize, you do.

Empathy isn’t a single behavior, but a whole class of behavior patterns that exists across species and shows up with varying degrees of complexity. It occurs in nested levels, with the inner core a necessary foundation for the other layers. The inner core consists of relatively simple forms of empathy such as body mimicry and emotional contagion, which are largely automatic physiological responses. The next layer consists of somewhat more complex behaviors such as emotional empathy and targeted helping. More complex still is cognitive empathy, or the ability to feel another individual’s emotion and understand the reasons for it. Finally, and most complex, is the capacity for attribution, in which an individual can fully adopt the other’s perspective, using the imagination.

Evolution of course doesn’t toss out one adaptation and replace it with another. Rather, during the course of evolution, modifications are made to existing structures and capacities and these changes tend to reflect the social and environmental conditions to which individuals are exposed. More complex forms of empathy such as cognitive empathy evolved from emotional contagion, which, in turn, probably evolved from emotional linkage of individuals, especially emotional linkage between mother and infant. All empathy behaviors, from simple to complex, likely share many proximate mechanisms.

The notion of empathy as nested levels mirrors a more general aspect of mammalian evolution. The mammalian brain is actually three brains in one, each successive stratum having been formed on top of the layer beneath it. Each layer of the brain has its own function, though all three are interconnected and interacting. The primitive brain—the reptilian brain—is charged with the task of physical survival, controlling breathing and heartbeat and generating the fight-or-flight response. The limbic system—

paleomammalian brain—controls emotion. And the neocortex, the outer and most recent part of the brain, allows for higher cognitive functions such as language and abstract thought. The three layers function independently, but are also interconnected and interdependent in complex ways that are only partially understood. So, while emotional contagion may be in some respects simpler and more primitive, and may arise from older parts of the brain, it is most likely inextricably connected with more complex, more cognitive forms of empathy. Cognitively advanced forms of empathy are probably influenced in some measure by the more primitive and automatic impulses.

Some scientists deny that animals have empathy. But they usually come to this conclusion because they have narrowly cast empathy to mean the ability to take the perspective of another. The capacity for imaginative attribution may, indeed, be found only in humans—though of course, how the fuck would you prove it's existence? However this is but one small piece of a much larger group of behaviors, many of which are certainly present in a broad range of mammals. It is premature to pronounce animals lacking in cognitively complex forms of empathy because we still know too little about empathy in animals to make such a claim. Cognitive empathy may be found, for example, in the hominoid primates and perhaps elephants, social carnivores, and cetaceans.

Animals living in social groups can benefit from being sensitive to the emotional states of other group members. Emotional contagion might, for example, facilitate defensive action in light of threat. If one prairie dog gives an alarm call, all members of the group will respond immediately with evasive action. The same holds true for birds: if you startle one bird away from the feeder, most if not all of the birds will disperse. And not only will all the sparrows fly off, but likely so will the robins, grackles, and finches, suggesting that emotional contagion may function between species. This behavior spreads out the costs of vigilance, allowing individuals more time to forage, mate, or care for young.

Yet empathy can be costly in various ways. These ways have not yet been explored in much depth but relate to what we might term the cost of an expanded self. A self that is linked to others also shares in the emotional experiences of others. When we see someone in distress, we too feel distress and perhaps anxiety. When we see someone experiencing fear, we too feel fear. And distress, anxiety, and fear are not free; they demand cognitive and metabolic attention, and can divert attention and energy from important tasks. Fear, panic, and distress cause the brain to release cortisol, the stress hormone. The release of cortisol in the body sets off a cascade of physiological effects: blood pressure goes up, digestion stops, pulse quickens.

Too much cortisol in the body can lead to impaired cognitive function, lowered immunity, and other costly changes. This is why misplaced empathy or too much empathy might be maladaptive. Too much of a good thing can be bad.

Empathy may be costly not only for the empathizer, but also for the individual who is the object of empathic response. Humans and animals alike may benefit from being able to hide emotions such as our excitement at finding a huge cache of great food or our fear during a struggle for dominance. The better those around us are at reading our facial expressions, tone of voice, body language, and olfactory messages, the less successful we will be at masking our intentions and feelings. The capacity for empathy creates in a society of animals a level of transparency that makes honest communication the norm and may explain why deception is considered more cognitively demanding than honesty.

What shapes behavior—what allows empathy to flourish in a person and also in other animals—is social environment and early development, particularly maternal nurturing. Nature may plant the seeds of empathy—the neural circuitry that can develop from emotional linkage and attachment into empathy—but if the seeds are not nourished, development can go wrong. There is a connection between early experiences—especially maternal nurturing—and the development of empathy. The bonding process between mother and infant facilitates the development of neurophysiological structures that underlie normal social behaviors such as empathy. We know that in humans a disruption of this bonding process can result in reduced capacity for empathy and an increased propensity toward violence. Early trauma has permanent effects on the brain, and thus on behavior. Trauma such as separation of the infant from its mother, or abuse or neglect by the mother, can lead to a permanent impairment in empathic social interaction.

Social disruption in animal societies, in this case elephants, has interfered with the normal development of young elephants, particularly by depriving them of appropriate maternal care and teaching. This early trauma can lead to empathic impairment in elephants, just as it can in humans. Elephants live in very tightly bonded matriarchal societies, with layers of extended family who participate in caring for and rearing young. In the early 1990s, there were an estimated ten-million wild elephants. These populations have been decimated by poaching, culls, and habitat loss, and only about a half a million elephants now survive in the wild. The complex social structures of elephant society are collapsing under the weight of loss and fragmentation. Infants have been orphaned, often after witnessing their parents being brutally killed. Some of the remaining elephants, particularly young males, are displaying symptoms very much like human post traumatic

stress disorder (PTSD): depression, abnormal startle response, unpredictable social behavior, and violent aggression.

The concept of ‘selfishness’ in biology, popularized by Richard Dawkin’s influential book *The Selfish Gene*, is amoral; it refers simply to the inclination or “drive” of each gene to promote its own reproductive success. Genes, as far as we know, do not have intentions. The evolution of morality, including unselfish behavior, is perfectly consistent with theories of “selfish genes.” We just need to remember that explanations about why a behavior evolved and what makes an animal exhibit that behavior right now are distinct. Unfortunately, it is almost impossible to wipe away the moral connotations etched into the word; even scientists seem to forget sometimes. Let’s be clear then. Selfish genes and moral animals—and not just apparently moral, but really, truly moral—are entirely comfortable together, as evolutionary phenomena.

We need to be careful not to make ‘moral’ (or ‘altruistic’ or ‘prosocial’) the opposite of ‘selfish.’ It isn’t. Many moral behaviors are motivated by self-concern, broadly understood. We conform to norms of behavior because otherwise we face social sanctioning, in the form of ostracism, embarrassment, shame, and payback.

There are many studies showing that kin selection is a strong force in the evolution of cooperation and altruism. One of the most famous examples of kin-selected altruism is the study of alarm-call behavior in Belding’s ground squirrels. Alarm calling carries a cost because it increases the likelihood of an individual being spotted by a predator. It turns out that males, who don’t nest near genetic relatives, sound the alarm less often than females, who do live in proximity to genetic relatives.

A great deal of the ‘why’ of social interaction falls under the radar, as it were. We don’t plan to cooperate or do an explicit calculation of its benefits; we just do it. Nor are we aware of the continual assessment of facial expressions and tones of voice that we unconsciously use to maintain a cooperative mood. The same is true for animals.

Science suggests that being a cooperative breeder isn’t just doing good—it also feels good. Rhesus monkeys eloquently make the case that maternal care and communal care feel good for those who do it. Every spring, when the rhesus monkeys have babies, juvenile females go nuts trying to lend a hand—and get their hands on them. They stay close by, attentively and tirelessly grooming the mothers of the beguiling infants until mom agrees that the sitter can have a moment with her baby. These sitters snatch the babies with all-consuming zeal turning them upside down to inspect the genitals, licking their faces, grooming them from all sides, and eventually dozing off with the babies firmly clutched in their arms. This nodding

off with the baby happens like clockwork and without exception, giving the impression that the babysitters are in a trance, or perhaps ecstatic. Clutching the babies close releases oxytocin in the sitters' brains and blood, lulling them into a delicious sleep. They invariably rouse after a few minutes in order to return the babies to their mothers.

Such observations of our nonhuman primate relatives have led anthropologists to conclude that we have emotional biases toward cooperation that can only be overcome with effortful cognitive control. In other words, caring is our first impulse; only our minds stand in the way of doing so every time.

“The social instincts lead an animal to take pleasure in the society of its fellows, to feel a certain amount of sympathy with them, and to perform various services for them.”

Oxytocin facilitates prosocial behavior by lowering the natural resistance that animals have toward being in proximity to others. Although oxytocin may have evolved to promote the mother-infant bond, it seems to function more broadly now in cultivating cooperative behavior by fostering social closeness and trust. We cannot consider cooperation in isolation from other prosocial behaviors.

Grooming, then, is not only a form of trading favors, but also a kind of cooperation aphrodisiac: it puts animals in a cooperative and affiliative mood, and may thus foster sociality. Perhaps an early step in the evolution of sociality lies in the shared pursuit of parasites rather than the more dramatic examples of cooperative hunting, or shared parental care of offspring. Sometimes the benefits being traded are of different kinds, other than grooming itself. In the De Hoop Nature Reserve, adult female chacma baboons without infants would trade grooming for the privilege of holding another female's infant. Similarly, spider monkeys exchanged affiliative behavior, particularly hugging, for the privilege of handling an infant.

There's little research that directly speaks to the emotional mechanisms on which cooperation and altruism rest. But we do know that in animals, emotions shape behavior in ways that enhance fitness. We also have a large body of research on the role of emotions in cooperation among humans. Given continuities in the architecture of human and animal psychology, comparative work may offer insights for further investigation of animal behavior. Perhaps the most basic emotion that motivates cooperative behavior is affiliation—a sense of liking and a feeling of social closeness. Affiliation arises not only out of familial relationships, but also out of long-term pair-bonding (love) and friendship. Animals who live in close proximity

may do more than simply tolerate the presence of others, they may actually enjoy social contact.

The reverse is also true. Ample research attests to the fact that social animals who are isolated, either in zoos or research settings, become depressed and stressed. We also know that endogenous opioid peptides (EOPs) foster affiliative and cooperative behaviors. Low levels of EOPs lead animals to seek social contact, and positive contact in turn leads to the release of EOPs. EOPs may be responsible for a kind of social addiction: when animals are isolated, EOP levels are low, and animals crave social contact. When animals engage socially, they get a hit of EOPs, which creates a feeling of euphoria.

There are four overlapping areas with which ethological investigations should be concerned, whether a researcher is interested in how herring gulls avoid being eaten by red foxes, how wasps find their homes after hunting excursions, how geese court one another, how dogs play, or how elephants comfort one another. Researchers should be interested in:

1. The evolution of a behavior.
2. Adaptation, or how the performance of a specific action allows an individual to fit into his or her environment and ultimately allows him or her to breed.
3. Causation, or what causes a particular behavior to occur.
4. Development or ontogeny, how a behavior arises and unfolds over the course of an individual's life, giving rise to individual differences.

For example, if we're interested in how and why dogs play, we want to answer the following four questions:

1. Why has play evolved in dogs, and why has it evolved in some animals, like dogs, but not in others?
2. How does play allow a dog to adapt to his or her environment, and how does it influence his or her reproductive fitness?
3. What causes dogs to play? For example, what stimuli elicit play behavior (e.g. the play bow)?
4. How does play behavior develop in young dogs and how does the behavior change as individuals grow older?

Ethologists often also talk about giving ultimate and proximate explanations for a particular behavior. An ethologist might be interested in an ultimate explanation for a behavior, seeking to understand why, for example, play has evolved and how it contributed to the reproductive fitness of an individual wolf. The first two research questions seek ultimate explanations. An ethologist might also, or instead, look for what are called the proximate explanations: What immediate goal is an individual pursuing and what internal mechanisms are guiding its behavior? What are the cognitive and affective underpinnings of the behavior? What is the trigger stimulus? For example, a proximate trigger might be a play invitation signal given by one wolf to another. The third and fourth questions relate to proximate explanations for behavior in that they look for what's going on now, in the immediate social context, not in the evolutionary past.

Research has shown that play behavior in rat pups causes the release of opioids into the brain, producing feelings of social comfort and pleasure. Rats also experience joy and even laugh when tickled.

Research has shown the presence of spindle cells in humpback whales, fin whales, killer whales, and sperm whales in the same area of their brains as spindle cells in human brains. Spindle cells in whales are found in the anterior cingulate cortex and frontoinsula cortex, two areas of the brain that are important in reactions that require rapid emotional judgments, such as deciding whether another animal is in pain and the feeling of whether an experience is pleasant or unpleasant. Whales, it turns out, have three times more spindle cells than humans. To sum up the significance of spindle cells in whales, this is consistent with a growing body of evidence for parallels between cetaceans and primates in cognitive abilities, behaviour, and social ecology.

While the data generated by social neuroscience are extremely valuable for learning more about animal minds, these studies are especially troubling because of the pain and suffering that individual experimental animals endure. The more we understand about animal cognition and emotions, the more ethically problematic this sort of research becomes.

Assholes in 1964 showed that a hungry rhesus monkey would not take food if doing so subjected another monkey to an electric shock. The monkeys refused to pull a chain that delivered them food if doing so gave a painful shock to a companion. One monkey refused to pull the food chain for a full twelve days, starving itself seemingly to avoid causing pain to another.

Also recall that, working with infant rhesus monkeys who had been taken from their mothers, Hall-of-Fame-level asshole Harlow showed that the desire for affection was stronger than the desire for food. Given a choice between a cold wire monkey with food and a soft cloth monkey without

food, the infants clung to the soft, foodless monkey. From other sadistic experiments he concluded that baby monkeys raised without social contact with peers and without real mothers grow up to be socially incompetent. The development of social and moral intelligence is stunted when the appropriate developmental cues are not triggered. These horrors led to later studies on attachment and on the important connection between the early nurturing of infants and children and the development of empathy.

Other assholes set up an experimental test in which rats were trained to press a lever in order to get a food reward. They then set up, in a neighboring cage, a torture chamber of sorts: the bottom of the cage was an electric grid on which the rats' delicate pink paws were placed. When a rat in the first cage pressed the food lever, a surge of electricity would run through the grid in the adjoining cage, giving the neighboring rat an electric shock. The assholes found that rats would not push the food lever if they could see that a fellow rat would receive a shock. Although the torturers refused to explain the reaction as empathy, this seems in retrospect to be the most parsimonious explanation.

Another early study in 1962 by some less sadistic shitbags showed that rats would help other rats in distress. One rat was suspended in air by a harness and a neighboring rat could press a level to lower the suspended rat. The suspended animal would typically squeak and wriggle in distress. The rats were apparently made uncomfortable by signs of distress in a fellow rat, and would act to alleviate the distress by pressing the lever. Empathy likely motivated the altruistic response.

The phenomenon is known as “witnessing effects.” Psychopaths in lab coats have conducted numerous studies indicating that mice and rats show a marked stress response to being in the same room as another rat subjected to decapitation. Rats show increased heart rate and blood pressure (both stress responses) when watching other rats being decapitated, and when a paper towel with dried blood from a decapitated rat is placed atop their cage. Witnessing effects have also been documented in mice, monkeys, and of course humans. Witnessing effects clearly arise out of the capacity for empathy, and add additional support to the data on empathy in rats and mice.

Studies of empathy in animals often are horribly cruel, and it is deeply ironic that we inflict pain on other animals to test them for empathy when good evolutionary biology—evolutionary continuity—tells us that they have it. It is also ironic that the animals most frequently used in research—mice and rats—presumably because they have less going on “up there” or “in there” than primates, turn out to have quite a bit more going on inside than researchers have assumed. Although noninvasive ethological fieldwork

can certainly provide data on animal empathy, it is likely that invasive laboratory research will continue. The findings on rat and mouse empathy will suggest ways in which we can make these studies—not just empathy research, but all research in which rats and mice suffer, particularly when they suffer in the presence of others—more humane and less stressful. After all, general stress levels experienced by laboratory animals compromise the reliability of the data.

Many things about an animal come to light only once we see them for what they are—subjects of their own lives. Jane Goodall broke scientific convention by naming her Gombe chimpanzees Flo and Fifi and David Greybeard, rather than simply referring to them as numbers. And her long-term research on chimpanzees has clearly contributed a great deal to our understanding of these animals and has led to an incredible amount of new research.

Consider, too, the reflections of George Schaller, one of the world's preeminent field biologists:

“Without emotion you have a dead study. How can you possibly sit for months and look at something you don't particularly like, that you see simply as an object? You're dealing with individual beings who have their own feelings, desires, and fears. To understand them is very difficult and you cannot do it unless you try to have some emotional contact and intuition. Some scientists will say they are wholly objective, but I think that's impossible.”

Schaller was asked what it was like to stare into the eyes of a gorilla:

“I felt a very definite kinship. You're looking at another being that is built like you, that you know is a close relative. You can see and interpret the expression on their faces. In other words, you have empathy with what they're doing. To try to know what an animal is thinking is impossible at this stage in our knowledge of species, but you can interpret their responses on the basis of your own. Besides, they're beautiful, they're individuals. You can recognize all of them by their faces.”

An animal isolated in a lab cage is made into an object for our study. In their natural setting, they're subjects of their own lives, living with their own families and within their own societies. We have the privilege to watch and take notes. In addition to identifying with the animals we study, we also need to spend a good deal of time with them.

Jane Goodall started out with about six months' worth of funding to study chimpanzees at the Gombe Stream Game Reserve but her preliminary findings were so significant that Louis Leakey, who had hired her in the first place, was able to secure funding for more time in the field. Fifty years later, data are still being collected on chimpanzees at Gombe, making this the longest continuous research on animals in a specific location. Since the lifespan of chimpanzees is between about forty and fifty years, Goodall has been there just long enough to witness a full generational cycle. She's been able to observe the entire reproductive and social life of the matriarch Flo, has watched Figan and Freud come into this world, become alpha males, and pass on into old age. She's gotten to know each chimpanzee, and can describe each one's personality and behavioral quirks as if they were close personal friends. It takes this kind of long-term immersion research to collect the data needed to really understand how animals live together as societies, and be able to recognize individual variation in behavior. Unfortunately, long-term behavioral studies of the sort Goodall and Schaller have championed are decreasing, and are being replaced by short-term studies.

Although stories are appealing to many people, some researchers view tales of this sort as nothing more than "just so" stories. It's true that anecdotes provide a kind of data that is qualitatively different from the hard numbers of empirical studies, and they cannot substitute for rigorous scientific research. But the use of stories, or "narrative ethology," is an important part of the science of animal behavior. A narrative is a story, or construction of observed reality, which through its telling gives an event meaning. Narrative is an act of interpretation. Seasoned ethologists often find that numbers and graphs don't do justice to the nuances and beauty of animal behavior. Instead, they often find themselves telling stories from the field to make a point or raise a question. Stories can stimulate thought, activate the imagination of scientists, lead to new questions, represent anomalies, and challenge conventions of thought.

Sometimes stories are about surprising, isolated events that challenge the scientific establishment's standing assumptions. The story of Nasty Nick, for example, raises the question of whether animals can be cruel or mean. And sometimes a single event will elicit competing narratives. Ethologists will disagree over what the events mean, as in the case of Binti Jua. Narrative ethology, which is practiced by ethologists and other researchers, is not the same as "animal stories" that proliferate on the Web or are told by folks standing around at the dog park. Narrative from seasoned ethologists provides interpretation informed by their knowledge about a particular species and its behavior, and their attention to context and individual peculiarities.

If animals really do have morality, how would this change our understanding of ethics within our own species? If morality comes “from nature,” as it were, does this make morality somehow less real or less binding? What about those who argue that morality is grounded in religious belief? Do animals have religion, too? And aren’t there important differences between our own systems of morality and those found in animal societies?

In suggesting that there’s continuity even in moral behavior, wild justice seems to jeopardize the special status of humans as separate from and above the rest of nature. This, in turn, seems to threaten an ideal of human dignity and right. Wild justice also raises questions about the mixing of biology and ethics, the mixing of facts and values, and what this means about how and even if evolutionary theory is applied to patterns of human social behavior. Should morality be wrested from the hands of the humanities and reside solely in the province of biology? In drawing a picture of animals as beings with rich cognitive, emotional, and social lives, wild justice invites a serious reconsideration of the uses to which we put animals in research, education, and for clothes and food, among other things.

Many people are uncomfortable with the idea of ascribing morality to animals because it seems to threaten the uniqueness of humans. This concern may take any number of forms. For example, many Christian theologians see a sharp line between humans (who are created in the image of God) and the rest of creation (who are not), and it is a matter of theological importance to respect this doctrinal distinction. Many philosophers believe that human uniqueness provides the fundamental grounding of human dignity, and thus serves to protect classes of humans (such as fetuses and the severely mentally handicapped) who might otherwise be treated as less than human, in other words, like animals. Some might also consider it important to maintain a sense of human uniqueness, or animal difference, because it serves as ethical justification for the use of animals in scientific research.

First, the idea that ascribing morality to animals could lead to loss of respect for vulnerable or “marginal” people is just bizarre—it follows no clear logical path. Second, human uniqueness, such as it is, cannot logically serve as ethical justification for the instrumental use of animals. There is, again, no clear logical path in this direction. Of course, human uniqueness has been used in this way. But this doesn’t make it logical. Human dignity does not carry as its correlate the indignity of animals.

Uniqueness is something to be celebrated, and can be a tool for gaining a deeper understanding of and empathy toward others. Each species has its own unique features that make it beautifully adapted and fascinating to study. And just as each individual human is unique, with unique physical features, personality, and life experiences, so is each individual animal. As

any dog or cat owner knows, there is a great deal of individuality from one animal to the next. There is significant behavioral and dispositional variation among individuals within a species—what we might call personality. All brown-eared bats may look alike to us, but to them, each individual is unique. We need to keep this individual variation in mind during ethological research on animals and when thinking about animal welfare—about what, for example, animals need to be happy and healthy.

Animals, at least according to most Western philosophical accounts, cannot be moral agents because they are guided solely by instinct. However, it's not true that animals act solely on instinct, so we need some concept of moral agency in animals. Nor is it true that humans act “autonomously” as this has been generally understood, so ideas of human agency also need to evolve as well.

Where there's flexibility and plasticity in behavior, there's choice, there's agency. However, even behavior that is conditioned or instinctual can count as moral. Indeed, research suggests that a good deal of human morality is conditioned and instinctive. It wouldn't make sense to say that humans are only moral agents in those rare circumstances in which they act on a moral abstraction. And we should remember that parents and teachers go to great lengths to condition children to behave in morally appropriate ways.

Charles Darwin proposed that any animal whatever, endowed with “wellmarked social instincts,” could develop of sense of conscience:

“Besides love and sympathy, animals exhibit other qualities connected with the social instincts, which in us would be called moral; and I agree with Agassiz that dogs possess something very much like a conscience.”

Darwin believed that animals possess the “power of self-command” in that they are capable choosing one course of action over another. He also pointed out that on occasion there would be an internal struggle over competing impulses. Darwin described conscience as an “inward monitor” that tells an animal that it would be better to follow one impulse rather than another. Many dogs will, for example, refrain from stealing food off the counter, even when their master is not present.

“The one course ought to have been followed, and the other ought not; the one would have been right and the other wrong.”

A scientific description cannot, according to the rules of formal logic, generate a moral imperative. We could easily say, ‘animals have morality,’ and go on treating them just the way we do. Impersonal logic, however,

can lead, and has led, to the most egregious treatment of animals in a wide variety of venues. It is worth noting that modern scientific research on animals, as well as the industrial farming of animals, has traditionally been justified by a scientific description of what animals are like. It's long been asserted as scientific fact that animals don't have complex thoughts or rich emotional lives. It is therefore, the old logic goes, morally acceptable to use animals however we please. As it turns out, the scientific description of the cognitive and emotional capacities of animals has undergone a major sea change in the last decade, and the old logic no longer works. In fact, the new logic imposes strong constraints on how we interact with other animals.

A scientifically accurate description has the power to alter our perception of reality and can thus alter our moral responses. The more cognitively sophisticated our perception of reality, the more deeply and accurately empathic we become. Interestingly, research has suggested that empathic understanding also leads to enhanced critical and moral reasoning. More careful and scientifically accurate description of the lives of animals may lead to increased sensitivity to their needs. If we understand animals to have rich emotional and social lives—to deeply feel many of the same emotions that we do, and to be as connected emotionally with family and friends as we are—it may increase our capacity to empathize with them and feel more truth for the suffering they experience.

A great deal of work remains to be done to reach a mature understanding of the moral lives of animals, and that's what makes questions about animal morality so exciting. Indeed, this is a project that will likely never reach completion because, as with most research, answers beget more questions. But for now there can be no doubt that many animals are moral beings. We're not alone in the moral arena. It's just too stingy and incorrect to take this narrow point of view.

Dangerous Supremacists

The Image of the Devil

From the animals that become dog and cat food and the puppy farms churning out increasingly unhealthy purebred canines, to the goldfish sold by the bag and the crickets by the box, pet ownership is problematic because it denies animals the right of self-determination. Ultimately, we bring them into our lives because we want them, then we dictate what they eat, where they live, how they behave, how they look, even whether they get to keep their sex organs.

Treating animals as commodities isn't new or shocking; humans have been meat-eaters and animal-skin-wearers for millennia. However, this is at odds with how we say we feel about our pets. The British pet industry is worth about £10.6bn; Americans spent more than \$66bn on their pets in 2016. A survey found that many British pet owners love their pet more than they love their partner (12%), their children (9%) or their best friend (24%). According to another study, 90% of pet-owning Britons think of their pet as a member of their family, with 16% listing their animals in the 2011 census.

It is morally problematic, because more people are thinking of pets as people. They consider them part of their family, they think of them as their best friend, they wouldn't sell them for a million dollars. At the same time, research is revealing that the emotional lives of animals, even relatively "simple" animals such as goldfish, are far more complex and rich than we once thought. The logical consequence is that the more we attribute them with these characteristics, the less right we have to control every single aspect of their lives.

Does this mean that, in 50 years or 100 years, we won't have pets? Institutions that exploit animals, such as the circus, are shutting down—animal rights activists claimed a significant victory recently with the closure of the Ringling Bros circus—and there are calls to end, or at least rethink, zoos. Meanwhile, the number of Britons who profess to be vegan is on the rise, skyrocketing 350% between 2006 and 2016.

Widespread petkeeping is a relatively recent phenomenon. Until the nineteenth century, most animals owned by households were working animals that lived alongside humans and were regarded unsentimentally. In 1698, for example, a Dorset farmer recorded in his diary:

“My old dog Quon was killed and baked for his grease, which yielded 11lb.”

However, in the nineteenth and twentieth centuries, animals began to feature less in our increasingly urban environments and, as disposable income grew, pets became more desirable. Even as people began to dote on their pets, though, animal life was not attributed any intrinsic value. In 1877, the city of New York rounded up 762 stray dogs and drowned them in the East River, shoving them into iron crates and lifting the crates by crane into the water. More recently, however, several countries have moved to change the legal status of animals. In 2015, the governments of Canada and New Zealand recognized animals as sentient beings, effectively declaring them no longer property (how this squares with New Zealand’s recent “war on possums” is unclear). While pets remain property in the UK, the Animal Welfare Act of 2006 stipulates that pet owners must provide a basic level of care for their animals. Pets are also property in the US, but 32 states, as well as Puerto Rico and Washington DC, now include provisions for pets under domestic violence protection orders. In 2001, Rhode Island changed its legislation to describe pet owners as “guardians,” a move that some animal rights’ advocates lauded, and others criticized for being nothing more than a change in name.

Before we congratulate ourselves on how far we have come, consider that 1.5m shelter animals—including 670,000 dogs and 860,000 cats—are euthanized each year in the US. The number of stray dogs euthanized annually in the UK is far lower—3,463—but the RSCPA says investigations into animal cruelty cases increased 5% year on year in 2016, to 400 calls a day.

Can I stick my dog in a car and take him to the vet and say: ‘I don’t want him any more, kill him,’ or take him to a city shelter and say: ‘I can’t keep him any more, I hope you can find a home for him, good luck’? If you can still do that, if you still have the right to do that, then they are still property. Crucially, our animals can’t tell us whether they are happy being pets. There is an illusion now that pets have more voice than in the past but it is maybe more that we are putting words into their mouth. Maybe we are humanizing them in a way that actually makes them invisible.

If you accept the argument that pet ownership is morally questionable, how do you put the brakes on such a vast industry?

“After he had become a vegan, eschewed leather shoes and convinced his girlfriend to go vegan, he considered his pet cockatiel. I remember; he looked up wistfully. He said he got the bird, took it outside, let it loose and it flew up. He said: ‘I knew she wouldn’t survive, that she probably starved. I guess I was doing it more for myself than for her.’”

For now, the argument over whether we should own animals is largely theoretical: we do have pets and giving them up might cause more harm than good. Moreover, caring for pets seems to many people to be the one area where we can actually do right by animals; convincing people of the opposite is a hard sell.

If the short history of pet ownership tells us anything, it is that our attitude towards animals is prone to change. You see these rises and falls in our relationships with pets. In the long haul, I think pet-keeping might fall out of fashion; I think it is possible that robots will take their place, or maybe pet owning will be for small numbers of people. Cultural trends come and go. The more we think of pets as people, the less ethical it may be to keep them.

“The greatness of a nation and its moral progress can be judged by the way its animals are treated.”

“Just because some of us can read and write and do a little math, that doesn’t mean we deserve to conquer the Universe.”

“If I were from an older, greatly superior culture from some other place in the vast universe, I would recommend that this planet be shunned. The human species is so arrogant that it doesn’t recognize its own superiors. The only way that humans in the mass will respect any other species, apparently, is the ability to beat them in warfare.

The whole philosophy that says that the one species must rule the other species has been cast out of the thinking of myself and my colleagues. We are often asked, ‘If the dolphins are so intelligent, why aren’t they ruling the world?’ My very considered answer is this: they may be too wise to try to rule the world.”

Because human supremacism—like other supremacisms—is not based on fact, but rather on preexisting bigotry (and the narcissism and tangible self-interest on which all bigotries are based), I don’t expect this book will cause many die-hard human supremacists to reconsider their supremacism,

just as books on male or white supremacy don't generally cause die-hard male or white supremacists to reconsider theirs. The book isn't written for them. This book is written to give support to the people—and there are a lot of us—who are not human supremacists, and who are disgusted with the attitudes and behaviors of the supremacists, who are attempting to stop the supremacists from killing all that lives. It is written for those who are appalled by nonhumans being tortured, displaced, destroyed, exterminated by supremacists in service to authoritarian technics. It is written for those who are tired of the incessant—I would say obsessive—propaganda required to prop up human supremacy. It is written for those who recognize the self-serving stupidity and selective blindness of the supremacist position. It is written for those who prefer a living planet to sterile authoritarian technology. It is written for those who prefer democratic decision-making processes to totalitarian societies. It is written for those who prefer life to machines.

Not only does how you perceive the world affect how you behave in the world, how you behave in the world further affects how you perceive the world. Enslaving, torturing, and killing the world not only proceeds from but also helps create a religion, a science, a philosophy, an epistemology, a literature, and so on—in short, a culture—that declares humans to be superior to all others and human function to be real function and human meaning to be real meaning.

We have been taught, in ways large and small, religious and secular, that life is based on hierarchies, and that those higher on these hierarchies dominate those lower, either by right or by might. We have been taught that there are myriad literal and metaphorical food chains where the one at the top is the king of the jungle. But what if the point is not to rule, but to participate? What if life less resembles the board games Risk or Monopoly, and more resembles a symphony? What if the point is not for the violin players to drown out the oboe players—or worse, literally drown them or at least drive them from the orchestra, and take their seats for more violin players to use—but to make music with them? What if the point is for us to attempt to learn our proper role in this symphony, and then play that role?

The human supremacist is engaged in one of man's oldest exercises in moral philosophy; that is, the search for a superior moral justification for selfishness.

I find it extraordinary—and of course, entirely expected—that so many human supremacists speak blithely of bending the entire world to “our” will, and attempt to force all of us to live with less of the planet—and to force all those exterminated to not live at all—but then they freak out at the possibility of anyone in any way constraining any of their own freedoms, at

the possibility of someone “commanding” them to live with fewer luxuries (luxuries that are gained by forcing others to bend to their will), and freak out as well at the possibility of reshaping this culture to be in line with the needs of the planet, the source of all life.

Unquestioned beliefs are the real authorities of any culture. Thus the first line of defense of human supremacism is no defense at all, literally. This is true for most forms of supremacism, as unquestioned assumptions form the most common base for any form of bigotry: Of course humans (men, whites, the civilized) are superior, why do you ask? Or more precisely: How could you possibly ask? Or even more precisely: What the hell are you talking about, you crazy person? Or more precisely yet, an awkward silence while everyone politely forgets you said anything at all.

And if some of the beliefs we must not question include the notions that human communities who do not share our unquestioned beliefs and values are not real communities; and that nonhuman communities (who certainly don’t share our unquestioned beliefs and values) are not real communities; and that theft from these (not real) communities is not theft; and that murder of these (not real) communities is not murder or genocide; and that our (not real) theft and (not real) murder of these other (not real) communities can continue forever; that the point of existence is to commit these (not real) thefts and murders; that these thefts and murders will not severely impinge upon our ability to steal from and murder these others; that one of the most unquestioned beliefs in our culture must be that we must never question our inability or unwillingness to question these beliefs; and that the real pity of a murdered planet is that we can no longer continue to steal from or murder it, then I guess we can understand how someone can say something so absurd.

We haven’t really gotten rid of God and the angels and kings, but replaced them with Pure Reason and machines.

Most of the scientific and “common sense” arguments used to defend human supremacism—and the same is true for various scientific and “common sense” means that have been used to defend white or male supremacism—are tautological, in that humans are using themselves as the standard by which all others are judged. Here’s another way to say this: humans choose human characteristics as the measure of what characteristics define superiority. It doesn’t much matter whether you’re a member of a religious group that decides you are the Chosen People and says that some God only you can hear told you that you and you alone are made in the image of this omnipotent God; or whether you’re more modern and project an anthropocentric version of sentience onto the real world, whereby beings are considered sentient primarily based on how closely they resemble humans. In either case you’re

projecting this culture's destructive notion of a hierarchical Great Chain of Being onto a beautiful, vibrant, living, sentient world full of others. That's fucking nuts. Or convenient. Or both.

Let us consider the beliefs of a hypothetical author: I'm superior to you. I'm smarter than you. I'm more sophisticated than you. My life is more meaningful than yours. You are, frankly, insignificant compared to me. I am a sentient being. You are a resource for me to exploit. It's that simple. How do I know this? Because I have more than twenty books out and you do not. Having more than twenty books out is the measure by which I have determined that we judge superiority, intelligence, sophistication, and a meaningful life.

How do I know that's the measure? Well, I decided that's the measure. And besides, it's just common sense. I remember years ago I read—or maybe someone told me, or maybe I made it up—that the most complex logical task anyone can do is write a book. It doesn't actually matter to me whether it's true, because it sounds right, and also because it supports my superiority. Look at it this way: obviously, I am able to think, and obviously I am able to communicate. By definition. Or else I wouldn't have more than twenty books out. And just as obviously, you are not able to think, and you are not able to communicate. Because if you did, you, too, would have more than twenty books out! QED.

I know what you're going to say: Stephen King. How can I be superior when Stephen King has written, at last count, more books than it is possible to count? But that's easy: I'm still superior because most of his books are novels. I understand that some of my books are novels, too, but mine still count and his don't because mine are strongly pro-feminist novels about fighting back against those who would abuse women or the land, which means they and I are both superior.

Yes, I know King wrote Dolores Claiborne, but that book doesn't count, because, well, I'm sure you can see why it doesn't count, right? Same with Rose Madder, by the way. I'm still superior and smarter. Aren't I? And don't even talk to me about all the other things you might have done. It doesn't matter. If you don't have more than twenty books out, I'm superior to you, smarter and more significant than you are.

What? You say you raised two children to be happy and healthy adults? Well, first I would correct your language. You didn't "raise children"; you produced offspring. And clearly producing offspring can't be a sign of intelligence or superiority; for crying out loud, mice produce offspring every six weeks. Producing offspring is not like writing, because writing is truly creative. It is the superior mind creating something out of nothing, with no help from anyone else. Producing offspring is just instinct, and takes

no talent or creativity whatsoever: a female comes in heat, is mounted by (never makes love with) a male (while being watched through binoculars by David Attenborough, who already a bit-too-breathlessly described their courtship rituals—don't worry, he brought along eco-friendly tissues), and their genes are passed on. Nothing but hormones and instinct.

And same with the so-called raising of these so-called children. Instinct, instinct, instinct. Just like it is with so-called mother bears and so-called mother elephants—and while we're at it, let's call them mother trees and mother bacteria. For crying out loud, if a "mother" mouse can "raise" her "babies," where's the talent? Where's the exclusivity? Birds do it. Bees do it. What makes you feel so special? So-called procreation is sure as hell not as much of a miracle as a book, which is a wondrous creation of the (and especially my) mind.

Now that we've so clearly shown we can dismiss mere bio-creation as any sort of sign of intelligence or superiority—it's just instinct and natural—let's move on to other so-called creations. What about monuments or other "great" engineering "achievements"? Why do my books qualify me as smarter than and superior to, for example, an engineer who creates a dam? Doesn't it take intelligence and superiority to build a dam? Well, apart from the fact that I—not dam builders—am defining the qualifying characteristics, I've only got one word for you: beavers.

Seriously, beavers build dams, and what are beavers? They're nothing but rodents with big teeth. Instinct! Never mind that beavers teach their children how to make dams—that's instinct too! And besides, beaver dams make some of the most biodiverse habitat in the world, and engineer-made dams kill rivers. So how does it feel, Mr. Big Shot Engineer, to be less competent than a fucking rodent with big teeth? Once again, where's the talent?

Another reason I'm superior to you is that I have a Bachelor's of Science degree in Mineral Engineering Physics. That proves I'm smart, in fact smarter than anyone who has ever lived, including those who died long before there was such a field of study as physics, and so never had the opportunity to get a degree in it. If they were so smart, they would have figured out a way. Likewise, my superiority based on my writing books extends over those who lived before the invention of the printing press; if they were as high as I on the Great Chain of Being, they would have overcome this trivial obstacle. And once again, I know what you're thinking: given the superiority of someone with a BS in physics, why, then, are those with a Master's or a PhD not even more superior? I think that's pretty obvious: I was smart enough to not stay in physics.

And here's another reason I'm smarter than and superior to you, and

that my life is meaningful while yours is not: the color of my skin. It's white, or more precisely, if you don't mind just a tiny bit of completely-deserved arrogance, my skin color is flesh tone. Why does my white (flesh-tone) skin make me superior to you? Because I'm white, that's why. Yet another reason I'm smarter than and superior to you has to do with my chest hair. I have just the right amount, which is some but not a lot. If I had a lot, of course that would make me too much like an animal, which would make me inferior. And if I had none, then I would make me too much like a woman, which would also make me inferior.

And how else do I know I'm smarter than you, that my life is significant and yours is not? Because I have a penis. I'm a man. A Man. I know what all you other men are thinking: you're thinking that you have a bigger, better penis than I do. But let me assure you: you don't have mine. I have it on the very best authority, in fact the only authority that matters—mine—that my penis is special.

Scientists have debated for years whether the nonhuman apes who are kidnapped and taught American Sign Language really have language or are merely mimicking. How, besides mimicking, do they think human children (and adults) learn language? The scientists consistently refuse to ask these key questions:

1. The nonhuman ape knows its own language plus human ASL; which of these creatures is bilingual, knowing the language of another species?
2. How could you possibly learn another's language if you do not believe this other has language?
3. If a bunch of nonhuman apes in white lab coats kidnapped a scientist and put him in a nonhuman ape version of a mobile home, how long would it take for the scientist to learn their language?
4. Why do scientists think they have the right to kidnap a nonhuman ape?
5. If we judge these nonhuman apes and these scientists by whether or not they kidnap innocent individuals, which species is morally superior?

In forests, the number of species of trees and other plants, the diversity of birds and animals, usually reflects the depth and duration of the local winter. Forty or fifty types of tree might grow in a Mississippi forest. But in northern Canada or Siberia, larch, spruce, fir, and pine pretty much does it. In the astounding fecundity of the Amazon basin some 12,500 species of

trees grow. The warm and wet parts of our world are the great storehouses of life.

We travel the Milky Way together, trees and men. We must expand the circle of human affection once again, make it wide enough to take in the sunlight eaters.

The idea of plant minds was darkly transformed by Roald Dahl in “The Sound Machine.” In this short story a man develops a radio capable of hearing frequencies normally out of range of the human ear, and as he listens one afternoon, he hears a series of painful screams. He suddenly realizes that they coincide with the snipping of blossoms off a rosebush; the radio reveals suburban yard work as genocide, with every cut of the pruning shears causing unbearable agony to sentient flora around him. This scenario may not be as far-fetched as it seems. Imagine the smell of fresh-cut grass. What smells like lazy summers to you is actually the panic pheromone released by each severed blade, letting its neighbors know that the fearsome lawnmower is coming for them too.

When trees are really thirsty, they begin to scream. If you’re out in the forest, you won’t be able to hear them, because this all takes place at ultrasonic levels. Scientists at the Swiss Federal Institute for Forest, Snow, and Landscape Research recorded the sounds, and this is how they explain them: Vibrations occur in the trunk when the flow of water from the roots to the leaves is interrupted. This is a purely mechanical event and it probably doesn’t mean anything.

And yet? We know how the sounds are produced, and if we were to look through a microscope to examine how humans produce sounds, what we would see wouldn’t be that different: the passage of air down the windpipe causes our vocal cords to vibrate. When I think about the research results it seems to me that these vibrations could indeed be much more than just vibrations—they could be cries of thirst. The trees might be screaming out a dire warning to their colleagues that water levels are running low.

For there to be something we would recognize as a brain, neurological processes must be involved, and for these, in addition to chemical messages, you need electrical impulses. And these are precisely what we can measure in the tree, and we’ve been able to do so since as far back as the nineteenth century. For some years now, a heated controversy has flared up among scientists. Can plants think? Are they intelligent? Some are of the opinion that brain-like structures can be found at root tips. In addition to signaling pathways, there are also numerous systems and molecules similar to those found in animals. When a root feels its way forward in the ground, it is aware of stimuli. Researchers measured electrical signals that led to changes in behavior after they were processed in a “transition zone.” If the

root encounters toxic substances, impenetrable stones, or saturated soil, it analyzes the situation and transmits the necessary adjustments to the growing tip. The root tip changes direction as a result of this communication and steers the growing root around the critical areas.

Right now, the majority of plant researchers are skeptical about whether such behavior points to a repository for intelligence, the faculty of memory, and emotions. Among other things, they get worked up about carrying over findings in similar situations with animals and, at the end of the day, about how this threatens to blur the boundary between plants and animals. And so what? What would be so awful about that? The distinction between plant and animal is, after all, arbitrary and depends on the way an organism feeds itself: the former photosynthesizes and the latter eats other living beings. And if you consider fungi and viruses we've already got quite a bit of blurriness going on. Finally, the only other big difference is in the amount of time it takes to process information and translate it into action. Does that mean that beings that live life in the slow lane are automatically worth less than ones on the fast track? Sometimes I suspect we would pay more attention to trees and other vegetation if we could establish beyond a doubt just how similar they are in many ways to animals.

Mimosas are tropical creeping herbs. They make particularly good research subjects, because it is easy to get them a bit riled up and they are easier to study in the laboratory than trees are. When they are touched, they close their feathery little leaves to protect themselves. Researchers designed an experiment where individual drops of water fell on the plants' foliage at regular intervals. At first, the anxious leaves closed immediately, but after a while, the little plants learned there was no danger of damage from the water droplets. After that, the leaves remained open despite the drops. The mimosas could remember and apply their lesson weeks later, even without any further tests.

However, unlike the mimosas, most plants seem to lack mind because they take so long to respond to their environment. Imagine someone who touched a hot stove and removed their hand only after a couple of hours—that person wouldn't seem like the sharpest tool in the shed. Curiously, it's also hard for us to see intelligence in things that move very quickly, to track the logic of darting dragonflies or scurrying cockroaches. It seems like minds are maximally perceived at human speed.

The technical term for this tendency is timescale anthropocentrism. 'Anthropo' comes from the Greek word *anthropos*, meaning human, and '-centrism' simply means a specific orientation or focus. Timescale anthropocentrism is the idea that we see the world—including minds—from the perspective of human time. This idea is illustrated by a study in which

participants were asked to rate the minds of different animals, some of which moved very slowly (e.g. sloths) and some of which moved very quickly (e.g., houseflies). Things that move with a human-like speed were perceived to have more mind.

We know that plants aren't intelligent because they don't have brains. Do you see it? Because we think humans think with our brains, we humans have decided that brains and central nervous systems are the only way that anyone can think and are therefore necessary for cognition. Therefore plants, not having brains and central nervous systems, cannot think. It's been proven. Thank goodness our supremacy withstood that one! Think about it. What if I said to you that because quite often my sexual pleasure involves a penis ejaculating, all sexual pleasure experienced by anyone must involve a penis ejaculating? Ridiculous and self-centered, right? Sex has evolved on this planet in a myriad of beautiful and ecstatic ways, as different for flowering plants as it is for great apes as it is for shellfish as it is for fungi. And what if I said that just because my breathing involves lungs, all breathing must involve lungs? Fish and trees and insects all say hello. How do you know it isn't the same for intelligence?

The fundamental assumption of supremacists is that until proven otherwise—and, in fact, long after—supremacists presume the other is not a subjective being. It's what men and whites and the civilized have been doing since the beginnings of their respective supremacies. It's what supremacists do.

The following is a description of sociopaths:

“Imagine, if you can, feeling absolutely no concern for another human being. No guilt. No remorse. No shame. Never once regretting a single selfish, lazy, cruel, unethical, or immoral action in your entire life. Nobody matters except you. Nobody deserves respect. Equality. Fairness. They are useless, ignorant, gullible fools, who are taking up space and the air you breathe.

Now I want you to add to this strange fantasy the ability to conceal from other people exactly what you are, to be able to hide your true nature. Nobody knows what you're really like, how little you care for other people, what you're capable of—imagine what you could achieve. Where others hesitate, you will act. Where others set boundaries, you will cross them, unhampered by any moral restraints or pangs of disquiet, any rules or ethics, with ice water in your veins and a heart of pure stone.”

This is a description of human supremacism.

Most are fearful of living in a world that is nearly infinitely complex, and nearly infinitely morally complex. It's much more convenient to live in a world where your morality is based on a clearly defined hierarchy, with you at the top. To interact with a machine is less complex and less morally complex than to interact with a community.

If your experience of the world is at variance with what this culture inculcates you into believing should be your experience of the world, what do you do? Many people respond by denying their own experience. Of course. That's the point of a supremacist philosophy.

One of the myths of modern culture is that science is value free. That's nonsense. Not only because reality is necessarily more complex than any analysis or interpretation of reality, which means that by definition, values must be imposed through what is and is not included in the analysis or interpretation; and not only because, protestations of some humans aside, the universe is far more complex than a human brain (and of course far more complex than a computer), and is far more complex than we are capable of thinking (and of course far more complex than machines are capable of computing). This myth of value-free science is only tenable if you've forgotten that unquestioned beliefs are the real authorities of any culture, and then if you presume that anything that questions those assumptions is "speculation" or "philosophizing" (as opposed to those more legitimate "analyses" that fail to question the assumptions).

When a supremacism of any sort is one of the unquestioned beliefs acting as a real authority of that culture, defenders of that supremacism nearly always perceive any questioning of any part of that supremacism as a "foolish distraction." They generally portray themselves—and quite often perceive themselves—as defenders of reasonableness and sanity, and perceive those questioning their supremacism as having come from the nuthouse. This is as true of human supremacists today as it was of defenders of race-based chattel slavery and as it was of defenders of the witch trials. And because the beliefs that underlie their supremacisms are unquestioned, proponents of supremacisms can say without intentional irony that they're not philosophizing or participating in wild speculations. Because their supremacist perspective is unquestioned—and the supremacists would prefer it remain that way—all questioning of that supremacism by definition will be classed as speculation, and all speculation on that subject will be discouraged. Of course, speculating about ways to escalate the ability of one's superior class to exploit all inferior classes is seen as innovation, creativity, and a sign of one's intelligence and superiority.

So, discuss your perception of nonhuman sentience, and you're a foolish distraction from the nuthouse who is speculating; figure out a way to use

cyanide to extract gold from rocks and leave behind a poisoned landscape, and you're a fucking hero and a shining example of human ingenuity.

Probably because they're members of this exploitative culture. It shouldn't surprise us that members of the same culture that gave us capitalism as the dominant economic model, based as it is on the insane notion that selfish individuals all attempting to maximally exploit each other will somehow create stable and healthy human communities (never mind that it never has and functionally cannot)—would give us variants of the selfish gene theory as the dominant biological model—based as it is on the equally insane notion that selfish individuals all attempting to maximally exploit each other will somehow create stable and healthy natural communities (never mind that it never has and functionally cannot). Both are justifications for what the dominant culture does: steal from everyone else. Absent is the reality of how communities survive and thrive. These must be absent, if members of our culture are going to feel good about themselves as they steal from and destroy everyone else, and as they ultimately kill the planet.

The truth is: All give. From each according to its gifts and the needs of the community. To each according to its needs and the needs of the community. These gifts can include their lives. For many, especially for the very young of some species, their lives are their only gift, as among tadpoles or many others, the overwhelming majority of them give gifts of their lives in the form of food not long after they are born.

How you perceive the world affects how you behave in and toward the world. If you perceive competition as the world's guiding principle, compete you will; if you perceive the world as being full of ruthless competitors you must overcome and exploit, you will do your part to ruthlessly overcome and exploit them. If, on the other hand, you perceive the world's guiding principle to be that of giving to the larger biotic community, you will give to the larger biotic community; if you perceive the world as being full of others who give to make it stronger, healthier, more alive, then you will do your part to make it so.

The lie is that the hierarchy—whether you call it the Great Chain of Being or the “food chain”—exists at all. There is no top of any food chain. It's all cycles within cycles. You eat the fish who ate the worm, and in time the worm eats you. It doesn't matter whether you are a gnat or an elephant, you eat and you will be eaten. That's life. Get over it.

Cooperation has been perverted into its toxic mimic through the conversion of living human animals into cogs in hierarchical social machines.

By now we've probably all heard of the Milgram experiment, where participants were led to believe they were taking on the role of “teacher” in a study on the relationship between pain and learning. An authority

figure told the teacher to administer electric shocks to a “learner” when the learner gave incorrect answers to questions. Unbeknownst to the teacher, the learner—who was in another room and could be heard, but not seen—was in on the experiment, and there were no electric shocks. But as the strength of the “shocks” would increase with each wrong answer, the learner would moan and scream as if in pain, and cry out about his heart condition. The authority figure would push the teacher to deliver ever stronger shocks to the learner. Toward the end the learner might begin banging on the wall, and then go ominously silent. Most people believed that nearly everyone would stand up to the authority figure and not harm another human being. But most people were wrong: in reality, more than 60 percent of the subjects obeyed the authority figure and tortured the helpless victim to the very end.

Now here’s my point: when researchers set up an experiment where a rat received food by pressing a lever, and then added the twist that pressing the lever shocked a rat in a nearby cage, the rat refused to press the lever. Different researchers replicated this experiment with rhesus monkeys, who also refused to torture their fellows. One monkey refused to eat for twelve days, literally starving himself instead of causing another pain. And who are the cooperative ones?

Scientists conducted an experiment in which they starved one capuchin monkey while those in cages nearby were fed (we can certainly ask what sort of sadist would conceptualize such an experiment, but we already know the answer). To their surprise, they found the starved monkey didn’t lose any weight. They could only conclude that the other monkeys were surreptitiously sharing their food. And who are the cooperative ones?

Whalers have long known that if they kill or wound one sperm whale, other whales will come to try to help their comrade. The whalers then kill the rest of the pod. And who are the cooperative ones?

Hunters knew that if they killed or wounded one Carolina parakeet, the parakeet’s friends would hover around to protect the wounded one. The hunters then killed the rest of the parakeets. In fact they drove them extinct. And who are the cooperative ones?

Slime molds are tiny beings who feed on microorganisms like bacteria, yeasts, and fungi who live in dead plant material. One of their gifts to the larger community is that they can contribute to the decomposition of dead vegetation. When this food is abundant, they live independently as single-celled organisms. But, and here’s where it gets even cooler, when food is less common, these single-celled beings can join together and begin to move as one, often following scents toward new food sources. The individuals can change their shape and become different functional parts of this collective; for example, they can become a stalk that produces fruiting bodies that

release spores. Yes, that says what you think it does. They can transition from single- to multi-celled creatures. And then move as one. And they can morph! This is precisely the opposite behavior of that predicted in many models proposed by mechanistic scientists. In the “run on the bank” model, and in the similar “grocery store running out of food” model, so long as there is plenty of money in the bank (or food in the grocery store), people are polite. They will wait in line. They will observe social niceties. But when resources become scarce, people push and shove their way to the front of the line. They lie and cheat and steal. They do not act communally. They in fact act anti-communally. But slime molds act precisely the opposite of what these models predict: when the going gets tough, slime molds recognize the importance of community. And who are the cooperative ones?

So many of the solutions to what members of this culture so often perceive as problems quite often lead to other problems, many of which probably could have been predicted were the people looking at these original “problems” both a) intelligent; and b) not evil. The only way I can see that someone putting in a dam could not predict that this would wipe out anadromous fish species, destroy the submerged lands, dispossess the human and nonhuman inhabitants, harm wetlands downriver, and so on, would be if those suggesting these solutions (dams) to problems (wanting electricity) were either a) unforgivably intelligent; or b) unforgivably evil. Take your pick. None of this is cognitively challenging in the least. And of course you could say that they are simply unforgivably entitled, and don’t care about those they harm, but a) that doesn’t seem very smart; and b) that seems pretty evil. And we can talk all we want about claims to virtue and about social systems that reward atrocious behavior and so on, but beneath it all, this is what it comes down to: are they really that stupid, or are they really that evil?

You could ask, ‘Well, how else are they supposed to generate the electricity they need to run their factories?’ But that’s not my problem, and coming up with a solution to that problem is not the responsibility of those who will be murdered by the dam. If you can’t generate electricity without causing significant harm to those humans and nonhumans who will not be receiving the benefits of this electricity, then you really are only solving the problem by foisting its harmful effects onto others, in which case you shouldn’t be calling yourself superior or intelligent, but instead a thief of these others’ lives. Theft and murder do not by themselves qualify you as intelligent or superior.

A reason it’s ridiculous to say that inventing refrigerators is a sign of intelligence and superiority is that if it is, what does that say about those Indigenous human cultures who never invented refrigerators, or cameras,

or telephones, or perhaps more to the point, iron blades, war chariots, galley ships, steel breastplates, tall ships, muzzle-loaders, breech-loaders, long-range artillery, machine guns, tanks, bombers, aircraft carriers, nuclear attack submarines, predator drones, and so on? Does this mean they were less intelligent, because they didn't invent backhoes and chainsaws? Does this mean they were inferior? Are those really arguments you want to make? If so, are you really that supremacist? Because the belief that the invention of any of these solutions is a sign of intelligence and/or superiority implies that the failure to invent any of these solutions is a sign of a lack of intelligence and/or superiority, which means that it implies that those who have invented these solutions are more intelligent and/or superior to those who did not. This means the civilized are superior to and/or more intelligent than Indigenous peoples. Another way to put this is that they are higher on the Great Chain of Being than are Primitives.

But perhaps the Tolowa, for example, never invented chainsaws, backhoes, or refrigerators at least in part because they had such a different social reward system and such a different way of perceiving and of living in the world, that many of the problems that led to these solutions may not even have been perceived as problems. If you've not exceeded your local carrying capacity, and you rely on salmon for food, and you ceremonially smoke them, and if you recognize that your life is tied up in theirs, and if the salmon stay as common (and delicious) as they have been forever (as they should if you don't exceed local carrying capacity, either through overconsumption or overproduction or overpopulation), there's really no reason to invent refrigeration. The meat stays freshest in the river. And if you're not planning on conquering your neighbor, there's really no reason for you to invent chariots or steel breastplates or machine guns, is there?

Technologies—and by extension, I would say many other forms of “solutions” to other forms of “problems”—do not exist in a vacuum. Technologies emerge from and then give rise to certain social forms. Technologies and their associated social forms can be democratic or they can be authoritarian. Democratic ones are those that emerge from and reinforce democratic or egalitarian social structures, whereas authoritarian ones are those that emerge from and reinforce authoritarian social structures.

The distinction is simple: does the technology require a large-scale hierarchical structure? Does it reinforce this structure? Does it lend itself to the monopolization of the technology, and therefore to control of those who fabricate the technology over those who use it? To put it in its simplest terms, is this technology something that anyone can make? Or is it a technology that requires massive hierarchical (and distant) organizations? We can ask all of these same questions not just about technologies, but

about all ‘problems’ and ‘solutions.’ Authoritarian and egalitarian societies may look at the same situation and perceive entirely different problems, to which they will perceive entirely different solutions. These solutions will then lead to the societies becoming more or less authoritarian or egalitarian. We can also say that unsustainable and sustainable societies may look at the same situation and see entirely different problems to which they will find entirely different solutions. And human supremacist cultures and non-human-supremacist cultures may also perceive different problems to which they will find different solutions.

When authoritarian, unsustainable, supremacist cultures encounter cultures which are none of these, they quite often conquer or destroy them. This is not only because unsustainable cultures must expand or collapse, but also because supremacist cultures by definition disrespect difference. But even when unsustainable cultures don’t outright conquer or destroy those who are sustainable, the sustainable cultures may still find themselves harmed, or if you prefer, infected.

For example, a sustainable non-supremacist culture may face the problem of keeping warm in the winter and may choose as a partial solution the wearing of skins of fur-bearing creatures they have killed. After being contacted/infected by an unsustainable and human supremacist culture, they may begin to see their landbase differently. Now they may see the same forest, the same creatures as before, but the new problem is not, ‘How do we keep warm?’ but rather ‘How do we make money?’ or ‘How do we gain trade goods? How can we get some of those steel pots and steel knives, which are ever-so-much more useful than our clay or reed pots and our stone knives?’ Their solution can then become, ‘By killing fur-bearing creatures to sell their pelts.’ And the culture has begun to move away from sustainability and interspecific cooperation and towards unsustainability and human supremacism. This is something that happened time and again across North America, as creature after creature who had lived with the Indigenous humans for millennia were quickly decimated, and the human cultures changed. Thus did technologies such as steel pots and steel knives play a role in changing cultures and landbases.

We must never forget that technologies affect our societies, and we must never forget to ask ourselves how these technologies affect our societies. Societies interested in sustainability and self-reliance have always asked themselves how new technologies will affect their communities. To not do so is a fatal mistake.

By 1800, about three-quarters of the people living in agricultural societies were living in some form of slavery, indenture, or serfdom, almost all of which could be blamed directly on agriculture. The only reason that isn’t

true today is that human slave energy has been temporarily replaced by fossil fuels; when these run out the human slave percentage will return to its former heights. And of course none of this is to speak of the nonhuman slavery upon which agriculture is completely reliant.

When a culture destroys its own landbase—through authoritarian agriculture, through associated urbanization, or through any other means for any reason—it then has two choices: collapse, or take someone else’s landbase. Since cultures rarely choose to collapse, this means once a culture has committed itself to an authoritarian agricultural way of life—which, by definition, destroys landbases—it is committed to expansion, which means, since someone else already lives there, to conquest. The alternative is starvation. This means the culture must be militarized, with all that implies socially, both internally and externally. Civilization originates in such agriculture, which requires slavery at home (and abroad) and conquest abroad. If you base your way of life on the use of a plow, you have to accept the slavery, ecocide, militarization (which also means a high rape culture), and conquest that comes with it.

“Yes, the pristine wilderness is a wonderful place to visit, but most rational people would rebel if forced to live there.”

First, until only a few thousand years ago—and across much of America, until only a few hundred years ago—what today is called “pristine wilderness” was not called ‘pristine wilderness,’ and it wasn’t a place for people to visit. It was called ‘home,’ and it was where people lived, people who fought against the conquest and enslavement of their homes, people who did prefer wetlands and starlight to condominiums and city lights. Also, saying that “most rational people would rebel if forced to live there,” implies that those who gladly lived there were not as rational as those who destroyed these “wildernesses” and the humans (and nonhumans) who called these places home. It implies they were not as rational as those who live in condo canyons. This is fully in line with the disturbingly common belief among members of the dominant culture that Indigenous peoples—a.k.a. people who live in “pristine wilderness,” a.k.a. “primitives”—are too often not perceived as fully rational. I’ll tell you what is not rational, or reasonable: harming the capacity of the earth, our only home, to support life. Nothing could be more unreasonable or irrational or stupid or evil than that.

We cannot forget the cultural component to this gadget-making. The Tolowa certainly invented some gadgets, such as baskets and hand-woven fishing nets, but they never allowed their gadget-making to become so compulsive as to cause them to destroy their landbase. As a consequence,

they were able to live here for at least 12,500 years without destroying the place. The dominant culture has been here for 150 years, and the place is trashed. Why would we do something so stupid as to invent gadgets that threaten our existence and the existence of life on this planet? And why would we presume this means we're superior? The answer: because our self-perceived superiority is based on our ability to enslave or destroy others.

Those who are addicted to power and control receive tangible benefits for feeding their addictions. This is one reason perpetrators of domestic violence—and slavers, and capitalists, and exploiters in general—rarely change: their behavior is gaining them tangible benefits. Never mind that doing so harms their relationships; if they're addicted to power and control, making others jump through hoops on command is by definition more important to them than having loving mutual relationships. The cliché is that addicts don't usually change till they hit bottom. But those who are addicted to power and control are not the ones who hit bottom; it's their victims who hit bottom. These particular addicts will not change so long as there is any other option, and quite often, not even then.

“If you take a look at biological success, which is essentially measured by how many of us there are. . .”

But this is not an appropriate or realistic measure of biological success. Instead it is one that is based on this culture's model of overshoot and conquest. We've all been taught that life is somehow like a computer game, where your success is measured by how many points you rack up; or like Risk, where your success is measured by how many little plastic armies you have and how much of the map you control. But this measure of biological success is simply the same old Biblical commandment to go forth and multiply projected onto the natural world. It's also, since they come from the same imperative, a projection of the dominant economic mindset onto the natural world, a capitalist mindset where your success is measured by how many dollars or how many franchises you own.

Switching terms again, but still coming from the same imperative, it's a projection onto the natural world of a colonialist or imperialist mindset where your success is measured by how much of other people's land you take over for your own use and to increase your numbers. That's the definition of a colonialist mindset. And it is precisely how this culture has maximized its numbers—succeeded, according to this metric—by taking over someone else's land (in this case, land needed by both Indigenous humans, and nonhumans). So many anti-imperialists understand all this when it comes to economic and social policy, but it is a measure of the hold that human supremacism

has over our minds and our discourse that these same anti-imperialists—and, in fact, most of us—cannot see that the definition of biological success they use is precisely the measure of success for colonialism or empire. In this case it is simply human empire, or more precisely, an empire of authoritarian technology.

I would argue that a far better measure of biological success would be whether the presence and population of a given species improves the health and resilience of the larger biotic community of whom it is a member and on whom it relies for sustenance, thereby ensuring its own species' survival as well as the survival of other members of its biotic community. How would we act differently if we allowed this definition of ecological success to influence our social policies?

At the same time that some humans have been killing the planet, and through many of the same processes, and for many of the same reasons, those same humans who have been killing the planet—the civilized, those who are enslaved to authoritarian forms—have been killing Indigenous humans, overrunning, committing genocide against, and often exterminating them. If you were to look at a time-lapse map of worsening ecological conditions and superimpose upon it a time-lapse map of the expansion of civilized, agricultural peoples, and over that a time-lapse map of land stolen from Indigenous peoples, you would find that the maps were pretty much the same.

Yet somehow, public intellectuals—and a lot of them—can get by saying that the destruction is caused because humans as a species are so damn smart. And a lot of listeners in this human supremacist culture nod their heads and thoughtfully rub their chins, NPR-style. But the same processes that led, and lead, to the murder of the planet also led, and lead, to land theft from Indigenous humans; in the former case it's land theft from nonhumans, and in the latter it's land theft from both the humans and the nonhumans with whom they live. How would these same listeners respond if the public intellectuals said that some humans, by which they meant civilized humans, have been able to overrun Indigenous nations because of the superior intelligence of the conquerors? 'Oh, the Europeans conquered North America and destroyed hundreds of Indigenous cultures because the Europeans are far more intelligent, and intelligence is a lethal mutation.' How would that sound? Because that's really what they're saying.

Saying our "intelligence" is a "lethal mutation" transforms the murder of the planet from the ongoing result of lots of very bad and very immoral ongoing social choices, which we can name, and which provide benefits for some classes of people at the expense of others, into something beyond our control, into something we can do nothing about, into a classic tragedy, with

us starring (of course) as the tragic hero whose tragic flaw is that he is just too damn smart for this world.

By calling the murder of the planet an act of intelligence, one is encouraging that destructiveness. Smart is good, right? We'd rather be smart than not smart, right? How would our society as a whole act differently if, instead of portraying the acts of destroying forests or killing oceans as signs and validations of our intelligence, we were to speak honestly about them, and say that they are acts of mind-boggling stupidity? How would we act differently if public intellectuals argued that this culture is killing the planet because we're so fucking stupid? Wouldn't that change our behavior? Of course if someone were to argue that humans are killing the planet because humans are lethally stupid, I would still point out that plenty of Indigenous cultures did not destroy their landbases. So I would argue that it is not that humans are stupid, but that this culture makes people stupid, in fact so stupid that they would rather kill the planet that is the source of our lives and the lives of all these other beautiful beings with whom we share this planet, than to acknowledge that they are making stupid social choice after stupid social choice.

A few decades ago an Indian nation in Montana wanted to conduct a traditional bison hunt. They were mandated to consult with federal managers, who came up with a plan: the Indians were to kill the old bulls, those who were past their sexual prime, and as such, useless in terms of passing on genetic material. Everybody wins: the Indians get their food and hides, the bison herd doesn't lose any necessary genetic materials (because the old bulls were too old to have sex ever again, the bison were, from a strict genetic perspective, already dead bulls walking), the federal managers get to kill some wild nature and file paperwork showing tangible actions leading to increased appropriations possibilities in the next fiscal year, and the human supremacists get to feel superior. Nonetheless, the Indians said that this is not what their teachings suggested. They insisted that the bulls had a role as elders in the bison community.

The managers were unswayed by this non-scientific argument. In a fight between "teachings" and the tools of scientific management (backed by the full power of the state), scientific management nearly always wins, and the world generally loses. The only way the Indians could have their traditional hunt is if they killed the animals the managers told them to. So they did.

That winter the remaining bison starved. Life is way more complex than managers think it is. It is more complex than any of us think it is. It is more complex than we are capable of thinking. Montana winters are cold and the snow can be deep. Bison need to eat. How do they get through the snow to the vegetation beneath? It ends up that the old bulls are the

only ones whose necks are strong enough to sweep away the heavy snow. They do this for their whole community. As usual, the managers make the decisions, and others pay the consequences.

Every single biome on the planet whom human supremacists have tried to manage has been dramatically harmed. Every single one. There has been not a single success, in terms of biotic health. How fucking arrogant, and how fucking stupid, do you have to be to not be able to discern the pattern in this? Further, and this is the real point, how much intelligence does it take to cut through the rhetoric and see that ‘agriculture’ and ‘running the whole Earth’ are euphemisms for ‘stealing’? Converting the entire landbase to human use is certainly stealing from the nonhumans who live there, and it is stealing from the humans living with those nonhumans, and it is stealing from those who would have lived in the future. ‘Running the whole Earth,’ likewise, is just another way to say ‘taking whatever we want and fuck everyone else.’ While using a euphemism may salve your conscience, and in the case of ‘running the whole Earth,’ may make you feel superior, it doesn’t change material reality. And material reality is more important than the words we use to describe it. Reality is also more important than our perceptions of it or our beliefs about it.

“If empire is inherently destructive, we might as well say good-bye to each other, because all of our energy and consumer goods come from empire, whether it’s coal from the internal colonies of Appalachia and the High Plains, tin from Bolivia, clothes from sweatshops in Haiti or Vietnam, steel from the slave-based factories in Brazil. Whatever it is. There is no reason to believe that empire and colonialism are inherently destructive.”

Imperialism can be defined as the taking (by force, threat of force, or even “persuasion,” if the power relations between the parties are grossly unequal) of another’s land or other resources for use at the center of empire. Using this definition, agriculture is imperialism, both against the land and against people of the land.

What makes the whole thing even more insane is that the economic system requires constant addition, and this addition requires and creates subtraction. Capitalism (and before it, civilization) requires that production grow—add two or three percent each year—and production is a measure of the subtraction, that is, of the conversion of the living into the dead: forests into 2x4s; schools of fish into fish sticks or sushi or fertilizer. The math is both simple and tragic. I think that for some people—especially those in power—the only math that matters is constant addition into their

bank accounts. But I think that so many of the rest of us do what we can to avoid this math because if we do the subtraction, do the addition, our own personal sum will be unbearable sorrow, terror, and a feeling of being entirely out of control. I think many of us do what we can to avoid this math because we know that if we do the subtraction, do the addition, our psyches and our consciences and our lives will forever be changed; and we know that no matter how fierce the momentum that leads to this subtraction and addition, no matter our fears that we may be crushed (or perhaps more fearsome, ridiculed), that we will be led in some way to oppose the subtraction of life and the addition of toxic substances to this planet that is our only home.

You're driving a car down a tunnel at 100 miles per hour directly at a brick wall. Do you turn to the passengers and say goodbye? Do you tell them, 'Our lives depend on this car not crashing. I see no evidence of a brick wall. And I see no evidence that car crashes must be inherently destructive'? No, you hit the brakes so hard your foot goes through the floor. If you can stop, great. If you can't, it becomes a question of increasing your odds of survival. I'd rather hit the wall at 90 than 100, 80 than 90, 70 than 80. With your own life and the lives of those you love at stake, every mile per hour you cut away counts.

But what does this culture do? It keeps its foot firmly on the gas. Now, let's say you're a passenger in this car. What do you do? Do you turn to those in the back seat and say goodbye? Do you pretend there is no brick wall? Do you write up a petition you and the other passengers can sign requesting that the driver cut speed by 20 percent by the year 2025? No, you scratch and claw and kick and bite and do everything you can to get the murderous suicidal asshole's foot off the gas, and press down with everything you've got on the brakes.

The center of authority in this new system is no longer a visible personality, an all-powerful king: even in totalitarian dictatorships the center now lies in the system itself, invisible but omnipresent: all its human components, even the technical and managerial elite, even the sacred priesthood of science, who alone have access to the secret knowledge by means of which total control is now swiftly being effected, are themselves trapped by the very perfection of the organization they have invented. Like the pharaohs of the Pyramid Age, these servants of the system identify its goods with their own kind of well-being: as with the divine king, their praise of the system is an act of self-worship; and again like the king, they are in the grip of an irrational compulsion to extend their means of control and expand the scope of their authority. In this new systems-centered collective, this pentagon of power, there is no visible presence who issues commands: unlike

Job's God, the new deities cannot be confronted, still less defied. Under the pretext of saving labor, the ultimate end of this authoritarian shit is to displace life, or rather, to transfer the attributes of life to the machine and the mechanical collective, allowing only so much of the organism to remain as may be controlled and manipulated.

Why has our age surrendered so easily to the controllers, the manipulators, the conditioners of an authoritarian society? The answer to this question is both paradoxical and ironic. Present day authoritarianism differs from that of the overtly brutal, half-baked authoritarian systems of the past in one highly favorable particular: it has accepted the basic principle of democracy, that every member of society should have a share in its goods. By progressively fulfilling this part of the democratic promise, our system has achieved a hold over the whole community that threatens to wipe out every other vestige of democracy.

The bargain we are being asked to ratify takes the form of a magnificent bribe. Under the democratic-authoritarian social contract, each member of the community—but mainly the global elite—may claim every material advantage, every intellectual and emotional stimulus he may desire, in quantities hardly available hitherto even for a restricted minority: food, housing, swift transportation, instantaneous communication, medical care, entertainment, education. But on one condition: that one must not merely ask for nothing that the system does not provide, but likewise agree to take everything offered, duly processed and fabricated, homogenized and equalized, in the precise quantities that the system, rather than the person, requires. Once one opts for the system no further choice remains. In a word, if one surrenders one's life at the source, authoritarian systems will give back as much of it as can be mechanically graded, quantitatively multiplied, collectively manipulated and magnified.

'Is this not a fair bargain?' those who speak for the system will ask. 'Are not the goods authoritarian society promises real goods? Is this not the horn of plenty that mankind has long dreamed of, and that every ruling class has tried to secure, at whatever cost of brutality and injustice, for itself?'

I would not belittle, still less deny, the many admirable products this technology has brought forth, products that a self-regulating economy would make good use of. I would only suggest that it is time to reckon up the human and nonhuman disadvantages and costs, to say nothing of the dangers, of our unqualified acceptance of the system itself. Even the immediate price is heavy; for the system is so far from being under effective human direction that it may poison us wholesale to provide us with food or exterminate us to provide national security, before we can enjoy its promised goods. Is it

really humanly profitable to give up the possibility of living a few years at Walden Pond, so to say, for the privilege of spending a lifetime in Walden Towers? Once our authoritarians consolidate their powers, with the aid of new forms of mass control—the panoply of tranquilizers and sedatives and aphrodisiacs, literally out of *Brave New World*—could democracy in any form survive? That question is absurd: life itself will not survive, except what is funneled through the mechanical collective. The spread of a sterilized scientific intelligence over the planet has not, will not, cannot, as too many so innocently imagine, be the happy consummation of divine purpose: it would rather ensure the final arrest of any further human development.

Forests care if salmon die. Salmon care if salmon die. Lampreys care if salmon die. Redwoods care if salmon die. Lots of creatures depend on salmon. Salmon help the entire region where they live. On the other hand, who cares if you die? What use are you to the real world? At least salmon help forests, which is more than can be said for most humans. Is the world a better place because you are alive? Not, is this culture better off? Not, have you put in a really nice garden? Not, have you raised children? I'm talking about wild nature. The real, physical world. The real, physical world is better because salmon are in it. The same can't be said of people who prefer industrial electricity to salmon. And for the record, we don't need industrial electricity. We need clean air, water, and food. And habitat. Not industrial electricity.

The label 'Anthropocene' gives no hint of the horrors this culture is inflicting. The Age of Man? Oh, that's nice. We're number one, right? Instead, the name must be horrific, it must be accurate, and it must produce shock and shame and outrage commensurate with this culture's atrocities: it is killing the planet, after all. It must call us to differentiate ourselves from this culture, to show that this label and this behavior do not belong to us. It must call us to show that we do not deserve it. It must call us to say and mean: 'Not one more Indigenous culture driven from their land, and not one more species driven extinct!' It must call us to fury and revulsion. It must call us to use our lives and if necessary our deaths to stop this insane culture from killing all we hold dear, from killing this planet that is the source of all life, including our own. If we're going to name this age after this culture, we must be honest, and call it The Age of the Sociopath—the Sociopocene. And then we need to end this fucking age, as quickly as possible, using whatever means are necessary.

Here's how conservation works in the Sociopocene: we gained the benefits, and now we're pretending that we face this terrible dilemma as to which of our victims we're going to save (for now). But that's not really a dilemma. Let's pretend I'm going to kill either you or your best friend. And no matter

whom I kill, I'm going to take everything you both own and everything you hold dear. I gain and both of you lose, including, for one of you, your life. I choose which one dies. That's not a dilemma for me. To qualify as a dilemma I have to have something at stake. Instead of a dilemma, it's murder and theft. But from a supremacist perspective, I'm not a murderer and thief. I'm a savior. I saved one of you from certain death (admittedly, at my own hands, but still it was my right to take both and I only took one!). And being this savior is more evidence of my superiority. A lesser being might have mindlessly killed you both. Gosh, aren't I great? And since I'm so smart, maybe I can come up with all sorts of criteria by which today I'll make my decision as to which of you I'll kill. Then tomorrow, I'll make another decision based on these or whatever other criteria I want as to whether to kill the survivor from today or your second-best friend. And the day after, I'll make this decision again with someone else you love.

I find it deeply troubling that at least some members of this culture can feel even remotely good about themselves for choosing who lives and who dies, if they don't also work toward stopping the actual cause of the murders. It's analogous to a guard at a Nazi death camp feeling like a hero for giving Sophie the choice as to which of her children he won't murder (tonight).

This culture is systematically and functionally killing the planet. All the wonderful and necessary work of every activist who is fighting as hard as she or he can to protect this or that wild place won't mean a fucking thing so long as this culture stands. And all this fine work that goes into creating decision-trees as to whom we deem worthy of saving and whom we will drive extinct is meaningless when we completely fail to address the cause of the murders in the first place.

A gang of sadistic, vicious, insane, entitled, sociopathic murderers has taken over your home, and is holding everyone you love captive. They are systematically pulling your loved ones from the room and torturing them to death. What do you do? Do you make decision-trees to help you make "difficult decisions" as to which of your loved ones you'll hand over next? Maybe you do. But I have to tell you I'd be more focused on stopping the murderous motherfuckers in their tracks, stopping the murders at their source. From the perspective of human supremacists, though, it is easier, more pleasing, and certainly reinforces one's own identity as superior, to "reluctantly" make "difficult decisions" as to who will be driven extinct. So long as we never, ever, ever question the supremacism and the culture that is driving them extinct.

We have sold whatever native intelligence and integrity and empathy and common sense we have in exchange for our cut of the swag. I hope you enjoy your share of the money we got for the ring that used to be on our

big sister's finger. I know I sure did. I bought myself a new computer. And Mom's liver paid this month's electricity bill.

But of course it's hard to make a man understand something when his entitlement depends on him not understanding it.

Before you can commit any mass atrocity, you have to have what some call a "claim to virtue," that is you have to convince others and especially yourself that you are not in fact committing an atrocity, but instead performing some virtuous act. So the Nazis weren't committing mass murder and genocide, but rather purifying the Aryan race. The Americans weren't committing mass murder and genocide, but rather manifesting their destiny. And are, of course, still doing so. Members of the dominant culture aren't killing the planet, they are "developing natural resources." And it's not mass murder, theft, and ecocide, it is "managing" forests, wetlands, rivers, and so on

All this talk of miracles and preaching and fire and brimstone and sacred missions is not coincidental. The technotopian vision is just a secular version of the same monotheistic conceit that life on Earth is a vale of tears and the real glory is in heaven. It doesn't much matter whether you believe the only meaning comes from a God who looks like an old man with a beard, or the only meaning comes from things created by man, you're still saying that the earth is meaningless. You're still showing contempt and hatred for the Earth. And it doesn't much matter whether the God you created tells you that you should have dominion over the Earth, and all creatures on Earth should fear you, or whether you believe it is human's manifest destiny to convert the Earth into machines and pollute the Earth (because that's what intelligent beings do), and you not only make all creatures fear you, you drive them extinct, you're still destroying the place. It doesn't matter whether you have the God you created tell you that you are the Chosen People (or Chosen Species), or whether your own delusions tell you that your vast intelligence is "a single candle flame, flickering weakly in a vast and drafty void," you still think your chosen stature allows you to exploit and/or exterminate all those you perceive as lesser than you, which is everyone. And it doesn't much matter whether you believe heaven is way up in the stars where God lives, or whether you believe heaven is way up in the stars where you want your spaceships to go, you still don't believe that the Earth is a good place to live.

There are some differences though. One is that it used to be that at least God was more powerful than Man. Now, though, we've gotten rid of that silly God talk and it is we who are on the path to becoming godlike in our capabilities. Another is that in the olden days the Heaven to which the hell on earth was contrasted was at least marginally pleasant, so long as you like harps, and petting zoos that contain both lambs and lions. This

new heaven on Mars promised by Musk sounds more like hell:

“If you were to stroll onto its surface without a spacesuit, your eyes and skin would peel away like sheets of burning paper, and your blood would turn to steam, killing you within 30 seconds. Even in a suit you’d be vulnerable to cosmic radiation, and dust storms that occasionally coat the entire Martian globe, in clouds of skin-burning particulates, small enough to penetrate the tightest of seams. Never again would you feel the sun and wind on your skin, unmediated.”

Indeed, you would probably be living underground at first, in a windowless cave, only this time there would be no wild horses to sketch on the walls.

It was written of passenger pigeons:

“I have seen them move in one unbroken column for hours across the sky, like some great river, ever varying in hue; and as the mighty stream sweeping on at sixty miles an hour, reached some deep valley, it would pour its living mass headlong down hundreds of feet, sounding as though a whirlwind was abroad in the land. I have stood by the grandest waterfall of America and regarded the descending torrents in wonder and astonishment, yet never have my astonishment, wonder, and admiration been so stirred as when I have witnessed these birds drop from their course like meteors from heaven.”

Gone, all gone. Killed by this culture that is Death, destroyer of worlds. If animals could conceive of the devil, his image would be man’s.

The world of life has become a world of no-life; persons have become nonpersons, a world of death. Death is no longer symbolically expressed by unpleasant-smelling feces or corpses. Its symbols are now clean, shining machines; humans are not attracted to smelly toilets, but to structures of aluminum and glass. But the reality behind this antiseptic façade becomes increasingly visible. Man, in the name of progress, is transforming the world into a stinking and poisonous place (and this is not symbolic). He pollutes the air, the water, the soil, the animals—and himself. He knows the facts, but in spite of many protesters, those in charge go on in the pursuit of technical “progress” and are willing to sacrifice all life in the worship of their idol. In earlier times men also sacrificed their children or war prisoners, but never before in history has man been willing to sacrifice all life to the Moloch—his own and that of all his descendants. It makes little difference

whether he does it intentionally or not. If he had no knowledge of the possible danger, he might be acquitted from responsibility. But it is his character that prevents him from making use of the knowledge he has.

You could—and frankly, a lot of human supremacists do—argue that questioning authoritarian technologies—which means questioning everything civilization is based on, including agriculture, including, of course, human supremacism—is insane and monstrous. I think that when what is at stake is life on this planet, and when it’s plain to see that from the beginning this way of life has been functionally destructive, that not questioning this way of life is what is insane and monstrous. What’s insane and monstrous is preferring this way of life over life on earth. But you don’t think that, this way is only rational.

But rationalization means something else, too, at which human supremacists also excel. In terms of “scientific management,” rationalization can be seen as the deliberate elimination of information unnecessary to achieving an immediate task. So the process of frying a hamburger at a fast-food restaurant can be said to have been “rationalized” if all extraneous movements and considerations have been removed. Another way to say this is that human supremacists excel at figuring out solutions to discrete problems by ignoring everything but the specific solution to the discrete problem. This is essentially the point of the scientific method: you try to eliminate all variables but one. Which is a functional problem with the scientific method, and why science is functionally so very good at making matter and energy jump through hoops on command, and simultaneously so very destructive of communities.

Step by step, that’s how this culture has built itself up. Step by step, the rest of the world has suffered because of it. Other cultures, other species. The entire world. A human supremacist sees a river. His factory requires electricity, which means he perceives himself as requiring electricity. From his perspective, water flowing to the ocean is serving no beneficial purpose. So he uses the collective knowledge of this culture to build a dam that generates electricity. So, having had the dam constructed for him, he has “solved” the “problem” of “needing” electricity. Humans and nonhumans who lived on the now-inundated lands above the dam pay the costs. Fish who lived in the river pay the costs. Those who ate the anadromous fish who spawned above the dam pay the costs. Those who lived along the lower banks of what was a free-flowing river pay the costs. Those who lived below the dam who require annual flooding pay the costs. Ocean beaches starved of sediment pay the costs. And on it goes.

Of course, in order to get to the point of building a big dam, other discrete problems had to be solved first, such as inventing concrete and steel,

but the same process held for each of these, as problems were solved, with each solution leading to consequences to be foisted off onto others. And on it goes. We can go through that same exercise for every significant invention of this culture, where every brilliant solution to every pressing problem emerges in part or in whole through ignoring the harm done to others by this solution.

A developer wants to put in a mall on top of one of the largest extant prairie dog villages along Colorado's Front Range. The village has 3,000 to 8,000 burrows. Prior to this human supremacist culture moving into the Great Plains, the largest prairie dog community in the world, which was in Texas, covered 25,000 square miles, and was home to perhaps 400 million prairie dogs. The total range for prairie dogs was about 150,000 to 200,000 square miles, and population was well over a billion. Now, prairie dogs have been reduced to about five percent of their range and two percent of their population. Yet because yet another rich person wants to build yet another mall (in this economy, with so many empty stores already?), much of this prairie dog community will be poisoned. That community includes the twenty or more other species who live with and depend upon prairie dogs. The prairie dogs (and some others) who are not poisoned will be buried alive by the bulldozers, then covered with concrete. This includes the pregnant females, who prefer not to leave their dens.

Prairie dogs have complex languages, with words for many threats. They have language to describe hawks, and to describe snakes, and to describe coyotes. They have language to describe a woman wearing a yellow shirt, and different language for a woman wearing a blue shirt. They have had to come up with language to describe a man with a gun. Do they, I wonder, have language to describe a bulldozer? Do they have language to describe the pregnant females of their community being buried alive? And do they have language to describe the murderous insatiability of human supremacists?

The fact is, wild animals do not make sense under capitalism. Capitalism operates according to a quite simple set of rules. Your desires are respected in accordance with the amount of financial resources you have available to you. Every wild animal is poor, thus no wild animal gets a vote over how economic resources shall be used.

The problem for animals is that they are not for anything. They are simply there. Those of us who wish to save them from having their habitats destroyed to make way for new Walmart supercenters might endeavor to find ways to make their lives profitable. We can pitch ecotourism—save nature because people will pay to come and look at it—but it might turn out that you only need one percent of nature as it currently exists to satisfy tourists' demands. As long as you preserve a walrus that people can come

and look at, the rest will remain an impediment to Growth. The walrus labor supply exceeds the human demand for walrus labor. And just as you are only compensated under capitalism to the extent that you are able to do something valuable for people who already have money (sorry, children, old people, and disabled people, you should have learned to code), animals are granted permission to live solely to the extent that they are capable of generating benefits for humans.

Wild animals are therefore a kind of massive global proletariat, being exploited and destroyed by the merciless human bourgeoisie. The lucky ones are the ones that have a marketable skill, such as 'being a pet,' and can exchange their labor (companionship and amusement) for room and board. Dogs do pretty well because we happen to like them. Pigs, unfortunately, have discovered that even though they are just as emotionally sophisticated as dogs, we enjoy their company less, and their most marketable commodity is their flesh.

It seems clear that one of the major functions of elephants in Africa, their job if you like, has been to convert woodland to grassland, forest to more open savannah. This is disadvantageous to the elephants themselves who, like otters in kelp, have to work harder for a living. But what they are doing is to create new possibilities for other species. The cycles we see in this are characteristic to the African ecosystem and have only been modified in part by recent human activity. Elephants, like humans, have been involved in massive landscaping projects for a long time, keeping Africa's equatorial ecology from going to its moist tropical climax, opening up the forest enough to let us see the trees, and at the same time opening up new habitats and new opportunities. Understanding this makes it seem imprudent to continue with attempts to manage elephant populations artificially by culling. Such actions are only likely to speed up a cycle that has already begun its own natural phase of decline. Meanwhile, great herds of zebra, wildebeest, and gazelle, plus all their predators and followers, have moved into the savannah, which has not only become symbolic of all Africa, but given an ape with ideas the chance to become human.

The ancestors of these creatures helped pave the way for our evolution. We thank their descendants by cutting off their faces.

Carnism

“Today’s FBI statistics annually show that officers practicing wildlife law enforcement in all its realms suffer a nine times higher injury and death rate than all other types of law enforcement.

The American people truly owe those folks a debt of gratitude for what they did to preserve the natural resources of this land for those yet to come. It is a fact that the wildlife one sees today in this country is a tribute to those wildlife officers who came before and those who currently hold that position, representing the ‘thin green line,’ and their front-line staffs.”

The killing of a wolf pup near Corral Creek outside Sun Valley, Idaho was done to protect the Flat Top Sheep Company. Once again this raises the question of why wildlife should be killed to increase the profitability of private enterprises operating on our public lands. It is especially disconcerting that the company did not implement minimum measures to protect its own sheep, instead, using a government-funded hired gun—USDA Wildlife Services—to kill wolves.

Grazing on public lands is a privilege, not a right. Why should Flat Top sheep, and their business interests, be allowed to jeopardize, harass, and kill wildlife? If I were to harass their sheep when I discovered them polluting our streams or otherwise damaging our public lands, I would be arrested. It’s important to note that these sheep (and all other livestock on our public lands) are creating ecological damage. His sheep pollute the water. Many studies have documented that sheep grazing can change vegetation favoring some grazing tolerant species at the cost of others sensitive to grazing pressure. The presence of domestic sheep can transmit diseases to wild bighorn sheep. And this is the primary reason bighorn sheep are absent in many mountain ranges that they once inhabited. Domestic sheep also trample and compact soil, reducing water infiltration.

The forage going into the company’s domestic animals is vegetation not supporting native herbivores and other wildlife. Everything from marmots to elk has less to eat, while insects that rely on flowering vegetation, including bees and hummingbirds are harmed by domestic sheep. Yet businessmen like him do not compensate the public for all these impacts. Instead, they get to graze their animals on public lands for a pittance, paying a paltry \$1.41 an AUM to feed five ewes and lambs. Not only is this a direct subsidy to the company’s bottom line, but the fact that we accept and allow his sheep to degrade our public lands and kill wildlife at so little cost is absurd.

Worse, according to the report in the Mountain Express, company herders did not even implement well-known predator deterrents like camping near the sheep band. The herders were two to three miles away from the sheep band.

One must say again why it's OK for private businesses to harass wildlife for their profit. Whether it is shooting guns or using noisemakers to scare wolves, these actions disrupt wildlife use of public lands. While he can graze his sheep elsewhere by renting or buying private pasture, wildlife like wolves and other predators have no place else to live. I do not believe we should continue to subsidize private businesses on our public lands, but if we do continue to permit welfare ranchers to operate, then at the least, we should demand if there's any conflict, the domestic animals are removed, not wildlife. It's time to stop subsidizing welfare ranchers with the destruction of our wildlife and the degradation of our plant communities.

One survivor told of the experience of being human cargo on a Middle Passage ship:

“I now saw myself deprived of all chance of returning to my native country. The stench of the hold while we were on the coast was so intolerably loathsome, that it was dangerous to remain there for any time. But now that the whole ship's cargo were confined together, it became absolutely pestilential. The closeness of the place and the heat of the climate, added to the number in the ship, which was so crowded that each had scarcely room to turn himself, almost suffocated us. This produced copious perspirations so that the air became unfit for respiration from a variety of loathsome smells, and brought on a sickness among the slaves, of which many died—thus falling victims of the improvident avarice, as I may call it, of their purchasers. This wretched situation was again aggravated by the galling of the chains, which now became insupportable, and the filth of the necessary tubs [toilets] into which the children often fell and were almost suffocated. The shrieks of the women and the groans of the dying rendered the whole a scene of horror almost inconceivable.”

If our factory farmed animals could write, would they pen something like this?

Animals suffer. They feel pain. They feel fear. They don't want to die. Unfortunately, an almost incomprehensible amount of them suffer and die in painful ways each and every day. According to one estimate, over 63

billion animals are slaughtered each year. Many of those animals are kept in horrific conditions before their deaths, but, even if an animal is allowed to go out to graze peacefully in a field before being slaughtered, death is still rather a cruel act. One cannot humanely kill a healthy living creature for the obvious reason that said creature does not want to die (at the very least, its consent in the matter cannot be meaningfully obtained).

Animals are harmed when they are exploited and killed for meat and other products, and this harm should be reduced whenever possible. I do not believe it is right for healthy, well-situated human beings to eat animal products that come from violence if they do it solely for the pleasure—for the taste—that comes from eating those products. A human's life might rightly be said to come before the life of an animal—if I could only save one from a burning building, I'd probably save a human over a mouse—but a human's desire for pleasure cannot trump an animal's need for life, especially because pleasure can be gotten elsewhere. We don't accept the notion that humans should be allowed to make dogs fight to the death because it brings those humans enjoyment, and we should similarly reject the idea that "bacon tastes good" is a reasonable justification for the torture and slaughter of billions of pigs.

Food deserts exist in the United States. In the Global South, where many struggle to live on the equivalent of less than \$1.70 a day, the food system has been ravaged by imperialism, colonialism, and capitalism. Capitalism is, after all, an incredibly cruel and wasteful system where, to name just one abuse, millions of dairy cows are kept in confined spaces, often unable to see the sun, and forced to have their newborn calves taken away, causing them psychological distress. This cruel process might be justifiable if it resulted in the end of world hunger, but cows are tortured for their entire lives only for companies to dump millions of tons of milk in order to keep prices up while millions of Americans go hungry. Profit, not the well-being of people, nor that of workers, and certainly not that of animals, drives the production of food under capitalism; if a company will reap a larger profit by charging more money to fewer people, then that is the course it will take.

Widespread animal and human welfare are incompatible with capitalism because it is an economic system that prizes wealth for a few at the expense of the great many. As a species, we need to transition from capitalism into some form of socialism, communism, anarchism; we need an economic model that puts power into the hands of working people and continues to produce enough for everyone while at the same time ensuring that the goods produced are actually distributed to those who need them. We should ensure a decent standard of living for all humans because all humans deserve a decent standard of living, but also because this would create the conditions

for the end of abusive animal farming practices and slaughterhouses. If everyone's nutrition needs were met, and met with plant protein (which is, after all, the source of all protein) then no longer would we need to cause billions of sentient creatures to suffer every year. This is a world that needs to be built. We cannot continue to justify the abuse and murder of animals if there are other viable avenues for feeding the world, but the world can only be fed if we prioritize people's needs over private greed.

Far too often, animal welfare advocates and socialists are framed as being fundamentally in opposition to each other. The former have a nasty habit of slipping into racist and/or classist modes of thought, blaming people in impoverished areas for their consumption practices while ignoring the underlying capitalist system that creates the conditions of impoverishment in the first place. Certainly, wherever possible, an individual should abstain from consuming animal products because of the horrendous treatment that animals experience under factory farming, but factory farming is not a problem caused by individuals. Rather, it is a symptom of the much larger disease that is capitalism, whose ruthless "efficiency" (read: desire and ability to maximize the profit of shareholders no matter the harm done to humans or animals) forces living beings into outrageously cruel conditions. Animal welfare activists miss a huge part of the picture when they protest the treatment of cows in slaughterhouses but not the treatment of workers in slaughterhouses. These are some of the most vulnerable people in the country, the working poor and immigrants, and the conditions they face on a daily basis are appalling. Beyond the violent and psychologically harmful experience of chopping up animals, slaughterhouse workers strain—and sometimes ruin—their bodies.

The furious pace of the work causes a set of chronic physical ailments called musculoskeletal disorders, or MSDs, an array of injuries to workers' muscles, tendons, ligaments, and nerves, that cause sprains, strains, or inflammation. One worker stuffed 7- to 10-pound hams in bags, at times up to 50 hams a minute. Starting with a wage of \$11.50 an hour, she worked 12-hour shifts, sometimes seven days a week. She was awarded employee of the month four times. Then, she started experiencing problems in her right shoulder. After reporting the pain to her supervisors, they told her that if she was injured, she should go home.

“The supervisors were very nasty. They wanted everything fast, they wanted to produce a lot of quantity. They didn't care about the people.”

And it would seem that conditions in slaughterhouses are only getting worse. The Trump administration has rolled back regulations that offered

some protection for workers in pig slaughterhouses. The regulatory rollback now means that plants can order increases to line speeds, requiring more pigs be slaughtered per minute, which puts an increased strain on workers' bodies and runs the risk of spreading disease because of the decrease in oversight.

The treatment of those creatures is heartbreakingly cruel, yet to have sympathy solely for the animals in slaughterhouses and not the workers who are living on the razor's edge of poverty, and who must deal with conditions that are hazardous to their health, is to do a disservice to one's fellow humans. Caring for animals should be a complement to caring for human beings, not a replacement, and animal welfare advocates are in the wrong when they ignore the human toll of meat production.

Socialists, however, can also be similarly dismissive of animal welfare concerns. As far back as the Communist Manifesto, leftists have portrayed advocates for animals as being frivolous and ignoring the "real" welfare issues in society (the aforementioned treatment of workers). This position, too, misses the mark; to be concerned with animal welfare is not frivolous because animal lives are not trivial. All sentient life—creatures that can think and feel, that can enjoy existence and fear death—deserves consideration and protection. This position is based off a simple moral intuition: that it is wrong to cause unnecessary pain and suffering. If that is true, it should not matter if suffering is inflicted on a pig or on a human; it is suffering all the same. To be confronted by a living thing in pain is to be confronted with something one recognizes to be wrong. Unfortunately, so much animal pain is hidden away from public view and, consequently, written off.

Ultimately, I believe that animal welfare advocates and socialists are, or ought to be, natural allies more than enemies. Both groups recognize that there is much unjust suffering in the world that can and should be brought to an end. The suffering that the two groups oppose are complementary—again, animals and workers suffer in the cruel conditions of the slaughterhouse, and resources that could go towards feeding human beings instead are inefficiently used to fatten livestock before slaughter—and, as that is the case, the efforts to combat them must also be complementary. We need to create a society that minimizes suffering, including the suffering of animals. To do that, we need human beings to have the security to walk away from dangerous working conditions, like slaughterhouses, and this necessitates a socialism that ensures healthcare, housing, and good jobs for all. Furthermore, we need people to be able to get their nutrition, and their pleasure in food, from non-animal sources, and this means we need a society that prioritizes the general welfare of all people over profits for a small few. Animals should no longer be exploited and made to suffer by humans, and neither should

humans be exploited and made to suffer by humans. Exploitation is the nature of the capitalist beast, and, until we get rid of it, both humans and animals will be seen as little more than pieces of meat.

“If meat is consumed, it is preferable to choose cow over chicken, for chickens feed fewer people, and the bad karma from killing is lessened when more people benefit.”

There is a myth that ape hunting is a problem because local people are hungry. The reality is that local people eat duikers or rats or squirrels or monkeys—if they eat meat at all—whereas the fancy stuff, the illicit delicacies, the chimpanzee body parts, the gobs of elephant flesh, the hippopotamus steaks, get siphoned away by upscale demand from the cities, where premium prices justify the risks of poaching and illegal transport. What brings the money are the protected species, things that are rare.

The culinary trade in such unusual wild animals, especially within the Pearl River Delta, has less to do with limited resources, dire necessity, and ancient traditions than with booming commerce and relatively recent fashions in conspicuous consumption. Close observers of Chinese culture call it the Era of Wild Flavor.

Wild Flavor (*yewei* in Mandarin) was considered a way of gaining “face,” prosperity, and good luck. Eating wild, was only one aspect of these new ostentations in upscale consumption, which might also involve patronizing a brothel where a thousand women stood on offer behind a glass wall. But the food vogue arose easily from earlier traditions in fancy cuisine, natural pharmaceuticals, and exotic aphrodisiacs (such as tiger penis), and went beyond them. One official claimed that two-thousand Wild Flavor restaurants were now operating within the city of Guangzhou alone.

The stench and the yelps of caged dogs may be stomach churning, but Lee Wha-jin happily slaps down dishes of dog-meat stew on the white plastic tabletops of his restaurant in the notorious Moran night market in Seoul. At the rear of shop after shop, eight-month-old puppies—considered to be the prime age for eating—are packed into tiny cages welded together in rows three or four high. Customers choose which of the live animals they want. The dog is then taken to the back of the shop where a flimsy curtain or a swinging door obscures the sight, but not the sound, of a hideous death.

Before arriving in the grim array of cages behind restaurants, most dogs have had to endure the misery of a Korean canine farm hidden in the hills of the countryside. It is not unusual for puppies to grow up ten to a cage, covered in sores and lice. The dogs’ deaths are as inhumane as their rearing. The majority are beaten to death, as it is thought to stimulate the

production of adrenaline that South Korean men believe will bolster their virility. Once dead, or nearly dead, the dogs are dropped into boiling water, skinned and hung by the jaw from a meat hook. Many cooks then use a blow torch to glaze the carcass.

Up until sometime in the 1800s, lobster was literally low-class food, eaten only by the poor and institutionalized. Even in the harsh penal environment of early America, some colonies had laws against feeding lobsters to inmates more than once a week because it was thought to be cruel and unusual, like making people eat rats. One reason for their low status was how plentiful lobsters were in old New England. “Unbelievable abundance” is how one source describes the situation, including accounts of Plymouth Pilgrims wading out and capturing all they wanted by hand, and of early Boston’s seashore being littered with lobsters after hard storms—these latter were treated as a smelly nuisance and ground up for fertilizer. There is also the fact that premodern lobster was cooked dead and then preserved, usually packed in salt or crude hermetic containers. Maine’s earliest lobster industry was based around a dozen such seaside canneries in the 1840s, from which lobster was shipped as far away as California, in demand only because it was cheap and high in protein, basically chewable fuel.

Now, of course, lobster is posh, a delicacy, only a step or two down from caviar. The meat is richer and more substantial than most fish, its taste subtle compared to the marine-gaminess of mussels and clams. In the US pop-food imagination, lobster is now the seafood analog to steak, with which it’s so often twinned as Surf ‘n’ Turf on the really expensive part of the chain steakhouse menu.

It’s not just that lobsters get boiled alive, it’s that you do it yourself—or at least it’s done specifically for you, on-site. In the case of the World’s Largest Lobster Cooker, which is highlighted as an attraction in the Maine Lobster Festival’s program, is right out there on the MLF’s north grounds for everyone to see. Try to imagine a Nebraska Beef Festival at which part of the festivities is watching trucks pull up and the live cattle get driven down the ramp and slaughtered right there on the World’s Largest Killing Floor or something—there’s no way.

There happen to be two main criteria that most ethicists agree on for determining whether a living creature has the capacity to suffer and so has genuine interests that it may or may not be our moral duty to consider. One is how much of the neurological hardware required for pain-experience the animal comes equipped with—nociceptors, prostaglandins, neuronal opioid receptors, et cetera. The other criterion is whether the animal demonstrates behavior associated with pain. And it takes a lot of intellectual gymnastics and behaviorist hairsplitting not to see struggling,

thrashing, and lid-clattering as just such pain-behavior. According to marine zoologists, it usually takes lobsters between 35 and 45 seconds to die in boiling water. No source I could find talks about how long it takes them to die in superheated steam; one rather hopes it's faster.

Lobsters do not, on the other hand, appear to have the equipment for making or absorbing natural opioids like endorphins and enkephalins, which are what more advanced nervous systems use to try to handle intense pain. From this fact, though, one could conclude either that lobsters are maybe even more vulnerable to pain, since they lack mammalian nervous systems' built-in analgesia, or, instead, that the absence of natural opioids implies an absence of the really intense pain-sensations that natural opioids are designed to mitigate. I for one can detect a marked upswing in mood as I contemplate this latter possibility. It could be that their lack of endorphin/enkephalin hardware means that lobsters' raw subjective experience of pain is so radically different from mammals' that it may not even deserve the term 'pain.' Perhaps lobsters are more like those frontal-lobotomy patients one reads about who report experiencing pain in a totally different way than you and I. These patients evidently do feel physical pain, neurologically speaking, but don't dislike it—though neither do they like it; it's more that they feel it but don't feel anything about it—the point being that the pain is not distressing to them or something they want to get away from. Maybe lobsters, who are also without frontal lobes, are detached from the neurological-registration-of-injury-or-hazard we call pain in just the same way. There is, after all, a difference between (1) pain as a purely neurological event, and (2) actual suffering, which seems crucially to involve an emotional component, an awareness of pain as unpleasant, as something to fear/dislike/want to avoid.

Still, after all the abstract intellection, there remain the facts of the frantically clanking lid, the pathetic clinging to the edge of the pot. Standing at the stove, it is hard to deny in any meaningful way that this is a living creature experiencing pain and wishing to avoid/escape the painful experience. To my lay mind, the lobster's behavior in the kettle appears to be the expression of a preference; and it may well be that an ability to form preferences is the decisive criterion for real suffering. The logic of this relation—preference→suffering—may be easiest to see in the negative case. If you cut certain kinds of worms in half, the halves will often keep crawling around and going about their vermiform business as if nothing had happened. When we assert, based on their post-op behavior, that these worms appear not to be suffering, what we're really saying is that there's no sign the worms know anything bad has happened or would prefer not to have gotten cut in half. Lobsters, though, are known to exhibit preferences. Experiments have shown that they can detect changes of only a degree or two in water

temperature; one reason for their complex migratory cycles—which can often cover 100-plus miles a year—is to pursue the temperatures they like best. And they’re bottom-dwellers and do not like bright light—if a tank of food-lobsters is out in the sunlight or a store’s fluorescence, the lobsters will always congregate in whatever part is darkest. Fairly solitary in the ocean, they also clearly dislike the crowding that’s part of their captivity in tanks, since one reason why lobsters’ claws are banded on capture is to keep them from attacking one another under the stress of close-quarter storage.

Of course, the most common sort of counterargument here would begin by objecting that “like best” is really just a metaphor, and a misleadingly anthropomorphic one at that. The counter-arguer would posit that the lobster seeks to maintain a certain optimal ambient temperature out of nothing but unconscious instinct (with a similar explanation for the low-light affinities). The thrust of such a counterargument will be that the lobster’s thrashings and clankings in the kettle express not unpreferred pain but involuntary reflexes, like your leg shooting out when the doctor hits your knee. Be advised that there are professional scientists, including many researchers who use animals in experiments, who hold to the view that nonhuman creatures have no real feelings at all, merely “behaviors.” Be further advised that this view has a long history that goes all the way back to Descartes, although its modern support comes mostly from behaviorist psychology.

The whole animal-cruelty-and-eating issue is not just complex, it’s also uncomfortable for just about everyone I know who enjoys a variety of foods and yet does not want to see herself as cruel or unfeeling. As far as I can tell, the main way of dealing with this conflict has been to avoid thinking about the whole unpleasant thing.

Is it significant that ‘lobster,’ ‘fish,’ and ‘chicken’ are our culture’s words for both the animal and the meat, whereas most mammals seem to require euphemisms like ‘beef’ and ‘pork’ that help us separate the meat we eat from the living creature the meat once was? Is this evidence that some kind of deep unease about eating “higher” animals is endemic enough to show up in English usage, but that the unease diminishes as we move out of the mammalian order? And is ‘lamb’/‘lamb’ the counterexample that sinks the whole theory, or are there special, biblical-historical reasons for that equivalence?

The truth is that if you, the festival attendee, permit yourself to think that lobsters can suffer and would rather not, the Maine Lobster Festival begins to take on the aspect of something like a Roman circus or medieval torture-fest. Does that comparison seem a bit much? If so, exactly why? Or what about this one: Is it possible that future generations will regard

our present agribusiness and eating practices in much the same way we now view Nero's entertainments or Mengele's experiments? For many their initial reaction is that such a comparison is hysterical, extreme—and yet the reason it seems extreme appears to be that they believe animals are less morally important than human beings. A lot less important since the moral comparison here is not the value of one human's life versus the value of one animal's life, but rather the value of one animal's life versus the value of one human's taste for a particular kind of protein. Even most diehard carniphiles will acknowledge that it's possible to live and eat well without consuming animals. And when it comes to defending such a belief, even to themselves, they have to acknowledge that (a) they have an obvious selfish interest in this belief, since they like to eat certain kinds of animals and want to be able to keep doing it, and (b) they haven't succeeded in working out any sort of personal ethical system in which the belief is truly defensible instead of just selfishly convenient.

Is the real point of my life simply to undergo as little pain and as much pleasure as possible? My behavior sure seems to indicate that this is what I believe, at least a lot of the time. But isn't this kind of a selfish way to live? Forget selfish—isn't it awful lonely? But if I decide to decide there's a different, less selfish, less lonely point to my life, won't the reason for this decision be my desire to be less lonely, meaning to suffer less overall pain? Can the decision to be less selfish ever be anything other than a selfish decision?

Is it possible really to love other people? If I'm lonely and in pain, everyone outside me is potential relief—I need them. But can you really love what you need so badly? Isn't a big part of love caring more about what the other person needs? How am I supposed to subordinate my own overwhelming need to somebody else's needs that I can't even feel directly? And yet if I can't do this, I'm damned to loneliness, which I definitely don't want so I'm back at trying to overcome my selfishness for self-interested reasons. Is there any way out of this bind?

Am I a good person? Deep down, do I even really want to be a good person, or do I only want to seem like a good person so that people (including myself) will approve of me? Is there a difference? How do I ever actually know whether I'm bullshitting myself, morally speaking?

“I'm not about to go vegan. I tend to think when you're at the top of the food chain it's okay to flaunt it, because I don't see anything complicated about drawing a moral boundary between us and other animals, and in fact find it offensive to women and people of color that all of a sudden there's talk of

extending human-rights-like legal protections to chimps, apes, and octopuses, just a generation or two after we finally broke the white-male monopoly on legal personhood.”

“We don’t see things as they are; we see them as we are.”

“The invisible and the nonexistent look very much alike.”

Why is it that we love our companion animals so much, animals that we call ‘pets,’ and get so much deep human value from those relationships, but then we turn around and call other animals ‘dinner,’ and by virtue of that semantic distinction feel entitled to treat those animals with any manner of cruelty as long as it lowers the price per pound?

There are laws in all fifty states prohibiting cruelty to animals. The laws vary from state to state, but not in one respect: In every state, the legislation that prohibits cruelty to animals exempts animals destined for human consumption. In every single one of the 50 states, if you are raising an animal for meat, for milk, or for eggs, you can without restriction subject that animal to conditions which, if you did that to a dog or a cat, would land you in jail.

It’s obvious that we have no rational reason to think some animals are friends and others are food. The only differences are tradition and the strength of the relationships we happen to have developed with the friend-animals, but that’s no more a justification of the distinction than it would be to say:

“I only eat people who aren’t my friends.”

Even though nobody can justify it, it continues. People solve the question ‘Why do you treat some animals as if they have personalities but other equally sophisticated animals as if they are inanimate lumps of flavor and calories?’ by simply pretending the question hasn’t been asked, or by making some remark like

“Well, if pigs would quit making themselves taste so good, I could quit eating them.”

The truth is disturbing, which is why it’s so easily ignored.

We need to restore our connection to animals of all kinds, not just for their sake. This isn’t just about animal rights. It’s about human responsibilities. Teaching a child not to step on a caterpillar is as valuable to the child as it is to the caterpillar.

Such a shift in perception can feel like a shift in lanes on a two-lane road: crossing the yellow line radically alters our experience. The reason we can have such a powerful response to a shift in perception is because our perceptions determine, in large part, our reality; how we perceive a situation—the meaning we make of it—determines what we think and how we feel about it. In turn, our thoughts and feelings often determine how we will act.

Something interesting happens when we are confronted with the meat from an animal we've classified as inedible: we automatically picture the living animal from which it came, and we tend to feel disgusted at the notion of eating it. The perceptual process follows this sequence: golden retriever meat (stimulus)→inedible animal (belief/perception)→image of living dog (thought)→disgust (feeling)→refusal or reluctance to eat (action).

While human beings may have an innate tendency to favor sweet flavors (sugar having been a useful source of calories) and to avoid those that are bitter and sour (such flavors often indicate a poisonous substance), most of our taste is, in fact, made up. In other words, within the broad repertoire of the human palate, we like the foods we've learned we're supposed to like. Food, particularly animal food, is highly symbolic, and it is this symbolism, coupled with and reinforced by tradition, that is largely responsible for our food preferences. For example, few people enjoy eating caviar until they're old enough to realize that liking caviar means they're sophisticated and refined; and in China, people eat animals' penises because they believe these organs affect sexual function but you're unlikely to find fried corn dicks at the next state fair.

Despite the fact that taste is largely acquired through culture, people around the world tend to view their preferences as rational and any deviation as offensive and disgusting. For instance, many people are disgusted at the thought of drinking milk that's been extracted from cows' udders. Others cannot fathom eating bacon, ham, beef, or chicken. Some view the consumption of eggs as akin to the consumption of fetuses. And consider how you might feel at the notion of eating deep-fried tarantula—hair, fangs, and all—as they do in Cambodia; sour, pickled ram's testicle pâté, as some do in Iceland; or duck embryos—eggs that have been fertilized and contain partially formed birds with feathers, bones, and incipient wings—as they do in some parts of Asia. When it comes to animal foods, all taste may be acquired taste.

The evidence strongly suggests that our lack of disgust is largely, if not entirely, learned. We aren't born with our schemas; they are constructed. Our schemas have evolved out of a highly structured belief system. This system dictates which animals are edible, and it enables us to consume them

by protecting us from feeling any emotional or psychological discomfort when doing so. The system teaches us how to not feel. The most obvious feeling we lose is disgust, yet beneath our disgust lies an emotion much more integral to our sense of self: our empathy.

Why must the system go to such lengths to block our empathy? Why all the psychological acrobatics? The answer is simple: because we care about animals, and we don't want them to suffer. And because we eat them. Our values and behaviors are incongruent, and this incongruence causes us a certain degree of moral discomfort. In order to alleviate this discomfort, we have three choices:

1. We can change our values to match our behaviors.
2. We can change our behaviors to match our values.
3. We can change our perception of our behaviors so that they appear to match our values.

It is around this third option that our schema of meat is shaped. As long as we neither value unnecessary animal suffering nor stop eating animals, our schema will distort our perceptions of animals and the meat we eat, so that we can feel comfortable enough to consume them. And the system that constructs our schema of meat equips us with the means by which to do this.

Such psychic numbing is adaptive, or beneficial, when it helps us to cope with violence. But it becomes maladaptive, or destructive, when it is used to enable violence, even if that violence is as far away as the factories in which animals are turned into meat.

Some Mechanisms of Psychic Numbing		
Avoidance	Deindividuation	Denial
Dichotomization	Dissociation	Justification
Objectification	Rationalization	Routinization

Have people from different cultures and times also used psychic numbing in order to kill and consume animals? Do tribal hunters, for instance, need to numb themselves when securing their prey? Before the Industrial Revolution, when many Americans procured their own meat, did they have to emotionally distance themselves from the animals? It would be impossible to argue that persons from all cultures, in all eras, have employed the same psychic numbing as those of us living in contemporary industrialized societies and who don't need meat to survive. Context determines, in large part, how

a person will react to eating meat. One's values, shaped largely by broader social and cultural structures, help determine how much psychological effort must go into distancing oneself from the reality of eating an animal. In societies where meat has been necessary for survival, people haven't had the luxury of reflecting on the ethics of their choices; their values must support eating animals, and they would likely be less distressed at the notion of eating meat. How animals are killed, too, affects our psychological reaction. Cruelty is often more disturbing than killing. Yet even in instances where eating meat has been a necessity, and the animals have been killed without the gratuitous violence that marks today's slaughterhouses, people have always avoided eating certain types of animals and have consistently striven to reconcile the killing and consumption of those they do consume.

So, why do you say pigs are lazy?

Because they just lie around all day.

Do pigs in the wild do this, or only pigs raised for their meat?

I don't know. Maybe when they're on a farm.

Why do you think pigs on a farm—or in a factory farm, to be more accurate—lie around?

Probably because they're in a pen or cage.

What makes pigs stupid?

They just are.

Actually, pigs are considered to be even more intelligent than dogs. Did you know that, in fact, pigs don't even have sweat glands? Are all pigs ugly?

Yes.

What about piglets?

Piglets are cute, but pigs are gross.

Why do you say pigs are dirty?

They roll in mud.

Why do they roll in mud?

Because they like dirt. They're dirty.

Actually, they roll in dirt to cool off when it's hot, since they don't sweat. Are dogs dirty?

Yeah, sometimes. Dogs can do really disgusting things.

Why didn't you include 'dirty' in your list for dogs?

Because they're not always dirty. Only sometimes.

Are pigs always dirty?

Yeah, they are.

How do you know this?

Because they always look dirty.

When do you see them?

I don't know. In pictures, I guess.

And they're always dirty in pictures?

No, not always. Pigs aren't always dirty.

You said dogs are loyal, intelligent, and cute. Why do you say this? How do you know?

I've seen them. I've lived with dogs. I've met lots of dogs.

What about dogs' feelings? How can you know that they actually feel emotions?

I swear my dog gets depressed when I'm down. My dog always got this guilty look and hid under the bed when she knew she did something wrong. Whenever we take my dog to the vet he shakes, he's so scared. Our dog used to cry and stop eating when he saw us packing to get ready to leave for vacation.

Does anybody here think it's possible that dogs don't have feelings?

(No hands are raised.)

What about pigs? Do you think pigs have emotions?

Sure.

Do you think they have the same emotions as dogs?

Maybe. Yeah, I guess.

Actually, most people don't know this, but pigs are so sensitive that they develop neurotic behaviors, such as self-mutilation, when in captivity. Do you think pigs feel pain?

Of course. All animals feel pain.

So why do we eat pigs and not dogs?

Because bacon tastes good. (laughter) Because dogs have personalities. You can't eat something that has a personality. They have names; they're individuals.

Do you think pigs have personalities? Are they individuals, like dogs?

Yeah, I guess if you get to know them they probably do.

Have you ever met a pig?

No.

So where did you get your information about pigs from?

Books. Television. Ads. Movies. I don't know. Society, I guess.

How might you feel about pigs if you thought of them as intelligent, sensitive individuals who are perhaps not sweaty, lazy, and greedy? If you got to know them firsthand, like you know dogs?

I'd feel weird eating them. I'd probably feel kind of guilty.

So why do we eat pigs and not dogs?

Because pigs are bred to be eaten.

Why do we breed pigs to eat them?

I don't know. I never thought about it. I guess, because it's just the way things are.

When our attitudes and behaviors toward animals are so inconsistent, and this inconsistency is so unexamined, we can safely say we have been fed absurdities. We tend to view the mainstream way of life as a reflection of universal values. Yet what we consider normal is, in fact, nothing more than the beliefs and behaviors of the majority.

“If we believe absurdities, we shall commit atrocities.”

Carnism is the belief system in which eating certain animals is considered ethical and appropriate. Carnists—people who eat meat—are not the same as carnivores. Carnivores are animals that are dependent on meat to survive. Carnists are also not merely omnivores. An omnivore is an animal—human or nonhuman—that has the physiological ability to ingest both plants and meat. But, like ‘carnivore,’ ‘omnivore’ is a term that describes one’s biological constitution, not one’s philosophical choice. Carnists eat meat not because they need to, but because they choose to, and choices always stem from beliefs.

“Make the lie big, make it simple, keep saying it, and eventually they will believe it.”

Both chickens and turkeys have been drastically altered by breeding designed to enlarge the breast, which is considered the most desirable part of the turkey to eat. In the case of the turkey, this process has gone so far that the standard American turkey, the descriptively named Broad Breasted White, is incapable of mating because the male’s big breast gets in the way. Here is an interesting question to drop into a lull in conversation around the Thanksgiving dinner table. Point to the turkey on the table and ask: if turkeys can’t mate, how was that turkey produced?

First you need to catch the male turkeys by the legs and hold them upside down so that another person can masturbate them. When the semen flows out, you use a vacuum pump to collect it in a syringe. You do this with one bird after another until the semen, diluted with an “extender,” fills the syringe, which is then taken to the hen house.

Once in the hen house you grab a hen by the legs, trying to cross both “ankles” in order to hold her feet and legs with one hand. The hens weigh 20

to 30 pounds and of course are terrified, beating their wings and struggling in panic. They go through this every week for more than a year, and they don't like it. Once you have grabbed her with one hand, you flop her down, chest first, on the edge of the pit with the tail end sticking up. You put your free hand over the vent and tail and pull the rump and tail feathers upward. At the same time, you pull the hand holding the feet downward, thus "breaking" the hen so that her rear is straight up and her vent open. Then the inseminator sticks their thumb right under the vent and pushes, which opens it further until the end of the oviduct is exposed. Into this, you insert a straw of semen connected to the end of a tube from an air compressor and pull a trigger, releasing a shot of compressed air that blows the semen solution from the straw and into the hen's oviduct. Then you let go of the hen and she flops away.

If you're doing this for Butterball, you're supposed to "break" one hen every 12 seconds, 300 an hour, for 10 hours a day. You'll need to dodge spurting shit from panicked birds, and, if you don't keep up the pace, torrents of verbal abuse from the foreman. Some have described it as the hardest, fastest, dirtiest, most disgusting, worst-paid work they have ever done. Seems like something Harvey Weinstein might be into though.

So that's where baby turkeys come from. Any questions kids?

We don't see them because we're not supposed to. As with any violent ideology, the populace must be shielded from direct exposure to the victims of the system, lest they begin questioning the system or their participation in it. This truth speaks for itself: why else would the meat industry go to such lengths to keep its practices invisible?

"You're going to lose hogs in a semitrailer no matter what. During the time I worked in rendering, there was large piles of dead hogs every day. When they come off the truck, they're solid as a block of ice. I went to pick up some hogs one day for chainsawing from a pile of about thirty frozen hogs, and I found two that were frozen but still alive. I could tell they were alive because they raised their heads up like, 'Help me.' I took my ax-chopper and chopped them to death."

"When the hogs smell blood, they don't want to go. I've seen hogs beaten, whipped, kicked in the head to get them up to the restrainer. One night I saw a driver get so angry at a hog he broke its back with a piece of a board. I've seen hog drivers take their prod and shove it up the hog's ass to get them to move. I

didn't appreciate that because it made the hogs twice as wild by the time they got to me."
